

## ***CELERRA T2 TECH GUIDE***

### **INTRODUCTION:**

The term “Celerra” generally applies to the entire physical “Celerra Cabinet” or system, the major components of which are the Control Station(s), and Data Movers (Blades). Data Movers, or Blades, are also referred to as Servers, the Celerra File Server [CFS], CIFS Servers, NFS Servers, etc. Data Movers operate independently of each other, and for normal operation, do not depend on the Control Station. The Control Station is used to configure, monitor, execute scripts/tasks, and manage the Servers. The Control Station is needed for communicating, changing, or configuring the system, for rebooting or “failing over” a Server, and for generating events and CallHomes, etc. When securing, shutting down, or rebooting a “server”, this is done using the server\_cpu or nas\_halt commands. The Control Station is usually shutdown or rebooted separately from the Servers [via CLI reboot, init 0, init 6, or other Linux shutdown commands].

### **CELERRA FUNCTION:**

Celerra Servers perform “File Sharing” using NFS, CIFS, iSCSI, and MPFS protocols (network access protocols). *Celerra Servers* run a specialized O/S called “**DART**” [Data Access in Real Time], more commonly referred to as “NAS”. The current NAS family is 6.0.

### **CELERRA PRODUCT LINES:**

#### **NS Series—Gateway:**

Single, dual, or quad Data Mover Gateway configurations connected to Symmetrix and/or CLARiiON CX Storage systems

#### **NS Series—Integrated:**

Single, dual, or quad Data Mover configurations connected to dedicated CLARiiON Storage Systems  
[NS700/NS500/NS600/NS80/NS350/NS40/NS20]

#### **NSX Gen I & II Series:**

High-end NAS platform based on NS design and connecting to either Symmetrix or CLARiiON storage

#### **CX3-Compatible NS Series:**

NS40, NS80, & NS20 (August 2007) are all based on the Clariion CX3 platforms

#### **NX4 low-end Model:**

NX4 is an Integrated-only low-end model based on the AX4-5F8 CLARiiON Mamba array, GA August 2008

#### **NS Mid-range ‘Unified Storage’ Series:**

NS-120, NS-480 Integrated/MPFS series using dedicated CX4 arrays, GA December 2008

#### **NS-960/NS-G8 Series:**

Integrated & Gateway high-end platform, respectively, GA February 2009, first Celerra front-end to be based on CX4 hardware. 2-8 Blades

#### **VG2/VG8 Gateways:** Mid and High-end systems, respectively. GA Sept 2010

#### **2010/2011:**

→Convergence of Clariion/Celerra family

### **LEGACY PRODUCT LINES:**

#### **EMC Celerra Clustered Network Server (CNS), CFS-14, SE, NS:**

→Celerra CNS (CFS-14 with Symm, aka Eagle), CNS-14 Golden Eagle, Celerra SE, Celerra NS600, CNS & Clariion CX600, CNS & Clariion FC4700

**Note:** CNS stands for “Clustered Network Server”, 2-14 DMs, 1-2 CSs

#### **# /nas/sbin/model**

CNS-14

### **CELERRA CONTROL STATION:**

- a.) User Interface for the Celerra system (CLI or GUI)
- b.) Vehicle for making configuration changes (CLI or GUI)
- c.) Automatically initiates Server failover/recovery and handles Callhome events when NAS Services are running
- d.) Logs Celerra Events—Server Log; NAS\_EVENTS; sys\_log; Celerra Manager
- e.) Monitors Health (heartbeat) of Servers via Internal Interfaces [using Ping protocol every 5 seconds]
- f.) Monitors Celerra Cabinet hardware—fans, batteries, temps, voltages, enclosures & blades via backplane/midplane
- g.) Manages power-up sequence

- h.) Used for troubleshooting, diagnostics, and monitoring of System and Datamovers
- i.) Performs hourly NAS database backups of NAS\_DB & DMBS Databases, and other CRON-scheduled functions
- j.) Uses NBS client to query and/or make changes to backend configurations related to the Celerra

## **CONTROL STATION MANAGEMENT:** Access Control, Management, Administration, Statistics, Monitoring

Access Control—ACL support; User & Primary Groups; Owner, Read, Write, Delete Operations; 0 [any used logged in], 2 [admin], 3 [operator], 4 [observer] Access Levels

Management-----Unix-based commands with SNMP support and Scripts; Dual Control Station support; GUI Management; Web. Administration---Installs, Upgrades, Volume & FS management, NIC configuration; NFS & CIFS setup, FS exports, FSCK, Extension of FileSystems; Automatic database backup of nasdb every hour for up to 12 hours.

Statistics-----sysstat; netstat; nfsstat

Monitoring-----Power, Battery, Temp; DataMovers; Environmental events; Uses RPC to communication with DataMovers over TCP/IP; Reporting errors and Call Homes.

**Note:** Dual Control Stations monitor each other using internal network & NAS MCD daemon—Standby CS1 takes over if CS0 stops responding. Control Station monitors each DataMover using ping broadcast every 5 seconds. Data Movers boot and execute “nas.exe” into RAM from the /nas/dos/nas.exe configuration files which are physically located on Hyper #3 [aka, the 3rd symm volume], which both CS & DM “see”—boot.cfg & boot.bat files specifically [Slot info read in /bin]

## **CONTROL STATION MODELS:**

Control Station	GA	Min S/W Rev	ECO #
100-520-581	1-Jun-2006	5.5.21	49235 "Samsung"
100-560-974 (Chivas)	1-Mar-2005	5.4.14	42990 2GB Memory
100-560-688 (Chivas DC)	9 May 2007	5.5.27.5	53241 DC NEBS CS
100-520-665 (Maynard)	22-Aug-2008	5.6.39	62238 2 GB Memory
100-520-606 (Dewars)	14-Aug-2007	5.5.26	52897 "1U Control Station (Falcon)" 2GB Memory
100-520-216	1-Aug-2004	5.2.9.6	39390 "1U Barracuda Control Station" Whalley 512MB Memory
100-520-503	14 Apr 2006	5.5.19	48415 "1U RoHS Barracuda CS" RoHS version of 216
005047772	1-Dec-2002	5.1.9.4	31421 "1U Control Station" 512MB Memory

### **CHIVAS CONTROL STATION:**

--NSX family, 2.8GHz, 2GB memory, 1GB cpu cache

#### **# cat /proc/meminfo**

MemTotal: 2068144 kB

#### **# cat /proc/cpuinfo**

```
processor      : 0
vendor_id     : GenuineIntel
cpu family    : 15
model         : 3
model name    : Intel(R) Pentium(R) 4 CPU 2.80GHz
stepping       : 4
cpu MHz       : 2802.601
cache size    : 1024 KB
```

#### **# /sbin/lspci | grep -i -c "pci bridge"**

4

**Note:** Chivas CS uses PCI bridge with (4) Ethernet slots

### **DEWARS CONTROL STATION:**

Introduced around Napa 5 timeframe, 2007. Used with new NS20 & NS40 variants, and NSX/NS80 platforms.

1U with floppy, CD-ROM, Pentium IV 2.4GHz CPU, 533MHz fsb, 2GB memory, 512MB cpu cache, 80GB SATA disk drive, built on “Falcon” chassis—Whalley Computer. Serial & LAN ports for network connectivity and field access. Bios password protected: “EMCBIO”.

Part Number: 100-520-606, with base 5.5.28.1 software

### **MAYNARD CONTROL STATION:**

See separate Maynard section: 100-520-665

## **CONTROL STATION CONTROL PROCESSES:**

### **NAS MASTER CONTROL DAEMON (MCD):**

#### **# ps -ef |grep nas\_m**

```
root  22394  1  0 Sep11 ?  00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/sys/nas_mcd.cfg
```

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Main file located in /nasmcd. Invoked by S95nas script upon bootup. Nas\_mcd configured via /nas/sys/nas\_mcd.cfg. nas\_mcd starts up all other nas processes and monitors Control Station. The NAS Master Control Daemon runs on both Control Stations and monitors each other's heartbeat. The 'heartbeat' timeout threshold is 4 seconds (or loss of 4 consecutive heartbeats). Normal operation is for a heartbeat ping to be sent over each dual internal network once every second. 4 consecutive losses of heartbeats on both internal interfaces will initiate a control station failover.

--nas\_mcd initiates failover  
--nas\_mcd initiates Call Homes  
--nas\_mcd logs Events to /nas/log/sys\_log  
--overwrites crontab on failover /nas/sbin/nasdb\_backup

### **CHANGING CS FAILOVER TIME:**

1. Edit following line in /etc/fc3.d/S95nas and add highlighted value:

(Line 303) export NAS\_DB NBSNAS\_DB; \$MCDHOME/\$NAS\_MCD **-t 30** -h \$MCDHOME \$SYS/\$NAS\_MCD\_CFG > /dev/null 2>&1 &

2. Reboot CS or stop and restart NAS Services

**Note:** Above example changes failover from default of 4 seconds to 30 seconds, which is equivalent to (30) heartbeats.

### **NAS MCD STARTUP FILE:**

#### **/nas/sys/nas\_mcd.cfg**

Contains startup scripts for the following Processes: Event Log; Box Monitor; CallHome; DB\_Backup; Syslog Trimmer; CmdErrlog Trimmer; Cmdlog Trimmer; Smmflog Trimmer; Srdflog Trimmer; HttpAccessLog Trimmer; HttpAgentLog Trimmer; Http Referlog Trimmer; HttpErrorlog Trimmer; JServer; CIFS Server Manager, Usrmapper, APL\_Task Mgr, WebUI, Indications Manager, etc.

### **BOX MONITOR:**

**# ps -ef |grep boxm**

root 25171 22394 0 Sep11 ? 00:00:08 /nas/sbin/nas\_boxmonitor /nas -i

Runs only on the Control Station acting as the Primary. Monitors health of cabinet and invokes DM failover. Spawns sub-processes for database management and configuration changes. Monitors SPB via Comm Boards.

**What do following sys log messages mean?**

May 8 13:33:26 2003 BoxMonitor:6:45 Slot 2 has rebooted. (0)

May 8 13:33:26 2003 BoxMonitor:6:45 Slot 3 has rebooted. (0)

**Jul 11 11:23:07 2003 BoxMonitor:6:45 Slot 3 has rebooted. (1)**

**Comment:** Sys\_log messages that contain a (0) indicate that Box Monitor process has been started & has contacted each DM—it does not mean that they have been rebooted! The (1) status at the end of the line would mean that the Server has been rebooted.

### **LISTING TYPES OF CELERRA CABINET:** NAS 5.0 +

**#/nasmcd/sbin/t2cab -l**

T2cab - Version 5.01.14 - 11/18/02

usage: t2cab -f

Returns the cabinet family and child of the family.

-f : Returns the Cabinet Family only

Where cabinet family is:

**0: Unknown Cabinet**

**1: Eagle Cabinet** [Old CFS-14 Style Cabinet—shoebox style]

**2: Golden Eagle Cabinet** [CNS-14 System]

**3: Celerra IP Cabinet** [Celerra NS systems, Clariion or Symm backend]

Golden Eagle Cabinet Children Include:

Golden Eagle 1

Eagle Cabinet Children Include:

The Spare Lplane connector is present :

No fans present - Raven.

4 fans present - Bobyx - Hawk with Bypass cable.

1,2,3 fans present - Illegal Cabinet configuration.

The Spare Lplane connector is not present :

1 fan present - Anaconda - Eagle.

4 fans present - Bobyx with out a Bypass cable.

No,2,3 fans present - Illegal Cabinet configuration.

**#/nasmcd/sbin/t2slot -f** [Returns a value from the list above that identifies the type of Cabinet]

**\$ /nas/sbin/t2cab**

1 - EAGLE CABINET

The Cabinet child is : 1 - an ANACONDA - EAGLE

**USE T2SLOT COMMAND TO VERIFY CONTROL STATION SLOT:**

**#/nasmcd/sbin/t2slot**

0

**ACCESSING BIOS ON LINUX CONTROL STATION:**

1. At Emulex LP8000 Bios message, press <Alt E>, then <s> to skip Bios
2. Select Emulex device
3. Configure Boot Device
4. Select Unused DID and ensure that starting LUN is set to 00
5. Select Boot Device as WWPN and reboot

**LATER CONTROL STATION MODELS REQUIRE BIOS PASSWORD:** e.g., NS700

1. Press F2 when displayed during initial system bootup

Entering SETUP...

Enter CURRENT Password: **emcbios** [password is not case-sensitive]

2. Available BIOS Menu Items:

Main      Advanced      Security      Boot      System Management      Exit

→To select an item from the Menu, use → arrow key, then enter

→Use esc once or twice to exit BIOS program without making any changes

**CONTROL STATION SYSTEM ERRORS ON STARTUP:**

Check the DMI Event Log for bios-related/hardware messages, aka SMBIOS System Management BIOS, or DMI

Security→Event Log Configuration <enter> select DMI Event Log or other option

**NAS SERVICES STARTUP SCRIPT:** /etc/rc.d/rc3.d

lrwxrwxrwx 1 root root 20 Mar 17 15:49 S95nas -> /etc/rc.d/init.d/nas (Special startup script)

**TRUSS & STRACE:** Traces System Calls, Signals Received, and Machine Faults on the CS for SCO [Linux uses “strace”]

-p process list -f follow child processes -c summarize -a show argument strings -e environment strings -v verbose -o output to a file

**\$truss -p /proc/503 [PID#]**

**Running “truss” Command on Control Station to Identify Errant Processes:**

**\$truss -aef /nas/sbin/getreason** [collect the output]

**\$truss -o /tmp/outfile -f /nas/sbin/getreason** [outputs to a file called ‘outfile’]

**\$strace -o /tmp/aaa -f server\_export server\_2 -p -u -P cifs -n testshare** [Use to output strace to file]

**\$strace -p 1260** [Use this command to attach to a running process and observe output]

**EXAMINING PROCESSES:**

**# cat /proc/4338/status**

Name: java

State: S (sleeping)

Pid: 4338

PPid: 4295

-----abridged-----

**# pstree -pau 1181** →Useful in laying out processes in tree fashion—nas\_mcd in this example

```
nas_mcd,1181) -h /nasmcd /nas/sys/nas_mcd.cfg
|_ch_monitor,2307) /nas/sbin/ch_monitor /nas
| `ch_monitor,2313) /nas/sbin/ch_monitor /nas
|   `sleep,28418) 1
|-cs_res_mon_drv,2443) /nas/sbin/cs_res_mon_driver
|   `sleep,21798) 1800
|-dirsSync,2517) /nas/sbin/dirsSync /nas /nbsnas 180
|   `sleep,27940) 180
|-dirsSync,2518) /nas/sbin/dirsSync -c /nas/sys /nasmcd/CHomeFiles 300
|   `sleep,28133) 300
|-evtClctrMon,2309) /nas/sbin/evntClctrMon
|   `sleep,27448) 300
```

**# ps -elf**

F	S	UID	PID	PPID	C	PRI	NI	ADDR	SZ	WCHAN	STIME	TTY	TIME
CMD													
100	S	root	1	0	0	68	0	-	350	do_sel	Apr14 ?	00:00:10	
init													

**GDB UTILITY:**

**# gdb -pid 385 bt**

**Note:** Linux utility that can be used to view threads of processes on the Control Station

**CONTROL STATION LOGS--TROUBLESHOOTING:**

**History:** \$more /home/nasadmin/.bash\_history [command history log from root shell]

**Operating System Logs & Information:**

\$var/log/messages [great source of info & system config]

\$var/log/boot.log [good source to see what services started or failed on bootup]

\$var/log/dmesg [Log during last boot up]

**TAILING MESSAGES LOG:**

# tail -f /var/log/messages -n0 [Opens logs with no previous lines showing]

**CELERRA DATA MOVERS:**

**NS700 MODEL FILE SERVER:**

Used in CX700, dual 3.1GHz P4 processors, 4GB RAM, 533MHz FSB, Barracuda Motherboard, supports 1 or 2 GBps fibre speeds, two 10/100 management ports using serial/peer-power connection to CS, (6) Broadcom GigE NICs, (2) Agilent 2-GB FC HBA's, Falcon Control Station, NAS 5.3.10.4 and higher

**# server\_sysconfig server\_2 -P**

server\_2 :

Processor = Intel Pentium 4

Processor speed (MHz) = 3100

Total main memory (MB) = 4024

Mother board = Barracuda XP

Bus speed (MHz) = 533

**Note:** Uses Agilent Fibre Channel HBA Controllers

**# server\_sysconfig server\_2 -pci**

server\_2 : PCI DEVICES:

On Board:

Agilent Fibre Channel Controller

0: fcp-0 IRQ: 22 addr: 500601601060101a

0: fcp-1 IRQ: 21 addr: 500601611060101a

0: fcp-2 IRQ: 18 addr: 500601621060101a

0: fcp-3 IRQ: 20 addr: 500601631060101a

Broadcom Gigabit Ethernet Controller

0: cge0 IRQ: 23

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

0: cge1 IRQ: 25

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

0: cge2 IRQ: 24

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

0: cge3 IRQ: 26

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

0: cge4 IRQ: 27

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

0: cge5 IRQ: 28

speed=auto duplex=auto txflowctl=disable rxfwctrl=disable

**X-Blade 60 HAMMERHEAD NSX DATA MOVER (XBlade 60):**

NSX platforms, dual 3.4GHz processors, 800MHz FSB, 4-16GB RAM, CMB-Hammerhead Motherboard, two 10/100 management ports using external management switch, supports 1 or 2GB fibre speeds, Chivas Control Station

**Note:** Uses Agilent Fibre Channel HBA Controllers. After introduction of the XBlade65 hardware, and NAS 5.5.22.2, the older XBlade 60 modules were converted to support 4Gb fibre, which, as it turns out, is not supported with any code prior to 5.5.22.2.

**X-Blade 65 HAMMERHEAD 2<sup>nd</sup> GENERATION NSX DATA MOVER (XBlade 65):**

NSX, dual 3.6GHz processors, 800MHz FSB, 4-16GB memory, CMB-H2G2 motherboard, two 10/100 management ports using external switch, supports 1, 2, or 4Gbps fibre speeds, has 8 GbE ports, Chivas Control Station

**NS40 X-Blade 40 CELERRA FILE SERVER:**

Introduced NAPA 2 5.5.22.2 with min. Flare support 03.22.040.5.005

Blade hardware used with NS40, NS20, NX4, NS-120, NS-480, NS-G2 platforms

Dual 2.8GHz P4 processors with 4GB DDR memory and 800MHz fsb, two 10/100 management ports using internal management switch, supports 1/2/4GBps fibre speeds, four GbE ports, Chivas Control Station with 2GB memory, avail. Gateway & Integrated; Supports up to 32TB of storage; Replacement for NS500 and low-end NS700.

**IO MODULES/PORTS:**

(2) 4Gbps FC ports for array connectivity

(2) 2Gbps FC ports for tape backup connectivity

(2) Serial ports

(4) 10/100/1000 BaseT Ethernet ports as one configuration, or (2) Optical GbE ports & (2) 10/100/1000BaseT ports as another config  
→Single Control Station connecting to Blades via Serial and Ethernet interfaces

→1 or 2 Data Mover configurations

→Supports Symm5, DMX, CX300/500/700, CX3-20/40 platforms

**NS-960/NS-G8 Blade:**

Introduced February 2009 with Foxglove platform, first Blades based on CX4 hardware, with slot IO Module architecture, and separate management switches similar to the NSX design.

**CELERRA FILE SYSTEM CAPACITIES:**

NS700, NSX, NS40, NS80, NX4, NS-120, NS-480, NS-960/NS-G8      Maximum file system size is 16TB with NAS 5.4-5.6

**DATA MOVER CAPACITY PER SERVER USING FIBRE CHANNEL STORAGE:**

Data Mover	NAS 5.3	NAS 5.4	NAS 5.5	NAS 5.6
NS700	8TB	16TB	16TB FC	16TB FC
NSX X-Blade 60	---	16TB FC/ATA	24TB FC/128TB MPFS	128TB FC/128TB MPFS
NSX X-Blade 65	---	----	24TB FC	128TB FC/128TB MPFS
NS20	---	----	16TB FC/ATA	32TB FC/48TB ATA/128TB MPFS
NS40	---	----	20TB FC/ATA	64TB FC/128TB MPFS
NS80/Gateway	---	----	24TB FC	128TB FC/128TB MPFS
NX4	---	----	----	16TB FC
NS-120	---	---	---	32TB FC/48TB ATA/96TB MPFS
NS-480	---	---	---	64TB FC/128TB MPFS
NS-960/NS-G8	---	---	---	128TB FC

**Capacity Increases when combining ATA drives with FC drives:**

NS500 & NS700 increases to 32TB per Data Mover if combining FC & ATA drives with NAS 5.6

NS20 increases to 48TB per blade if combining FC & ATA drives with NAS 5.6

NS40 increases to 64TB per blade if combining FC & ATA drives with NAS 5.6

NS80 & NSX increases to 64TB per blade if combining FC & ATA drives with NAS 5.6

**MAX FILE SIZE:**

16TB, but only 4TB if using Quotas with filesize policy, a hard limit

**CELERRA GUIDELINES:**

Max File Systems/Celerra: 2048 file systems/blade, max. of 4096 total file systems per Celerra

Max Files/Directory: 500,000

Max Ckpts/fs: 32

Max Sub-directories/fs: 65,533 per Celerra Release Notes

Max Depth/Shares: 8

**Max File Systems per Blade:**

2048/4096 for NSX

Note: See Primus emc94606 for more details on total number of file systems that can be mounted.

**Max Shares/fs:**

500 to 4000 [2.2.39.1+], depending on Share Name length of 12 characters and 27 character path & 50 character comment field [limitation is based on a 512kb size limit for the boot.cfg file].

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
NAS 4.x & higher, with 510 Data Movers, can now support up to 10,000 CIFS Shares. Each Share normally uses a single inode, which occupies one disk block, or 512 bytes. If a Share's path and comments add up to 80 characters or more, we must allocate a full 8000 bytes for the Share entry on the rootfs of the DM—if this happens, then the overall number of Shares supported may be considerably less than 10,000. Latest known size limitation of the boot.cfg file is 640kb (NAS 5.5 and below).

**Celerra Storage Block Size:**

8k [this is NOT changeable]

**Max Share Length:**

Max. of 255 characters when using I18N, but depends on UTF-8 character set. ASCII mode max. sharename length is 12 characters.

**Max ACE Entries/Share:**

900

**Max File Name Length:**

255 bytes, depending on I18N dialect

**Max Path Length:**

1024 bytes

**Max Directory Name Length:**

256 characters

**Microsoft Windows Limitations:**

NT 4.0 Server Manager=12 Characters; Net Share Command=80 Characters NT 4.0/WIN2K; WIN2K Computer Management Console=80 Characters NT 4.0/WIN2K

**Max Netbios/Compnames/Blade:**

29 (NAS 4.2)

Limit of (10) Netbios Aliases per DataMover Interface

**NAS 5.0+:**

512 theoretical, limited by localgroups file

**Max Netbios/Compname Name Length:**

15 characters for NetBIOS protocol & 63 UTF-8 characters for Compnames, with 48 character comment field limit

**Max Username Length:**

20 characters

**Max Unix Name Length:**

8 characters

**Max UID Value:**

$2^{31} - 1 = 2,147,483,647$

**Max GID Value/Blade (pre 2.2.46):**

65,535

**Max GID Value/Blade (NAS 2.2.46 +):**

2,147,483,647

**Max GIDs/File System:**

65,535

**Max Windows Domains Membership/Blade:**

32 default, 512 max with following parameter enabled: **param cifs lsarpc.maxDomains=512**

**Note:** Represents max number of domains accessible by DM (increase if ACLs contain more than 32 domains)

**Max TCP Connections/Blade:**

Default for tcp.maxStreams has been changed to 65,535 since NAS 5.3, and is also the maximum value

**Max Users/Cifs Users/TCP Connection:**

16,000 default, 65,536 maximum number FID,TID,UIDs [param cifs listBlocks= increments of 256]

**Max Open files:**

10,000 default, tunable to 40,000 tested [TCP maxStreams]

**Max Multiplexed Connections:**

Clients are limited to total of 127 outstanding requests to Server without first receiving replies

**Max Open files/Blade:**

15,000 in file open cache by default DM507; max. 40,000 tested NS700 & 510 DM; 200,000 for NAS 5.3/5.4 Increase by setting param & rebooting

**file initialize nodes=65536 dnlc=262144** [Listed here as an example only, not a recommended blanket setting]

**CIFS BLOCK SIZE NEGOTIATION FOR DM:**

DM Default=64k; param cifs W95BufSz=; param cifs NTBufSz=; param cifs W2KBufSz; --to increase buffer size negotiated

**Max Tree Quotas:**

Max number per file system—2047 Max size of Tree Quota per file system—4TB

**Max VLANs/Blade:**

4094

**Max VDMs/Blade:**

29 per DM

**CELERRA OPERATING SYSTEM LAYERS:**

Layer 1: Operating system with kernel and kernel debugger

Layer 2: Hardware device drivers for media, network, and scsi driver components

Layer 3: I/O layer for UDP, TCP/IP, CAM, Storage, and components

Layer 4: File system layer, consisting of VFS (Virtual File System), Security, and shared files within a cluster

Layer 5: Programming interfaces for RPC, Common File System (CFS/UFS)

Layer 6: Applications such as CIFS, PAX, NDMP, NFS, FTP, ONCRPC, HTTP, NIS, & SNMP

Layer 7: Management, Configuration, and System components

**DART KERNEL:**

--multiple threads run simultaneously for one physical process

--Real Time threads only run on a single processor at a time

--Dart Domains, or threads, include ‘General Purpose’ threads that are preemptive and accept blocking operation, ‘Real Time’ threads, which are single threaded and non-preemptive, and ‘Interrupt’ threads for Interrupt Services Routines.

**STRUCTURE OF DART KERNEL:**

Execution Contexts; Mutexes & Synchronizer; Thread Management; Scheduling Basics; MP—Specific; Time Services; Network Application; Utilities; Memory allocation & management; Boot Process; Debugging

**NAS CODE VERSIONS:**

5.4.20.1 (5 = code generation; 4 = code family within generation; 20 = maintenance release; 1 = [1-2 digits partial spin; 3 digits = emergency release; 4 digits = debug code; 5 digits = specific eng. integration build]

**O/S EXECUTION CONTEXTS:** (3) Types of Domains

**GP** → General Purpose domains includes all system threads, are preemptible, and accept blocking operations

**RT** → Real Time threads are single non-preemptible threads dedicated to stream, network, and timer callbacks [gets cpu every 20 ms]

**Interrupt** → Interrupt domains include all ISR (Interrupt Service Routines)

**SYNCHRONIZER:** (4) Types of Objects

**DART LOCKS:** Mutexes & RWLocks

**Mutexes:** Mutexes coordinate MUTUAL Exclusive access to objects. The Sthread\_Mutex is used to protect data accessed by GP domains and blocks other threads. Sthread\_MutexSpl protects data accessed from GP or RT domains. Sthread\_MutexRT is an exclusive RT spinlock of a CPU and prevents preemption except for interrupts—used for operations that change the network stack, such as streams. Each of the different mutexes has two types of interfaces for locking, unlocking, etc.

**RWLock:** Read threads can share access to resources while Write threads require exclusive access.

**Events:** A mechanism that allows threads to await completion of an action, and upon completion, receive a Boolean status of the action if successful or not.

**Condition Variables:** Allows for certain threads to suspend themselves while waiting for a condition to be met, using different signals to awaken the thread, etc.

**DART THREAD TYPES:**

Single RT Thread, highest priority, executes services routines from I/O interrupts

Single IDLE Thread per processor, runs when no other threads run

GP Threads are used by applications

**STHREAD:** (7) types of threads

Yield, Join, Suicide, Detach, Wait, Signal, Broadcast threads

**SCHEDULING BASICS:**

**Soft:** These threads can run on any CPU

**Hard:** These threads run only on the CPU upon which it was created

**MP SPECIFIC:** [Multi Processor operations]

**Atomic Operations:**

**Parallelization & Optimization Guidelines:** using hashed linked lists and dqueue

**Processor Context:** one context per processor in global memory

**TIME SERVICES:**

Timers and User-specified callbacks

**NETWORK APPLICATION:**

Network applications contain a Stream module and GP module. A ‘Collector’ takes a stream head and directs to a GP thread. A ‘collector’ has a queue of waiting threads and stream heads to manage, used typically for TCP protocol & NFS.

**DQUEUE:**

Macros that define generic doubly linked lists

**PROJECT CLASS:**

Allows groups of threads to collaborate on a project.

**DART KERNEL MEMORY MANAGEMENT:**

**Intro:** DART kernel manages memory in a multi-tiered approach via (4) levels, from lowest level to highest

1. Page Level Allocator (PLA): This tier manages the allocation and freeing of virtually contiguous ranges of pages, maintains ownership list of allocated pages.

2. malloc() /free(): Takes memory requests and obtains free blocks from PLA to build blocks or pools of memory to use

3. new() / delete(): calls malloc() and then the constructor of the object or calls the object destructor and then free()

4. Mempool Allocators: Provides for more efficient repeated allocations and deletions of fixed size objects. In otherwords, is designed to better manage the shrinking and growing of the memory pool requirements for system operation

→DART uses a 32-bit virtual memory implementation based on 4GB logical and physical address space (no paging from memory to disk)

→Page sizes vary from 4KB up to 2MB in size

→Memory addresses are 32-bit in size

→DART boot.cfg lives in the DOS physical memory space, which is the first 640KB, and is loaded at 0x500

→DART image used Gload to load into memory starting at physical address 1MB

## **CELERRA FILESYSTEMS: BEST PRACTICES**

### **SYMMETRIX vs. CELERRA STRIPING**

**SYMMETRIX STRIPING RULES:** 2, 15, 64, or 512 cylinder stripes

Symm striping not normally recommended because uses sequential write operations to a single disk. For example, if you had a 2 cyl stripe, Celerra would have to perform (140) 8k writes before going to next vol.--uses only a single controller. Results=Huge performance drop.

**Exception:** Best MPFS performance use 2 cylinder striping--pre NAS 4.0? (another source says to use Celerra striped at 128 or 256k)

**CELERRA STRIPING RULES:** 8, 16, 24, 32, 128, 512k, etc.

Use Stripe Size 32768 for older NAS Codes across (5) symm devices. NAS 4.2 sets stripe depth to 128 or 512k.

Example, for 32k Celerra Stripe, data would be written to single spindles in (4) writes. Striping can distribute workload across multiple disks simultaneously. Striping reduces cache-hit rate & increases Queue handling. MPFS recommendation is to use 128 or 256k Celerra Striping. NAS 5.5.21.0 to standardize new AVM profile striping of 32768 for clar\_r5\_performance, clar\_r5\_economy, clar\_r1.

**IO QUEUE DEPTH:**

**CLARIION RULES:**

Clariion queue depth is 12 IO's per LUN

**CELERRA QUEUE DEPTH:**

64KiB for each dVol, which translates into 8 I/Os per dVol. Each dVol maps to one CLARiiON LUN.

## **FILE SYSTEM EXTENSION ISSUES:**

**Common Problems:**

1. Extend volume issued, not completed by DART, but CS db updated
2. Extend file system issued, not completed by DART, but CS db updated
3. Multiple extension attempts can leave DART memory and CS db in mis-matched condition

**WHAT OCCURS DURING FILE SYSTEM EXTENSION:**

1. CS database is updated first in the /nas/volume directory when nas\_fs -xtend is run
2. CS sends DART a command to extend. DART creates volume structure in memory, then creates new volume [command may fail if all camdisk paths not available or there is an incorrect volume reference]
3. CS sends DART file system extension command to create cylinder groups on new volume and adjusts Superblock info. DART unmounts & remounts the extended fs.
4. CS updates /nas/server/slot\_x/volume file and /nas/dos/slot\_x/boot.cfg file

**TROUBLESHOOTING STEPS:**

→Check cmd\_log.err for failure msg and size of extension attempt

→Check server\_log to see if volume and file has been extended

→Use following commands to piece file system pieces together and to determine where extension failed

→If Replication is involved, the recovery may be more difficult

→Compare nas\_fs -i and nas\_fs -s to see if volumes and fs sizes are same—if not, then NAS\_DB was updated, but actual extend did not complete

→Find filesystem entry for file system, and corresponding volumes file entry—check last field of volumes entry to see what the last volume was that was used for an extension

→Use .server\_config “volume” commands to see if DM memory was updated with fs extension activity

# nas\_fs -i <fs\_name>

# nas\_fs -E <fs\_name>

# nas\_volume -i

# .server\_config server\_2 -v "volume info 581"

# .server\_config server\_2 -v "volume DBbuild 581"

# .server\_config server\_2 -v "volume tree 581"

# .server\_config server\_2 -v "volume usertree 581"

**Note:** File system extension failures still plague both CLI & Celerra Manager. Especially common are file system extensions to replicating file systems, where the target is extended first, but source fails. Do not use ctrl + Z, ctrl + c, resize SSH or Telnet windows while performing an extension.

#### FS EXTENSION PIECES:

Control Station NAS\_DB

Data Mover “volume extend” and “file extend” in Server Log [i.e., DM memory]

**Note:** It’s possible for either CS NAS\_DB or Data Mover to become inconsistent if, at any point, the extension fails

#### EXAMPLE OF FILE SYSTEM INFORMATION BEFORE 1<sup>st</sup> EXTENSION:

# nas\_fs -I | grep fs20 →From this, we see that File System fs20 is built on volume 88

```
id    inuse type acl  volume   name      server  
23     y     1  0    88      fs20

## **LARGE DIRECTORY & LARGE NUMBERS OF FILES HASHING PARAMETER TUNING:**

Following params are used in situations where customers have very large directories and may need to use these tunable params:

**param ufs dirBlkHashSize=64** [Directory Block size hash param]

**param ufs inoBlkHashSize=6007**

**param ufs inoHashTableSize=15013**

**Note:** Please do not implement above params without consulting TS2/Eng. Above params are meant to be applied to specific sites that might be experienced high CPU activity due to large directory hashing or to large numbers of files within a file system.

See Primus' emc108564 & emc109199 for CPU idle problems with large directory searches and share enumeration algorithms.

**param ufs scanLimit=32**

**Note:** Param to allow cache hash table to be increased to support large directories and files

**param cifs pathCache=0** [To avoid caching of Path]

**Note:** Windows Operating Systems use B-Tree algorithm, which operates differently than bucket hashing of chunks of data pathCache is used to retrieve full pathname of opened file from FID and it must be prime number

## **COMMENT ON VERY LARGE DIRECTORIES:**

Very large directories, as shown below, can create performance issues due to the CPU usage required to parse. Unfortunately, even after deleting the files and subdirectories that create the very large directory, the directory space is not reclaimed—once expanded, the size is fixed until the actual directory is deleted. So, the fix for such a condition would be to actually migrate any relevant files/folders from the very large directory and then delete the original directory.

```
# ls -l  
total 608  
drwxr-xr-x  2 root  root  603136 Dec 13 10:32 largedirectory  
drwxr-xr-x  2 root  root   80 Dec 13 10:32 largedirectory1
```

## **CELLERRA INODE LIMITATIONS:**

Superblocks impose a ceiling of 257 million inodes for any single file system, meaning that a 2TB vs. 4TB file system would have approximately the same number of total inodes available. This inode limit can be adjusted with the following param for any file system >than 2TB in size:

param ufs inodelimit=<hex value up to 4 billion>

**ufs.inodelimit**      **0x0104402c**    **0x0f600000**    **0x0f600000**

### **FILESYSTEM INODE BEHAVIOR:**

Uxfs filesystem flushes inode entries for each filesystem every 30 seconds, similar to other Unix O/S, via use of sync threads.

UFS: 3: deleteEntry(): wait for sync thread to flush blkno 18147617

UFS: 3: flushentries(): wait for ufsDirty thread to flush blkno 2062525

**Note:** Above Log message is benign and indicates condition where cached disk block and ondisk block are not in sync, a normal condition of conflict between inode flush and customer action in that Uxfs prioritizes changes to inode blocks in these situations.

### **CELERRA FILE SYSTEM TYPES/VOLUME TYPES:**

1=uxfs (default Celerra Universal Extended File System type) (or slice for volume type)

2=stripe volume

3=meta volume

4=sfs (secondary file system)

5=rawfs (unformatted file system, such as ufslog; also a SFS in IP Replication)

6=mirrdfs (mirrored file system, as in BCV Snapshots)

7=ckpt (Checkpoint file system, as in SnapSure)

8=mgfs (Migration file system, as in CDMS migrations)

11=vpfs (volume pool file system, as in Checkpoint & IP replication)

100=group file system

101= root\_avm\_fs\_group

102=nmf file system

**Note:** NAS 5.1.9.4—during Farcopy/Nearcopy refresh of an imported filesystem, will show an “inuse” value of “f”, meaning ‘frozen’ and not mountable

### **CELERRA UFS LOG (UFS Transaction Log):**

The UFSLOG supplements the on-disk file system by recording metadata changes to file systems as changes occur. DART stores this log on a separate disk for all data movers. Metadata changes are first written synchronously to the log, with periodic cache flushes committing the log to the on-disk structures, every 30 seconds. After a system crash, while the on-disk structures may contain stale data, the ufslog has a record of all completed operations and is played back in order to recover file system consistency. In cases where a HWM is hit on the log, I/O to the backend is suspended while data is flushed to on-disk storage. Celerra UFSlog writes metadata to disk in async manner, and to log in sequential fashion. One physical ufslog device is used by all Servers, making all Servers able to read the log. UFSLogs reside on LUN 1, with (16) total UFSLogs at 64MB in size each.

### **UFSLOG STRIPING:**

A method for striping the log across a number of backend volumes to improve write performance for heavily used systems. Log is normally contained on a single Volume and divided into different areas for DM work. Striping is only done after Symmtop data and logs are reviewed between TS2 & EE. New stripe depth for the log is 32k.

### **UFS LOG LOCATION (LUN 1):**

**→UFSLOG is not mapped to the Control Station**

**→UFSLOG is located on LUN 1 for all Data Movers**

**→UFSLOG size is 64MB since NAS 5.1**

**# /nas/sbin/rootnas\_disk -i root\_ldisk**

```
id      = 2
name    = root_ldisk
acl     = 0
in_use  = True
size (MB) = 11499
type    = STD
symm_id = 000284701110
symm_dev = 0003      →Physical Symm device is 03
volume_name = root_ldisk
servers  = server_2,server_3,server_4,server_5,server_6
server = server_2      addr=c2t01      FA=14A  FAport=0 [Highlighted portion shows as LUN 1]
server = server_2      addr=c18t011  FA=03A  FAport=0
```

**# nas\_disk -l**

```

id inuse sizeMB storageID-devID type name servers
1 y 11499 000284701110-0002 STD root_disk 1,2,3,4,5
2 y 11499 000284701110-0003 STD root_ldisk 1,2,3,4,5

```

**UFS LOG COMPONENTS :**

Entry Header : UFS\_LogEntryHdr

Transaction Header: UFS\_LogTransHdr

Data Area

**UFS LOG OPERATION :**

The ufs transaction log is a fixed-size circular log file divided into equal segments that consists of a “header” and a “tail”. Each log entry reflects a change to the file system that are not yet written to disk storage, and are identified by a “record number”, starting from 0 to highest numbered record. The record number identifies the position of the record in the log. Tail entries reflect the highest record numbers, with the head reflecting the lowest numbers. Each Server has a single write synchronous UxFS log for all file systems.

Unlike journaled file systems, data is not written to this log.

**HOW UFS LOG MAINTAINS FILE SYSTEM CONSISTENCY UPON REBOOTS OR PANICS:**

Provided file systems are not marked dirty, after system reboots, the usflog records are replayed for all entries between the Head & Tail, restoring the state of the file system for all transactions prior to the reboot event. Metadata logging writes first, synchronously, to the log, and upon “sync” operations are flushed from cache to disk. Each NFS request creates log entries. UFSlog maintains a list of all completed operations.

**EXAMPLES OF PARAMETER CHANGES THAT MAY HELP UFSLOG FLUSH ISSUES—NAS 5.6.45:**

```

param ufs nFlushDir=64
param ufs nFlushIno=64
param ufs nFlushCyl=32
param ufs dirtyListSz=2048
param ufs syncInterval=15000
param ufs nFlushCyl=32 (default with 5.6.48)
param ufs logThreshold=91 (default with 5.6.48)

```

## **WHILE TRUE SCRIPT TO SEE UFSLOG SIZES ON CELERRA:**

**# for i in 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16**

> do

> /nas/sbin/rootnas\_volume -s root\_ufslog\_\$i

> done

total = 1 avail = 0 used = 1 ( 100% ) (sizes in MB)

total = 1 avail = 0 used = 1 ( 100% ) (sizes in MB)

total = 1 avail = 0 used = 1 ( 100% ) (sizes in MB)

-----output abridged-----

**Note:** Ufslog is incorrectly sized at 1MB in above example and is full in all the slots indicated

## **CELERRA UXFS(Universal Extended File System) FILE SYSTEM:**

File Systems are created using mkfs utility into standard 8kb blocks. Max. file system size is 2TB and single file size 1TB. File system is divided into a number of 64MB Cylinder Groups (CGs) with bitmaps for inodes and blocks that are of equal size, except for the last one. Cylinder Groups have headers that describe its state, may span more than one disk block, but is predetermined in size at the time of file system creation. Cylinder Groups also spread metadata across entire storage space, rather than just a few cylinders. Header contains an object defined by “struct cg”, followed by free block and inode maps. Uxfs itself is a read-optimized implementation of the BSD Fast File System using write-ahead metadata logging [supporting online maintenance, large files, dynamic directory hashing] and delayed writes for better write performance (for combining I/O’s). UXFS uses indexed allocation where file information is stored within an inode using single, double, or triple indirect block indexing.

### **EXAMPLE:**

```
long cs_ndir; //number of directories
long cs_nbfree; //number of free blocks
long cs_nifree; //number of free inodes
long cs_nffree; //number of free frags
```

**Note:** Superblock contains struct checksum of overall file system free block and inode information, which should equal the sum of the values of each individual Cylinder Group header.

**CELERRA FILE SYSTEM LAYOUT:****Superblock→Alternate Superblock→Cylinder Groups→Inodes→Data**

→**Superblock**—persistent and dynamic info about file system (copies are in each cylinder group), such as the number of blocks, data blocks, cylinder groups, cylinders, free inodes and free data blocks, replicated to all Cylinder Groups. Also contains disk offset for superblock, offset of CG block, start offset for Inode and Data blocks, number of cylinders/inodes per group, number blocks in fs, basic block size, number fragments per block, number of free inodes & free data blocks.

→**Cylinder Groups**—contains bitmap of free/inuse data blocks, free inodes in cylinder group, and bitmap of all inodes for the group—code uses struct cg to maintain information. Each Cylinder Group consists of a Header, bitmap for free/inuse data blocks, bitmap for free inodes, and map of all inodes for CG

→**Inodes**—Inodes are stored after the CG summary block, and are a contiguous section of blocks. Each inode uses 128 bytes, with one inode per data block. Inodes contain UID, GID, File Size in number of 512 byte blocks used, Timestamps, CIFS Flags, ACL ID, Direct and Indirect Blocks, as well as mode and links information. The use of Inodes in this manner for UxFS is called ‘Indexed’ allocation. Block Indexing of ‘data’ is done using 18 direct pointers for first 144k bytes, then indirect blocks to locate the rest of the file [single indirect, double, triple, etc.]

→**Directories**—DART supports regular and inline directories in “dirent structure” [“.” Inode number→”. .” Reclen ramelen→Dirent “name”]. Regular directories are in BSD style and are stored in 512 byte data blocks, same as for files. Inline directories use the inode for directory entries and are the default type of directory used—they do not use data blocks! When an inline directory can no longer fit all of its information into the inode, then it is migrated into a regular directory, using data blocks [dot and dot-dot entries are stored by inode number only]

**→File System limitations**

--max size of mount name—512 bytes, stored in superblock

--max size of file name—255 bytes

--max size of directory entry—512 bytes

--max PathLength—1024 bytes

--Data Blocks are 8k, with one inode created per 8k block at file system creation

**CELERRA FILE SYSTEM STRUCTURE:**

Block→SuperBlock→Alternate SuperBlock→Inode→Storage Block→Direct Block→Indirect Block→Cylinder

Group→Bitmap→Special Files→VFS→V-node→Free list→Replay Log→In-core inode→Volume Manager

**FILE SYSTEM LAYOUT:**

Label	Boot Block	Offset
Super Block		Alternate Super Block
Cylinder Group map		Cylinder Group Map
Inode Blocks		Inode Blocks
Storage Blocks		Storage Blocks
(Cylinder Group 0)		(Cylinder Groups 1-n)

**FILE SYSTEM BLOCKS:**

Basic unit of size for file system (8k Celerra) and is not related to disk block or sector size. Celerra does not allow for fragmented blocks. All blocks are sequential, as presented to DART by the Volume Manager.

**SUPERBLOCK:**

Located at fixed offset on file system disk partition, cylinder group 1, stores max data blocks & max number of files. Also stores dynamic summary information about file system blocks, fragments, inodes, directories, label, size of inode block list, number free blocks & inodes, free block list, free inode list. Most alternate superblocks do not hold dynamic data.

**ALTERNATE SUPERBLOCK:**

Copy of superblock information contained in each cylinder group, at different offsets for redundancy; only first alternate superblock has persistent & dynamic data.

**INODE:**

Index node exists for each file & directory in a filesystem. File type, info, link count, UID/GID, RWX permissions, size in bytes, data block addresses in direct & indirect blocks, A-M-C-time. Celerra inodes are on contiguous blocks starting after CG summary block, and contains 128 bytes. Each 8K block holds 64 inodes.

**CELERRA INODE:**

Type/mode      Link count

UID & permissions

File size in bytes

A, C, M-time

(18) 4-byte direct blocks (Direct Blocks are 8k in size with 4-byte addresses)

1<sup>st</sup> Indirect Block (1<sup>st</sup> Indirect Block size is 2048 \* 8k blocks)

2<sup>nd</sup> Indirect Block (2<sup>nd</sup> indirect block is 2048 \* 2048 \* 8k blocks)

3<sup>rd</sup> Indirect Block (files only)

GID & permissions

8K disk blocks used

Generation number

CIFS Flags

ACL ID

#### **FILE SYSTEM IN-CORE INODE:**

An in-memory version of file inode is maintained once file is opened. Contains all of regular inode information, plus pointers to inode free list, hash queues, lock status, etc.

#### **CYLINDER GROUPS:**

Each CG contains 8192 \* 8k blocks, summary block contains used inode bitmap, free storage block bitmap.

#### **SPECIAL FILES:**

Denoted by inode, used to store critical data such as ACLs, quotas, etc.

#### **DIRECTORY FILE:**

Regular file containing file and sub-directory names

#### **MPD DIRECTORY:**

4-byte inode number

DOS attributes

Reclen (record length)

DOS/Windows/Unix file names

#### **COMPAT DIRECTORY:**

Stores only UNIX names—DOS & Windows long names stored in Shadow file

#### **FILE SYSTEM LAYERS:**

Vfs/v-node layer between User and File System layer—allows system calls, such as mount, quotas, fsck, etc

### **BSD FILE SYSTEM FSCK:**

→ Most fs corruption occurs from improper shutdown or startup, and hardware failures

→ FSCK is a multi-pass program and there are conditions where fsck and/or phases must be repeated to complete the repairs

→ FSCK is automatic & non-interactive when encountering expected corruption issues, but interactive when requiring User action

→ Most common corruption is to Superblock Summary Information, which changes with any block or inode change

#### **Superblock:**

Inconsistencies checked for file system size, number of inodes, free block count, free inode count

#### **Cylinder Group Block Maps:**

Ensures that all blocks marked as free are not claimed by any files, and corrects free-inode count if required

#### **Inode Status:**

Verifies state of each inode, link count of each inode to directories, range of each block claimed by an inode, number data blocks claimed by an inode, checks validity of directory data blocks. Orphaned inodes have a stored link count that is non-zero, but an actual link count of zero, and are placed in lost+found by fsck.

#### **FS Connectivity:**

Directories are checked for proper links into the file system and are moved to lost+found if they are not linked

#### **Cylinder Groups:**

Checks Free blocks vs. used-inode maps

### **SMALL LIST OF TYPICAL FSCK ERRORS & MEANINGS:**

#### **Partially Truncated Inode I:**

Inode size shorter than number of blocks allocated, occurs during system crash. FSCK will truncate to correct size.

#### **Partially Allocated Inode I:**

Inode is neither allocated or unallocated—contents will be zeroed

#### **Incorrect Block Count I:**

Block count is x, but should be y. FSCK changes value to y

#### **Unallocated I:**

Directory or file entry points to unallocated inode. FSCK will remove the entry

#### **CG C Bad Magic Number:**

CG C has corrupt cylinder group map—not usually repairable

#### **Blk Missing in Bit Maps (Salvage):**

Cylinder group block map missing free blocks. FSCK will reconstruct the free block map.

#### **Free Blk Count Wrong in Superblock (Salvage):**

Superblock free block info wrong. FSCK will reconstruct free block info.

### **MAC DB:**

File system is divided into cylinder groups of 8k blocks, with primary and alternate superblocks. Mac\_db tools works in 16 sector chunks. Duplicate superblocks are located at block 2, or offset 32 from start of CG. CG summary is at offset 48, block 3.

#### **CG Magic Numbers:**

--Superblock = 0x011954

--Cylinder Group = 0x90255

--Inodes start at block 4 and end at block 127

--Directories are in ‘inline’ style and regular, with each entry as “inum” (4 bytes), “reclen” (2 bytes, “nameLEN (2 bytes), & name.

#### **STRUCT CG MAPS:**

**Blocks:** Map that records total free blocks per cylinder in each cylinder group

**Rotational Positions:** Method for keeping track of number of free blocks in each rotational position for each cylinder

**Used inodes:** Bitmap with one bit per inode in the Cylinder Group. When bit is set the inode is in use.

**Free Blocks:** Bitmap with one bit per inode in the CG. When bit is set the block is free.

#### **CYLINDER SUMMARIES IN PRACTICE:**

##### **File System Initialization:**

Cylinder summaries are recomputed only at the time of file system mounting, as is the superblock information. This is accomplished by scanning each bit in the used inode and free block maps, which can take time, depending on filesystem size. Also, at mount time, an object called “UFS\_CgBlkEntry” is initialized, and contains pointers to two copies of the Cylinder Groups—an active copy that reflects the current state of the CG, and a committed copy that reflects changes to CG once changes are committed to disk.

##### **File System Synchronization:**

The “real-time” mutex in the UFS\_CgBlkEntry objects controls access to the CGs. Normal CG operations keep the mutex locked, running in real time. CGs are loaded into memory at time of mounting to avoid race conditions that would otherwise occur if reading CG into memory and accessing it in real time.

##### **CG Active and Committed Maps:**

The use of two copies of the CGs requires an accurate transaction-logging filesystem, where metadata that is not committed to the log must not be written to disk. Active, in-memory changes to the CGs are the most important, as numerous operations depending on the accuracy of the current state of the CGs.

‘Allocation Operations’ are those operations that look for free blocks or inodes in the active map, marking them as in use. Once committed to the transaction log, the free block or inode is also marked “in use” in the committed map as well [next flush of the ufs log will write the committed map changes to disk so that only “committed changes” are written to disk].

‘Free Operations’ do not change either CG map until the transaction is committed to the ufslog, then updates the active & committed maps.

##### **Block Allocation:**

Blocks for files are allocated by “UFS\_Vnode::alloc()”, which in turn calls the “UFS\_FileSystem::hashalloc()” to search through the cylinder groups. Other calls are used as well.

##### **Inode Allocation:**

Inodes are allocated by “UFS\_FileSystem::ialloc(), which also uses the hashalloc() to search CGs. (1) inode is allocated for each 8k storage block upon file system creation. Inode density can be increased at creation time, but would only be useful if file system contains large number of symbolic links or zero-length files, directories.

#### **PRESENT CYLINDER GROUP FILE SYSTEM LIMITATIONS:**

--Mount times can be substantial due to the way that CG summaries are computed

--CGs are maintained in memory, which can be substantial [not to mention subject to fragmentation?]

--Cannot allocate or free ranges of blocks in a single operation, causing block chain writes and file deletes to be slow

--Many of the original algorithms written for optimal file system performance were designed for JBOD environments and not Symm!

#### **CELLERRA FILE SYSTEM MEMORY IMPLEMENTATION:**

Celerra memory buffers use 8192 bytes per page

#### **VNODE/VFS File System Layer:**

Contains number of references in the file system. File systems cannot be unmounted until reference counts go down to a default number. Also contains device ID, whether fs is RO, number of free blocks.

##### **Functions of VFS File System:**

--mounting and unmounting file system

--Pausing, Resuming, Freezing, Thawing file system for various operations, such as Replication, Checkpoints, Timefinder, etc.

--Reserving/Unreserving blocks for file system

--Reference Count increment/decrement

--Sync

--Quota support

--ACL related functions

--File System extends

### **Functions of VFS\_Vnode:**

**Purpose:** Maintains data needed for generic vnode. VFS\_Vnode performs operations on files [block read/writes, setattr/getattr, ACL ID, Quota, Block reservations, Directory & Symbolic link operations]

→ Pointers to File\_NamingNode—directory lookups, mkdir, symlink, open, close, data read/write, sync, ioctl, setfl, setattr, locking.  
File Naming Node maintains UnixName, NTName, & pointers to parent node

--Pointer to file system

--Reference count

--Vnode cache

--Vnode freelist

--Block size

--State

### **File Naming Node:**

Base class for the following four classes used in logical grouping of vnode operations such as directory lookups, mkdirs, symlinks, for Setup operations such as opens & closes, for Data Read/Write operations (R, W, Sync), Attribute control operations (ioctl, setfl, setattr), and Locking operations (rwlock, rwunlock, etc.).

File\_FileNode—object class conducting operations such as opens, reopens, locks, ioList, and buffer cache map (blktoBufMap)

File\_DirNode—creates and deletes files, directories, symbolic links, File renaming, Lookuppath, add to DNLC

File\_SymLinkNode—Provides for symbolic link operations

File\_RootDirNode—implements root directory operations

### **METADATA LOGGING**—ufslog—see above

### **DATA I/O OPERATIONS:**

**Buffer Cached Objects**—access to buffers are coordinated by immutable and mutable references (read-only, exclusive access, respectively). All buffers have a streams reference count that is maintained in “db\_ref”. The count number is the number of msgb’s that point to it. Buffers are accessed by DART, Disk, FS, and TCP Layers.

**CFS Layer**—each file contains a bufmap, with an object name of ForkBlk2BufMap, consisting of direct and indirect maps.

**UFS Layer**—Directory Blocks and Indirect Blocks—related to dirty buffer status.

## **CELERRA UFS FILE SYSTEM LAYER:**

### **UFS FileSystem:**

Directory Block Cache—dirty directory blocks and indirect blocks

Inode Cache

Quota Record Hash—hash table for each User quota records, and one hash table for Group quota records

GID 16-32bit Mapping

UFS Hash Table

Sync Threads

### **Cylinder Group Object:**

UFS\_CgBlkEntry object used for block and inode allocation routines for maintaining Cylinder Group information

### **UFS\_Vnode Object:**

Implements virtual functions and maintains inode number, quota descriptors, directory blocks and indirect block hash, inode flags

### **Inode Cache:**

Each UFS FS Object has an inode cache (InoCache), with pointers to hash queue of inodeblocks. Sync thread flushes dirty blocks to the inode cache.

### **UFS\_DirBlkCache:**

Links directory blocks and indirect blocks of file system.

### **Directory and Indirect Block Hashing:**

Hashed list of directory and indirect blocks of a file as UFS\_DirBlkEntry objects.

### **Directory Hashing:**

Uxfs file system creates a complete hash table of the directory in memory.

## **CELERRA JOURNALED FILESYSTEM LAYOUT:**

### **TWO MAIN TYPES OF INFORMATION STORED ON DISKS:**

1. Data Blocks [data blocks & fragments]

2. Metadata Data Structures—designed to speed access to Data Blocks [Superblock, Cylinder Groups, Information Tables, Inodes]

**Note:** Changes to files or directories require metadata updates in RAM. These updates are then flushed to disk to the journal log, or “ufslog”. After system crashes, the system will ‘replay’ the ufslog to bring the filesystem back to a certain consistent point.

**Boot Block:** Block that stores procedures used in booting an OS—left blank if file system not used for booting

**Superblock:** Contains filesystem information, such as size, status, label, size of logical block, date/time of last update, cylinder group size, number data blocks in cylinder group, summary data block, file system state [clean, stable, active]

**Cylinder Group Map:** Blocks marked free that are not used for inodes, indirect address blocks, or storage blocks. Also keeps track of fragments to keep disk fragmentation from occurring.

**Inode:** 128 bytes that contain file information [except name--stored in the directory inode]. Inodes are stored in cylinder information block and consist of file type [regular, directory, block/character special, symbolic link, pipe, socket]; mode of file; number of hard links; UID of Owner; GID ownership, number of bytes in file, date/time created, last access time, last modified time.

**Storage or Data Block:** All other space in filesystem used for data blocks, not meta data. Celerra data blocks are allocated in 8k blocks and 1k fragmentations.

**Directories:** 512 bytes

**FILESYSTEM SUMMARY ISSUE:** ‘Rolling Panics’ due to filesystem summary data being wrong

NAS Codes prior to 4.2.17.0 or 5.0.17.0 → Problems in calculating file system summary to cylinder group information

**param ufs verifySummary=1** → forces summary between cylinder groups and filesystem prior to mounting, instead of after

## **REASONS FOR JOURNALED FILE SYSTEM MAINTENANCE [File System Checking]:**

*Requirements for File System Checking*

**Symmetrix Connectivity/Storage:** Major Backend disruptions or problems could impact Host systems that are direct-attached, such as Celerra. Normal CS procedure after Server Panics, or evidence of Backend Connectivity issues, is to engage Symmetrix PSE Lab to checkout Symmetrix Backend.

**Fibre Channel Fabric:** Fabric issues have the potential to create connectivity issues during Registered State Change Notifications (RSCN), whether intentional or switch-related. Code versions prior to NAS 4.2, 5.0, & 5.1 contain numerous improvements to the way that State Change Notifications, and loss of Back-End connectivity, are handled by the Data Mover. Firmware revisions are also factors.

**Hosts and Applications:** Hosts and Applications have the potential to cause file system corruption and panics, especially if the application or Host has access to Celerra file systems when it should not have access. An example of this might be ECC, VolumeLogix, or some other 3rd Party software that has access to the Symmetrix Backend. It has been observed during certain conditions that Hosts and/or Software such as VolumeLogix had illegal access to volumes on the Symmetrix that should have been exclusive only to the Celerra. Also, some Host operations can create code panics.

**Code-Related Issues:** Outdated NAS code can also be a factor, as certain families are no longer actively patched. The general consensus is that all Operating Systems are subject to potential fs "corruption" and therefore have their own set of tools or utilities to ensure that File Systems are maintained in a "consistent" and usable state. DART file system is based on BSD Unix [Berkeley Fast File System], and relies on ufs journal logging, as well as file system checks & verifications, to ensure that file systems remain consistent. Unfortunately, there are trade-offs between file system "reliability" and "system performance". With Operating System code, changes are often committed to memory, and then later written to disk and the file system--due to performance considerations, these changes are not verified before being written to disk, which does introduce the potential, however small, that file system corruption or problems can occur under unique sets of circumstances. When these problems do occur, Vendors [including EMC] try to ensure that the problem is identified and quickly corrected.

**Previous Server Panics:** Previous panics can introduce the potential for fs damage, depending on the issue, and issues may lay dormant for some time until a certain part of the filesystem is accessed that contains a truncated inode, etc.

## **CELLERRA AND SCSI DISK STORAGE:**

--sector format is 512 bytes (Clariion uses 520 bytes, but when configured with Celerra, presents 512)

--LBA—Logical Block Addressing is used to store & retrieve info

--Celerra writes unique label to every data LUN it sees—can see this with inlines—primus emc68161

--DM supports up to 4096 LUNS down each HBA channel (16 chains \* 16 targets \* 16 LUNS = 4096)

--Celerra uses SCSI-3 standard

## **FA ASSIGNMENTS ON SYMMETRIX:**

Enginuity symm code from 5566-5670 limits the number of devices per SA or FA processor to 2048. The restriction applies to the SA/FA processor, not the port. Since many processors have multiple port assignments, the total must be used when calculating. If all ports were in use on a 4-port processor, then the total logical devices allowed (Celerra Luns) would be 512 per port. But, if only a single port were being used, the total number of Celerra Luns could be 2048—for two ports in use it would be 1024/port, etc. So, the generally stated Celerra limit of 512 Luns/port for DMX systems, is not strictly true.

--5266-5267 code can support 904 devices per processor

--5264-5265 can support only 554 devices per processor (Symm 8000 2-port FA would mean only 256 devices per port)

--5670 & 5671 supports 2048 devices per FA processor

--5771 supports 4096 devices per processor

DMX/DM2 supports 512 devices per FA port

DMX3 supports 2048 devices per FA port

## **CLARIION UNCORRECTABLE SECTOR, PARITY ERRORS:**

### **HOW CLARIION HANDLES MEDIA ERRORS:**

CLARiiON arrays report errors when data cannot be read from a drive, as does Symmetrix. Historically, Symmetrix systems have always reported 0x03/0x11 Errors when hard Read errors occur (Symm uncorrectables remap their bad sectors automatically, though Celerra may panic if trying to read an uncorrectable), and CLARiiON reported hard media errors as 04x00. With the advent of Flare 19 (and backported to Flare 16), CLARiiON will now report Hard Read (i.e., unrecoverable errors) Errors to the Host as scsi error 03x11. Additionally, Clariion arrays continuously run a background sniffer utility (aka Background Verify) that checks for soft errors and other inconsistencies, and tries to fix. When attempts to correct the media or data error fails, and if Flare cannot rebuild data from parity drives (e.g., double-faulted disk drive in same Raid Group), then a dual unrecoverable read failure occurs and the data becomes “uncorrectable”, or “invalidated”, and essentially “unrecoverable”, subject to a hard error to the accessing Host, which for Celerra means a panic. So, the Uncorrectable Error could already exist and be known as a bad sector by the CLARiiON well before a Host tries to perform a Read to the bad sector. Or, the media error could turn into a Hard Uncorrectable Error if the Host is trying to Read data and the CLARiiON cannot honor the READ, essentially marking the sector Invalid.

### **SCSCI CAM ERRORS REPORTED BY HOST:**

0x03 Medium Error  
0x11 Unrecovered Read Error  
cdb: 28 (Read operation)

### **Uncorrectable Errors:**

CLARiiON event codes logged by FLARE whenever data is unable to be read from a particular drive location, and subsequent attempts to reconstruct the data from other drives within the RG have failed.

### **Invalidated Errors:**

CLARiiON event codes are logged by FLARE when media errors become unrecoverable, the data is marked as being void of valid information. At this point, a hard error is returned to the Host and it becomes an Uncorrectable sector error. Both CLARiiON and NAS have developed tools that can identify the exact location and files affected by the Invalidated errors, and then write to the bad sector to “fix” or revalidate the sector—the data obviously is still gone, but the Hard Error on Reads for the given sectors are resolved. The CLARiiON BRT tool was released with FLARE 19 Patch 030. The traditional NAS tool is Volcopy/MapBlock, while Napa 3 introduces the Revector tool to help streamline the process, and GrandNapa provides further enhancements with the cse\_recover tool whereby the backend will actually do the sector repair work, making it much faster than the sector by sector read that the Celerra must perform.

### **Coherency Errors:**

Events on Clariion backends that are related to—  
--Hardware problems with drives  
--Frumon code problems with LCCs  
--Flare bug affecting ATA drives

### **HOW DATA MOVER HANDLES MEDIA ERRORS:**

For DART, when reading data from the backend, and receiving an 04x00 or 03x11 error from the CLARiiON (or 03x11 Error from Symmetrix), will panic with IO failure—can lead to Rolling panics if client keeps reading same sectors. From the Data Mover perspective, the hard backend Read errors are seen at the CAM layer and reported by the Volume layer, as opposed to the File System layer. Since the Errors are at the Volume level, FSCK by itself cannot repair, and hence the need for the VolCopy repair tool, or improved tools that Napa 3 and GrandNapa will provide.

## **DIAGNOSING UNCORRECTABLE SECTOR ERROR ISSUES ON CLARIION BACKENDS:**

### **Primary Symptom are Intermittent IO Failure Panics on Data Mover:**

IO failure despite all retries/failovers  
<![CDATA[Slot 2: 1147480411: I/O Error: c0t1112 Irp 0x70f66b04 CamStatus 0x84 ScsiStatus 0x02 Sense 0x03/0x11/0x00

**VOLCOPY/FSCCK/MAPBLK--TRADITIONAL METHOD FOR HANDLING UNCORRECTABLE SECTOR ISSUES:**

**Note 1:** NAS 5.5.23.2 (Napa 3) introduces a new Revector tool that can be used in place of VolCopy tool for those situations where a Data Mover has panicked with an 0x03/0x11Error (Unrecovered Read Error)—VolCopy will still be required for all other situations where Revector does not apply.

**Note 2:** Unfortunately, a change has been made with NAS 5.5.23.2 and VOLCOPY can only be run against the Basic Volume ID—it cannot be used to run against the metavolume, which is the traditional method for using Volcopy.

**WORKAROUNDS FOR NAS 5.5.23.2:**

**VOLCOPY ON STANDBY SERVER—pre NAS 5.5.23.2:**

1. If Volcopy method is required, upload a pre-5.5.23.2 nas.exe and run the VolCopy on the Standby Server
2. Run FSCK/Builtin Mapblk on Production Server if running 5.5.23.2 or higher.
  - a.) Create “ME\_Hyper\_<metavolID>\_Repaired.txt” file on the rootfs of the production Server and add each Bad Block number, as found in the Server Log, to separate lines in this file.
  - b.) Start FSCK with indicator that DART should use the Repaired.txt file located in the rootfs to record the file information in the Report.txt file:

**\$ .server\_config server\_2 “file fsck uxfs 283=44 mapblock=1”**

**VOLCOPY ON PRODUCTION SERVER—pre NAS 5.5.23.2**

1. Create the empty Repaired.txt file on the rootfs of the Production Server:

# touch ME\_Hyper\_<metavolID>\_Repaired.txt

2. Set the ReportBadBlocks param

3. Run the Volcopy—it will populate the Bad Block information in the Repaired.txt file, rather than having to sort through Server Logs:

**# .server\_config server\_2 “volcopy src=283 threads=100 repair file= ME\_Hyper\_<metavolID>\_Repaired.txt”**

**Note:** Do not use the “file=” syntax with NAS 5.4, it will panic the Server

4. Edit results of this file to leave only Bad Block number on each line

256003932

512005200 (etc.)

5. To use the integrated FSCK/Mapblock feature, run the FSCK from the Production Server using NAS 5.5.23.2 or higher

**\$ .server\_config server\_2 “file fsck uxfs 283=44 mapblock=1”**

**1. Server panics with Uncorrectable Sector error.** may or may not successfully failover, and may or may not develop into a Rolling Panic—if an application, or NFS Client is out there and continually tries to Read the same bad sector each time the DM is back up, then the Server would panic again, etc.

**Panic Header:**

**DART panic message: >>PANIC in file: ./BVolumeIrp.cxx at line: 298 : IO failure despite all retries/failovers**

**Server Log:**

2006-09-04 08:47:32: STORAGE: 3: readBlock() : Volume 118 Bad Block Index ec84faf01157377652: UFS: 3: readBlock failed, err 16

b.) If LUNs are found with errors, Background Verify is run & then checked for number of errors (sniffer)

**\$ /nas/sbin/navicli -h 192.168.1.201 setsniffer 33 1 -bvtimer HIGH** →BV started on affected LUN 33

**\$ /nas/sbin/navicli -h 192.168.1.201 getsniffer 33**

VERIFY RESULTS FOR UNIT 33

Sniffing state: ENABLED

Sniffing rate (100 ms/IO): 5

Background verify priority: High

Historical Total of all Non-Volatile Recovery Verifies (0 passes)

---

Corrected Uncorrectable

Checksum errors 0 25

c.) Based on whatever else is happening with array, CLARiiON may recommend drive replacements, LCC Card replacements, etc., and once backend is stabilized, and the RG parity rebuilds have completed, will most likely recommend an Unbind and Rebind on the affected LUNs, and a Flare Upgrade to help resolve known Uncorrectables issues with ATA drives.

**5. NAS Support offers recommendation for corrective actions**—VolCopy, FSCK, and Mapblk repair method may be used as a way to correct the Backend Sector problems, restore the file system to a consistent state, and identify whatever files/directories have been affected (when possible).

**Note 1:** Generally speaking, the number of Uncorrectable Errors for any given case should be relatively small (under ten) if systems are running FLARE 19 Patch 030 and higher, while systems running older FLARE versions may have hundreds of Errors per affected LUN. ATA drives are particularly susceptible to the issues involved with Uncorrectables, though on rare occasions, Fibre Channel drives will also have Uncorrectables.

- a.) NAS Support identifies the file systems associated with the LUNs that CLARiiON has identified as having Uncorrectables
- b.) Permanently unmount and delete any associated Checkpoints
- c.) Abort any associated Replication Sessions with the affected production file system (? Not sure of this step)
- d.) Permanently unmount the production file system

**Note 2:** In cases where the bad sectors are verified as “unused”, or are only associated with a Checkpoint file system, the only corrective action that would need to take place would be to delete the checkpoint file system or leave the “unused” blocks alone, as the working assumption is that the “unused” bad blocks will always be written to next, as opposed to being Read from, thereby revalidating the data.

## **6. Perform VolCopy repair work using the Standby Data Mover.**

**Note:** If required, upload the latest nas.exe to perform the VolCopy and subsequent FSCK work, and reboot the Data Mover.

## **7. Set the following parameter to allow for the VolCopy tool to identify and then write to the bad sectors:**

**\$ .server\_config server\_3 “param volume allowReportBadBlock=1”**

**Note:** Setting this param is no longer required with NAS 5.5.23.x and higher

## **8. Associate Vol. Structure & CTL information to the Standby Data Mover using the virtual mount:**

**\$ server\_mount server\_3 -v fs1**

**9. Start the VolCopy repair process on appropriate metavolume** (finds bad sectors on indicated metavolume or dvolume, writes 0’s to revalidate the data, and records LBA block information in Server Log):

**\$ .server\_config server\_3 “volcopy src=<vol\_ID\_of\_fsf> threads=10 repair”**

server\_3 : commands processed: 0

Error 5: server\_3 : Input/output errorRPC: Timed out →Normal output, check Server Log to verify that VolCopy has started

**\$ .server\_config server\_3 “volcopy src=<vol\_ID\_of\_fsf> abort”** →Use to abort a Volcopy session 5.5.23+  
**Server Log:**

2006-09-02 00:16:41: STORAGE: 4: BEGIN:volcopy repair-Vol:118 srcStart:0 threads:10 xferSize:128 nBlks:778240000

**Note:** Save all output from Server Log and record each BadBlock number

## **10. Monitor VolCopy progress using CLI or Server Log:**

**\$ .server\_config server\_3 -v “volcopy display”**

VC 1: Volcopy src:251 dst: command:3 threads:10

numBlocks:32768000000 blocksCopied:30685721728 progress:93% interleaved:yes

### **Server Log:**

2006-09-02 15:49:44: STORAGE: 4: RepThread:VC118\_20 Volume 118 repair is in-progress(Status:5%)

2006-09-02 16:01:53: STORAGE: 4: RepThread:VC118\_20 Volume 118 repair is in-progress(Status:10%)

2006-09-02 16:14:07: STORAGE: 4: RepThread:VC118\_20 Volume 118 repair is in-progress(Status:15%)

2006-09-02 16:26:19: STORAGE: 4: RepThread:VC118\_20 Volume 118 repair is in-progress(Status:20%)

## **11. After completion of VolCopy repairs, reset parameter to 0:**

### **Server Log:**

2006-09-02 19:42:12: STORAGE: 4: END:volcopy repair-Vol:118 srcStart:0 threads: 1 xferSize:128 nBlks:1868605824

2006-09-02 19:42:12: STORAGE: 4: volcopy: Volume repair on 118 succeeded.

2006-09-02 19:42:12: ADMIN: 4: Command succeeded: volcopy src=118 repair

### **Example of Bad Block Found by VolCopy Process in Server Log:**

2006-09-02 00:18:22: STORAGE: 4: **VC\_118:6816047**

**\$ .server\_config server\_3 “param volume allowReportBadBlock=0”**

## **12. Using the Standby Server, run FSCK on the affected file system(s).**

**\$ .server\_config server\_3 "logsys set severity FSTOOLS=LOG\_DBG3"**

**Note:** Do not set LOG\_DBG3 for NAS Versions 5.4 or 5.5 as the proper FSCK logging is automatically done

**\$ .server\_config server\_3 "file fsck ufs 118=23"**

**Note:** Where 118 is Volume ID and 23 is FSID

## **13. Virtually unmount the file system(s) from the Standby Server when FSCK is completed:**

**\$ server\_umount server\_3 -v fs1**

## **14. Remount file system on the Production Server**

**\$ server\_mount server\_2 fs1 /fs1**

**Note:** At this point, the actual Volume and File System repair processes have been completed, and Mapblk is used to find and map affected sectors to actual file system inodes, etc.

## **15. From the Control Station, create mountpoint & mount the DM file system in preparation for MapBlock:**

**# mkdir /mapblk**

**# mount server\_2:/fs1 /mapblk** [Mounting Data Mover file system fs1 to /mapblk mountpoint on CS]

**Note:** May need to NFS export the file system to CS if the mount command fails due to lack of permissions

**# server\_export server\_2 -o anon=0 /fs1**

## **16. Use MapBlock Utility to map each logical bad block found in the Server Log, as seen by VolCopy process, to an actual inode owner (file system object), then run find command to map inode to file name.**

**Note:** Run MapBlock to map each bad block to an inode, & output to file. Run find or ls to map each found inode to a file name.

a.) Upload the mapblk utility from the GTSCentral/dms website [mapblk.gz] to the CS and unzip:

/home/nasadmin/mapblk

# ls -la

-rw----- 1 root root 332461 Oct 12 09:13 mapblk

b.) For older NAS Versions, the badBlock message that was generated by VolCopy (written to the Server Log) process was different than the current message [VC\_147:6816047], yet still requires division by 16 to obtain the true LBA block number to plug into the mapblk utility.

### **Old NAS BadBlock Message in Server Log:**

**Log Msg:** srccvol:282 badBlock: 623520562 size:512

**Divide:** # echo \$(( 623520562 / 16 ))

**Result:** 38970035.125 → Always round down to nearest whole number to get 8k block number for inode = 38970035

### **New NAS BadBlock Message in Server Log:**

2006-09-02 00:18:22: STORAGE: 4: VC\_118:6816047

**Divide:** # echo \$(( 6816047 / 16 ))

**Result:** 426002.9375 → Always round down to nearest whole number to get 8k block number for inode = 426002

**# /home/nasadmin/mapblk/mapblk server\_2 118 426002**

file system size 48640000

data block in inode 71641

**Note:** Optionally, run mapblk in the background and input to a file to capture the inode numbers

**# nohup /home/nasadmin/mapblk/mapblk server\_2 118 426002 >>fs1.mapblkinode.log &**

**Note:** Above command will output an inode number for the block and Volume ID indicated into the file. Repeat these steps until every badblock has an associated inode in the output file.

c.) Match the inode number to file names using the following process while in the /mapblk mountpoint to the production fs:

**# find . -ls > /tmp/inode\_to\_name\_list.log &**

**Note:** Alternatively, run the find in the background for instances where you are only finding one or two inodes

**# nohup find /mapblk -inum <inode\_no> >>fs1.inode\_name\_map.log &**

17. Advise customer of affected filenames for potential backup Restore

## **CELERRA VOLUME COPY REPAIR TOOL & PROCESS:**

There have been recent cases where Clariion backends are recording uncorrectable scsi sector errors. For Celerra, there are several types of blocks that can be affected by these errors: directory, metadata, & indirect blocks. For ‘data blocks’, a new utility called ‘Volume Copy’ has been bundled into a special nvolvopy.exe, and more recently, with updated versions of NAS 5.4 & 5.5.

The Volume Copy utility works at the volume level by basically writing 0’s to the bad sector, which serves to revalidate the sector, though the data itself is lost. After the Volcopy and fsck procedures are run, the file system can generally be remounted and data restored as necessary—volume copy does not understand file system structures. Since the uncorrectable sector errors are issued by the storage system at the volume layer, an FSCK alone will not correct the issue, since FSCK works only at the FS layer. An “I/O failure despite all retries” is an error that occurs between the CAM & Volume Layer, not the file system layer.

### **CAM→Volume Layer→File System Layer**

0x03/0x11 uncorrectable sector errors, as reported by Symmetrix (and now Clariion with Flare 19+)

04/00 soft media errors, as reported by Clariion storage systems

**Note:** The Volcopy Utility can only be run with NAS versions 5.3 or higher, on either Clariion or Symmetrix backends. Volcopy and FSCK are the only two parts of the toolset that correct the problem, with Volcopy finding and writing zeroes to the uncorrectable sectors, and FSCK putting the file system back into a consistent state afterwards. Mapblk is a reporting tool to determine inode file names from the block number listed in Server log. Not all identified bad blocks will have a filename because some bad blocks could be free space or metadata. Some additional concerns before using VolCopy would be to try and ID the file systems involved. If all file systems on an affected LUN can be taken offline, then run the Volcopy tool against the whole lun.

## **STANDARD CELERRA I/O RETRY MECHANISM:**

Each path has a timeout value of 40 secs for a Read or Write IO failure, up to a total of 240 secs max (4 minutes). Be aware that for IO Failure panics that involve NFS clients, NFS clients will automatically retry to Read or Write to the same file when the Data Mover comes up, in essence creating a Rolling Panic situation.

## **VALID NAS VERSIONS FOR VOLCOPY:**

5.3.25.0, 5.4.19.4 and above

## **SYMPTOMS & CAUSE:**

Data Mover may intermittently panic with "IO failure despite all retries/failovers" and log "CamStats 84 ScsiStatus 02 Sense 0400 00" errors. Basic cause would be a backend event such as,double-faulted Raid Group, power outage without battery backup. In reality,

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
many of the Uncorrectable issues emanate from the use of ATA drives on CLARiiON backends. Flare 19 Patch 027 was issued to correct a problem where writes could be successful, but later Reads of the data became media errors. ATA drives also could timeout during error handling and result in faulted drives, and uncorrectable errors. Patch 034 fixes sector remapping issue for RAID 3 if different size ATA drives are used within same RG, which resulted in uncorrectables in upper half of drives. Patch 030 fixes rebuild issue that could cause hard error, uncorrectable.

### **BASIC STEPS INVOLVED WITH VOLCOPY REPAIR:**

1. Provide SPCollects to Clariion and engage—they will need to run manual BV to determine # of uncorrectables—BV does resolve some issues. Often it appears that bad disk drives are the cause of the problem and may require unbind of luns, disk replacement, rebind of luns, and restore from Tape or other means.
2. Identify affected file systems, determine whether to use file system volume or disk volume method
3. Set param volume allowReportBadBlock=1 and reboot Data Mover to enable VolCopy Tool
4. Unmount affected file systems and delete any associated Checkpoints or IP Replication SavVols
5. Conduct virtual fs mount using -v
6. Run volcopy tool
7. Virtually unmount file system(s), turn off the allowReportBadBlock param, and reboot the Data Mover
8. FSCK the affected file systems
9. Run MapBlock to map LBA address from Server Log to an inode number

### **TYPICAL BAD LBA BLOCK BEING REPORTED BY VOLCOPY:**

STORAGE:4: VC\_90:12583135

### **BASIC VOLCOPY PROCEDURE--see Primus emc117301:**

#### **I. CORRECTING THE BAD SECTORS & RESTORING FILE SYSTEMS TO CONSISTENCY:**

**Prerequisites:** Always have Symmetrix or Clariion backend completely checked out prior to running this procedure, and then only use this procedure with the explicit approval of Escalation Engineering, as it requires a special nas.exe version. Volcopy can be run against file systems, as in the procedure below, or against the disk itself. Volcopy reads in 64k chunks, but once it encounters a sector error, will begin reading in 512 bytes, sector-by-sector within the 64k chunk, zeroing out bad sectors and logging the lba information message in the Server Log. The VC output in Server Log is the 512 byte sector within the file system that is corrupt, not an 8k block.

#### **RUNNING VOLCOPY AGAINST THE DISK VOLUME vs. FILE SYSTEM:**

1. Run steps 1-6 in the above Volcopy procedure
2. Record the chain target & lun information for each path to the disk volume in question from Server Log  
Command succeeded: volume disk 1515 c32t3l12 disk\_id=71
3. Virtually unmount the file system from the Standby server
4. Read in each path to the disk using the following:

**\$server\_config server\_2 "volume disk 1515 c32t3l12 disk\_id=71"** (repeat for each path)

5. Run volcopy against the disk volume

**\$server\_config server\_2 "volcopy src=1515 threads=10 repair"**

6. Reboot data mover after completion and run FSCK

#### **Some Server Log messages during VolCopy Repairs:**

2006-04-14 04:03:05: STORAGE: 4: BEGIN:volcopy repair-Vol:4996 srcStart:0 threads:10 xferSize:128 nBlks:6704695296

2006-04-14 05:41:19: STORAGE: 4: RepThread:VC4996\_0 Volume 4996 repair is in-progress(Status:5%)

### **UNCORRECTABLE SECTOR ERRORS GETWELL PLAN:**

Engineering is implementing a phased plan to handle the uncorrectable sector error issues. One of the major problems with Clariion arrays is that Media Errors were not being reported as 03/11 errors, as the Symm has always done, but no different from generic Hardware Errors 04/00. With advent of FLARE 19, arrays will be able to properly report Media errors as 03/11 errors.

#### **PHASE 0:**

Current manual process, whereby Server panics (rolling panic) on the Bad Sector errors, file system becomes unavailable until manual VolCopy recovery procedure is run. If file system involves Checkpoints or Replication, must delete or deactivate. FSCK only corrects for metadata issues, cannot repair data blocks.

#### **PHASE 1:**

Bad Sector media error of 03/11 will be reported if running FLARE 19. Celerra will still panic, initiate the volcopy repair during reboot, will fsck if bad sector is in the pfs, will invalidate SnapShots, will deactivate Replication Sessions, runs Fs\_mapObjects tool to find damaged objects, then reassign bad sectors. DM will not be available during this repair process, and will be in loaded state.

#### **PHASE 2:**

Similar to Phase 1 except that Data Mover will come to contacted state and service all other file systems while repair is being done in background.

#### **PHASE 3:**

Try to prevent panic. Will freeze file system, runs volcopy procedure, fsck's, unfreezes and re-exports as required.

### **PHASE I & PHASE I PRIME UNCORRECTABLE SECTOR CODE FIX PLAN:**

#### **Phase I Napa 3:**

Depends on Flare 19 patch 034 for 03x11 scsi sense key during DM Panic. Server reboots with affected fs unmounted (no more Rolling Panics), use revector tool to repair bad blocks as listed in sys\_log, fsck & mapblk automatically map inodes to file names for bad blocks, remount file system

### **\$ .server\_config server\_2 “revector start vol=xxx”**

After the revector tool is run, the file system can be mounted, at which time FSCK and MapBlock will be run, and upon completion, the file system will be mounted. In practice, though, run the nas\_fsck manually, which also invokes the mapblk tool and will ensure that the File System mount information will be consistent with the Control Station db. For Cognac release, the Data Mover will recover automatically, with the eventual plan being that the Data Mover will be able to log the errors & fix without panicking at all.

#### **Phase I Prime GrandNapa:**

Depends on Flare 19 patch 034 for 03x11 sense key error during DM panic. Uses new cse\_recover script on Control Station to invoke CLARiiON BRT tool to cleanup and report on bad sectors. See section under ‘GrandNapa’ for more details.

## **SEVERAL UNCORRECTABLE REPAIR METHODS:**

### **I. VolCopy, FSCK, MapBlock**

→DART driven repairwork, very slow & manual for each bad sector, dependent on CLARiiON Support’s intervention & analysis of SPCollects & BV

→Before NAS 5.5.23.2 (Napa 3) and Flare 19 Patch 030, the only Celerra method of recovery was VolCopy

### **II. Revector Tool—Phase I Napa 3 [5.5.23]**

→DART driven repairwork, very slow, but much manual work reduced, BV may still need to be redone and VolCopy method used to repair bad sectors that fall outside the file system metavolume associated with the Panic

→DART will panic, but recover with affected file system <unmounted>

### **III. Cse\_recover Tool—Phase I Prime GrandNapa [5.5.27.5]**

→SP driven repairwork, much manual work reduced, very fast, but BV may still be needed to address other Uncorrectables that fall outside the metavolume associated with the triggering Panic event

Keep in mind that at any given time, you may need to use a combination of the above tools on a system

#### **Example:**

Napa 3 & Flare 19 P034 are in place. Server panics, Bad Sector identified, Revector tool used. However, other Uncorrectable events may have affected other metavolumes and luns, especially across the same Raid Group—Run BV to determine if there are other Uncorrectables and then follow the traditional VolCopy repair method to fix

## **COGNAC 5.6.36.4 UNCORRECTABLE UPDATE:**

Due to an oversight, the revector tool and cse\_recover tools were never built into the Cognac family. AR114835 ports the cse\_recover tool into 5.6.37.

## **REVECTOR REPAIR METHODOLOGY FOR NAPA 3:**

### **CAVEATS:**

→Tool must be used with Napa 3 +, Flare 19 patch 034 +, an 03x11 SCSI error in Panic Header, and be run on the Production Server  
→Run manual FSCK using nas\_fsck—do not use server\_mount to invoke FSCK after revector repairwork

### **General Process that occurs:**

→Server panics, recovers gracefully with affected file system <unmounted>--No autofsck allowed in Phase I or Phase I Prime

→Associated Checkpoints & Repl. Sessions become inactive

→FSCopy operations will abort

→Examine crash header to determine Vol ID & block number of affected file system--check Server Log & Sys\_log to confirm entries

→Start the Revector command to correct the bad blocks

→After Revector completes, abort Replication Sessions on affected file system

→Track progress of Revector in Server Log--a list of repaired blocks is written to a “...Repaired.txt” file on the rootfs of the DM

→Run nas\_fsck on Production Server, which runs fsck, runs MapBlock & automatically creates the filename-to-inode-to-path file for customers--replaces “...Repaired.txt” file with a “...Report.txt” file

→Remount file system on Production Server

→Present tidy list to customer & restore files from Backup

### **Panic Handler States for Volume Recovery Situation:**

DISKID\_SET—Panic Handler disk\_id & bad sector address for basic volume set in PH just prior to panic when media error encountered

HYPERVOL\_SET—Panic Handler state after reboot—LUN-based physical blocks are reverse mapped to hyper-based logical block numbers and file written to Data Mover rootfs

REVECTORING\_IN\_PROG—Panic Handler state during the revector recovery process. If interrupted, can be resumed (this state won’t be used for Phase I Prime cse\_recover)

REVECTORING\_DONE—Panic handler state at end of the sector cleaning process. This entry is removed once the FSCK/MapBlock process has been completed, and file system can be normally remounted and accessed

### **Repair Process:**

1. Uncorrectable occurs

2. Data Mover tries to Read invalid sector & generates 03x11 scsi errors
3. Data Mover panics, reboots, comes back online without bad file system

#### # server\_mount server\_2

root\_fs\_2 on / ufs,perm,rw  
sector on /sector ufs,perm,rw

#### **bolsha on /bolsha ufs,perm,rw,<unmounted>**

4. Check Panic Header, Sys\_log, or run “mepanic dump” to obtain Revector information:

#### **DART panic/fault message:**

>>PANIC in file: ../BVolumeIrp.cxx at line: 323 :  
IO failure on Vol:130, blkNo:5248, SKey:0x311

#### **Sys\_log:**

Nov 3 15:57:56 2006 UFS:3:7 Slot 3: 1162587599: Mount failed, Please start Revectoring using "revector start vol=137"

5. Run Revector Tool on Production Server to repair bad blocks

#### **# .server\_config server\_2 "revector start vol=137"**

6. Check progress in Server Log:

2006-11-03 17:01:00: STORAGE: 4: RepThread:VC130\_0 Volume 130 repair is in-progress(Status:91%)  
2006-11-03 17:02:12: STORAGE: 3: 8: Revector Completed:BasicVol:130, 19 blks repaired, total 40959984 nBlks covered

7. Use “mepanic” command to verify if the revector has completed—State 4 indicates that revector process is done

#### **# .server\_config server\_2 -v "mepanic dump"**

1187038890: STORAGE: 4: State: 4 HyperVol: 105 :: LBlkNo: 115102576

8. Revector process creates Repaired.txt file & writes to rootfs

#### **[root@laip2 slot\_2]# cat ME\_Hyper\_137\_Repaired.txt**

5248  
5235

5249 --output abbreviated--

9. Run nas\_fsck on Production Server (Invokes MapBlock):

#### **# nas\_fsck -start bolsha**

id = 74  
name = bolsha  
volume = v137  
fsck\_server = server\_2  
status = In-progress  
2006-11-03 17:05:17: FSTOOLS: 4: 0: FsId: 74 Fsck Started (Manual).  
2006-11-03 17:05:17: STORAGE: 3: Found bad sector 5248 on Vol:137 repair state 4  
2006-11-03 17:05:17: FSTOOLS: 4: starting fsck  
2006-11-03 17:05:17: FSTOOLS: 4: 6: MAPBLOCK:: MapBlock Started  
2006-11-03 17:05:17: FSTOOLS: 4: \*\* Last Mounted on /bolsha  
2006-11-03 17:05:17: FSTOOLS: 4: Phase 1: Validate Inodes  
2006-11-03 17:05:17: FSTOOLS: 4: 0 % complete  
2006-11-03 17:05:25: FSTOOLS: 4: Aclchk fsid 74: 100% complete  
2006-11-03 17:05:26: FSTOOLS: 4: MAPBLOCK:: Finding Pathnames: Completed.

10. After fsck completes, the Repaired.txt file is replaced with the Report.txt that contains File name, Sector No., Block No., Inode No., and path

#### **[root@laip2 slot\_2]# cat ME\_FS\_74\_Report.txt**

-----MapBlock Output-----

| Sector No.           | Block No | Inode No | Path            |
|----------------------|----------|----------|-----------------|
| 5248                 | 328      | 25       | /data1/         |
| 2k3tools/rktools.exe |          |          |                 |
| 5249                 | 328      | 25       | Duplicate Entry |
| 5250                 | 328      | 25       | Duplicate Entry |

#### **Server Panic During FSCK:**

2007-10-18 04:10:26: FSTOOLS: 4: 0: FsId: 2553 Fsck Started.  
2007-10-18 04:10:26: STORAGE: 3: Found bad sector 884688320 on Vol:12552 repair state 2  
2007-10-18 04:10:26: UFS: 3: Fsck failed as revectoring for Media Error affected HyperVol:12552 not done  
2007-10-18 04:10:26: UFS: 3: File fsck failed for fs 2553 with status IO\_Error  
2007-10-18 04:10:26: FSTOOLS: 4: 2: FsId: 2553 Fsck Failed

**Note:** If there is a problem during FSCK, such as a Server panic, and the FSCK needs to be run again, you may need to run the following command in order to reset the proper Panic Handler flags to allow the FSCK to run on the affected file system volumes

#### **\$ .server\_config server\_7 -v “mepanic reset all”**

11. Remount file system and verify:  
**# server\_mount server\_2 -a**
12. Provide customer file list for restore purposes

### **CLARIION TOOL:** Bad Blocks Reporting & Clean-up Tool (BRT)

In certain situations, this tool may be used by Clariion TS2 to clear invalid sectors and map bad blocks to data files

#### **BRT PROCEDURE:**

1. Use naviseclli to obtain list of invalidated sectors (Flare 16 & 19) from Windows or Solaris host using correct agent
2. Use naviseclli to clear bad blocks by zeroing out
3. Map bad blocks to data files
4. Restore identified files from backup source

## **INTEGRATEDS FAIL TO CALL HOME FOR UNCORRECTABLE ERRORS FROM NAVIEVENTMONITOR:**

/nas/log/sys\_log: (AR79015 fixes this issue in 5.4.27, 5.5.25, and 5.6.36 versions)

May 12 21:00:01 2006 NaviEventMonitor:3:3 Backend Event Number 0x957 Host OEM-XOO25IL9VL9 Storage Array  
APM00041700339 SPA Device

APM00041700339 SPA Device

Bus 1 Enclosure 1 Disk 8 SoftwareRev 6.19.0 (4.14) Unknown Error 2.19.0.701.5.027 Description Parity Invalidated

**Note:** See AR79015 for more details—fixed in NAS Versions 5.4.27.0 & 5.5.25.0. For Captive or Integrated NS systems, Celerra uses a navilog\_mon entry in the nas\_mcd.cfg file to run the navilog\_mon process, which collects CLARiiON events from NaviEventMonitor [Naviagent] and then posts to the sys\_log using /nas/sbin/postevent. Unfortunately, none of the Uncorrectable errors are delivered with a Severity of CRITICAL, so the Celerra does not CallHome.

#### **# cat /nas/sys/nas\_mcd.cfg**

```
daemon "Navi Event Monitor"  
  executable  "/nas/sbin/navilog_mon"  
  optional    no  
  autorestart yes
```

## **BACKEND EVENTS THAT INTEGRATED CELERRAS WILL CALLHOME FOR:**

**# nas\_event -list -a callhome |grep Navi**

NaviEventMonitor 4 Navi Event with severity CRITICAL was received

NaviEventMonitor 100 A control lun has been cache compromised

**Note:** Navi Events with severity CRITICAL will generate CallHomes, as will the event 100 for Cache Compromised Control Luns

#### **NAVI EVENTS:**

#### **# nas\_event -l -f NaviEventMonitor**

```
id description  
1 Navi Event with severity INFORMATION was received  
2 Navi Event with severity WARNING was received  
3 Navi Event with severity ERROR was received  
4 Navi Event with severity CRITICAL was received  
5 Unknown Navi Event was received  
10 Navi Event Monitor has terminatedF  
100 A control lun has been cache compromised  
101 A control lun has been trespassed  
200 Device group has changed status  
201 A SFP on the CLARiiON is reporting an error status
```

#### **# cat /nas/sys/nas\_eventlog.cfg**

```
#  
# Navi Event Monitor
```

```
#  
facilitypolicy 138, 0  
disposition range=0-1000, logfile "/nas/log/sys_log"  
disposition range=4-4, callhome immediate  
disposition range=4-4, exec "/nas/tools/automaticcollection -getlogs"  
disposition range=100-100, callhome immediate  
disposition range=100-100, exec "/nas/tools/automaticcollection -getlogs"
```

#### **EXAMPLES FROM SYS LOG:**

Aug 27 11:42:51 2007 NaviEventMonitor:**2:4** Backend Event Number 0xa07 Error Host OEM-2MYA58ZGAQT Storage Array APM00062101038 SPB Device Bus 1 Enclosure 0 Disk 1 SoftwareRev 6.24.1 (5.0) BaseRev 2.19.0.500.5.040 Description CRU Powered Down

Aug 27 11:42:51 2007 NaviEventMonitor:**3:3** Backend Event Number 0x906 Host OEM-2MYA58ZGAQT Storage Array APM00062101038 SPB Device Bus 1 Enclosure 0 Disk 1 SoftwareRev 6.24.1

**2:4 →Severity 2 = Critical, Event ID 4**

**3:3 →Severity 3 = Error, Event ID 3**

#### **EXAMPLE BACKEND EVENT THAT GENERATES CELERRA CALLHOME FOR INTEGRATED:**

**Situation:** SP Reboot will generate the 0xa23 event, reported by Clariion as a severity CRITICAL issue, and Celerra reports in sys\_log as a Critical 2, which generates a CallHome

##### **sys log:**

Feb 28 19:48:09 2007 NaviEventMonitor:**2:4** Backend Event Number 0xa23 Error Host SPA Storage Array APM00063303725 SPA Device SP B SoftwareRev 6.24.1 (0.0) BaseRev 3.24.0.40.5.007 Description Peer SP Down.

**2:4 →2 is severity level = Critical, while 4 is Event ID**

##### **getlog from SPA:**

02/28/2007 19:47:01 SP B (a23) Peer SP Down. [0x03] 0 0

##### **# cat /nas/log/ConnectHome/RSC\***

<![CDATA[Backend Event Number 0xa23 Error Host SPA Storage Array APM00063303725 SPA Device SP B SoftwareRev 6.24.1 (0.0) BaseRev 3.24.0.40.5.007 Description Peer SP Down.

#### **CLARIION NAVIEVENTMONITOR:**

Clariion uses an external events file (callhome\_template) hosted on an external Windows management system that monitors events on the array and takes action depending on the Rules. This file is similar to nas\_eventlog.cfg and changes from release to release. For Integrated arrays, this callhome\_template is not configured and NaviEvents are forwarded to Celerra for disposition. NAS & CLARiiON do not coordinate CallHome levels, leading to the problem whereby Uncorrectable Sector errors can occur on the backend but the Celerra does not consider these CallHome worthy. This is fixed with AR79015, NAS 5.4.27.0 & 5.5.25.0—Celerra should now see an Uncorrectable event from NaviEventMonitor as a CRITICAL (4) event from the Backend, and will generate a CallHome.

#### **NAVIAGENT:**

##### **# ps -ef |grep navi**

```
root 25176 21500 0 May28 ? 00:00:01 /usr/bin/perl /nas/sbin/navilog_mon  
root 25181 21500 0 May28 ? 00:00:50 /nas/opt/Navisphere/bin/naviagent -d -f /nas/etc/Navisphere/agent.config -r /nas/log
```

→Naviagent is a daemon that reads events delivered from the CLARiiON, processes the events as defined in the /nas/sys/storage\_eventlog.cfg file, and sends the events to the sys\_log. Events meeting the CallHome criteria then generate a CallHome.

→Naviagent keeps track of which events have been already processed so as not to repost

→Naviagent runs as a daemon controlled by the NAS Master Control Daemon [see /nas/sys/nas\_mcd.cfg]

daemon "Navi Event Monitor"

```
executable "/nas/sbin/navilog_mon"  
optional no  
autorestart yes  
daemon "Naviagent"  
executable "/nas/sbin/start_naviagent"  
optional no  
autorestart yes  
ioaccess no
```

#### **VIEWING CLARIION EVENTS USING NAVISPHERE:**

- a.) Obtain the appropriate Flare template file from Clariion Support—Call\_Home\_Template\_6.24.0.tpl
- b.) Open Navisphere>Monitors tab>Templates>import templates>browse to template file of choice and load

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
c.) Rightclick the imported template file>properties>Advanced: All events are listed under the CRITICAL, ERROR, WARNING, & INFORMATION icons for review

**Note:** Please note that not all events are “enabled” by default

## **MISCELLANEOUS HARDWARE & SETTINGS:**

### **MODEMTEST COMMAND:**

**# /nas/sbin/modemtst**

Modem test V0.7

All ports are busy now, try again later

**Note:** emc74010 documents that a software fix is now available with 5.4.17.0 & 5.3.20.0. It was found that HUP was not calling Login process after being terminated, no matter what the reason for the termination, and therefore could not properly reset ttyS0 modem connection. The fix is built into “mgetty-1.1.30-0.7.EMC.02” and now allows the Linux login process to properly receive a HUP signal upon disconnect and then to properly reset the modem port. See AR53833.

**# rpm -q mgetty**

mgetty-1.1.30-0.7.EMC.02

**/etc/mgetty+sendfax/mgetty.config**

data-only y (this line must not be commented out)

### **VARIOUS NAS 5.6 MODEM ISSUES:**

#### **1. ETA emc188184 Modem Stops Dialing Home after Upgrading:**

The **/etc/mgetty+sendfax/mgetty.config** file did not carryover from 5.5 with the proper string:

##### **Modem Test indicates the issue:**

Error 14504231224: Test failed for the Primary Modem.

##### **Wrong entry:**

fax-id 49 115 xxxxxxxx

##### **Correct entry:**

data-only y

**Note:** See AR118928 & AR118933 for more details. Issue fixed with NAS 5.6.38.2 and higher. A workaround for a system that is not running NAS 5.6.38 or higher is to add the following lines to the /nas/opt/connectemc/modem.cfg file:

# cat /opt/connectemc/modem.cfg

**set dial display on**

**set modem command init-string AT+FCLASS=0\{13}**

#### **2. ETA emc192298 Cannot Dial into Celerra Modem after Upgrade to 5.6.38:**

There is an issue with the Control Station startup scripts where the link file /dev/callhome is not recreated during reboots. This link file is necessary to associate the modem port (usually ttyS0) with the /dev/callhome service. The engineering solution is to place the following command inside the /nasmcd/sbin/ch\_mgetty\_monitor script in order to ensure that the link is always present for Dial In service. The Dial Out CallHome service is not affected because it always runs /nas/sbin/modemtst, which automatically recreates the /dev/callhome link if necessary.

##### **FIX:**

**# ln -sf /dev/ttyS0 /dev/callhome**

##### **Example of output when modemtst is run and the /dev/callhome link does not exist (modemtst will recreate the link):**

# /nas/sbin/modemtst

modemtst: version 1.0

modemtst: No callhome port /dev/callhome

modemtst: Callhome port: /dev/callhome --> /dev/ttyS0

modemtst: Modem /dev/ttyS0 OK

modemtst: Deleted symlink /dev/callhome --> /dev/ttyS0

modemtst: Callhome port: /dev/callhome --> /dev/ttyS0

##### **/nasmcd/sbin/ch\_mgetty monitor script:**

→Script ensures that mgetty process is started and monitoring the /dev/callhome device in order to deliver CallHome events

→Monitors for ConnectHome event files and delivers CallHomes—replaces ch\_exec function

→Provides for capability to Dial into modems even without NAS Services running

# ps -eafl |grep mgetty

4 S root 8359 1 0 81 0 - 922 wait Jul14 ? 00:00:00 /bin/sh /nasmcd/sbin/ch\_mgetty\_monitor

### **NORMAL MODEMTEST OUTPUT:**

**# /nas/sbin/modemtst**

Modem test V0.7

Modem OK.

**Note:** Typical test reinitializes modem by testing for Carrier, Send, Receive signals before returning TR light to on status

## **PROBLEM WITH FAX LINES CALLING CONTROL STATION:**

**Note:** NAS 5.4.20.1 will prevent mgetty from monopolizing the modem due to fax calls

### **# rpm -q mgetty**

mgetty-1.1.30-0.7.EMC.02 (new version)

### **WORKAROUND FIX FOR OTHER VERSIONS:**

1. Edit /etc/mgetty+sendfax/mgetty.config to add following statement just above the ----port specific section----

### **data-only y**

----- port specific section -----

2. Grep for mgetty callhome process and kill the process—process will auto restart

# ps -ef |grep mgetty

root 1753 1 0 2005 ? 00:00:02 /bin/sh /nasmcd/sbin/ch\_mgetty\_m

#kill 1753

## **OTHER TROUBLESHOOTING COMMANDS:**

### **# ps -ef |grep -i mget**

```
root 1191 1 0 17:31 ? 00:00:00 /sbin/mgetty -x 0 ttyS1
root 6582 1 0 17:44 ? 00:00:00 /sbin/mgetty -x 0 ttyS0
```

### **# /usr/sbin/lsof /dev/ttYS\*** [Shows info about serial ports opened on CS0]

| COMMAND | PID  | USER | FD | TYPE | DEVICE | SIZE  | NODE NAME  |
|---------|------|------|----|------|--------|-------|------------|
| mgetty  | 1191 | root | 0u | CHR  | 4,65   | 70965 | /dev/ttYS1 |
| mgetty  | 1191 | root | 1u | CHR  | 4,65   | 70965 | /dev/ttYS1 |
| mgetty  | 1191 | root | 2u | CHR  | 4,65   | 70965 | /dev/ttYS1 |
| mgetty  | 6736 | root | 0u | CHR  | 4,64   | 70964 | /dev/ttYS0 |
| mgetty  | 6736 | root | 1u | CHR  | 4,64   | 70964 | /dev/ttYS0 |
| mgetty  | 6736 | root | 2u | CHR  | 4,64   | 70964 | /dev/ttYS0 |

### **# setserial**

setserial version 2.17, 27-Jan-2000

```
usage: setserial serial-device -abqvVWz [cmd1 [arg]] ...
       setserial -g [-abGv] device1 ...
-----abridged output-----
```

### **# ls -la /var/run/mgetty\***

```
-rw-r--r-- 1 root root 5 Oct 8 17:51 /var/run/mgetty.pid.ttyS0
-rw-r--r-- 1 root root 5 Oct 8 17:31 /var/run/mgetty.pid.ttyS1
```

### **# /sbin/fuser -u -v /dev/ttYS\***

| USER       | PID  | ACCESS | COMMAND      |
|------------|------|--------|--------------|
| /dev/ttYS0 | root | 7666   | f.... mgetty |
| /dev/ttYS1 | root | 1191   | f.... mgetty |

## **STOPPING AND RESTARTING MGETTY PROCESS:**

1. Verify mgetty process:

### **# ps -ef |grep mget**

```
root 1353 1 0 09:51 ? 00:00:00 [mgetty]
root 10598 1 0 10:49 ? 00:00:00 /sbin/mgetty -x 0 ttYS0
```

2. Vi and comment out Serial Port line "S0:3:respawn"

### **#vi /etc/inittab**

# Run mgetty to monitor serial port

#S0:3:respawn:+/sbin/mgetty -x 0 ttYS0 [Comment out this line]

3. Shutdown mgetty process by running:

### **# /sbin/telinit q**

4. Verify that mgetty stops:

### **# ps -ef |grep mget**

```
root 1353 1 0 09:51 ? 00:00:00 [mgetty]
root 31111 20844 0 11:18 pts/0 00:00:00 grep mget
```

5. To restart, uncomment the line in /etc/inittab and start the mgetty process, then verify that it runs:

### **#vi /etc/inittab**

```
S0:3:respawn:+/sbin/mgetty -x 0 ttyS0
# /sbin/telinit q [Starts mgetty process by reexamining /etc/inittab file]
# ps -ef |grep mget
root    1353   1  0 09:51 ?    00:00:00 [mgetty]
root    7065   1  0 11:23 ?    00:00:00 /sbin/mgetty -x 0 ttyS0
```

## **CONFIGURING MODEM ACCESS TO LINUX CS WITHOUT NAS OPERATIONAL:**

```
#rm /etc/nologin.ttyS0
#/sbin/mgetty -x -0 ttyS0
```

## **HOOKING UP KEYBOARD & MONITOR DIRECTLY TO DATAMOVER:** Keybd = lower 'db9' connection

- Step 1. Connect keyboard to lower db9 port on DM
- Step 2. Connect monitor to db15 video port
- Step 3. Plug monitor into a/c
- Step 4. Type following message: Console>logsys add output console
- Step 5. Run commands on datamover

## **CONNECTING DIRECTLY TO NX4, NS-120, NS-480, NS40, NS20 BLADE CONSOLE:**

1. Connect serial cable from Laptop (COM1 or COM2) to upper serial maintenance port (indicated by wrench symbol) on the back of the Blade using mini-DB9 cable
2. Open and configure Hyperterminal session using the following settings:  
Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that Autodetect & ANSI are selected for terminal emulation)
3. Click on 'Call' icon to connect to Data Mover console:  
CONSOLE>
4. Set output to the console and run direct commands to the Server:

**CONSOLE>logsys add output console**

1233070880: ADMIN: 6: Command succeeded: logsys add output console

**CONSOLE> version**

Product = EMC Celerra File Server

Version = T5.6.43.4 (CMB\_SLEDGEHAMMER 32-bit)

Debug = DEBUGOFF

BIOS = 3.58

POST = Rev. 01.50

1233070896: ADMIN: 6: Command succeeded: version

CONSOLE>ifconfig

**Note:** Version command for DART is available only with 5.6.43 and later

5. Reset the console output to log:

**CONSOLE>logsys delete output console**

## **CELERRA PERFORMANCE TROUBLESHOOTING:**

### **Two Performance Measurements:**

1. Response Times (User's Perspective): Timespan between User request and actual response
2. Throughput: Number of transactions accomplished in a given time by the Server (truest picture of actual work being done)

### **Two Types of Performance Problems:**

1. System Timeouts--usually indicated with application, client, or Celerra logs or error messages
2. Performance Decreases--without error messages; Requires Network Traces & Careful analysis

### **Criteria for Busy Systems:**

- Greater than 70% utility of any component
- FC IOPS exceeding 100 I/O per second
- ATA IOPS exceeding 50
- Number of dirty pages exceeds the High Watermark
- Disk Queues greater than 10

### **Basic Systems Involved:**

1. Disk Subsystems--I/O Reads & Writes. UFS filesystems consist of 'superblocks', 'Inode Tables', & 512kb 'Data Blocks'. Superblocks contain filesystem information such as total number of free data blocks, number of free inodes, etc. Inodes contain all information about a file, except for its name, which is located in the directory. Data is addressed in 512 blocks. The physical disk is further divided into cylinder groups, which are collections of tracks over a number of multiple platters. The concept of 'cylinder groups' was introduced to improve disk performance, as files are stored in cylinder groups to reduce access times. Each cylinder

group also contains a copy of the primary superblock for the filesystem. Data is stored in “blocks” and “fragments” (8kb/1kb). In summary, information is stored on disk as ‘data’ and as ‘metadata’. When files are being created, deleted, or updated, updates are made to metadata in memory, then flushed to disk in a ‘metadata’ journal log fashion (Celerra ufslog). Only entire transactions are logged to this ufslog, which allows for complete transaction replaying of filesystem information after system crashes, etc.

### **Important I/O Factors:**

- Sequential I/O optimizes disk subsystems by using less random access and more sequential access with fewer disk movements, and can optimize I/O further with prefetch caching mechanisms
- Read vs. Write operations are factors
- I/O request size affects I/O time—request size is size of I/O used to transfer data from disk to memory, and vice versa, and is usually a function of file system block size
- Average customer file system is 70% Reads & 30% Writes

### **Typical Situations Using Random I/O Patterns:**

- Home Directories
- Transactional Databases
- SnapSure SavVol Reads
- IP Replication activity

### **Typical Situations Using Sequential Read I/O:**

- Backup to disk Restores
- Policy Engines and Indexing
- Imaging

### **Typical Situations Using Sequential Write I/O:**

- SnapSure SavVol writes
- Backup to Disk backups
- Imaging

### **Disk Bottleneck Indicators:**

High disk utilization; large disk queue lengths; larger % time waiting for disk I/O; large I/O rates; low buffer cache hit ratio; large run queues with idle CPU

2. Network--Lookups, connections, session builds/teardowns, Reads, Writes, Locks, etc.
3. CPU—CPU’s run one instruction per cycle. CPU’s utilize high speed cache to maintain data and instructions to keep the CPU busy. High speed cache can be accessed in one CPU cycle. TLB cache is used to speed up translation of virtual memory addresses to physical memory addresses. Users affect CPU usage in two ways: Application processes and System Kernel calls that result from User operations.

### **CPU Bottleneck Indicators:**

0% Idle; Large Run Queues over time; Slow response times; High % system calls

4. Code—Code is executed as “processes” running in RAM and executed in two modes--User & Kernel Level. Kernel level is the only level allowed to access hardware directly, such as I/O, IPC, Network communications, etc. (this is why such things as NIC drivers are also kernel-level drivers). Unix is a multi-user and multitasking Operating System where User and Kernel modes are measured by time.

**Processes:** Processes are started from code stored on disk and are created by a parent from a fork system call, which are then placed into memory to begin execution of code. Paging & Swapping operations only apply to the “data” pages of a running process. If processes have to wait before being executed, they may be written to swap space. Processes can be stopped by signals issued from Hardware (Processor), Software (Kernel O/S or Application), or User (ctrl + c on keyboard). CPU Scheduler takes processes and schedules them with a finite amount of CPU time (quantum or time slices, usually 100ms), depending on priority. (3) Types of CPU priorities are “real-time” (1-127), “system” (128-177), and “user” (178-251)—the latter two makeup “timeshare processes”. When processes have to wait to be executed, their priority increases. When processes are being executed, their priority lowers.

**Buffer Cache:** Data read from or written to disk are stored in “buffer cache”, a RAM pool designed to minimize physical I/O from disk. Both Reads and Writes are copied to buffer cache—writes are written periodically to disk by the syncer daemon. Buffer cache contains “data” and “metadata” (superblocks or mounted file systems, inodes of open files, cylinder group information tables, etc), and are usually written synchronously to disk, which is the quickest method. Asynchronous writes are safer, but not generally used due to longer time and overhead involved.

### **Static Buffer Cache vs. Dynamic Buffer Cache:**

Static buffers are the traditional kernel parameters “nbuf” and “bufpages”, usually 10% of physical RAM in size. Nbuf defines the number of files that can have a buffer cache entry, while “bufpages” defines the actual size of buffer cache in 4kb pages.

**Caution:** Increasing “buffer cache” will reduce amount of memory available for other processes and can result in excessive paging.

### **How to Analyze a Customer's Environment:** BPS=(Block Size \* Parallel Requests) /latency

1. Block Size--increasing this value may help
2. Parallel Requests--add to this as well
3. Latency--Reduce this [usually this is the primary Networking variable that can be influenced]

### **Difference Between Direct-Attached and Network-Attached-Storage:**

1. Networking requires more overhead for Users or Host access for Authentication & Communication

2. Direct Attached Storage uses only (1) Host to (1) Disk Device & requires no Authentication or Access Protocols

**Other Considerations Regarding Performance Issues:**

1. Is the Application designed for network operations? [operational latencies are inherent with NAS]
2. NFS v. CIFS Operating Systems handle networking & I/O differently

**Built-In Network Performance Enhancers:**

1. Cache--Memory used to store data for future operations
2. Buffers--collection points for data
3. Queues--executes I/O's in parallel
4. Locking--several locking mechanisms in use

**File Locking Modes: Usually handled by O/S**

1. Exclusive--Read/Write access exclusively granted to (1) client at a time; Write buffers used Read Ahead & Write Back buffers  
Shared--Read only access to multiple clients. No Write buffers involved.

Nolock--Concurrent Read/Write operations controlled by O/S. No Read Ahead or Write Back buffers used.

**NFS LOCKING & I/O BEHAVIOR:** Stateless protocol using LOCKD & STATD daemons for locking; Server does not cache data; Clients can retry after 'failures' without ill effect; Session builds not required, making this fault tolerant; Very fast Write operations to disk; NFS negotiates I/O size during mount operation for NFSv3 but with NFSv2 only 8k I/O transfer sizes used for Reads/Writes. Journal filesystem uses (1) device & can be taxed by NFS operations--writes much faster to disk than CIFS.

**Note:** If a Server crashes or loses connectivity while Clients have established locks, Server keeps track of these locks and will notify each Client of their previous locks, allowing a 'grace period' of 45sec for reclaiming locks.

**CIFS LOCKING & I/O BEHAVIOR:** Stateful protocol with 'oplocks' builtin; Requires overhead for Session builds, no fault tolerance; Server caches I/O ops.; CIFS is sequential in behavior and does not allow parallel sessions for single files; I/O varies from 4 - 64k and is negotiated during Session Setup.

**ETHERNET NETWORKS:**

Switches & NICs autonegotiate Speed & Duplexing via Hardware controls [Limit this through SW commands]

Switches support Full & Half Duplex, while Hubs are purely Half Duplex

**Rule of Thumb:** Always set Speed & Duplexing uniformly throughout the network

**Exception:** Datamover can be auto full if connected to Switch port that is also auto full, and communicate to a Half-Duplex client on a Hub if the Hub port connected to the Switch is set correctly to half duplex [Switch, not Hub, will handle buffering]. This is called the concept of "Link Partners", where the Host setting & Switch Port settings must match, Host-to-Host does not matter.

**Gigabit Ethernet:**

Data travels at light speed, same as 100 Base-T, but because clock times are 10x faster, can place more data on wire in less time. This mechanism requires 'flow control' for both sides to communicate properly--ensure Flow Control is either disabled on both ends or enabled.

**CELERRA PERFORMANCE MECHANISMS:**

Memory on DMs used to cache metadata for Inode & Session information, ACL's & Auth. Info [Do not Cache data--Symm does this] Async Threshold--Number of FBA block changes collected prior to sending I/O to disk subsystem. By default, Celerra does 32 FBA block changes (16kb). Max. Async Threshold for NFSv3 should not exceed Write Size.

**Note:** Celerra does not conduct automatic load balancing between FA ports

**FileSystem:** Celerra uses 8k block sizes. Max I/O size for NAS NFSv2 is 8k.

**Quotas:** Consider not setting asynch threshold to 1; Using async=1 means that the User's quota is recalculated every 1k change in file size to provide for more accuracy--yet gives less performance. If performance is paramount, do not set this value to 1--performance drops to 512 bytes per I/O, not 8k.

**Device Striping:** In general, use Celerra striping of 32k or more for best file system performance across a min. of (5) devices. If Symm Striping is required, use 2 cyl striping.

**CELERRA PERFORMANCE TESTING NUMBERS:** [www.spec.org/sfs97r1](http://www.spec.org/sfs97r1)

**510 DM with CX600 and DART 5.0**

NFS throughput 16014 ops/sec with 11.1 msec response using Jumbo GigE Alteon NIC with Cisco 6509 GigE Switch & Seagate 73GB 10K drives; 2GB Write & 1.47GB Read cache

**510 DM with Symm 8430 and DART 4.0**

NFS throughput 16772 ops/sec with 9.4 msec response using Jumbo GigE Alteon NIC & Seagate 73GB 10K drives; 2GB Write & 16GB Symm Cache

**514 DM with DMX1000 and Dart 5.1**

NFS throughput 25156 ops/sec with 6.1 msec using Jumbo GigE Intel card and Cisco 6509 Switch, Cheetah 146GB 10K drives, 32GB Cache

**3.06GHz DM with CX700/NS700G and Dart 5.2**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
NFS throughput 71482 ops/sec [dual DM] with 11.2 msec using Jumbo GigE Intel card and Cisco 6509 Switch, Seagate 146GB 10K drives, 3 GB Mirrored Write Cache  
**2 GHz DM with NS600 and Dart 5.1**  
NFS throughput 25656 ops/sec (dual DM) with 6.5 msec using Jumbo GigE and Cisco 6509 Switch, Seagate 73GB drives, 2048 Mirrored write cache

## **CELERRA SYSTEM PERFORMANCE TOOLS:**

**SAR (System Activity Reporter) COMMAND:** CLI Statistics for Processes, System Calls, File Systems, Hard Disks, Processors, Memory, Kernel, I/O  
**\$/usr/sbin/sar -u 5 5** or \$sar -u 1 5 [Provides STATS on CS0 CPU activity, et al for SCO 2.1.3]

## **CLARIION PERFORMANCE/TROUBLESHOOTING CLARIION PERFORMANCE:**

### **I. KTRACES:**

Use “ktraces” to capture real-time host traffic on the Clariion FrontEnd SP’s using Symm Remote—collect one report for each SP. This capture is non-intrusive and does not impact SP’s. Ideally, run a 3-minute capture, analyze, then collect a larger timespan if required. Typically this tool would be used in conjunction with the Navisphere Analyzer capture to review BackEnd stats. This tool is built-into each Clariion platform—files with .ktr extension. These traces are analyzed by Clariion Engineers.

### **II. KTCONS:**

--Tool used to look at Ktraces:  
#ktcons -il  
>!load fdb  
>!spstat (or other commands)  
Ktrace:  
>!load fdb  
>!redirect c:\ktrace.txt  
>!ktrace -T -a -rstd

### **III. NAVISPHERE ANALYZER (NaviAnalyzer):**

This tool requires software installation on each Array. Use this tool to evaluate Clariion BackEnd performance—analyzed by Clariion Engineers. Peak SP iops on CX600 platform 19,300 (I/O Operations). High Cache hit rates will lead to more SP cpu utilization as they have to work harder since there are less backend calls. SP CPU of 85% or higher is nearly maximum. BackEnd iops of 2000 is maximum for this platform.

→On Array and Off Array versions, produces .nar files

**nas/opt/Navisphere/bin/# java -jar archiveretrieve.jar -User nasadmin -Password nasadmin -Address 10.241.168.57 -File <filename> -Location /tmp**

**Note:** Use above syntax to pull .nar files off Celerra for Integrated systems—may need to define path “c:\analyzer\xxxx”

**Response Times (variable) = Service Time (Static) \* Queue Depth (variable)**

#### **Retrieving NAR files on Flare 26 Systems:**

**# /nas/sbin/navisecli -h ss1\_spa analyzer -archiveretrieve -file archive.nar -location c:\Temp\ -overwrite y -retry 3**

#### **RUNNING NAVIANALYZER FROM CELERRA:**

```
$ /nas/sbin/navisecli -h A_APM00074402116 analyzer -archive -new
$ /nas/sbin/navisecli -h B_APM00074402116 analyzer -archive -new
$ /nas/sbin/navisecli -h A_APM00074402116 analyzer -status
Running. Started on 12/22/2009 19:48:51
$ /nas/sbin/navisecli -h B_APM00074402116 analyzer -status
Running. Started on 12/22/2009 19:48:51
$ /nas/sbin/navisecli -h A_APM00074402116 analyzer -stop
$ /nas/sbin/navisecli -h B_APM00074402116 analyzer -stop
$ /nas/sbin/navisecli -h A_APM00074402116 analyzer -archive -list
32 540 12/22/2009 21:02:33 APM00074402116_SPA_2009-12-23_02-02-32-GMT_M05-00.naz
$ /nas/sbin/navisecli -h B_APM00074402116 analyzer -archive -list
0 551 12/22/2009 21:05:10 APM00074402116_SPB_2009-12-23_02-05-09-GMT_M05-00.naz
$ /nas/sbin/navisecli -h A_APM00074402116 analyzer -archive -file
$ /nas/sbin/navisecli -h B_APM00074402116 analyzer -archive -file
```

### **IV. OTHER TOOLS/CONSIDERATIONS:**

→FBI or RLS Collector: Backend loop troubleshooting, runs automatically with Flare 19  
→Background Verify (Navicli getsniffer runs in background continuously looking for marginal or bad sectors—see emc32911)  
→Cache settings are important—look for High Cache Utilization, Flush rartes  
→Look for high LUN Utilization  
→Look for high I/O queue lengths and response times

## **V. SPCOLLECTS:** Flare 13 +

→Run collection scripts to gather data for TS2 Clariion analysis in order to determine hardware issues, takes about 5 minutes, run navicli spcollect –messner command, no info returned at prompt to indicate success, command is running. SPCollects are written to the /dump directory on the XP SP system, with \_data.zip suffix and current date. Most useful info generally in the \_sus.zip files.  
→Contents of zip are evt.zip (XP event logs, read only from Clariion), fbi.zip (Backend issues), isc.zip (iSCSI), ktd.zip, nav.zip (navicli), psm.zip, rtp.zip (applications), run.zip, sus.zip (Array info & KTfiles, most important logs when looking at backend)

#/nas/sbin/navicli -h spa spcollect –messner [password=messner]

#/nas/sbin/navicli -h spa managefiles –list

C:\dumps\xxx.zip

# /nas/sbin/navicli -h 155.33.25.81 managefiles -retrieve

-file SPA\_APM00044700202\_d6368\_12-14-2005\_20-24-00\_data.zip

→FLARE 19 allows automatic collection of SPCollects, but only one current copy is retained (spcollect –set –auto on)

→SPCollects can be gathered by GUI, FLARE 19, or via CLI, or direct SP Access via EMCRemote connection

## **VI. TOOLS TO ANALYZE SPCOLLECTS & CLARIION INFO:**

**Triage:** DOS bat file tool, creates triage-notes.txt & merged Triage\_logs.txt from SPA & SPB (Triage requires both SPCollects)

**SPLAT:** SP Log Analysis Tool—used to analyze logs & can also look at SPCollects

**Note:** Can download the above tools from Clariion website. CAP2 contains SPLAT

## **CAP2:**

Main purpose of tool is to analyze and report on SPCollects in XML format

→XML formatted report, array configuration and health assessment, launches Splat or FBI Remote—upload/download from SYR Input files for CAP are SPCollects, XML reports, getall files, Connectrix Switch logs, etc.

→Lays out data by Tabs, such as Issues, Hosts, LUN Info, SPInfo, Analysis, etc.

## **VII. REMOTE ACCESS TOOLS FOR CLARIION:**

a. EMCRemote running on a Windows system

b. Primary method now is for Webex session

c. Serial connection with laptop plugged into SP Ethernet port

→Navicli talks directly to agent running on SPs

→GUI or Jar commands go to a cimom process running on the SPs, using HTTP requests to the Navisphere Mgmt Port

## **VIII. OTHER CLARIION TOOLS:**

### **NST (Navisphere Service Taskbar):**

As of Flare 24, the NST can be used by both Customers and CE's to perform various hardware and software tasks on the CLARiiON, such as: Add DAE; Add disks; Replace disk (DRU); Update Flare software via Software Assistant (NDU); Update drive firmware; Register the storage system; Send hardware change information to SYR system; Verifies & prepares Storage System healthcheck report; Latest version 06.28.53 supports FC Solid State Drives (SSD).

**Note:** A network firewall may affect the ability for the NST tool to provide updates, though the tool will say that it is the latest version. In reality, a User would need to check and download the latest .exe file from CLARiiON.

#### **Installation & Use of the NST:**

1. Download the setup\_NST.exe from Powerlink>Products>Hardware/Platforms>CLARiiON CX3 Series>Interoperability/Documentation Tools>CLARiiON Tools

\* Download the Navisphere Service Taskbar

2. Execute setup\_NST.exe and accept defaults

3. Launch NST>Do you want to launch Navisphere Service Taskbar Now? Select yes to launch.

**Navisphere Service Taskbar** [Utilities highlighted in blue]

File Tools Help

**Hardware Registration**>Register Storage System

**Hardware Installation**>Install Disk Array Enclosure & Install Disk

**Software Assistant**>Prepare for Installation & Install Software>(3) Options for Prepare for Installation section: Download software and verify storage environment; Download software only; Verify storage environment only

**Hardware Maintenance**>Verify Storage System & Replace Disk

4. Connect to CLARiiON using File>Connect>Navisphere CONNECTION:

Enter IP Address of SP and login with proper Username and Password if Global security is in place

5. Once logged in, select a Utility. Reports are logged on the local harddrive: c:\emc\repository\APM00030600872

**Comments:** System produces healthcheck reports of the Storage System, validates existing software, assists in downloading and upgrading software, including Rules Checking, provides assistance in adding or replacing disks, adding DAEs, etc.

## **SPQ—Storage Processor Qualifier:**

HealthCheck tool for SPs, using SPCollects as input files

## **TRIAGE:**

## **CELERRA BEST PRACTICES/CELERRA PERFORMANCE (Updated NAS 5.5):**

**Note:** See the 5.5 Best Practices for Performance white paper as found on PowerLink for more detailed and accurate information. With NAS 5.6, there was no overall Best Practices white paper published. Check Celerra forum for related information.

### **I. STORAGE ARRAY RECOMMENDATIONS:**

1. Dedicate separate spindles for NAS & SAN workloads & maximize spindle count whenever possible
- Note:** NAS environments typically have high thread counts & random I/O. SAN environments are characterized by sequential I/O
2. Do not build file systems on single Symm metavolumes or Clariion MetaLuns—if absolutely required, build on sets of metaluns
- Note:** Symm metavolume of (8) hypers will only queue (1) outstanding I/O for Celerra, as in the case of synchronous SRDF, but if built on Celerra metas over (8) striped volumes, will increase outstanding queue depth to (8) I/O's. Clariion queue depth based on (8) I/O's per disk volumes, so spread the lun across (8) disk volumes would increase queue depth to (64) I/O's. A key concept here is that I/O parallelism is best obtained when striping file systems over multiple hypers.
3. Do not mix different RAID group types when creating file system LUNs (AVM follows this rule)—an exception is that Clariion R3 allows file systems to span 4+1 & 8+1 RGs. For (2) luns in a RG for FC drives, set one to SPA, one to SPB. For (2) luns in a RG with ATA drives, set all to one SP or the other.
4. For CLARiiON arrays with more than 15 FC drives, create first shelf with R5 4+1 & Hot Spare, then 4+1, HS, HS, HS, HS, all other shelves would be R5 4+1, 4+1, 4+1
5. Balance data Luns across SPs, bus, and DAE's (ignore control luns), keep in mind that all LUNs in same ATA Raid Group must be owned by the same SP
6. Avoid using ATA drives for random I/O or AVM clar\_r1 volume pools
7. For CX & CX3 arrays, assign minimum Read cache of 32MB and the balance to Write Cache [max 3072 for CX; max 1053 for CX3-20; max 2500MB for CX3-40; max 3072MB for CX3-80]; most Clariion Read cache is used for prefetch, while DMs have their own Read cache.

**Note:** Change cache settings on captive NS600/700 systems using [`#/nas/sbin/setup\_backend/nas\_raid cache configure`](#)

Some systems may require more Read cache if Reads are extensive and performance is being impacted

8. ATA-only Gateway systems, set Clariion write cache HWM to 80 & LWM to 60
  9. For CX3 backends, R5 [clarata\_archive 4+1] or R3 will provide good sequential IO writes, while CX series should use R3 [clarata\_r3]. Max. Clariion disk I/O size is 2MB.
  10. Attributes of a busy system are if any component in system is over 70% utilized; throughput per FC spindle exceeds 100 IOPS, 50 IOPS for ATA; number of dirty pages exceeds memory HWM; Disk queue greater than 10
  11. Attributes of sequential IO: average Read size 64KB; average Write size 512KB; Read throughput=Read Cache hits/sec; Write throughput=Full Stripe Writes/sec
  12. Default cache page setting for Clariion is 8kb for Integrated array, which matches Celerra 8kb I/O size
  13. Default Clariion LUN stripe element size for RAID5 luns is 64kb (Navicli reports stripe size element in 512-byte blocks)
  14. Storage templates are used only for Captive Systems and will automatically bind (2) luns per Raid group (manually create 2 luns/raid group if storage template is not used)
  15. Consider disabling prefetching if small random access is being done by clients (param file prefetch=0)
  16. Not recommended to rely on Celerra auto file system extensions if performance is key as this will tend to fragment the file system if small extensions are being done with AVM
- Fibre Channel Drives support CTQ (Command Tag Queuing) for up to 24 simultaneous commands  
--ATA Drives do not support CTQ (more missed spins around the platter)

#### **Symm LUN Addressing Support:**

Symm 8000 supports Luns 0-255 (00-FF) per FA port (processor); DMX2 supports 512 Luns per port--Luns 0-511 & 512-1023 (Hex 00-1FF & 200-3FF); DMX3 supports 2048 LUNs per port.

### **II. AVM STORAGE RULES:**

1. Allow AVM to create file systems on system-defined pools whenever possible (use user-defined pools with AVM if user intervention required)

**Note:** AVM will create LUNs from same storage array; create LUNs from different RAID groups to max. spindle count; use same RAID group types and sizes when creating new LUNs; chooses least utilized LUNs first, then to achieve SP balancing, then to achieve bus balancing, then dvolumes with the highest ID numbers first. AVM will also create pool volumes of (4) disk volumes first, then (3) volume pool, (2) volume pool, and single metavolume last. AVM will use same pool volume types first when creating LUNs.

--nas\_disk -l shows order that luns are discovered on the bus, with SPA first, then SPB

--Do not span LUNs across different storage platforms [AVM could do this if multiple pool volumes are used—consider manually creating user-defined pools for each storage array—AVM will then build file systems from correct pools]

--Do not extend file systems with same disk spindles, use same number of spindles for extension as for original, if possible

--Do not use AVM system-defined pools on top of Symmetrix parity RAID

--File Systems can be created from only one Storage Pool, but an extension can occur from a storage pool of different disk types

--Do not span file systems across more than one storage array

### **CELERRA STRIPE SIZE ELEMENT RULES:**

--Use 32KB stripe size for NFS/CIFS for both Clariion & Symm

--Use 256KB stripe size for MPFS on both Clariion & Symm

--Use 64KB for ATA Backup2Disk on CLARiiON

### **CLARIION AVM RULES:**

--Balance spindles, RAID groups, LUNs per dvolume, SPs, and Storage arrays

--File Systems are created on min. of (4) dvols when Fibre Channel drives (clar\_r5\_performance), with each dvol in separate RG, striped together, and then sliced

--File Systems are created on min. of (2) dvols when ATA drives (clarata\_r3)

--RAID3 designed for ATA drives, highly sequential I/O

### **SYMMETRIX AVM RULES:**

--(8) consecutive dvols are used when creating volumes

--Relies on BIN file ordering to balance I/O across spindles and directors

### **SYMMETRIX STORAGE POOLS:**

--When creating pools, first 8 unused disk volumes of the same size are striped together in 32k stripes

--If volumes are not of the same size, then they are concatenated together [i.e., will not stripe dissimilar disk sizes together]

--If 8 disk volumes cannot be found, then logic looks for 4 unused disks, then 2, then 1

--Symmetrix profile is not greedy in that all pool space is used up before a new pool is created

--AVM not so commonly used for Symm layouts because it does not load balance on the FA's

--But, AVM's can stripe and slice, or stripe and not slice (using slice=n)

SYMM\_STD & SYMM\_STD\_RDF\_SRC

### **CLARIION FC & ATA DRIVE STORAGE POOLS:**

--LUNs must start with 4 identically sized volumes

--LUNs must be from different RAID groups

--LUNs must match storage profile in use

--Balance LUNs between SPA and SPB, and balance on Bus 0 and 1

--Storage Templates can only be used on Captive Clariion arrays

--Original ATA template was RAID5 6+1 NAS 5.1, targeted for sequential I/O—Clariion did not yet support RAID3 [RAID3 added NAS 5.4] CLAR\_R5\_PERFORMANCE (5 drives); CLAR\_R5\_ECONOMY (9 drives); CLAR\_R1 (2 drives FC); CLARATA\_ARCHIVE (6+1R5)

--NAS 5.4 introduces RAID3 support, using Raid3 4+1 and 8+1 for ATA drives

--When creating pools for file systems, AVM will search out highest available dvolume on SPB first, and work its way down to the lowest dvolume number, then does same thing with SPA luns

### **NAS 5.1 AVM:**

→Uses (2) LUNs per pool entry as minimum

→SPA highest to lowest dvolumes first, then SPB highest to lowest

### **NAS 5.2 AVM:**

→Uses (4) LUNs per pool entry as minimum

→SPB highest to lowest dvolumes first, then SPA...

### **NAS 5.5.21.0:**

→AVM profile for clar\_r5\_performance, clar\_r5\_economy, clar\_r1, will be updated to have a stripe size of 32768K (a change from 8192K)

**Note:** If space remains available in used disk volumes (existing pool members) of the storage pool, the stripe size remains at 8 KB. When allocating space from unused disk volumes (new pool members), the strip element size automatically defaults to 32 KB.

### **NAS 5.5.26.2:**

→RAID-5 6+1 support for ATA/LCFC drives added for CX3 arrays, as well as RAID-5 4+1 support, and traditional RAID-3 4+1 & 8+1. RAID-5 support is not recommended for CX platforms with ATA/LCFC drives.

→AVM profile for clarata\_archive stripe size default changes from 8KB to 64KB

### **FILE SYSTEM RULES:**

--do not span storage arrays

--use most spindles possible when building fs

--build most important file systems first (will use more spindles, hence better I/O performance)

--largest file system size 2TB based on SCSI address limitation for a single volume

--up to 16TB file system possible if striped across enough volumes to maintain 2TB SCSI limitation per single volume

### **III. NAS NETWORK PROTOCOL RULES:**

--on dirty networks consider enabling flow control for rxflowctrl and txflowctrl

--ensure speed & duplex settings are set the same on all Host & Switch ports

--Do not set tcp.ackpush unless legacy clients require

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

- consider using sndcwnd param to limit DM window size when switch buffers are limited (seen with DM gigabit vs. client 100MB)
- max. performance by using ports in following order: cge0, cge3, cge1, cge4, cge2, cge5 (ports 0, 1, 2 are on one bus, 3, 4, 5 are on another bus)
- Use TOE or copper interfaces when possible (DM 514 uses optical interfaces)
- consider using cifssyncwrite mount option if workload is database related for both CIFS and NFS (will degrade performance for nondatabase workloads). Guarantees that writes to file server are done synchronously
- Also consider disabling oplocks in write-intensive database environments
- Set cifs.prealloc parameter from default 0 to 6

**Note:** prealloc size is size allocated to client for writes between requests to write more data. For example, default 0=8kb block size. Setting to 6 increases block size to 512KB and client will not need to request to write data so often.

- Do not increase CIFS threads to more than 256 (take CAVA into consideration when calculating threads used)
- Do not change file.asyncthreshold param from 32 (max number blocks cached by NFSv3 for asynchronous writes). Changing the value downward will flush data to disk more frequently.
- Safely increase NFS threads from 256 to 512 for 510DM and higher systems

## **IV. I/O CHARACTERISTICS:**

### **CHARACTERISTICS OF SEQUENTIAL I/O:**

- average read size >=64kb
- average write size >=512kb
- Read iops/sec=Read cache hits/sec
- Write iops/sec=Full Stripe Writes/sec (write I/O's are being coalesced into full stripe writes)

### **WORKLOAD TYPES:**

- transactional databases tend to have small, multi-threaded I/Os 8k or less that are randomly distributed
- Checkpoint SavVols are highly sequential & write-intensive by design, while reads are seldom and random
- Backup-to-Disk uses large, sequential, single-threaded write I/O's and few reads
- Home Directories are generally highly random and small 8k size
- Imaging consists of large, sequential, single-streamed reads and writes

## **V. HARDWARE—DISK DRIVES:**

### **ATA vs. FIBRE CHANNEL DRIVES:**

- 5400-7200rpm vs. 10,000rpm FC drives
- ATA drives can only handle single command at a time while FC drives support command tag queuing for up to 24 simultaneous commands
- ATA drives best for sequential I/O such as for backups

## **VI. iSCSI:**

- DM can be CPU-constrained when <than 16kb sequential I/O
- BackEnd FC interconnect become bottleneck for large >16kb sequential I/O and random reads
- BackEnd disks are spindle-bound with small <16kb random reads and writes

## **VII. CONFIGURING ETHERNET & FIBRE CHANNEL PORTS:**

- Most basic rule-of-thumb is to leave Celerra Fibre Channel & Ethernet ports set to auto-negotiate, if the respective Switches also auto-negotiate
- If a FC or Ethernet switch port is hard-coded to a certain speed, then the respective Celerra port also needs to be hard-coded e.g., Ethernet switch set to 100 Full Duplex, then Data Mover or Control Station interface should also be set to 100 Full Duplex
- Leave Internal network interfaces to auto-negotiate at all times

### **Exceptions:**

- For FC AUX ports, if the Switch is hard-coded, it is still recommended to let the Celerra autonegotiate speed and topology.
- For NS500 AUX port, which only runs at 2GB, meaning that both DM and Switch should be hard-coded to 2GB
- For 10/100 Fast Ethernet ports on Celerra, the recommendation would be to have the ports set to Full Duplex on DM and Switch
- For GbE ports on Celerra, let the ports autonegotiate
- For Control Station external NIC, which is also Fast Ethernet, hard-code to 100 Full Duplex on CS & Switch

## **LINUX CONTROL STATION STATISTICS:**

**#top**

**Outputting TOP to File:**

**#top -b -n1 >top.out &**

**#vmstat 5 15**

**#free | # free -m**

**# free -mt** (free memory in Megabytes with Totals)

|      | total | used | free | shared | buffers | cached |
|------|-------|------|------|--------|---------|--------|
| Mem: | 502   | 205  | 297  | 0      | 82      | 46     |

```
-/+ buffers/cache:    76    426
```

```
Swap:      509      0    509
```

```
Total:    1012    205    807
```

**# cat /proc/meminfo**

**# vmstat 5 15**

| procs | memory | swap  | io     | system | cpu                        |

[Super Daemon for Linux processes]

[Daemon that writes NAS\_EVENTS to Sys\_Log]

[Kernel daemon that writes entries to Server Logs]

**Note:** If the “load average: values in the top output exceeds 5.0, that indicates an extreme memory load on the CS. JServer is allowed to use up to 230MB memory and WebUI up to 96MB.

## **USEFUL LOG FOR CONTROL STATION RESOURCE ALLOCATION ISSUES:**

**/nas/log/cs\_res\_mon.log**

20060608.170840:apache:summary: npids=12, cpusec=0, cpu%=0.0, memK=40920, mem%=3.4  
 20060608.170840:apl\_sched:summary: npids=1, cpusec=0, cpu%=0.0, memK=12926, mem%=0.1  
 20060608.170840:jserver:summary: npids=60, cpusec=1712, cpu%=0.8, memK=165036, mem%=8.4  
 20060608.170840:nasdb\_backup:summary: npids=0, cpusec=0, cpu%=0.0, memK=0, mem%=0.0  
 20060608.170840:tomcat:summary: npids=43, cpusec=111, cpu%=0.0, memK=79506, mem%=8.8

**Note:** Log could be useful in viewing a realtime CS resource issue, or for detecting trends on what processes are taking up the most CS resources. Typically, nas\_cmd or APL processes can use up to 25% of total memory, while Tomcat & Apache are usually limited to 10% of the total memory, and JServer 16%.

## **USING IOSTAT TO VERIFY ACTIVITY ON CONTROL STATION PARTITIONS:**

**# /usr/bin/iotstat -d 5 -x /dev/nde1**

Linux 2.4.9-34.5307.EMC (celerra-cs0) 02/01/2006

| Device | rrqm/s | wrqm/s | r/s  | w/s  | rsec/s | wsec/s | avgrq-sz | avgqu-sz | await     | svctm     | %util |
|--------|--------|--------|------|------|--------|--------|----------|----------|-----------|-----------|-------|
| nde1   | 0.21   | 0.02   | 0.03 | 0.00 | 0.25   | 0.02   | 8.08     | 5.16     | 151229.17 | 143016.67 | 47.57 |

**Note:** iostat monitors system input/output to devices, and provides statistics for CPU & DEVICE usage since last reboot. –c switch used to output CPU utilization; -d switch used to output device utilization –x is followed by the device to query

## **CELERRA DATAMOVER TROUBLESHOOTING:**

**\$server\_config server\_6 “help <topic>” “wins help” “ds help”**

**Note:** Use above syntax to help in finding syntax and useful commands by subject

```
# .server_config server_2 -v "wins help"  
1144097232: SMB: 4: wins addr=<WINS IP addr> name=<host>  
1144097232: SMB: 4: [type=0x00 .. 0xFF] [timeout=n(sec)] [broadcast]  
1144097232: SMB: 4: [who (force name to *, smb_hostQueryName() test)]  
# .server_config server_2 -v "help fc"  
# .server_config server_2 -v "help ds"
```

### **RUNNING LIST ON DATA MOVER:**

```
$ .server_config server_2 -v "ls .etc"  
$ .server_config server_2 -v "ls"  
.etc  
.etc_common  
fs1  
security.evt  
system.evt -----abridged-----
```

### **SERVER MOUNTS:**

```
# .server_config server_2 -v "file mountdisplay"  
# .server_config server_2 -v "unexportall"
```

### **SERVER CPU & RAM ISSUES:**

```
$server_sysstat server_2 [% cpu idle]  
$server_config server_2 -v "printstats cpu" [CPU Histogram of Usage—no longer valid for 4.x code]  
$server_config server_2 -v "cpu display"
```

Note: This command seems to start a counter that logs a CPU Idle entry every (5) minutes

```
$server_config server_2 -v "printstats mem"
```

### **INCREASING I/O PERFORMANCE ON DATAMOVERS:**

Increase Queue Length on Tachyon Fibre Channel Cards in NS600 in NAS 5.1.9.4 or lower:

```
param fcTach device_q_length=256
```

```
param fcTach per_target_q_length=256
```

Allowing Parallel I/O Operations to BackEnd in NAS 5.1.9.4 or lower:

```
param file prefetch=1
```

Note: In some cases, upgrading from 4.2 to 5.1 may result in poor performance if I/O's are random. An ‘enhancement’ was made in 5.1 to address primarily sequential I/O performance. Set following param to return values to 4.1 level:

```
param file prefetch=0
```

### **SERVER PROCESSES:**

```
$/nas/sbin/server_profile server_x [Use to profile CPU Utilization for a DM--dumps to Server Log]
```

Note: NAS 4.0 – 4.2, & <5.0.14 has potential for panicking DM if run against 507 as it looks for dual processors.

### **REFINING SERVER PROFILE FOR SPECIFIC MEMORY RANGES:**

- 1.) #.server\_config server\_x “profile zero”
- 2.) #.server\_config server\_x “profile on start=4a2f68 end=4b8d54” [Run for 3 minutes before running ‘profile off’]
- 3.) #.server\_config server\_x “profile off”
- 4.) #.server\_config server\_x “profile print”
- 5.) #server\_log server\_x -s >slogx\_profile

### **RUNNING SERVER PROFILES ON NAS 5.2 AND HIGHER:**

- 1.) #.server\_config server\_x “profile zero”
- 2.) #.server\_config server\_x “profile on all function” [Resets all functions-let profile run for about 3 minutes]
- 3.) #.server\_config server\_x “profile off”
- 4.) #.server\_config server\_x “profile print”
- 5.) #server\_log server\_x -a -s >slogx.0617

Note: With 5.2, we no longer need to specify “start=...”ranges as exact function names are now printed in the Server Log.

**Caution:** Do not run “profile on function” command on any system prior to NAS 5.2.20.x as it may cause the DM to panic! This **problem has been fixed with NAS 5.3.19.2, 5.2.20.0, & 5.4.17.5**

## CELERRA NFS/RPC STATISTICS:

\$server\_nfsstat server\_2 -rpc | -nfs | -z { zeroes out all stats} -c [client] -s [server] -r [rpc stats only] -n [nfs only]

\$rpcinfo -p server\_2 [Prints port map and RPC programs]

\$server\_config server\_2 -v “printstats rpc” [Various RPC Calls & Statistics]

\$server\_nfsstat server\_2 -s

server\_2 :

Read/write size and alignment distribution (v3):

| size          | read    | crossed | write    | crossed | →Crossed means an I/O exceeded 8k boundary, forcing DM to do extra buffer read |
|---------------|---------|---------|----------|---------|--|
| 1 - 1         | 0       | 0       | 183      | 0       |  |
| 2 - 3         | 3       | 0       | 400586   | 0       |  |
| 4 - 7         | 39      | 0       | 12430    | 0       |  |
| 8 - 15        | 102     | 0       | 18140    | 0       |  |
| 16 - 31       | 100     | 0       | 4281     | 0       |  |
| 32 - 63       | 191     | 0       | 12464    | 0       |  |
| 64 - 127      | 330     | 0       | 94552    | 1125    |  |
| 128 - 255     | 538926  | 9992    | 751543   | 5791    |  |
| 256 - 511     | 490406  | 88200   | 10726464 | 6775    |  |
| 512 - 1023    | 3666    | 0       | 2078183  | 0       |  |
| 1024 - 2047   | 271057  | 15049   | 541734   | 9618    |  |
| 2048 - 4095   | 181237  | 0       | 1110809  | 0       |  |
| 4096 - 8191   | 5210239 | 0       | 1587799  | 32689   |  |
| 8192 - 16383  | 1552627 | 21820   | 407415   | 32985   |  |
| 16384 - 32767 | 79206   | 620     | 60851    | 5       |  |
| 32768 - 65535 | 3024210 | 981     | 3607389  | 1       |  |

**Example:**

# /usr/sbin/rpcinfo -p server\_2 legrep "portmap|nfs|mount"

```
100003 2 udp 2049 nfs
100003 3 udp 2049 nfs
100003 2 tcp 2049 nfs
100003 3 tcp 2049 nfs
100005 3 tcp 1234 mountd
100005 2 tcp 1234 mountd
100005 1 tcp 1234 mountd
100005 3 udp 1234 mountd
100005 2 udp 1234 mountd
100005 1 udp 1234 mountd
100000 2 udp 111 portmapper
100000 2 tcp 111 portmapper
```

## TROUBLESHOOTING NETWORK ISSUES:

## **TROUBLESHOOTING CIFS ISSUES:**

**# /nas/tools/cifsdebug server\_2** (NAS 5.4 & 5.5, but not aware of this being actively used)

It is possible that this script would fill up the server log of the server if executed, thus causing the server log to wrap around. The script will save the server log prior to running this script so important info is not lost after executing the script. In this script, the severity of KERBEROS, SMB, LDAP, and param NTsec will be altered to capture additional messages if there are errors. At the end of the script, those will be set back to their default values. If you have set those variables to other values prior to the execution of the script, remember to set them back to the desired values. The script will tar up the directory where you specified to save the output files, and it will name the file result.tar. Please submit that file to Engineering for analysis.

Do you wish to continue [yes or no]: yes

Please enter the Celerra CIFS server name: mview\_dm2

Please enter the interface name (not device name such as fxp, cge, etc, but something like 10\_6\_3\_200): foo

Please enter the share name you are connecting: Bogus

Please enter the path name to the directory or file you having issue with (it should look like /filesystemmountpoint/<dir or file>): /m3

Please enter the user name you connect the share with (please don't include domain name): tmatta

Please enter the IP address of the DC: 192.1.4.217

Please enter the Fully Qualified Domain name (eg. test.emc.com): 2k3.pvt.dns

Please enter the Not Fully Qualified Domain name (eg. test): 2k3

\*\*\*\*\*

Please obtain a network trace of the issue for analysis if possible.

Please force a panic if CIFS activities seem to be hung.

Other thing you can do that's not appropriate in this script is to change the DM password with the DC, and see if the process can complete successfully

.server\_config server\_2 -v 16384 "srwpwd compname=<server on Celerra> change"

If you suspect one of the DC is causing an issue, deactivate it by this command:

.server\_config server\_2 -v "pdc invalidate=<IP of the DC>"

To re-enable the DC, do:

.server\_config server\_2 -v "pdc validate=<IP of the DC>"

### # .server\_config server\_2 -v "srpwd display" | "srpwd dump"

1080226076: SMB: 4: srpwd V=1 fileV=1 2 records

1080226076: SMB: 4: srvPwdUpdate for MOUSE: Next in 657 minutes (period=10020)

1080226076: ADMIN: 4: Command succeeded: srpwd display

**Note:** Above output shows that CIFS Server ‘Mouse’ has a valid Password with the Domain and will be changed in 657 minutes. Notice that the value 10020 is in minutes and translates into one week’s time—this is the default for changing Server passwd with the Domain Controllers with NAS 5.2. Please note that NAS 5.5 rearchitected the entire machine account password implementation, and it is now similar to Windows 2000.

### # .server\_config server\_5 -v "srpwd compname=name change"

**Note:** Do NOT run above command unless specified by TS2 or Eng. as this will change the Server’s password in the Domain and may be disruptive to customer. NAS 5.2 changes its Server password every 7 days.

#### Command Says it Fails, but Actually is Successful in Changing Password:

1080226308: SMB: 3: srpwd unknown action=0

1080226308: ADMIN: 3: Command failed: srpwd compname=mouse

#### Output of “srpwd display” after running password change command:

1080226354: SMB: 4: srpwd V=1 fileV=1 2 records

1080226354: SMB: 4: srvPwdUpdate for MOUSE: Next in **10020** minutes (period=10020)

1080226354: ADMIN: 4: Command succeeded: srpwd display

#### NAS 5.5 Values for Machine Account Password Feature:

**param cifs srpwd maxHistory=2** (stores (2) passwords by default)

**param cifs srpwd.updtMinutes=0** (In minutes--disabled by default)

### # server\_param server\_2 -facility cifs -i srpwd.maxHistory

71=>GROUP 2002 Domain Guests.TS_NAS:S-1-5-15-209b5669-55a118ba-7e4b2f8f-202
```

```
$ .server_config server_5 -v "sidcache global status" [SID Cache Hit ratio]
```

#### NSLOOKUP TOOL:

```
#nslookup
```

```
>set type=SRV
> _ldap._tcp.dc._msdcs.nas.us.dg.com      [Shows DC List, IP Addresses, Port 389]
> _ldap._tcp.nas.us.dg.com                  [Shows LDAP Servers]
> _kerberos._udp.nas.us.dg.com            [Shows list of Kerberos Services & Port 88]
> _kpasswd._tcp.nas.us.dg.com             [Shows list of Password Servers Port 464]
> set type=PTR
> 10.240.16.113
> set type=a
> 10.240.16.113 [or Hostname 'cpc233120']
```

#### NBTSTAT TOOL:

```
c:>nbtstat -n | -a |IP address for remote server [Good for observing registered WINS entries for systems]
```

#### MAC THREADS:

NAS 5.4 and above uses 28 MAC threads (CPU Threads) to perform work and service processes, delivering payload in XML formatted messages. Prior to 5.4, 16 threads were used. MAC threads are synchronous in that a command is issued, and the MAC thread is tied up until it receives a reply.

#### CS-to-DART MAC COMMUNICATIONS—default 20 sec. timeout for MAC requests:

Certain Celerra services and communications use MAC, such as # server\_mount. The default timeout value for these commands is 20secs., which can cause problems during failover & other situations where the file systems are being remounted. See AR81156. Fix will entail extending the timeout values of the ‘build’ function for the HTTP client when mounting large file systems. What happens is that the ‘build’ function takes time, during which the CS is supposed to wait before issuing the Mount command so as to not incur the 20sec. MAC request timeout if it takes >than 20 seconds to mount. The ‘build’ formula is “fs\_size/10 + 120secs”.

#### USING MAC DB TO DETERMINE HWM AND NUMBER OF CIFS THREADS IN USE:

1. Create link to MAC\_DB Tool

**Note:** Run the Mac Tool from the /nas/tools directory

**#/nas/tools/ln -s mac\_db \_mac\_db**

2. Run MAC Commands on Server\_2:

**#/nas/tools/\_mac\_db server\_2**

**macdb> sym/nActiveCifsThreads**

\_nActiveCifsThreads: abef68 [Number of actual CIFS threads in use at time command was run]

\_nActiveCifsThreadsAbsolute: abef6c [Total number of CIFS threads used since last initialization of CIFS]

**macdb> x/d 0xabef68**

00abef68: 00000002 [Decimal counter value represents number of actual CIFS threads in use at time of command]

**macdb> sym/maxActiveCi**

\_maxActiveCifsThreads: abef64 [High Water Mark number of CIFS threads used at one time since last reboot]

**macdb> x/d 0xabef64**

00abef64: 00000053 [Decimal counter represents HWM for simultaneous CIFS threads in use since last reboot]

3. Exiting the Mac interface:

**macdb>quit**

**Other CIFS Counters in NAS Code:**

**# strings - /nas/dos/bin/nas.exe | grep -i cifsthread**

\_maxActiveCifsThreads

\_nActiveCifsThreads

\_nActiveCifsThreadsAbsolute

\_cifsThreadCounts

## **WINS LOOKUP EXAMPLES:**

**# .server\_config server\_2 -v "wins addr=172.16.1.3 name=df type=0x1c"**

1053649027: SMB: 4: DF <1c> 8000 (Group NetBios Name, B Node) Addr=172.17.24.46

1053649027: SMB: 4: DF <1c> 8000 (Group NetBios Name, B Node) Addr=172.17.24.8

**Comment:** Above output are DC records found in Wins database

## **KERBEROS AUTHENTICATION FOR LOGONS** (*rc4-hmac encryption algorithm*):

HMAC is Hash Message Authentication Code—besides hashing a variable input into a set hash output, a Shared secret is also hashed to help authenticate the sender—used in IPSEC.

**TWO TYPES OF WINDOWS LOGONS:** Network Logon and Interactive Logon

### **CLIENT SYSTEM NETWORK LOGON (system):**

The network logon involves the computer during machine startup, or ‘discovery’. After NIC is initialized and provided an IP address by DHCP, the workstation uses DNS query to locate the LDAP service (default-first-site-name). Client then uses LDAP query to locate DC, and negotiates SMB dialect with Server.

Client then requires Secure Channel with DC and negotiates this via the Netlogon service using a NULL SMB session to the DC’s IPC\$ share. An RPC pipe is then opened and the Client & DC exchange authentication challenges to construct a session key. The session key is then updated with the Client’s computer account credentials and forwarded back to the DC. After the DC calculates and compares the credentials to its session key, the Secure Channel is established, but must wait for the Authentication protocol to complete its work. Once the Authentication Package completes its processing (Using NTLM, NTLMv2, or KERBEROS), the DC will reply and send a copy of the SAM or AD to the Netlogon process for the Client.

Once the Secure Channel is setup, client uses DNS query to locate the KDC service to obtain a logon session key, or TGS with the KDC—Kerberos authentication occurs.

Next, Client will connect to IPC\$ share on DC to start DFS referral process, if applicable. Client then does RPC to DC to convert its name into a DN (Distinguished Name). Armed with the DN, the client can then download any updated GPOs that might apply. If NetBIOS is enabled, the browser election process begins. Then, time synchronization occurs. Client finally launches DNS query for SOA and does Dynamic DNS update.

### **CLIENT USER INTERACTIVE LOGON (user):**

Essentially, when a user initiates the Ctrl + Alt + Delete key sequence (aka, SAS—Secure Attention Sequence), and types in their username and password, this information is encrypted and passed to the WinLogon service, which in turn creates a unique logon SID, and calls the LSA service, which in turn calls the appropriate Authentication package, which may already have a cached set of credentials in its local SAM database. Whether the Authentication package retrieves cached User credentials or has to connect to the DC to obtain credentials, the username, hashed password, user SID, and group SIDs are retrieved and stored by the LSA.

The LSA then checks privileges of the user logging in to determine ability to log in, then constructs a default ACL for the User’s primary token. The token is passed to WinLogon for use in creating the User ACL in the DACL of the workstation. WinLogon creates an application and screensaver Desktop to contain a DACL to allow both the User and WinLogon to access.

After Kerberos authentication sequence, an RPC call is made to the DC to convert User's name to a DN. Using the DN, the User's client system uses LDAP to query DC for Group Policies to be applied to User, as well as any DFS referral information.

### **WINDOWS LSA (LOCAL SECURITY AUTHORITY):**

Windows subsystem that manages local security & audit policies & provides user authentication services, such as when a User logs on. LSA RPC calls are named pipes calls between a local security authority and the domain security authority. The LSA stores local policy information in a set of (4) LSA Policy Objects:

- Global Policy Information
- Trusted Domain Information
- User, Group, Local account information
- Private Data such as Server account passwords

### **NAMED PIPES:**

Named Pipes are IPC (InterProcess) Communications between Client & Server as a mechanism for exchanging data between a local process and a remote process on separate computers over the network. For the Windows realm, IPC communications are built into the SMB protocol using DCE/RPC. When in use, Named Pipes are mounted in the \PIPE directory. The SMB IPC\$ share uses Named Pipes when using DCE/RPC services. For an NT 4.0 network, the DOSConnectNamedPipe API is called when using the "net use" command [\\server\IPC\\$](#). NT 4.0 uses SMB and MSRPC services for IPC communications. IPC is used between applications and RPC enables applications to call functions from a local system to a remote system (Remote Procedure Call).

### **MS MSRPC is an implementation of DCE-RPC transports:**

ncacn\_np: DCE-RPC over SMB (named pipes IPC\$ share)—used during Join & Unjoin process

ncacn\_ip\_tcp: DCE-RPC over TCP (Endpoint mapper service (EPM) to discover dynamic TCP points, port 135), intrasite AD replication

### **MSRPC ACTIVE DIRECTORY lsass.exe RPC INTERFACES:**

samr: Security Account Manager RPC service \pipe\lsarpc

lsarpc: Local Security Authority RPC service \pipe\lsarpc

netlogon: netlogon RPC service \pipe\netlogon

drsuci: Active Directory RPC access service—queries to AD using MSRPC vs. LDAP; used AD database replication

frsrpc: AD file replication service between DC's. repadmin.exe & replmon.exe are AD replication admin tools—multi-master replication for sysvol shares

### **OTHER MSRPC INTERFACES:**

epm: endpoint mapper port 135 over TCP, discovers dynamically allocated ports

### **TYPICAL RPC SERVICES FOR MSRPC ACTIVE DIRECTORY INTERFACES:**

SAMR→SAM Security Account Manager RPC service

LSARPC→LSA Local Security Authority RPC service

NETLOGON→Netlogon RPC service

DRSUAPI→AD RPC access service

These services typically use the Endpoint Mapper Service (EPM) to discover TCP ports to use when establishing communications to Named Pipes. ncacn\_np MSRPC transport is used for SMB sessions to IPC\$ share for Joins and Unjoins.

\pipe\lsarpc→lsarpc interface

\pipe\samr→samr interface

\pipe\netlogon→netlogon interface

### **USING NIS CALLS FROM DATA MOVER:**

#### **Typical map names are:**

group.byname

group.bygid

passwd.byname

passwd.byuid

hosts.byname

hosts.byaddr

netgroup

netgroup.byhost

netgroup.byuser

# .server\_config server\_2 -v "yp status"

# .server\_config server\_2 -v "yp match atd.gmeds.com tzn2y3 passwd.byname"

\$ .server\_config server\_2 -v "yp match mynisdomain 5003 group.bygid"

\$ .server\_config server\_2 -v "yp match mynisdomain corp002 hosts.byname"

#### **SAMPLE OUTPUT:**

# .server\_config server\_2 -v "yp match FRL 5068-rcs groupbyname"

**UNIX ID=0 Type=3 →Group found in Trusted Domain but no Domain Range has been defined in Usermapper**

## II. RESOLVING SIDS TO NAMES:

**\$ .server\_config server\_5 -v "lsarpc if=ana0 sid=15-52dabe9d-5b5506ca-28a68b82-201"**

Finding User Name from SID=0

Interface 'ana0' Address=192.10.0.103

UserName0='SEINFELD\Domain Users' (0) use=2 nameType=0

S-1-5-15-52dabe9d-5b5506ca-28a68b82-201 Domain Users

UNIX ID=201 Type=1

1068056402: VC: 5: abortCheckWait(smb\_share=0x0)

1068056402: ADMIN: 4: Command succeeded: lsarpc if=ana0 sid=15-52dabe9d-5b5506ca-28a68b82-201

**Note:** Be aware of the syntax used to resolve SIDs—drop the “S-1-5-“ or else the syntax will fail!

## III. RESOLVING BY RSIDS [Relative ID]:

**\$ .server\_config server\_5 -v "lsarpc if=ana0 rsid=201"**

Finding User Name from SID=0

Interface 'ana0' Address=192.10.0.103

UserName0='SEINFELD\Domain Users' (0) use=2 nameType=0

S-1-5-15-52dabe9d-5b5506ca-28a68b82-201 Domain Users

UNIX ID=201 Type=1

1068056363: VC: 5: abortCheckWait(smb\_share=0x0)

1068056363: ADMIN: 4: Command succeeded: lsarpc if=ana0 rsid=201

## IV. VERIFYING DOMAIN TRUSTS BETWEEN DOMAINS:

## # .server\_config server\_2 -v "lsarpc if=136\_141\_250\_52 trust"

```
1071778331: SMB: 4:  
Default values:  
Interface 'elv0' Addr='136.141.250.52'  
1071778331: SMB: 4: Local Well Known SID set for BUILTIN domain:  
1071778331: SMB: 4: SID[2]=20.200.  
1071778331: SMB: 4: Trusted domain 0=RHROOT  
1071778331: SMB: 4: Trusted domain 1=NARNTL  
1071778331: SMB: 4: SID=S-1-5-15-52dabe9d-75932ae1-2b3be507  
1071778331: SMB: 4: Trusted domain 2=EM  
1071778331: SMB: 4: SID=S-1-5-15-66417ccd-74ba50f4-2b3be507
```

### Lookup trusted domains OK

```
1071778331: VC: 5: abortCheckWait(smb_share=0x0)  
1071778331: ADMIN: 4: Command succeeded: lsarpc if=136_141_250_52 trust
```

### NAS 5.5.29 ISSUE WITH TRUSTED DOMAINS THAT ARE QUARANTINED:

NAS code changes behavior so that DART does not query for SIDs from trusted domains that have the quarantine bit set, resulting in access & CIFS outage issues (DM interprets quarantine bit as an unhealthy domain and won't try SID lookups to the domain). Param value was changed to 4. Starting with NAS 5.5.31.4, the default behavior will return to 0. Set the following param to 0 to avoid this behavior:

## # .server\_config server\_2 -v "param cifs lsarpc.queries.trustAttributes=0"

Mask of unsupported and excluded trusted domains for lookupSID queries

### Output from PDC Dump shows Quarantine bit Set:

```
SMB: 4: Trusted domain:domain1.corp [DOMAIN1]  
GUID:00000000-0000-0000-0000-000000000000  
SMB: 4: Flags=0x22 Ix=0 Type=0x2 Attr=0x4 <----- Quarantined  
SMB: 4: SID=S-1-5-15-f2d83cd-591ede04-3fca17b0
```

### V. RESOLVING GROUPS USING LSARPC CALLS:

## # .server\_config server\_2 -v "lsarpc if=10\_43\_3\_46 user='domain admins'"

```
40c6194d DCf2b210c TTNDAPACDC2[APAC] 9 setCurrentDC Ctx=f74d404 Old=0 New=f2b2104  
Finding User SID from Name=0  
Interface '10_43_3_46' Address=10.43.3.46  
UserName0='APAC\domain admins' (0) use=2 nameType=0  
S-1-5-15-53fce379-23e444b6-6b635f23-200 domain admins  
UNIX ID=32770 Type=1  
1086724429: VC: 5: abortCheckWait(smb_share=0x0)  
40c6194d DCf2b210c TTNDAPACDC2[APAC] 8 setCurrentDC Ctx=f74d404 Old=f2b2104 New=0  
1086724429: ADMIN: 4: Command succeeded: lsarpc if=10_43_3_46 user='domain admins'
```

### VI. PERFORMING SAMR CALLS:

## # .server\_config server\_2 -v "samr if=10\_241\_169\_49 user=nas1"

```
1099322602: SECURITY: 3: /etc/group does not exists and NIS not started  
1099322602: SMB: 4: NT_Access_Credential::RequestFromSID User=MOUSE\nas1  
S-1-5-15-42f831d9-66417ccd-28a68b82-45d  
1099322602: SMB: 4: RID=0201 GID=2002 A:7 U:2 ='Domain Users'  
1099322602: SMB: 4: RID=0462 GID=2009 A:7 U:2 ='NAS Users'  
1099322602: SMB: 4: Primary=201 Nb=2 isValid=1 isAdmin=0  
Finding User Groups from UserName=0
```

```
1099322602: VC: 5: abortCheckWait(smb_share=0x0)  
1099322602: ADMIN: 4: Command succeeded: samr if=10_241_169_49 user=nas1
```

### VII. CONDUCTING USER SID-TO-UID/GID LOOKUP ON DM:

## \$ .server\_config server\_7 -v "lsarpc if=ana0 user=nasadmin"

```
1040941811: SMB: 4:  
Default values:  
Interface 'elv0' Addr='192.10.2.30'  
1040941811: SMB: 4: Local Well Known SID set for BUILTIN domain:  
1040941811: SMB: 4: SID[2]=20.200.  
Finding User SID from Name=0  
Interface 'elv0' Address=192.10.2.30  
UserName0='T2DOM3\nasadmin' (0) use=1 nameType=0  
S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-46a nasadmin  
UNIX ID=602 Type=0  
1040941811: ADMIN: 4: Command succeeded: lsarpc if=ana0 user=nasadmin
```

**Note:** DM will always interrogate Domain Controller when this command is used. Usermapper or local passwd/group files must be available for this lookup to succeed. If the User/Group account is valid and a previous mapping has not been made, a new mapping will be issued as a result of this query. Potentially, given a list of User accounts for a Domain, you could script this command to query every account and build a new Usrmapper database. Or, after conducting a 2.0 to 3.0 Usrmapper upgrade, you could forcibly populate SIDs into the database by running lsarpc calls, though this would have a large timeout drawback with accounts that no longer had a valid SID in the Domain—i.e., were deleted.

### **UNSUCCESSFUL USER/GROUP LOOKUP--ACCOUNT DOES NOT EXIST IN DOMAIN:**

# .server\_config server\_5 -v "lsarpc if=ana0 user=nas29"

```
1068044799: SMB: 5: ExtractDomain:No Domain in reply  
1068044799: SMB: 5: ExtractSIDs:Usr='(NULL)\nas29' RID=ffffffff U=8 D=ffffffff UID=0 T=-1 (17)  
1068044799: SMB: 5: lookupNames:bad reply=c0000073  
1068044799: SMB: 5: MsError sendLookupNames=21 NTStatus=c0000073
```

Finding User SID from Name=c0000073

```
1068044799: VC: 5: abortCheckWait(smb_share=0x0)  
1068044799: ADMIN: 3: Command failed: lsarpc if=ana0 user=nas29
```

Error 4020: server\_5 : failed to complete command

**Note:** We cannot retrieve a valid SID for the User or Group, meaning they do not exist in the Domain--see following translation of the NT Status Error:

C:>err c0000073

# for hex 0xc0000073 / decimal -1073741709 :

STATUS\_NONE\_MAPPED ntstatus.h

### **UNSUCCESSFUL USER/GROUP LOOKUP:**

# .server\_config server\_5 -v "lsarpc if=ana0 user=nas23"

server\_5 : commands processed: 0

Error 5: server\_5 : Input/output errorRPC: Timed out

**Note:** If the account is a valid User/Group in the Windows Domain, this error could indicate that Usermapper is not running or is unable to map the account. It might also indicate that local passwd/group files are not resolving the User/Group either.

Use the LSARPC command when troubleshooting User and Group accounts. All LSARPC calls go to the Domain Controllers to be resolved and are never resolved locally from cache!

### **LSARPC LOOKUP WHEN DM RESOLVES GROUP TO DC BUT CANNOT MAP:**

\$ .server\_config server\_2 -v "lsarpc if=128\_206\_8\_41 user='research admins'"

```
1121275488: USRMAP: 3: Usermapper[127.0.0.1] unreachable  
1121275488: RPC: 5: CLIENT::CLIENT 29dda604: Port acquisition failed for Rpc service 536870919 version 3 on host 28.206.8.40  
1121275488: USRMAP: 3: Usermapper[128.206.8.40] unreachable  
1121275488: SMB: 5: Unix group 'research=20admins' unknown

```

Finding User Name from SID=0

Interface '40\_152\_0\_47' Address=40.152.0.47

UserName0='LATINAMERICAS-1-5-15-850152b-20db1f76-5bd73fc6' (0) use=8 nameType=0

S-1-5-15-850152b-20db1f76-5bd73fc6 S-1-5-15-850152b-20db1f76-5bd73fc6

**UNIX ID=0 Type=3 →Shows that Group is not mappable because Domain Range has not been configured in Usermapper**

Use Lsarpc Trust command to see if Domain Users group is a trusted Domain:

```
# .server_config server_2 -v 32768 "lsarpc trust"
```

```
1145035488: SMB: 4: Trusted domain: AMERICA
1145035488: SMB: 4: Flags=0x22 Ix=0 Type=0x1 Attr=0x1000000
1145035488: SMB: 4: SID=S-1-5-15-850152b-99999999-5bd73fc6
```

Internal Usermapper in CONFIG MODE not UNIVERSAL MODE:

```
# .server_config server_2 -v "usrmapsvc info"
```

```
1145034041: USRMAP: 4: Usrmapper service: Enabled
1145034041: USRMAP: 4: Service Class: Primary
1145034041: USRMAP: 4: Database File system: Root
1145034041: USRMAP: 4: Configuration = usrmap.cfg
1145034041: USRMAP: 4: Mapping mode: config
```

No range defined for the AMERICA Domain:

```
# cat usrmap.cfg
```

```
emc,emc.example.com:100000:100001:170000:100001:170000
ogre,ogre.beast.com:600000:600001:670000:600001:670000
indy:700000:700001:870000:700001:870000
_history_sid_range_:900000:900001:970000:900001:970000
```

Use NTCRED to Show Credentials for User:

```
# .server_config server_2 -v 32768 "ntcred user=c036907" |grep 201
```

```
1145035867: SMB: 4: PRIMARY = S-1-5-315b0c1e-88888888-4b0672e8-201
1145035867: SMB: 4: gid=0x493e2 S-1-5-315b0c1e-88888888-4b0672e8-201
1145035867: SMB: 4: gid=0xaee61 S-1-5-15-7a1736d2-77777777-27dd07ca-201 →0xaee61 (700001 decimal) example of Domain
Users group that is mapped
1145035867: SMB: 4: gid=0xffffe S-1-5-15-850152b-99999999-5bd73fc6-201 →0xffffe means Domain Users group for
AMERICA could not be resolved
```

**Comment:** Impact to Users is hard to gauge, but there were reports of performance issues when certain Users accessed the Celerra, perhaps related to timeout delays associated with SIDs that the Data Mover tries to resolve and map, but could not. In this example, the customer had many trusted domains, and Users with Group membership to trusted domains that were not mapped in the usrmap.cfg file. The correct resolution to the problem would be to add the trusted domains to the usrmap.cfg file.

DEBUGGING MEMORY LEAKS ON DATA MOVER:

```
$ .server_config server_3 -v "meminfo"
```

**Note:** Below output represents various memory buckets that DART uses  
1716162599 calls to malloc, 1715768442 to free, 419990763 to realloc

| Size  | In Use | Free   | Total nallocs | nfree       |

**# .server\_config server\_2 -v "displayby full"**

---

Name: **logdisk**: NBS1: 1: Disk\_ID: 1 Owner: SP-A blocks: 23068544 paths: 2 IOs pending: 0 IOs in-progress: 0

---

c0t0l0: DGC RAID 5 SN: 600601607eb50900d1206ceed844db11 SP-A IOs: 0

c16t0l0: DGC RAID 5 SN: 600601607eb50900d1206ceed844db11 SP-B IOs: 0

**Note:** Good command to see IO's pending on Disk devices

## **READDING LOGDSK VOLUMES BACK TO DM:**

**\$ .server\_config server\_x “volume disk 1 c0t0l0 disk\_id=1 size=11263”**

## **IMPORTANCE OF LOGDSK NBS1 VOLUME:**

It is important that the logdisk volume has at least one communication path to SPA and SPB, as seen by this error message that resulted during a recent NAS 5.5 Upgrade that runs the automatic post-upgrade healthchecks:

### **PUHC FAILS WITH:**

**# nas\_storage -check -all**

Discovering storage (may take several minutes)

Error 5017: storage health check failed

server\_2 one or more system volumes are HA compromised

# ./dbchk -p

Error: storage system name does not match previous entry, had 'APM00041202945' now have 'APM00041202944' for 'DGC RAID 5 02190600100006NI'.

Error: val does not match previous entry, had '7' now have '31' for 'DGC RAID 502190600100006NT'.

**Resolution:**

Manually add paths for the logdsk volume, or failover and fallback server to rebuild paths

# server\_log server\_3 -s |grep -i logdsk

2007-02-20 14:08:57: ADMIN: 4: Command succeeded: volume disk logdsk c0t0l0

2007-02-20 14:08:57: ADMIN: 4: Command succeeded: volume disk logdsk c16t0l0

**COMPARING VOLUME INFORMATION ON CS TO DM:**

#nas\_volume -i -size id=&lt;id number disk volume&gt;

\$ .server\_config server\_x -v "volume disk &lt;id number disk volume&gt;"

\$ .server\_config server\_2 -v "volume display"

List of all volumes :

## **USING VOLTEST VOLUME PERFORMANCE CAPTURE FOR I/O:**

**Note:** Voltest can provide Write and Read performance statistics on specific meta volumes (such as Celerra File Systems), related to Block I/O size, random or sequential I/O, and number of threads for the Write or Read Operation.

**# .server\_config server\_2 -v "voltest begin 167 rd xfersize=16 sequential threads=10 seconds=5"**

**# .server\_config server\_2 -v "voltest kill 167"**

**Note:** 167 is the ‘meta’ volume id of the file system, rd=read, wr=write, xfersize=I/O block size to use.

### **SAMPLE OUTPUT:**

| Volume | RdOps    | WrOps    | nBytes   | Elapsed  | Bytes/sec | Ops/sec  |
|--------|----------|----------|----------|----------|-----------|----------|
| 167    | 00019f01 | 00000000 | 33e02000 | 00:04:25 | 174061977 | 00021247 |
| 167    | 00019fef | 00000000 | 33dde000 | 00:04:30 | 174035763 | 00021244 |
| 167    | 000194ef | 00000000 | 329de000 | 00:04:35 | 169841459 | 00020732 |

**WARNING:** *Do not use this tool for performance analysis on live production systems as there are a lot of issues—causes panics and systems to go down!*

## **PROFILING CELERRA 'FRONT-END' SCSI PERFORMANCE WITH SYMMETRIX:**

1. **.server\_config ALL -v "printstats scsi reset"** [Zeroes out stats]
2. **.server\_config ALL -v "printstats filewrite reset"** [Zeroes out stats]
3. Rerun “printstats scsi” and “printstats filewrite” command at collection intervals
4. **\$server\_nfsstat ALL -a**
5. **\$server\_sysstat ALL**
6. **\$server\_nfsstat ALL -zero** [Zero out nfsstats after each collection period; Total ncalls are important under RPC Totals]

**Methodology:** Set up a collection interval of 15, 30, or 60 minutes. Idle % is important from SCSI channels of each datamover.

Total average miliseconds for filewrites is important. Normal performance levels should be <20msec. Total “ncalls” for each Server under the “RPC” totals should be divided by the frequency in minutes of your collection period, and divided again by 60 to determine total “nfs” calls to the DataMover’s FrontEnd per second. Important Note here is that several 506/507 datamovers have the capability of overloading a 4.8 Symmetrix.

### **"printstats scsi reset"**

ctr0: maxpend 13, byteCount 521237181480, busy 191547461675546, **idle 227473190304343 = 54%**

ctr1: maxpend 13, byteCount 521344578600, busy 191314482426539, **idle 227704907759274 = 54%**

### **"printstats filewrite reset"**

total 71014793 blocks in 494958755 ticks, **ave 27 msec**

### **"server nfsstat ALL -a"**

**Server rpc:** [Server\_2]

| ncalls | nBadRpcData | nDuplicates | nResends | nBadAuths |
|--------|-------------|-------------|----------|-----------|
|--------|-------------|-------------|----------|-----------|

**341399** 9 0 0 0

**What to Look For on Symmetrix Side:** Engage PSE III or Level 2 Symmetrix

- Channel I/O on Front-End SCSI HBA's
- Total Write Pending on Symmetrix
- Format Pending on Symmetrix
- Cache Fall-Through Time (Read Cache)
- Read/Write Ratio on Channels

### **USING PRINTSTATS TO INVESTIGATE VOLUME PERFORMANCE STATS:**

**\$ .server\_config server\_2 -v "printstats volume full"**

Volume Rd Reqs Wr Reqs Rd Ops Wr Ops

**\$ .server\_config server\_2 -v "printstats volume reset"**

**\$ .server\_config server\_2 "printstats basic\_volume full"**

**\$ .server\_config server\_2 "printstats basic\_volume reset"**

### **USEFUL PROFILING TOOLS:**

- server\_profile utility
- tcp\_dump utility or other network trace tool
- server\_panic command to induce panic dump for analysis

### **CONDUCTING NETWORK TRACES ON DATAMOVER USING TCPDUMP:** NAS 4.x +

**Step 1. Link server mgr to server tcpdump on CS:**

**# ln -s /nas/bin/server\_mgr /nas/sbin/server\_tcpdump**

**Step 2. Start network capture:**

**# /nas/sbin/server\_tcpdump server\_2 -start ace0 -w /mnt01/tcpdump.log -max 1000** (size in kb) **-s 1514**

Or **# /nas/sbin/server\_tcpdump server\_2 -start fsn0 -w /artwkgrp/artwkgrp/dmp.tst** (NAS 5.4)

Or **# /nas/sbin/server\_tcpdump server\_2 -start cge1 -w /fs\_quota/tcpdump.log -max 1000 -s 1514**

server\_2 :

Packet capturing started.

**Step 3. Monitor capture:**

**# /nas/sbin/server\_tcpdump server\_2 -display**

server\_2 :

Packet capturing OK on device: cge1 , to file: /fs\_quota/tcpdump.log-1  
pkts captured: 38 filtered out: 0 dropped: 0

**Step 4. Stopping the capture:**

**# /nas/sbin/server\_tcpdump server\_2 -stop ace0**

server\_2 :

Packet capturing stopped.

**Step 5. Review trace on CS or download and review using Ethereal, etc.:**

**# /usr/sbin/tcpdump -r /nasmcd/quota/slot\_2/fs\_quota/dump\_nosnap.log -n |more**

**Switches:** -display | -stop ace0 | -host [IP Address only, & don't abbreviate] | -s snaplen [packet size bytes]

**Note 1:**

Try to use -s 1514 whenever possible to prevent truncation of SMB packets

**Note 2:**

\$ /nas/sbin/server\_tcpdump server\_2 -start cge5 -w /tmp/dmp.out → Cannot use tcpdump from DM to write to Control Station  
PacketCapture: failed to initialize asynclog object

### **Engineering Facility to Run TCPDUMP:**

**\$ .server\_config server\_2 -v “netcap action=start device=ace0 filename=/dump/dump.log”** [root of DM]

**\$ .server\_config server\_2 -v “netcap action=display”**

**\$ /nas/sbin/server\_tcpdump server\_2 -display** [Info regarding current tcpdump]

**\$ .server\_config server\_2 -v “netcap action=stop device=ace0”**

**\$/usr/sbin/tcpdump -r /nas/rootfs/slot\_2/dump/dump.log -n** [Reading the capture from Control Station?]

**Note:** TCPDUMP requires the following passwd file entry in /etc/shadow [/etc/passwd] in order to start up:

pcap::!12475:0:99999:7:::

## **OBTAINING TCPDUMP OF DATAMOVER DURING AN NFS OR CIFS STARTUP:**

1. Edit netd file and place following at top of file: netcap action=start device=ana0 filename=/tcpdump.cap
2. Conduct data mover failover
3. Stop tcpdump and analyze (remove netd file entry when done with activity)

## **LINUX CONTROL STATION TCPDUMP:**

Step 1. #/usr/sbin/tcpdump -s 2000 -w /tmp/dump1 host 192.1.5.44 and 192.1.5.23

Step 2. Starts capture between the two nodes; Use “ctrl + c” to stop capture

Step 3. Display Capture: #/usr/sbin/tcpdump -vvex -r /tmp/dump1 |more

## **CAPTURING TRAFFIC ON CS INTERFACE:**

**#/usr/sbin/tcpdump -i eth2 -c 1000 -w /nas/log/toftp2/tcpdump.log &**

## **TESTING I/O PERFORMANCE TO DATAMOVER FROM SUN SOLARIS CLIENT:**

#dd if=/dev/zero of=/mnt/test1 skip=8 bs=1000 count=10000 [Creates write activity]

#/nas/symcli/bin/symdev show 002 [Run command on Control Station to monitor activity]

## **CIFS PERFORMANCE ISSUES & TUNING VARIABLES:**

### **CLIENT SIDE PARAMETERS:**

RW Threads    TCP/IP Parameters    FileSystem Tuning (DNLC & Nodes)    Driver (Jumbo)

**DNLC CACHE (Directory Name Lookup Cache):** Used to speed up name-to-inode mappings

The Directory Name Lookup Cache caches directory/file name pairs whenever a file name is requested from a directory, when doing an NFS Lookup operation. Dart DNLC is expected to be a 100% reliable cache of lookup hits and misses. This means that if an positive match is found, the file must exist and the handle not be stale; if a negative match is found, the file must definitely not exist; and if no match is found, the file may or may not exist, and a further lookup is necessary. The DNLC applies to Unix names only; CIFS lookups went through the Shadow, however, with MPD, we now allow unicode CIFS names to also be cached. The CFS layer must keep the DNLC accurate. This requires that any remove, rename, rmdir, or equivalent operation must make sure to remove the corresponding entry(ies) from the DNLC. It is desired, but not critical, that any lookup add the entry to the DNLC cache. Also, any unmount or freeze must delete all DNLC entries for the corresponding file system. Entries are cached in the DNLC cache as hashed nfs filehandles and are designed to enhance performance as entries can be retrieved from cache much faster than doing another Lookup operation. Negative entries are created if the file lookup fails (ENOENT). Subsequent lookups for the same file name that has a NOENT entry will be dismissed since the name is known to not exist, preventing a duplicate directory Lookup for the same file name. NFS creates will check this cache first to make sure the name does not already exist.

### **DNLC CACHE BUG LEADS TO STALE FILEHANDLES:**

DNLC::add does a lock drop when the lookup fails. That allows two entries to be created at once during multiple lookups for the same entry. However, only one entry is removed by remove() or rename(), the other is left behind, and becomes a stale filehandle. Because the cache mistakenly allows two entries to be created, when NFS directories are deleted and then recreated elsewhere in the same file system tree, the DNLC cache still contains an invalid entry and the ERR\_STALE filehandle condition occurs. AR47569.

### **CLEARING DNLC CACHE ENTRIES FOR SPECIFIC FILE SYSTEM:**

**\$server\_config server\_2 -v "file cleardnlc uxfs fs=115"**

**Nodes:** Max number of Files & Directories that can be opened in a System

**file initialize nodes=65536 dnlc=262144**

### **Ofcache--Open Files Cache:**

→Used for very large numbers of files being opened and reused—default value=15360. Important consideration here is that this value must be smaller than the “nodes” value in the /nas/server/slot\_3/file—long NFS filenames can cause panics and other performance problems:

/nas/server/slot\_3/netd

**nfs start openfiles=15360 nfsd=96**

**# .server\_config server\_x -v "printstats ofcache"** →CIFS small file dirty cache flushing

Open File Cache Statistics

28 access, 10128 checked

8 hits, 20 misses

20 opens, 6 closes, 0 reopens

OfCache hit ratio 28%

→Beginning with NAS 5.6.36, the Open Files Cache is now used by the CIFS protocol, in addition to the traditional NFS user. This enhancement was put into place for CIFS to provide a safeguard against data loss on the CIFS side during system crashes. By default, data is flushed from cache to disk every 10 minutes for open CIFS files. This feature is also called CIFS data trickle sync. See emc208635 for more information and a regression issue resolved at 5.6.44 that caused high CPU utilization and poor system performance.

#### **Disabling of Cache for CIFS:**

**“param cifs ofCache=0”**

#### **Example Of DNLC Server Log Entry:**

##### **UFS: 4: expanding Offset chunk list to 4076 offsets**

Log Entry indicates that Data Mover is busy expanding the dnlc (directory name lookup cache) entries

**Note:** This can happen if directories are being searched in a linear fashion, such as from Tape Backup programs, or Unix find or ls commands. Applications such as viruschecker are also dependent on these parameters.

\$more /nas/server/slot\_2/file

**file initialize nodes=22528 dnlc=65536**

### **EXAMPLE OF FILE NODES & DNLC SYMPTOMS:**

#### **Windows Client Cannot Access Share:**

Error message from Windows client when trying to access the Celerra share: The disk in drive G is not formatted. Do you want to format it now?

#### **Server Log Has Following Messages:**

SHADOW: 3: Couldn't get node from handle Status:3

SHADOW: 4: forceRebuild

**Solution:** Increase nodes & dnlc values per primus emc53040

### **STALE NFS HANDLES ISSUE:**

Due to problem in code, DNLC can have multiple entries for file handles. Deleting a file handle would leave the other handle, resulting in stale file handle error, or complaints that file already exists, etc. AR47720. Fixed 5.3.12.x, 5.2.16.2, though similar issues seen as late as 5.4.15 code.

### **FLUSHING DNLC CACHE ON DATA MOVER:**

**#.server\_config server\_2 -v "file cleardnlc uxfss fs=<fsid>"**

**Note:** Use the cleardnlc command to flush the cache during the time of an access problem to see if access is restored.

**# .server\_config server\_2 -v "file cleardnlc uxfss fs=33"**

1143648779: CFS: 5: DNLC: erased 187023 entries

### **SERVER SIDE PARAMETERS:**

Caching      Storage Load Balancing      Processes (Threads)      Hash Tables

NFS Threads--sometimes adding more will help performance

CIFS Threads--Configure more when many simultaneous Clients connected--Default=32; Not uncommon to see 500 threads

Pathcache--to improve response times when Clients request list of open files from Server

SID Caching--recursive tree copies with ACLs

Oplock Timeouts

Groupcache

### **NETWORK PARAMETERS:**

Jumbo Packets      Switches

### **STORAGE PARAMETERS:**

Stripe Size      Number of Disks      RAID      Caching

### **INCREASING DATAMOVER CIFS THREADS:**

#### **Step 1. Stop CIFS service**

**Step 2. Increase threads: # server\_setup server\_2 -P cifs -o start=200**

**Note:** Default number of threads was 32 [NAS 5.1 increased to 96 threads if resident DM memory allowed]; Maximum number of threads=999. Big problem with this fix is that it is not persistent. If you set threads to a higher level, then stop and start cifs without specifying threads, it will revert back to original value. But since the values are written to the netd and boot.cfg file, reboots will retain the value.

#### **NETD & BOOT.CFG ENTRY:**

**cifs start=96**

## **INCREASING GLOBAL SID CACHING CAPABILITY OF DATAMOVER:** [4.1 Code]

**Purpose:** Used to increase connection performance when many Users are connecting with large numbers of Group memberships. Parameter specifies max number of Global Group SIDs that Celerra caches. Requires less communications with AD Servers to obtain multiple SIDs, especially as it pertains to SIDHistory and multiple Global Group lookups

**param cifs sidcache.globalSidCacheSize=1901** [Should be a prime number]

**Note:** Default Global SID Cache is 401 with all NAS versions above 4.1, but there is a sidcache.size param where the default value is really 53 entries. The cache table will fill up to 53 entries and then use LRU mechanism to delete oldest used entry before adding a new entry.

**# .server\_config server\_2 -v "param cifs sidcache.size"**

cifs.sidcache.size INT 0x010b12fc 53 53 (0,201650) TRUE RESTART 'Per connection SID cache size for ACL mapping'

### **NAS 5.1 +:**

**param cifs sidcache.globalSidCacheSize=401**

**Note:** Parameter name has changed but default is still 401

## **DATA MOVER CACHING:**

Data Mover does not cache User or Group names, but does cache SID GID mappings.

## **INCREASING THE NUMBER OF CIFS SESSIONS PER TCP CONNECTION:**

**Symptoms in Server Log:** "SMB: 3 : addUser: too many sessions (128/128) for FR9203687D"

Datamover is limited to a maximum of 128 CIFS Sessions per TCP connection by default. In very busy CIFS environments, or those that use Terminal Servers (Citrix Metaframe), it's possible to exhaust the number of CIFS Sessions.

**Solution:** Increase "SessUsers" value from default 128 to 512 [New default recently raised to 2048]

**param cifs LanmanServer.SessUsers=2048** [New default 5.2.16.2 & higher]

**Note:** Defined as max number of SMB sessions a single client can open on DM over a single TCP connection. Closest Microsoft Windows setting is MaxWorkItems & MaxMpxCt. Engineering param document implies that there are multiple TCP connections involved, which is wrong. Terminal Server would be one example of a single system using one TCP connection to the data mover and servicing many CIFS sessions from different Users over that connection. Normal PC connection uses no more than two users for the connection (Anonymous + currently logged in user)

**Comment:** Typical environment requiring this change would be Terminal Servers, Citrix Metaframe, or IIS/FTP Servers, where many User SMB Sessions can be multiplexed over the same TCP connection.

## **PARAMETER TO CLEANUP IDLE SMB SESSIONS ON DATA MOVER(see emc115144):**

**param cifs LanmanServer.IdleUserAutoLogoff=720** [minutes] [NAS 5.1.20.4 & 5.2.7.0]

**param cifs LanmanServer.IdleUserAutoLogoffCnxToo=1** [new with 5.3.17.1—not in 5.4 or 5.5]

**Note:** With multiplexed SMB Sessions over a single TCP connection, as in the case of IIS Servers, Citrix MetaFrame, and Terminal Servers, sessions may not cleanup properly, eventually reaching the ceiling in the number of "LanmanServer.SessUsers" sessions that can be opened for a single TCP connection. Though you can increase the Lanman Sessions allowed, the above parameter will allow the data mover to clean-up orphaned SMB Sessions after the stipulated time period, in this case 720 minutes = 12 hours. To try and determine who is failing to breakdown the Session, conduct network trace and look for Session Setups followed by SMB Logoff after the SMB Session is completed. Not known at this time whether this is strictly a MS issue or a code issue. See ARs 35973 & 39039. Starting in 5.3.17, a new param (cifs.LanmanServer.IdleUserAutoLogoffCnxToo) controls whether idle connections are disconnected when idle users are logged off—by default, when a user is idle for the period set by IdleUserAutoLogoff (and has no open files) the user session and its associated connections will be logged off/disconnected.

## **CITRIX OR TERMINAL SERVER ‘CIFS Farm’ PARAMS:**

**param cifs farm.MinUsers (default set to 2)**

**param cifs farm.IdleUserAutoLogoff (default 15 minutes)**

**Note:** New parameters put into place with NAS 5.4.16.1 & 5.3.18.2. See emc115144. No longer sure if LanmanServer.IdleUserAutoLogoff param is valid any longer.

**param cifs farm.MinUsers** (set to 2 by default)

**Note:** Dart will now detect that user is running a multiuser application when more than two connections are established from same client. Default behavior also enforces cleanup of idle cifs connections every 15 minutes.

**# .server\_config server\_2 -v "param fulldescription cifs farm.IdleUserAutoLogoff"**

cifs.farm.IdleUserAutoLogoff 0x0157809c 0x0000000f 0x0000000f

1157121478: ADMIN: 4: Command succeeded: param fulldescription cifs farm.IdleUserAutoLogoff

**Note:** Default is on, set to 15 minutes

**# .server\_config server\_2 -v "param cifs farm.MinUsers"**

cifs.farm.MinUsers INT 0x01578098 2 2 (0,4294967295) FALSE REBOOT 'NA'

# .server\_config server\_2 -v "param cifs LanmanServer.IdleUserAutoLogoff"

cifs.LanmanServer.IdleUserAutoLogoff INT 0x015780a4 4294967295 4294967295 (0,4294967295) TRUE NONE 'Minutes until an idle user is logged off (default:off)'

1157121337: ADMIN: 4: Command succeeded: param cifs LanmanServer.IdleUserAutoLogoff

**Note:** Default is off

# .server\_config server\_2 -v "param cifs farm.IdleUserAutoLogoff"

cifs.farm.IdleUserAutoLogoff INT 0x0157809c 15 15 (0,4294967295) FALSE REBOOT 'NA'

# server\_param server\_2 -facility cifs -info LanmanServer.IdleUserAutoLogoff -v

server\_2 :

```
name      = LanmanServer.IdleUserAutoLogoff
facility_name = cifs
default_value = 4294967295
current_value = 4294967295
configured_value =
user_action = none
change_effective = immediate
range      = (0,4294967295)
description = Minutes until an idle user is logged off (default:off)
detailed_description
```

This parameter sets the number of minutes after which an idle user having no open files is automatically logged off the server. The default behavior is for the user to be logged off when it is explicitly requested by the client or when the TCP connection is reset. Setting this parameter causes the Celerra to free resources associated with user sessions which have been orphaned by the client. Minimum value = 0 Maximum value = 0xFFFFFFF Setting param cifs.LanmanServer.IdleUserAutoLogoff=15 results in the idle user's credential being automatically logged off the server after 15 minutes.

## **TERMINAL SERVICES THINCLIENT MAX OPEN FILES LIMITATION:**

Windows NT multiplexes all file requests sent to a single server over a single virtual circuit. Since ‘SMB’ “shares” this virtual circuit with each additional User, the max number of Open File Handles limit could be reached.

**NT 4.0:** Maximum number of Open File Handles on a single Virtual Circuit=2048

**Windows 2000:** Limit=8192

**Increase this Value with Registry Change:**

HKLM>System>CurrentControlSet>Services>Rdr>Parameters>Add Value>MultipleUsersOnConnection REG\_DWORD Data: 0

**Note:** This situation would only occur if there is a single Terminal Server having all users connect via SMB to a single File Server

## **Enhancing Performance for Very Large CIFS Directory Structures:**

UFS Hashing Table Algorithms and CIFS Path Caching can be tweaked by Engineering, but requires very specific customer tailoring:

**param ufs inoHashTableSize=10069**

**param cifs pathCache=317**

**Note:** pathCache is used to retrieve full pathname of opened file from FID and it must be prime number

## **NEWER PARAM TWEAK SETTINGS:**

**param ufs dirBlkHashSize=64**

**param ufs inoBlkHashSize=6007**

**param ufs inoHashTableSize=15013**

## **Max Number Client TCP Connections to the DataMover:**

Max number of connections/concurrent sessions per Datamover using 2.2.35.4+: 20,000/3000

Max number of concurrent TCP connections prior to 2.2.35.4: 2000

## **CELERRA & TCP RETRANSMISSIONS:** Circumstances in which the Celerra will retransmit packet to Client

1. Fast Retransmits: Done anytime (3) consecutive ACKS are out of order

2. Slow Retransmit: Default wait time is set at (1) second [most NT clients wait much less, 200ms]

## **Calculating TCP Retransmission Rate:**

Conduct Server\_netstat -s over a period of time and observe ‘packets sent’ and ‘data packets retransmitted’.

(Retransmissions/packets sent) \* 100 = % retransmissions

Anything above .1% is considered high. Useful when debugging problems that are related to Clients “reading” from the Data Mover. For Slow Writes to the Data Mover from a Client, examine the Client for TCP retransmissions.

## **TCP STREAMS PERFORMANCE EXAMPLE:**

**Symptom in Server Log:** 1018712517: TCP: 3: OpenStream() fails

### **Resolution:**

With NAS 5.1.20.4 and higher, the following parameter values are now the default. Notice that these params are dependent on each other and must be increased together. The old defaults were 2048 for maxStreams and 9973 for pcbMaxCache.

**param tcp pcbCacheSize=16993** Hex Value=0x00004261 Decimal Value=16993

**param tcp pcbMaxCacheSize=39839** Hex= 0x00009b9f Decimal=39839 [Max cache allocated for TCP connections]

**param tcp maxStreams=16384** Hex Value=0x00004000 Decimal Value=16384

**Note:** Current guidance for systems requiring changes to their current maxStreams values are to apply the values referenced above. NAS 5.3 & higher makes default maxStreams value 65,535 and no longer uses pcbMaxCacheSize or pcbCacheSize values—instead, now use a hashed list instead of cache.

## **TCP MAXSTREAMS ON DATAMOVER: Old Default=2048 New Default=16384**

Can have 2048 concurrent TCP dialogues taking place on the Celerra server [reads—writes—logons]

This is *not* the maximum number of connections that can be in place, however.

**\$server\_config server\_2 -v “param tcp”** [Current Open TCP Streams for a DataMover—“tcp.maxStreams”]

**Note:** TCP maxStreams represents the number of TCP streams on the system. With CIFS, this usually relates to the total number of Clients connecting separately to the data mover—streams can also be used by FTP, HTTP, and NFS access.

## **INCREASING TCP MAXSTREAMS VALUE:**

### **1. Edit Param File for Single Server or Globally:**

**\$/nas/server/slot\_2/param** or **\$/nas/site/slot\_param**

**param tcp pcbCacheSize=16993** Hex Value=0x00004261 Decimal Value=16993

**param tcp pcbMaxCacheSize=39839** Hex Value= 0x00009b9f Decimal Value=39839

**param tcp maxStreams=16384** Hex Value=0x00004000 Decimal Value=16384

**Note:** pcbCacheSize and MaxCacheSize values are replaced with a hash list with NAS 5.3. These values only represent caching capability and is meant as a performance function.

### **2. Reboot Datamover or Failover/Fallback**

**Note:** The above values are not hardware dependent, but may be load-dependent, depending on the growth and size of the Customer's User community. In otherwords, a data mover with 512MB or 3GB of RAM can handle the new defaults with no problem as memory is not allocated until the active connection is made. As usual, validate that the system load is not exceeding the ability of the current hardware to handle the load.

## **TCP KEEPALIVE MECHANISM:**

In some cases it might be necessary to change the default values so that fewer datamover resources are consumed for transient clients. In otherwords, we maintain the “keepalive” TCP connection even after a client closes connection without breaking it down properly.

**/nas/server/slot\_x/param**

**param cifs tcpkeepalive=0xff01030a**

[Default: 01=1 minute keepalive interval message; 03=3 retries before assuming connection lost; 0a=10 minutes between retries]

## **OBSERVING TCP PROTOCOL STATS ON SERVER:**

**\$server\_netstat server\_2 -s -p tcp**

## **DISABLING NFS OVER TCP ON DM:**

1. #vi /nas/server/slot\_x/netd

2. Change following line to read:

nfs start openfiles=15360 nfsd=96 tcp=0

3. Reboot DM

**Note:** If using NFS over UDP, the timeo retransmission timer may estimate values that are unreasonably small

## **TCP/NFS/UFS/CIFS PERFORMANCE TWEAKING:**

**Example:** Changing parameters to allow for increased "fs" memory caching for users pertaining to the "NFS" parameter called "openfiles". Allowing for 16,000 simultaneous User TCP connections and increased "openfiles" capability at two files each:

### **I. TCP PARAMETERS:**

**param tcp maxStreams=8192** [old values—current code sets to max 65535 as default]

### **TCP MAXSTREAMS DEFINED:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Controls the number of concurrent TCP Streams that can be in use at any given instant on the DataMover. Default is 2048. This does not equate to 2048 Users, just 2048 active TCP Sessions. Increases to this value are often necessary when the Server Log records “TCP: 3: OpenStream() fails” or “TCP: 3: Too many connections in the listen queue.”

**param tcp pcbCacheSize=5077** [this param is obsolete in newer NAS versions]

#### **TCP PCBCACHESIZE DEFINED: 401-9973**

Buffer that caches information about current TCP connections. Allows for quick use of ‘lingering’ connections. Default is 401. But, if increased, should be set to a Prime Number. Cache entries receive a ttl, but if entries fill the buffer before old cache expires, then TCP requests are handled in a serial manner, which in turn creates a heavy CPU Utilization, often symptomatic of system resources being starved. Often, “server\_profiling” should be conducted before adjusting this value. Protocol Control Blocks (PCB) Maximum value is 9973.

#### **REVISED MAXSTREAMS AND PCBCACHE TABLES:**

**param tcp pcbCacheSize=16993** Hex Value=0x00004261 Decimal Value=16993

**param tcp pcbMaxCacheSize=39839** Hex Value= 0x00009b9f Decimal Value=39839

**param tcp maxStreams=16384** Hex Value=0x00004000 Decimal Value=16384

**Note:** Current guidance for systems requiring changes to their current maxStreams values are to apply the values referenced above. The above values should always be set concurrently across all three parameters.

#### **LISTEN QUEUE LOGON ERRORS FOR CIFS:**

“Too many connections in port 139’s listen queue”

“Too many connections in port 445’s listen queue”

**Note:** DataMover by default only queues 100 backlogged User Logon requests at any given time. For NT 4.0 environments, an overflow results in above message for Port 139 and for Windows 2000, for Port 445. Increasing following parameter will queue more logon requests—default =64 Hex or 100 decimal:

**param tcp backlog=256**

#### **II. NFS PROTOCOL PARAMETERS:**

##### **a.) Increasing NFS Threads (daemons) Running on Celerra:**

/nas/server/slot\_x/netd

**nfs start openfiles=15360 nfsd=96**

**Note:** Default Values above--Increase nfsd to 250 or 512 if more NFS threads required! Decrease or Increase the number of “openfiles” depending on the Client load for NFS. Values of 44032 are not uncommon if there are a large number of Clients and Openfiles to support.

##### **b.) Increasing NFS Port 2049 Listen Queue:**

/nas/site/slot\_param or /nas/server/slot\_x/param

**param tcp backlog=256**

Default Value = 96; can increase to 256 and 384, but probably should not go higher without specific Eng. recommendation

**Server Log Symptom:** 2002-06-19 18:49:32: TCP: 3: Too many connections in port 2049’s listen queue

**Client Symptom:** Major NFS Timeout logged in /var/adm/messages: “Server Not Responding”

#### **III. UFS/CIFS FILE SYSTEM PARAMETERS: /nas/server/slot\_x/file**

**file initialize nodes=22528 dnlc=65536** [default values]

**file initialize nodes=45056 dnlc=131072**

##### **NODES & DNLC DEFINED:**

Nodes by default is set to 22,528, which tracks open files. Both parameters together are used to track open files. In cases where there are very large numbers of open files, this value, along with DNLC may need to be increased. Where there are linear filesystem searches or backup jobs, this also may impact these parameters. DNLC by default is set to 65,536. Please note that these values are constantly changing and are different in the latest NAS code and hardware models.

##### **NAS VERSION 5.5:**

# cat file

**file initialize nodes=256000 dnlc=384000**

**Note:** DNLC=Directory Name Lookup Cache

#### **FILE NODES AND DNLC VALUES ARE DETERMINED DURING SETUP SLOT:**

DM Memory > than 512 sets values to "file initialize nodes=65536 dnlc=262144"

DM Memory = 512 sets values to "file initialize nodes=22528 dnlc=65536"

DM Memory < than 512 sets values to "file initialize nodes=10240 dnlc=8192"

**Note:** Normally, memory values are determined during setup\_slot using server\_sysconfig -P at getreason code 4 or 5, but on occasion, if DM is still at state “3” then DM will be set to minimize parameters. This may occur during setup\_slot and also during replacement of nas.exe files. One side effect is that virus checker may be impacted—see “vnodes”.

#### **IV. LOST DELAYED WRITES OVER NETWORK:**

This error is commonly seen when using applications over wan networks, such as Oracle Databases, SQL Server, Terminal Services and ThinClients, and Internet Information Server (IIS), where network latency, and resource issues exist between Client/Server.

**Windows Client PopUp Message:** "Windows was unable to save all the data for the file xxx. The data has been lost. This error may be caused by a failure of your computer hardware or network connection. Please try to save this file elsewhere."

#### **INCREASING CELERRA TCP CONGESTION WINDOW SIZE:**

**param tcp sndcwnd=16384 | 32768 | 65536 | 131072**

**Note:** Default=0, meaning that we use the size of receive window from client

Congestion Window is the max amount of data Celerra can send to client without waiting for ACK

**param tcp sndcwnd=1**

**Note:** Setting value to 1 translates into min. of 2 TCP segments of 1460 bytes—useful for troubleshooting some client issues

#### **REDUCING WINDOW SIZE TO AVOID CONGESTION WINDOW TCP TIMEOUTS:**

**param RCP tcpwindow=128000** (do not know if this syntax is correct)

**Note:** Typical values would be 128 or 64k, purpose is to try and prevent the Congestion Window being hit as this slows TCP down due to timeout, retransmit, and restart values. Seems to be most applicable to Remote IP Replication environments. Current NAS 5.4 default is 0.

#### **RCP SESSION TABLE ISSUE:**

An issue with RPC where we get connections half opened that eventually fill the RCP session table--for revisions prior to 5.4.18, the solution is to reboot the DM. With 5.4.18, these connections are cleared by the DM.

**Possible Workaround is to Stop & Restart RCP Daemon:**

**\$server\_config server\_x -v "rcpstop"**

**\$server\_config server\_x -v "rep"**

Sample Server Log Message→2005-10-02 02:10:58: RCPD: 4: RCP connection from 10.17.155.71:38013

**\$ .server\_config server\_2 -v "volmcast display interface"**

1154954222: RCPD: 4: ip:192.1.6.202

1154954222: RCPD: 4: ip:192.1.6.204

#### **EXAMPLE OF TUNING ON MS CLIENTS & CELERRA SERVERS:**

##### **WINDOWS 2000 SERVERS:** [Changes made based on Microsoft TechNet]

MaxCmds--default setting is 50 [Max value is 65,535]; Value increased to 2048

maxMpxCt--default is 125 [Max value is 64,535]; Value increased to 2048

maxWorkItems--default 500 [Max value is 65,535]; Value increased to 8192

##### **CELERRA NAS SERVERS:**

**Windows Value=MaxCmds:**

**param cifs LanmanServer.MaxMpxCt=2048** Celerra Default Value=128; Increased to 2048

**Note:** This parameter appears to be the same as the cifs maxMpxCount param

**Windows Value=MaxMpxCt:**

**# server\_param server\_2 -facility cifs -info maxMpxCount**

server\_2 :

```
name      = maxMpxCount
facility_name = cifs
default_value = 127
current_value = 127
configured_value =
user_action = restart Service
change_effective = restart Service
range     = (5,2048)
description = Unacknowledged command count max (default:127)
```

**# server\_param server\_2 -facility cifs -modify maxMpxCount -value 2048**

**param cifs maxMpxCount**

**Note:** Use the server\_param command to change the default value from 127 to 2048. Please note that the CIFS service must be restarted before the new settings go into effect. The maxMpxCount default is 127 and represents max number of CIFS client commands allowed without acknowledgement by DM. Value is negotiated via SMB sessions with the Client [from the Server] and then enforced by the Client Redirector. Whenever the “maxMpxCt” values are changed, the “MaxWorkItems” must also be increased by a value of 4x the maxMpxCt value.

#### **Windows Value=MaxWorkItems:**

# server\_param server\_2 -facility cifs -info LanmanServer.SessUsers

server\_2 :

```
name      = LanmanServer.SessUsers
facility_name = cifs
default_value = 2048
current_value = 2048
configured_value =
user_action = none
change_effective = immediate
range     = (1,16383)
description = Maximum sessions from a single client (default:128)
```

**param cifs LanmanServer.SessUsers=2048** (old default 128, new default 2048)

**Note:** Represents maximum number of TCP sessions a Client can open with the DM

#### **DEFINITIONS:**

**MaxWorkItems:** Max. number receive buffers that Server Service allocates. Symptoms are that buffer limit is reached and TCP must initiate Flow Control--this decreases network performance. Extreme cases, no new client connections will be allowed.

MaxMpxCt is related to MaxWorkItems—together they influence the number of outstanding concurrent network requests for SMB Connections that a NAS Device or Server can service at any given time.

**MaxMpxCt:** Max. number of simultaneous client requests to a Server. During SMB negotiation, this value is passed to Redirector Service, which must enforce the limit. Value needs to be raised with maxWorkItems. See TechNet: Q271148; Q191370; Q232890

#### **Increasing Values on Windows 2000 Clients/Servers:**

**MaxCmds:** Run: regedit32>HKEY\_LOCAL\_MACHINE>System>CurrentControlSet>Services>lanmanworkstation>parameters>MaxCmds

**MaxMpxCt:** Run: regedit32>HKEY\_LOCAL\_MACHINE>System>CurrentControlSet>Services>lanmanserver>parameters>MaxMpxCt

#### **Monitoring Windows 2000 Systems (MaxCmds & MaxMpxCt):**

Monitor values by using Performance Monitor and adding the "Current Commands" counter for the "Redirector"--this allows tracking of number of concurrent outstanding SMB network requests on an IIS Server.

#### **THEORETICAL ETHERNET CAPACITY (Mbits vs. Mbytes):**

10Mbps → 1.25MBps

100Mbps → 12.5MBps

1000Mbps → 125MBps

#### **THREE BASIC PERFORMANCE FACTORS FOR TCP/IP:**

I. TCP/IP WINDOW SIZE—limited to 32-bits when using the “Sliding Scale”

II. TCP/IP PACKET-LOSS RECOVERY MECHANISMS

III. ROUND-TRIP CALCULATIONS TO DETERMINE RTO (Retransmission Timeout Interval)

#### **I. TCP/IP WINDOW SIZE:**

Original TCP Window Size limited to what the TCP Header (16-bits, or max 65K bytes) could report

New ‘Sliding Window’ extension expands this limitation to 32-bit Windows, used only in SYN segments during Session Setup.

#### **MICROSOFT WINDOWS TCP WINDOW SIZE:**

Win9x – NT 4.0 = 8760

Win2k = 16k

Win2k SP3, XP SP1 = 65k

#### **TCP SLIDING WINDOW:**

**Note:** TCP Sliding Window is the amount of data that the Sender can expect to send before receiving an acknowledgement from Receiver. The ‘Sliding Window’ serves as a means for flow control & congestion control. The “max receive window” is the amount of “receive buffer space” that a Host has.

**Example:** If Sliding Window is 64Kb, Sender must wait for ACK, after sending 64Kb of data, prior to sending more data.

#### **Port Numbers:**

Endpoint ports that combined with TCP form a “connect-oriented” socket

Well-Known Ports—0-1023

Registered Ports—1024-49151

Dynamic/Private Ports—49152-65535

**ACK:**

Acknowledge—Receiver sends an ACK that equals a sequence number plus amount of data in bytes. TCP Sessions agree to initial sequence numbers.

## **II. TCP/IP PACKET-LOSS RECOVERY MECHANISMS:**

**Intro:** TCP/IP performance is dictated by the “transfer rate” (bandwidth=mbps) and round-trip delay (network latency) of packets over the network. Traditional TCP/IP networks used a “slow-start” mechanism whenever more than (1) packet was lost in a single Window Transmission—this necessitated a retransmission timeout and slow re-start & greatly affected data in pipeline.

New algorithms, called Fast Retransmits/Fast Recovery, can better handle multiple packet loss per Window, using SACK (Selective Acknowledgements—Receiver keeps Sender informed of status of Receive Buffer Queue).

### **(4) BASIC TCP ALGORITHMS:**

#### **SLOW START:** (SSTHRESH) All systems should now implement ‘slow start threshold size’ (ssthresh) by default

Seeks to avoid flooding router buffers and slowing internet links by ramping up new packets at a rate determined by acknowledgments returned. From Sender’s machine, this is the ‘congestion window’ [cwnd], as opposed to the ‘sliding tcp advertised window’ from the Receiver. So, in theory, each time an ACK is received, the congestion window index can be increased, but never greater than the “advertised window”. The “cwnd” window starts out at a value of “one segment” for ‘slow start.’ So, capacity is reached when intermediate routers begin discarding packets and then the congestion window value is lowered decrementally.

#### **CONGESTION AVOIDANCE:** (CWND) Method for dealing with packet loss

Timeouts and duplicate ACKs are prime indicators of packet loss on the internetwork. Basically, can occur whenever a large data pipe flows into a smaller pipe, or when there are multiple streams going to a Router, all meaning that a bottleneck & packet loss are occurring. In reality, both “slow start” and “congestion avoidance” are implemented in parallel, although they are different algorithms. Bottomline, whenever timeouts are detected, TCP must slow down using either congestion avoidance or “slow start” to ramp back up. If “cwnd” is less than or equal to ssthresh, TCP is in ‘slow start’. Typically, if timeouts occur, the “cwnd” is set to one segment, which is the same as a “slow start”.

**FAST RETRANSMIT:** Theory here is that duplicate ACKs are being sent by one end, which may be indicative of lost segments or reordered packets. In general, up to (3) consecutive ACKs can be received before a retransmission is requested, and usually done so prior to the expiration of a ‘slow retransmission’ timer.

**Note:** Windows NT systems use 200-250ms RTO. Windows 2000 & Solaris use much smaller RTO retransmission timers of around 50ms. Celerra uses a 500ms fastRTO timer and does not use SACK (Selective Acknowledgements). Therefore, on networks where multiple packets are being dropped for same TCP window, Celerra performs slow retransmit [i.e., waits before sending retransmit request to Client, giving appearance that Celerra is slower to respond].

**FAST RECOVERY:** An algorithm that allows TCP to use ‘congestion avoidance’ instead of ‘slow start’ whenever duplicate ACKs are received and requested for retransmits. As analogy, the data stream only slows down rather than stops, picking up steam again as things settle out on the network. Fast Retransmit (RTO) & Fast Recovery usually work together. Generally, during retransmits, the congestion avoidance rate goes down to  $\frac{1}{2}$  of what the initial rate was—then builds up from there.

## **III. ROUND-TRIP CALCULATIONS TO DETERMINE RTO**

TCP/IP implements ‘reliable’ delivery because it retransmits segments that are not acknowledged before a RTO value expires. RTO is determined by estimating mean and variance of a measured RTT (Round-Trip Time) between Sender & Receiver.

### **CELLERRA TCP FAST RETRANSMIT:**

Fast retransmissions are completely separate and unique from the Celerra fastRTO feature, and are triggered by duplicate ACKs or RTOs which can be triggered when receiving TCP connection times out while waiting for a segment ACK. FastRTO only determines whether the retransmission timeout value is subject to 3 clock ticks of 500ms or a single clock tick of 500ms.

### **CELLERRA fastRTO (Retransmission Timeout) vs. WINDOWS NT/2000:**

**Symptom:** Celerra appears to function slower than Windows 2000/NT 4.0 Servers with respect to TCP Fast Retransmissions for lost or out-of-order network packets. Over large WAN's, this difference in RTO functionality may become noticeable. Celerra's default RTO (Retransmission Timeout) is 1.5secs—setting fastRTO to 1 changes timeout value to .5secs, more closely resembling Windows.

**Cause:** Celerra Implements TCP Retransmits (RTO) differently than native Windows NT or 2000 Operating Systems by using a Slow TCP Clock mechanism of 500ms before implementing a retransmit request to the Client. Windows implements a Fast TCP Clock of 200ms before requesting retransmits for "lost" or "out-of-order" packets. Both Windows & Celerra will request retransmission after receiving (3) or more duplicate ACKs, because it is assumed that (3) or more duplicate ACKs indicates packet loss. In some cases involving numerous dropped packets, Celerra performance may be affected and require following RTO tuning:  
/nas/site/slot\_param or /nas/server/slot\_x/param

**param tcp fastRTO=1**

**Note:** Changes Retransmission Timeout value from 1.5secs to .5secs. Celerra uses two clocks for TCP, a 200ms clock and a 500ms clock. The 200ms clock is used for TCP Delayed ACK, while the slow 500ms clock is used by the fastRTO feature. When changing RTO from 0 to 1, Celerra will now use a single slow clock of 500ms before initiating retransmission request for lost or missing packets. At its default value, Celerra uses (3) slow clock ticks of 500ms before RTO (hence the 1.5sec delay).

**OTHER O/S BEHAVIOR:**

Linux & Solaris tend to use fastRTO under 100ms

**SCSI NEGOTIATION/CONFIGURATION:**

**\$server\_config server\_2 -v "chimconfig" [SCSI negotiation]**

**Output:**

TID 0: Ultra = 1 (1), WIDE, speed 200, offset 8 Tagged 1 Qdepth 128  
TID 1: Ultra = 1 (1), WIDE, speed 200, offset 8 Tagged 1 Qdepth 128  
TID 2: Ultra = 1 (1), WIDE, speed 200, offset 8 Tagged 1 Qdepth 128  
TID 7: Ultra = 0 (0), NARROW, speed 100, offset 0 Tagged 0 Qdepth 0

**SERVER LOG CATEGORY PRECEDENCE NUMBERS:**

2003-02-07 14:17:41: ADMIN: 4: Command succeeded: rquotad action=start

2003-02-07 14:17:41: NDMP: 3: RecBuf in NDMP Pool (count:0), NDMPMAXBUFSIZ is 131072

**0 = Emergency**

**1 = Alert**

**2 = Critical**

**3 = Error**

**4 = Warning**

**5 = Notice**

**6 = info**

**7 = Debug**

**HOW TO SET INCREASED LOGGING LEVELS ON DATAMOVERS:**

**SMB PROTOCOL:**

**\$server\_config server\_2 "logsys set severity SMB=LOG\_DBG3"**

**\$server\_config server\_2 "logsys set severity SMB=LOG\_ERR** [Turn off]

**\$server\_config server\_3 "logsys set severity SMB=LOG\_DEBUG"**

**Note:** LOG\_DEBUG can be used against various modules

**\$server\_config server\_3 "logsys set severity SMB=LOG\_PRINTF"** [Turn off]

**HOW TO DETERMINE WHAT LOGGING LEVEL IS SET ON A FEATURE:**

**# .server\_config server\_2 -v "logsys get severity SMB"**

1143253668: LIB: 4: Server log severity for facility SMB is 4

**Note:** Log level 4 is normal

**TURNING OFF ALL SMB LOG MESSAGES EXCEPT FOR EMERGENCY, ALERT, CRITICAL:**

1. Add following line to the bottom of /nas/server/slot\_x/start file

**logsys set severity SMB=LOG\_CRIT**

2. Reboot Data Mover

**FSCK/FS MAINT:**

**\$server\_config server\_x "logsys set severity FSTOOLS=LOG\_DBG3"**

**NDMP LOGGING:**

**\$server\_config server\_2 "logsys set severity NDMP=LOG\_DBG3"**

**\$server\_config server\_2 "logsys set severity PAX=LOG\_DBG3"**

**\$server\_config server\_2 "logsys set severity NDMP=LOG\_PRINTF** [Turn off]

**\$server\_config server\_2 "logsys set severity PAX=LOG\_PRINTF** [Turn off]

**CIFS LOGON's:**

**\$server\_config server\_3 -v "param NTsec logonTraces=6"**

**\$server\_config server\_3 -v "param NTsec logonTraces=3"** [Turn off]

**SETTING LOGGING FOR ONLY CRITICAL EVENTS:**

# .server\_config server\_2 -v "logsys set severity UFS=LOG\_CRIT"

### **VERIFYING CURRENT LOGGING LEVEL FOR CATEGORIES:**

# .server\_config server\_2 -v "logsys get severity SMB"

1158591814: LIB: 4: Server log severity for facility SMB is 4

### **SYMMTOP SYMMETRIX TOOL:**

Tool to look at SA Port stats, Caching Issues, “Disk Hotspots”.

### **SOLARIS SERVER STATISTICS:**

\$iostat -d [BSD disk activity tool--variety of possible switches for memory, processes, CPU, etc.]

/var/adm/messages dmesg

showrev -p vxdisk list vxprint vxprint -ht [Veritas configuration information]

## **II. CELERRA OPERATING SYSTEM:**

### **CELERRA VOLUME & SERVER MANAGER:**

→"NAS" commands are executed by /nas/bin/volume\_mngr, which links to nas\_cmd

lrwxrwxrwx 1 nasadmin nasadmin 9 Oct 2 14:13 volume\_mngr -> ./nas\_cmd

→"SERVER" commands are executed by /nas/bin/server\_mngr, which links to nas\_cmd

lrwxrwxrwx 1 nasadmin nasadmin 9 Oct 2 14:13 server\_mngr -> ./nas\_cmd

### **SIX TYPES OF CELERRA VOLUMES:**

Basic Volume →Physical volume from which other types are created

Slice Volume →Small volume created from another logical volume for easier management

Stripe Volume →Arrangement of volumes that together appear as a single volume, from basic or slice volumes, with data layered across the volumes in a striping fashion

Hyper Volume →Larger capacity volume created from any type, used for file systems [better known as a metavolume]

Filter Volume →Volume that provides snapshot support

RamDisk Volume →Logical volume created in memory

### **EMC NAS File System:**

After NAS install, new directory created at Linux root, /nas

/nas/dos> directory where DOS partition is mapped for DM's to T&L00; contains Boot & Config files for each Server

/nas/dos/bin> sibpost, gload [loads DART sw], nas [DART SW] executables for servers

/nas/dos/slot\_1 [thru16]; Boot.bat and Boot.cfg files for each DataMover server

/nas/bin> File System and Administration commands

/nas/sbin> Utilities, System files and services; /nas/sbin/getboxmask -r [slots that are powered up]

/nas/sbin/getreason [status of each DM & CS]

0=BIOS check, boot sequence 1=SIB Post 2=Fail SIB 3=DM Booting DOS 4=DM running NAS 5=DM normal &

BoxMon up

6=CS only [singleuser mode] 7=DM crash 9=Reboot 10=Primary CS only; 11=Secondary CS only

/nas/server>Files for each DM configuration; \$nas\_server\_1 - 16

/nas/volume> DB files for Volume manager;

/nas/log > NAS Log Files: install.log/upgrade.log/sys\_log.log/cmd\_log/cmd\_log.err

/nas/log/nas\_log.al.trace →File contains Eiffel dump outputs from scripts which fail to run

### **PROBLEM WITH /NAS AT 100% FULL:**

If nas goes to 100%, cannot create new Shares from either NT Server Manager GUI or CLI as Nasadmin.

#### **SYMPTOMS:**

##### **Server Log Error:**

2003-07-02 13:17:35: SMB: 3: srvsvcAddShare:shareReq2CS no share created

/nas:

# df -k .

Filesystem 1k-blocks Used Available Use% Mounted on

/dev/sde1 1818352 1797024 0 100% /nas

##### **Server export Fails as Nasadmin:**

\$ server\_export server\_10 -P cifs -n aaustin86 /fs-21/Home/dFBnycBUC110/aaustin6

server\_10 : unable to acquire lock(s), try later

**Server Export as Root Succeeds:**

```
# server_export server_10 -P cifs -n aaustin86 /fs-21//Home/dFBnycBUC110/aaustin6  
server_10 : done
```

**Strace of Server Export Shows Problem:**

```
$strace -o /tmp/aaa -f server_export server_2 -p -u -P cifs -n testshare  
server_2 : unable to acquire lock(s), try later
```

```
-----  
14365 getpid() = 14365  
14365 open("/nas/lock/db/1_1_0__", O_WRONLY|O_CREAT|O_EXCL|O_SYNC, 0644) = 6  
14365 write(6, "\0358\0\0X\2\0\0", 8) = -1 ENOSPC (No space left on device)
```

**Note:** Root can still write to fs as long as there are blocks left to write to, whereas all other Users will be denied writes at 100%

**OBTAINING SLOT STATUS IF BOX MONITOR SHUT OFF:**

**#/nasmcd/getreason**

**Note:** This command will return slot status even if Box Monitor is disabled or if you are telneted into CS1 running as Secondary

**UNIX TIME VALUES:** Number of seconds since epoch—Epoch is defined as 00:00:00 January 1, 1970 UTC

*st\_atim* Time when file data was last accessed. Changed by the following system calls: *creat, mknod, pipe, utime, and read*. The seconds portion of *st\_atim* is available as *st\_atime*.  
*st\_mtim* Time when data was last modified. Changed by the following system calls: *creat, mknod, pipe, utime, and write*. The seconds portion of *st\_mtim* is available as *st\_mtime*.  
*st\_ctim* Time when file status was last changed. Changed by the following system calls: *chmod, chown, creat, link, mknod, pipe, unlink, utime, and write*. The seconds portion of *st\_ctim* is available as *st\_ctime*.

**DISABLING DART A-Time UPDATES DURING READS:**

**param ufs updateAccTime=0**

**Note:** Do not apply this change without considering applications that depend on atimes, like Cava, DHSM, etc.

**DART FILE SYSTEM TIMES (3) STD UNIX TIMES & (1) SMB CIFS TIME:**

**atime (access)** - modified when file is opened for read. Last time file accessed. **#ls -lut** shows atime.

**mtime (modified)** - modified when file is opened for write. Last time file modified. **#ls -l** shows mtime.

**ctime (change)** - modified when file is opened for write, or when metadata is changed (renamed, linked, utimed, chowned), which is equivalent to SMB last access, last write, and change in perms, respectively. Last inode change time for the file. **#ls -lc** shows ctime. Ctime represents time since Epoch (00:00:00 UTC, January 1, 1970)

**(create time)** is in Shadow File until 5.2 & the MPD, then moves to the directory entry. SMB adds the creation time.

**Note:** On Linux CS, if a file is read, only the atime changes. But, if the file is changed by writing to it, all three times are changed—atime, mtime, ctime.

**VIEWING ACCESS, MODIFY, & CHANGE TIMES FOR UNIX FILES: Use “stat” command!!**

```
$ stat test.txt
```

**File:** "test.txt"

Access: Mon Jun 17 02:49:34 2002(00003.09:21:30) “atime” = last file access time [read, utime, pipe, mknod, creat]

Modify: Fri Mar 22 18:49:22 2002(00089.16:21:42) “mtime” = last file data modification [creat,mknod,pipe,utime,write]

Change: Fri Mar 22 18:49:11 2002(00089.16:21:53) “ctime” = last file status change

[chmod,chown,creat,link,mknod,pipe,unlink,utime,write]

**How to Determine if /nas and/or /nas/dos Directory is Intact and O.K. on the Symmetrix:**

Step 1. Run **#df -k** to locate device per example: **\$/dev/dsk/c0b0t0d1p1 /nas/dos**

Step 2. Run **#dd if=/dev/dsk/c0b0t0d1p1 of=/dev/null count=1**

Step 3. Device is corrupt if you see:      “UX:dd:ERROR: Cannot open /dev/dsk/c0b0t0d1p1: No such device”  
Device o.k. if you see this:      “1+0 records in 1+0 records out”

**Difference Between /nas/server/slot\_x Directory and /nas/server/server\_x Directory:**

/nas/server/server\_x directory is created based on the order that a DataMover is setup, not by slot number

/nas/server/slot\_x conversely is based on actual slot numbering and does not change

**\$nas\_server -l** [this command will list out the Index values, which are used to create the “server” directory]

**# nas\_server -l**

id type acl slot groupID state name

```

1   1  1000 2      0  server_2
2   1  1000 3      0  server_3
4   4  1000 5      0  server_5

```

**# nas\_server -l id=1**

```

id  type acl slot groupID state name
1   1  1000 2      0  server_2
2   1  1000 3      0  server_3
4   4  1000 5      0  server_5

```

**CELERRA REASON CODES FOR DATA MOVERS AND CONTROL STATIONS:****# /nas/sbin/getreason**

10 - slot\_0 primary control station  
 11 - slot\_1 secondary control station  
 5 - slot\_2 contacted  
 5 - slot\_3 contacted

**# /nas/sbin/getreason -s 3**

5

**TABLES OF REASON CODES:**

|       |   |
|-------|---|
| 0     | Reset (or unknown state)  |
| 1     | DOS boot phase, BIOS check, boot sequence   |
| 2     | SIB POST failures (i.e., hardware failures)   |
| 3     | DART is loaded on data mover, DOS boot and execution of boot.bat, boot.cfg  |
| 4     | DART is ready on data mover, running, and mac threads started   |
| 5     | DART is in contact with Control Station box monitor   |
| 6     | Control Station is ready, but is not running NAS service  |
| 7     | DART is in panic state  |
| 9     | DART reboot is pending or in halted state   |
| 10    | Primary control station reason code   |
| 11    | Secondary control station reason code   |
| 13    | DART panicked and completed memory dump (single DM configurations only, same as code 7, but done with dump)   |
| 14    | This reason code can be set for the Blade for any of the following:<br><ul style="list-style-type: none"> <li>• Data Mover enclosure-ID was not found at boot time</li> <li>• Data Mover's local network interface MAC address is different from MAC address in configuration file</li> <li>• Data Mover's serial number is different from serial number in configuration file</li> <li>• Data Mover was PXE booted with install configuration</li> <li>• SLIC IO Module configuration mismatch (Foxglove systems)</li> </ul> |
| 15    | Data Mover is flashing firmware. DART is flashing BIOS and/or POST firmware. DM cannot be reset   |
| 17    | Data Mover Hardware fault detected  |
| 18    | DM Memory Test Failure. BIOS detected memory error  |
| 19    | DM POST Test Failure. General POST error  |
| 20    | DM POST NVRAM test failure. Invalid NVRAM content error (checksum, WWN, etc.)   |
| 21    | DM POST invalid peer DM type  |
| 22    | DM POST invalid DM part number  |
| 23    | DM POST Fibre Channel test failure. Error in Blade Fibre connection (controller, Fibre discovery, etc)  |
| 24    | DM POST network test failure. Error in Ethernet controller  |
| 25    | DM T2NET Error. Unable to get blade reason code due to management switch problems   |
| Error | Failed To Get Reason Code. DM or CS may not be present in the slot or NS DM might be powered off  |

**While True Scripts:**

```

$while true          $while true
>do                >do
>/nas/sbin/getreason >/nas/sbin/getreason -s 4 [specific slot]
>sleep 8            >sleep 8
>done               >done

```

**Example of Another While True Loop:**

```

$while true
>do server_netstat server_4 -a -s -i |grep ana0
>sleep 10

```

>done

### **Another While True Loop to Monitor CPU Usages:**

```
$while true  
>do /nas/bin/server_sysstat ALL |grep idle  
>sleep 5  
>echo 5 seconds  
>done
```

## **UNIX FILE SYSTEMS:**

Collection of hierarchical directories & files; (2) Types of Owners: Users & Groups: >ls -l r-w-x

**File Access Protection:** \$chmod [access-string, divided into Access Class; Operator; & Access Type]

**Access Class:** u; g; o; a    **Operator:** +; -; =    **Access Type:** r; w; x; ...

>chmod a +w lead [all users have write access to file called 'lead']

\$chmod 777 \* [symbolic mode, indicating full access for all users to directory applied]

#chmod g+r filetest [grants Read access to 'filetest' to group 'g']

## **FILE PERMISSIONS WITH UNIX:**

UNIX contains permissions for files that control access, also called its “access mode.”

### **Users can have (3) types of permissions for files:**

Permission to Read [Read file contents or list directories]

Permission to Write [Write changes to a file or create & remove files in directories]

Permission to Execute [run a program, or access files in a directory]

### **Users can also fall into (3) categories, which affect how the above (3) permissions are given:**

Owner—Other Users in file’s Group—Everyone else

Files usually get UID of user that creates file and GID of the Group that owns the directory

### **Files also have (3) special components for executable files:**

Setuid bit—this sets the process’ UID to that of the file that is being executed

Setgid bit—this sets the process’ GID to that of the file that is being executed

Sticky bit—saves a program’s text image on a swap device so as to load quicker when run. For directories, prevents Users from removing files from a directory when they are not the owner

### **SEARCHING DIRECTORIES FOR STICKY BIT FILES:**

**#ls -l /usr/bin |grep '^.....s'**

## **CHMOD COMMAND:**

Chmod is used to assign or change the “mode” of a file based on a person’s or other’s attributes. Mode is expressed in absolute (Octals) or Symbolic (g+s; g-s; =)

## **ADD VALUES FOR EACH CATEGORY (UGO):**

|   |                                      |
|---|--------------------------------------|
| 0 | = no permissions                     |
| 1 | = execute only (1)                   |
| 2 | = write only (2)                     |
| 3 | = write and execute (2+1)            |
| 4 | = read only (4)                      |
| 5 | = read and execute (4+1)             |
| 6 | = read and write (4+2)               |
| 7 | = read and write and execute (4+2+1) |

## **ACCESS PERMS EXPRESSED IN 3-DIGITS:**

|                 | user | group | others |
|-----------------|------|-------|--------|
| chmod 640 file1 | rw-  | r--   | ---    |
| chmod 754 file1 | rwx  | r-x   | r--    |
| chmod 664 file1 | rw-  | rw-   | r--    |

## **OCTAL VALUES:** Range from 0-7

#chmod 0400 file [Read by Owner]

#chmod 0200 file [Write by Owner]

#chmod 0100 file [Execute by Owner]

#chmod 0700 file [Read-Write-Execute by Owner]

#chmod 0040 file [Read by Group, etc...]

#chmod 0004 file [Read by Other, etc....]

**EXAMPLES:**

#chmod 444 file [read perms to Everyone]  
#chmod 066 file [Read-Write to Group & Other]

**SYMBOLIC VALUES:** +, -, =, u,g,o,a; r, w, x, l, s, t

+add perms - removes perms =assign perms absolutely

u=user's perms

g=group's

o=other's

a=all persons

r=read

w=write

x=execute

l=mandatory locking

s=user or group set-ID

t=sticky bit

u, g, o [User, Group, Other]

**EXAMPLES:**

#chmod -R g-s\* [Recursively removes the set group id bit [setgid, sbits, etc] from a parent directory down  
drwxr-sr-x

#ls -ld →outputs l-bit for locking or sbit for setgid in following position: -----s---

#chmod a-x file [Deny execute perms to everyone]

#chmod go+rw file [Read-Write to Group & Other]

#chmod +l file [Locks file when accessed]

**SET GROUP ID (SGID) BIT:**

When the sgid bit is set, means that a User that executes a program will have the same privileges as the group owner of the program.

**STICKY BIT:**

When the sbit (sticky bit) is set on a directory it means that all files will inherit the default directory GID and not that of the process used to create the file itself. For certain directories that may be open to the category OTHER, when the sticky bit has been set on the directory, the files within can only be deleted by the Owner of the File or Directory, or Root. If the SetGid bit is set on a directory where “satom” is owner and group is “sysadmin”, then all files created in this directory will inherit the group “sysadmin” ownership & override the primary Unix group ownership of other Users’ groups. Sbit cannot be set or unset in ‘absolute’ mode, only via ‘symbolic’ mode.

g-s →removes sbit setting

g+s →sets the sbit

# chmod sato 1000 [Turns sticky bit on]

**Example:**

```
drwxrwsrwx 2 satom sysadmin 512 Apr 21 14:17 .
drwxrwxrwx 40 root users 4608 Apr 21 14:14 ..
-rw-r--r-- 1 satom sysadmin 0 Apr 21 14:15 satom.file
```

**Note:** Celerra now employs the SGID bit as the default in NAS 5.1 and higher for files created in directories using UNIX rules

**SET USER ID (suid) BIT:**

When the suid attribute is set on the access permissions for a program, a user executing the program has the same privileges as the owner of the program—if the owner were root, that would mean root privileges—only applies to executable programs or scripts.

**Note:** The SUID/SGID attributes are cleared when files are written to, meaning that an application should do a SETATTR after writing to insure that the appropriate attributes are put back—this is behavior in line with POSIX standards.

**Octal Permission Values:**

4=100 Binary = Read [View a File or list a Directory]

2=010 Binary = Write [Change File or Directory]

1=001 Binary = Execute [Execute a file or cd to a directory]

**Default Directory Permissions are 755**

**Note:** Add 4+2+1 to obtain the 7, the highest possible value

**Default File Permissions are 644**

**Note:** Values from Left to Right: User—Group—Other

Default CIFS Umask is 022 [Octal Value 22 = Hexvalue 0x12], which is UGO Octal Value 755 for any files created from NT for Unix. By default, UNIX creates files with a perm of 666 and directories with 777. Celerra uses a default Umask of 022, which equates to default file perms of 644 and directories of 755.

### **Standard Unix Directories Permissions:**

READ—Allows users to list names of files in the directory only

EXECUTE—Users can utilize files that can be explicitly named

READ/EXECUTE—Users can List & Utilize files

READ/WRITE/EXECUTE—Users can List, Utilize, and Delete/Add files in the directory

**Note:** For Unix over NFS, new files derive permissions from client's umask

For CIFS created files, Unix permissions are derived from a configurable “umask” value set on the File System!

For CIFS created files, default is to have a UGO of 755 applied [i.e., a umask of 022]

### **UNIX PERMISSIONS:** Traditional Unix uses (3) bits each to define USER, GROUP, and OTHER “rwx” permissions

Read—list files only, in directories

Execute—utilize files that you can name

Read/execute—list and utilize files

Read/write/execute—list files in directories, utilize files, create/delete files

Unix file permission sets contains Unix UIDs and GIDs

### **LEGAL/ILLEGAL UNIX CHARACTERS IN FILE NAMES:**

**Note:** Though the rules don't seem to be hard and fast across the unix front, here is some information related to characters that are allowed, or not allowed, or not recommended, for use with unix names:

#### **Legal Characters:**

**A thru Z**

**a thru z**

**0-9**

**. - -**

#### **Illegal Characters:**

**spaces \* ? ! | \ / ‘ “ { } < > ; , ^ ( ) \$ ~**

Also recommended that hyphen – is not used at beginning of a name, nor period . , as it indicates a special file

### **LEGAL INTERNET HOSTNAME CHARACTERS:**

RFC 952 defines what a valid Internet Host name should consist of for characters—it's common for Unix hostnames to contain an underscore in the name, for example, but this is not a legal Internet Hostname, so the correct approach is for Unix hostnames to be renamed to conform to the Internet Hostname requirements

→A name is defined as a Net, Host, Gateway, or Domain name

→A name is a text string up to 24 characters in length, consisting of alpha-numeric A-Z (upper or lower case, does not matter), 0-9, and can include a minus sign (-) or a period (.), except that periods are only allowed as delimiters for domain style names

→First character must be an alpha character

→Last character of the Hostname must not be a minus (-) or period (.)

→No blanks or spaces are allowed as character entries for the name

### **SUPERUSER ACCOUNT & NFS EXPORTS [aka root]: Default is for no hosts allowed 'root' access**

**root=hostname | netgroup | subnet | IP address** [used to specify access for User "root"]

When accessing remote file systems over NFS, the "root" user's UID is normally mapped to the anonymous user account called "nobody", which has a UID of -2 and a "nogroup" GID of -2 [For non-negative unix systems, these values translate into a 16-bit unsigned representation of 65534].

**Note:** NFS handles requests for Users without valid credentials by mapping them also to the "anonymous" user account. Linux versions have a no\_root\_squash export option that will allow NFS clients to mount an export with Root privileges.

\$ server\_export server\_5

**export "/fs06" root=172.0.0.0/255.0.0.0**

**Note:** This is an example of a file system exported to allow superuser root to connect from a remote system, to this Celerra file system, and retain root privileges on the Celerra file system. It does not mean that regular unix users will have root privileges when connecting to this file system—all other user accounts will still be governed by normal UNIX mode permission bits on files & dirs.

### **STANDARD UNIX SHELLS:**

Bourne shell (sh) original shell found on all unix systems, used for simple programs

C shell (csh) uses C-like programming syntax for writing scripts

TC shell (tcsh) Default C-Shell & emacs-style editing

Korn shell (ksh) more features than Bourne, considered the standard, combines C & TC shells

Bourne Again shell (bash) GNU, uses C & K shells and is compatible with Bourne

**Note:** #ps -s [Shell processes running and commands that are running]

## **DETERMINING RUNNING SHELL:**

#echo \$SHELL

/bin/bash

## **SHELL CAPABILITIES:**

|                      | Bourne | C    | TC  | Korn | BASH |
|----------------------|--------|------|-----|------|------|
| command history      | No     | Yes  | Yes | Yes  | Yes  |
| command alias        | No     | Yes  | Yes | Yes  | Yes  |
| shell scripts        | Yes    | Yes  | Yes | Yes  | Yes  |
| filename completion  | No     | Yes* | Yes | Yes* | Yes  |
| command line editing | No     | No   | Yes | Yes* | Yes  |
| job control          | No     | Yes  | Yes | Yes  | Yes  |

## **BINARY COMPUTER LANGUAGE:**

--Binary is a contraction of “binary digit”

--4-bits is a single hex digit while 8-bits form “bytes” or ‘characters’

--Words are 16-bits long and are called Short Integers, often signed +32768 or -32768

--Double-Words are Long Integers at 32-bits in length

--Kilobytes are expressed in powers of 2. A single K is 1024 bytes ( $2^{10}$  bytes). 512K is actually  $512 \times 1024$ , or 523,288 bytes.

## **HEXADECIMAL BASE 16 NUMBERING SYSTEM:**

### **HEX    BINARY**

|   |      |
|---|------|
| 0 | 0000 |
| 1 | 0001 |
| 2 | 0010 |
| 3 | 0011 |
| 4 | 0100 |
| 5 | 0101 |
| 6 | 0110 |
| 7 | 0111 |
| 8 | 1000 |
| 9 | 1001 |
| A | 1010 |
| B | 1011 |
| C | 1100 |
| D | 1101 |
| E | 1110 |
| F | 1111 |

## **LINUX USER ENVIRONMENT & STARTUP SCRIPTS:**

### **BOURNE SHELL :** sh /bin/bash

/etc/skel → startup scripts for basic shells ; .bashrc = BASH config file ; .bash\_logout ; .bash\_profile for startup environment

/etc/profile → Executed when User logs in, defines HISTSIZE, MAIL, and system environmental [.bashrc & .bash\_profile]

/etc/profile.d → contains scripts

/etc/bashrc → global aliases and system settings

### **C-SHELL:** csh /bin/csh

/etc/login [.login & .cshrc]

#chsh [Changing Shell]

#env

## **HANDLING NFS ALIAS NAMES CELERRA REMOTE MOUNTS:**

Normally, if a Server is rebooted, and Clients have locks on files, the Server will notify the client using statd.hostname that the file is available to reclaim the lock. With alias names, however, we must add the name of the data mover interface to the list of names in statd.hostname so that we properly notify the Client using our “alias”.

## **USING ANON EXPORT FOR NFS:** /etc/exports   Default is to allow UID 'nobody' or value 65534 access

anon=uid Use this option to specify access by UID: Example: anon=100

Set NFS access mappings to specific UID's using the "anon=100" syntax when "exporting" file systems for NFS

Set NFS access mappings to specific HOSTS using "access=taco,root=taco"

Further, if you export NFS to a specific HOST as ReadWrite [rw=taco:mountpoint,access=100] then all others will mount RO

Using anon=0 has the effect of forcing all Anonymous Users to become the “nobody” user -2 for the remote mount  
root= allows a remotely connecting user to have the net effect of being local “root” on the remote file system

### **CLIENT ACCESS FOR NFS EXPORTS: Default is to allow mount access to all machines**

**Resolution Order:** /etc/hosts → /etc/netgroup → NIS → DNS

Provide mount access to clients listed, either by **Hostname | IP Address | subnet | netgroup**

#### **Standard NT Directory Permissions:**

R—Read a File or Directory

W—Write to a File or create File in a Directory

X—Execute a File or enter a Directory

P—Owner [right to change ACL's on a File or Directory]

D—Delete a File or Directory

O—Take ownership of a File or Directory

**Note:** For NT, new files inherit the ACL's of the parent directory

### **OUTPUTTING DIFFERENCE BETWEEN FILES:**

\$diff file1 file2 > diff.txt

#### **Calculating Total Number of Files Possible for Our Default 8k FileSystem:**

**Note:** This is based on (1)inode per every 8k block, which is our FileSystem data block size

File System Size: 8.613GB

Default Inode: 1/8k block

Solution: 8,613,000,000/8000bytes = 1,076,625 max files for this FileSystem [Only if every single data file was exactly 8k or less]

### **VIEWING FREE INODES ON DATAMOVER FILESYSTEM:**

**\$server\_df server\_4 -i fs06**

fs06 1023358 8 1023350 0% /NFS6

**Specifying Inode Density for a new File System:** #nas\_fs -n mv10fs -type ufs -c mv10 -o nbpi=4096

**Verify:** #server\_df server\_2 -i mv10 or \$nas\_fs mv10fs -i

#### **Two Ways to Change Inode Densities:**

I. By “Extending” a File System, which adds more inodes

II. Back-up File System, create new FS with higher Inode density, then Restore File System to new.

**Variables:** \$echo \$VAR \$export VAR{\$PATH; \$SHELL} #set #env \$echo ~ [outputs Home directory to screen]

### **COMPARISION OF UNIX COMMANDS/DIRECTORIES/FUNCTIONS:**

|                     | <b><i>Linux</i></b>              | <b><i>Solaris</i></b>        | <b><i>AIX</i></b>    | <b><i>HP-UX</i></b>      |
|---------------------|----------------------------------|------------------------------|----------------------|--------------------------|
| Password File:      | /etc/passwd                      | same                         | same                 | same                     |
|                     | /etc/shadow                      | same                         | /etc/security/passwd | /tcb/files/auth/r/root   |
| Max UID's:          | 65535                            | 2147483647                   | 4294967295           | 2147483647               |
| Nobody's ID:        | 99                               | 60001/65534                  | 4294967294           | -2                       |
| HostID:             | hostid                           | same                         | same                 | uname -i                 |
| Perf. Monitor:      | top                              | top                          | top/monitor          | top/glance               |
| Memory Stats:       | vmstat                           | same                         | same                 | same                     |
| I/O Stats:          | iostat                           | same                         | same                 | same                     |
| Network IP Config:  | /etc/sysconfig/ /network-scripts | /etc/inet /etc/defaultrouter | lsattr -E -l inet0   | /etc/rc.config.d/netconf |
| Name Service:       | /etc/nsswitch.conf               | same                         | /etc/netsvc.conf     | /etc/nsswitch.conf       |
| Network Params:     | sysctl -a  grep net              | ndd /dev/tcp                 | no -a                | ndd -h                   |
| NIC Config:         | ifconfig -a                      | same                         | same                 | lanscan -v               |

## UNIX Vi EDITOR:

# cat -etv filename [displays exact characters within text file!]

## DETERMINING SHELL & SETTING BOURNE SHELL EDITOR:

1. #echo \$\$SHELL →/bin/bash
2. #export TERM
3. #TERM=vt100
4. #tset [Use ctrl + U to kill shell process; Use ctrl + C to Interrupt Shell processes]

## CHANGING SHELL:

#chsh

**Insert:** i inserts before cursor; I inserts at beginning of line; a appends after cursor; A appends at end of line; o Opens line below; O opens line above; c change operation; C change to end of line; R overwrite text; s sub character; S sub entire line

**Basic Operators:** c Begin a change; d Begin a deletion; y Begin a copy; See cc; dd; yy usages

**Moving around a File:** H top of screen; M goes to middle; L goes to last line; Ctrl + F scrolls fwd one screen; Ctrl + B back Ctrl + G to end of file

## Down & Up One Page:

**ctrl F = Page Down; ctrl B = Page Up ; Shift H top of page; Shift M middle of page; Shift L last line of page**

**Moving across a Line:** Use “f” and character string you wish to go to to move to that section; w to move forward a whole word

**Searching:** /text will go forward to find instances of “text”; n repeats search fwd; N repeats backwards; G to bottom of file;

**Editing:** [a =append x=delete esc=edit r=replace] Input v. Command mode :wq! :q! ZZ=quit program & saves file; R replace with new text; r replaces character; x deletes character;

## Deleting With Vi:

dd deletes current line; D deletes remainder of line

2000dd → Deletes first two thousand lines in the file, etc.

## JOINING TWO LINES TOGETHER IN VI:

Go to end of line above the other; esc J

## COPYING A LINE IN VI EDITOR:

esc : set nu :t 12 [Copies Line 12 into new line 13]

## Copying Contents of File1 to Specific Line in File2:

#vi file1 & go to line to import; !!cat file2 [pulls contents of file2 to line number below cursor]

#vi file1 & go to line to import; :r file2

## Copying & Pasting Entries within File:

Y—yanks current line; paste to appropriate line using ‘P’ for above cursor and ‘p’ for below cursor

15yy—yanks 15 lines underneath cursor; paste to destination using P or p

## Copying Line below Cursor:

:co or :t150 [Copies line 150 & inserts to line 151]

## Opening File and Saving buffer as New File Name:

# vi file

# esc :w <newname>

# :q

## OTHER MOVE AND COPY EXAMPLES:

:line1mdestline

Move (cut) line number, line1, to the line number, destline

:line1, line2mdestline

Move (cut) lines between and including line1 and line2 below line number, destline

:line1tdestline

Transfer (copy) line number, line1, to the line just below line number, destline

:line1, line2tdestline

Transfer (copy) lines between and including line1 and line2 below line number, destline

## MOVING LINES IN VI EDITOR:

:m 1 2 [Moves Line 1 to line 2]

**Using Vi With Line Numbers:** Open Vi session, then “esc” + : set nu

**Other Editors:** vuepad emacs

X deletes backwards; YY copies; p pastes below cursor; . repeats command

ex Editor: Enter : when in Vi to enter the “ex” mode: Substituting characters within a whole file :%s/sh/ksh/

^ beginning of file \$ end of file . carriage return s substitution cmd

#### **EDITING IN BINARY MODE:**

# vi file esc : set binary

#### **SAVING PORTION OF FILE TO NEW FILE IN Vi EDITOR:**

**ma** (mark text at the top of the region to be saved)

**mb** (mark text at the bottom of the region to be saved)

**:a,'b w filename**

#### **CONVERTING DOS FILES TO UNIX:**

# /usr/bin/dos2unix -n dos\_file unix\_file

# sed -e 's/\$//' dosfile.txt > unixfile.txt

**Note:** Different switches available, above converts file to unix format and writes to a new filename. Unix text files end with “LINE FEED” character “\$”, but dos files end with “CARRIAGE RETURN + LINE FEED”.

In some cases, may also need to open file in vi after converting from dos2unix, then save as new filename. Rename file as needed.

# vi file # esc :w <newfile> # :q

#### **USING STRINGS TO CONDUCT CHARACTER SEARCHES:**

# for i in \*.db;do echo \$i; strings \$ilegrep -i "\.ab"; done

**Note:** Searches through all files with .db suffix and greps for any lines with “.ab” characters

#### **READING BINARY FILES:**

1. One tool to try is “strings”, as in this example: #strings usrmappc.db

2. Alternate tool to try is “od -c” or “od -a” command against a file

#### **USING TEE SWITCH TO OUTPUT TO FILE:**

\$ server\_netstat server\_4 |wc -l | tee -a /tmp/chk.out [Appends output to file called "chk.out"]

#### **SETTING VI EDITOR IN PRIVILEGED & NONPRIVILEGED MODES:**

\$ set o -vi Press the Esc key; then use ‘k’ to move forward, ‘j’ to move back; r replace; l to move across line; Shift + \$ to end j and k keys for down and up respectively; h and l keys for backwards and forward on a single line

# ksh -o vi Press Esc key, then use ‘k’ and ‘j’ options

#### **USEFUL COMMANDS:**

wc -l [number of lines in a file] wc -c [word count]

#### **OUTPUTTING DIRECTORY LISTING TO FILE:**

# ls |more >directory.list

#### **LISTING DIRECTORY CONTENTS IN ORDER OF CREATION TIME:**

\$ ls -lt

-rw-rw-r-- 1 nasadmin nasadmin 1043 Oct 1 17:46 test

-rwxrwxrwx 1 root root 243 Sep 30 20:49 loop

#### **LISTING DIRECTORY CONTENTS BY FILE TYPE:**

# ls -laF

drwxrws--- 3 nasadmin nasadmin 4096 Dec 13 12:56 ..

-rwxrwxr-x 1 nasadmin nasadmin 151 Dec 8 12:28 .old\_schedules.tar.gz\*

-rw-r--r-- 1 root root 0 Dec 13 12:55 regular\_file

srwxr-xr-x 1 nasadmin root 0 Dec 9 16:48 .scheduler\_socket=

**Note:** -F switch appends a character to each file name based on file type. \*=executable; / = dirs; @=symbolic links; l = FIFOs; = for sockets; nothing for regular files

#### **DETERMINING PATH LENGTHS:**

# less /home/nasadmin/ts2/dan\_fs.log.gz | awk '{print length, \$0}'|sort -nr|head -10

#### **CONDUCTING COMPLETE LISTING OF NAS SERVER SLOTS:**

**\$ ls -l /nas/server/slot\_\*/\***

**Note:** Useful in that it will list out all files in each slot for SCCS

### **COMPARING DIFFERENCES IN TEXT FILES:**

**# diff file1 file2**

**# sdiff file1 file2** (side by side comparison of files—useful if you have a monitor that can display both lines across the screen)

### **COMPARING DIFFERENCES IN BINARY FILES:**

**# cmp file1 file2 or # cmp file\*** [compares all files named ‘file’]

## **VARIOUS METHODS FOR REMOVING DOS CONTROL CHARACTERS FROM ASCII FILES**

### **USING VI & LINUX COMMAND:**

**Method 1:** Open file with vi and use **# esc :1,\$ s'^M'g**

**Note:** To type '^M, press ctrl key while typing "v" and the "M". Also, type *two single apostrophes*, not 'quotes'!

**Method 2:** vi file; **# esc :% s<ctrl v><ctrl M> //g**

**Method 3:** Open file with vi editor: **#esc :%s<ctrl + v><enter> //g**

**Method 4:** vi file **# esc :1,\$ s<ctrl + v ctrl + m> //g**

**Method 5:** Use Linux DOS2UNIX conversion command

**# /usr/bin/dos2unix -n passwd.bad passwd.new**

### **HOW TO REMOVE LINES WITH ONLY WHITE SPACE FROM A FILE:**

Open file with vi editor: **:g/^<ctrl + v><tab> \*\$/d**

### **How to Ensure that there are no Extra Lines or Spaces in a File Using Vi Editor:**

**esc : set list**

**esc : set nu**

**esc : 100** [Brings you to line 100]

### **SUBSTITUTING WORDS IN A FILE:**

**: % s /old/new/g** [Will replace the word 'old' with 'new']

### **REPLACING “SPACES” WITH LETTERS USING VI:**

**#vi usrmap.db**

**:,\$s/ /xxx/g**

**Note:** Replaces “spaces” with “xxx” throughout file

### **REMOVING LETTERS “XXX” FROM FILE:**

**:.,\$s/XXX//g**

**:1,\$s/@//g** (removes all @ from file)

### **ADDING COLON TO END OF EACH LINE:**

**esc : 1,\$s/\$:/ or :g/\$s//:/g**

### **REMOVING & REPLACING ITEMS USING VI [Substitutions]:**

Group File: S-1-5-15-139d2e78-56b177fd-5475b975-2d61e.\*:58393:ats.cs.mgmt.dir:

1. **: 1, \$s\\$.dir//** [Removes the dir from end of sentence on each line in file]

2. **: 1, \$s\\$.//g** [Removes all periods throughout file]

3. **: 1,\$s/:\$.dir:/ (enter)** [Places “.dir.” at end of each line in file]

### **TRANSLATING CONTENTS OF FILES FROM ONE LETTER TO ANOTHER:**

**# cat file1 | tr 1 2** [Translates all instances of the numeral “1” and puts a “2”]

### **SUBSTITUTING PATTERNS:**

**Example:** Substituting all instances of “info” with “information”

**esc : 1,\$s/info/information /g** [drop “g” to substitute single instances]

## **PASSWORD & GROUP FILE RULES FOR CELERRA:**

1. All characters must be in lowercase
2. The Windows domain must be appended to the user or group name unless the CIFS resolver parameter is set to one
3. All non-alphanumeric characters must be substituted with their hexadecimal equivalent

## **VALID GROUP FILE FORMAT:**

S-1-5-15-242a3a09-1f6d0078-5fc894f0-203\*:32770:domain=20computers.csfb:

S-1-5-15-242a3a09-1f6d0078-5fc894f0-64c25\*:32771:appocdefaultr.csfb:

S-1-5-15-242a3a09-1f6d0078-5fc894f0-201\*:32772:domain=20users.csfb:

## **VALID PASSWORD FILE FORMAT:**

S-1-5-15-242a3a09-1f6d0078-5fc894f0-28a7\*:32768:32768:user mreilly from domain csfb:/usr/S-1-5-15-242a3a09-1f6d0078-5fc894f0-28a7:/bin/sh

S-1-5-15-74581049-1930354d-375b3a1a-172c\*:32769:32768:user mreilly from domain \_history\_sid\_range\_:/usr/S-1-5-15-74581049-1930354d-375b3a1a-172c:/bin/sh

S-1-5-15-242a3a09-1f6d0078-5fc894f0-60720\*:32770:32768:user jwilensk from domain csfb:/usr/S-1-5-15-242a3a09-1f6d0078-5fc894f0-60720:/bin/sh

## **USERMAPPER EDITS—PRODUCING A PASSWD FILE FROM USRMAPUSRC.DB FILE:**

```
1. #strings usrmapusrc.db >users.strings
2. #cat users.strings |grep :user |sort -t: -k4,4 -k3,3 -k1,1 -u >users.strings.sorted
3. Run following script to convert the Version 3 format to Unix Passwd file format
#!/convertv1users.sh users.strings.sorted >passwd
# $1 is assumed to be a file in the dumpfilesall 3 format of
# SID:*:uid:domid:user xxx from domain yyy/usr/SID:/bin/sh
# This format is converted to the /etc/passwd format of
# xxx.yyy:*:uid:domid:SID:/usr/SID:/bin/sh
# sed converts the string ":user xxx from domain yyy:" to :xxx.yyy"
# awk uses : as a delimiter and prints the fields in the correct order
#
if [ -f "$1" ]; then
cat $1 | sed 's/^(.*:*)user \(.*\) from domain \([^\:]*[^\:]*\)\(.*\)\(\.\*)/\1\2.\3\4/' | awk -F : '{print $5":*:$3:$4:$1:$6:$7;}' 
else
    echo "syntax: $0 <input file name>"
    exit
fi
```

## **PRODUCING GROUP FILE FROM USRMAPGRPC.DB FILE:**

1. #strings usrmapgrpc.db | egrep ".\*:\*:\*:\$" | sort -t : -k 3,3 -k 1,1 -u > groups.strings.sorted

2. Run following script to convert the Version 3 format to Unix Group file format

```
#!/convertv1groups.sh groups.strings.sorted >group
# $1 is assumed to be a group file in dumpfilesall 3 format of
# SID:*:domid:name.domain
# This is converted to the /etc/group format of
# name.domain:*:domid:SID

if [ -f "$1" ]; then
cat $1 | awk -F : '{print $4":*:$3:$1;}' 
else
    echo "usage: $0 <input file name>"j
    exit
fi
```

**Caution:** The above scripts work, just remember that the 4<sup>th</sup> colon is not added to the group file and would need to be done manually—just use the following command in vi to add the colon! Also, inspect the beginning and ends of each file as there may be a junk line or two that would need removal:

**esc :1,\$s/\$:/**

## **REMOVING PERIODS FROM GROUP NAMES BUT RETAINING “.” BEFORE DOMAIN NAME:**

**# cat usrmap.group | sed ‘s/\..\*\.\./ > usrmapgrp.db**

## **MANUALLY VERIFYING GAPS IN UID/GID RANGES IN GROUP & PASSWD FILES:**

```
# cat usrmap.passwd |awk -F : '{print $3;}'
```

## **CHECKING PASSWD/GROUP FILES FOR DUPLICATE UID/GIDs:**

```
# cat usrmap.passwd |cut -d ":" -f3 |sort |uniq -c |awk ' $1 != "1" {print $1, $2}'  
# cat usrmap.group |cut -d ":" -f3 |sort |uniq -c |awk ' $1 != "1" {print $1, $2}'
```

Note: Duplicates will print to screen like the following example

```
2 32900
```

```
2 32901
```

## **STRIPPING OUT DUPLICATES FROM FILES USING UNIQ SWITCH:**

```
# cat dump.group [produced from dump 1] | sort -k 3,3 -g -t: -r -o group.rsort  
# cat group.rsort |sort -k 1,1 -t: -u -o group.unique  
# cat group.unique |sort -k 3,3 -g -t: -o group.final.sorted
```

## **Displaying Exact Contents of a File to Include Octal, Hex, Character Formats:**

```
$ od -c data_file
```

## **IMPORTING USRMAPPER PASSWORD/GROUP FILES INTO EXCEL FOR NEW CONVERSION:**

1. Conduct usrmap\_control dumpfilesall 3
2. Download usrmap.passwd and usrmap.group to desktop
3. Open Excel program>File>Open usrmap.passwd
  - a.) Text Import Wizard appears--\*Delimited should be only thing checked
  - b.) Select 'Next'
  - c.) Keep 'Tab' and select 'Other' and enter colon ':' →Next
  - d.) Click 'Finish'
4. Save as a new name—‘passwd.imported’
5. Make edits to the ‘passwd.imported’ & ‘group.imported’ files as necessary
6. Push files back to Linux CS and convert from Text Delimited to Colon Delimited

```
#vi usrmap.db
```

```
esc :%s/<enter tab key once to create tab character>/:/g [This globally substitutes tab character with : ]
```

7. If group file is missing colon at end of each line, use following command to add it back:

```
#vi usrmapgrp.db
```

```
esc :1,$$/:/
```

## **REMOVING EXCEL TAB DELIMITERS FROM A FILE FOR LINUX:**

```
esc :%s/<enter tab key once to create tab character>/:/g
```

## **BEST PRACTICES TO CONSIDER WHEN COPYING OR TARRING FILES:**

```
# cp -p * conagra [Maintains Unix permissions, ownership, and dates of files copied from one directory to another]  
# tar -cpf newfiles.tar * [Maintains Unix permissions, ownership, and dates when tarring up files]  
# tar -xpf newfiles.tar [Same as above, but when ‘untarring’ files]  
# tar -zcpf newfiles.tar.gz * [Tar and zip all files in one operation]  
# tar -ztvf newfiles.tar.gz [Look at contents of a zipped tar file]  
# tar -chf ~/sys_logs.tar sys_log* [Handy cmd to tar up all sys_logs, including the symbol. linked file]  
# tar -zcpf /home/nasadmin/bak/usrmap.bak.tar.gz usrmapper [Tars & zips ./etc/usrmapper directory to a file and location specified--Run from ./etc directory]  
# (cd /etc;tar -cvf - .) | tar -xvf -
```

## **UNTARRING SINGLE FILE FROM ZIPPED TARBALL:**

1. Identify required file:

```
# tar -tzvf usrmap.tar.gz |more
```

2. Extract file:

```
# tar -xvf usrmap.tar.gz nas/cifs/usrmapperV3/linux/dbcfg/sidname.db
```

Caution: Restores to path indicated

## **USEFUL LINUX COMMANDS:**

```
# stat [command shows file creation, modification, and last access times]
# file * [shows all the files and file-types in a directory]
# locate portmap [Shows locations and path for the file or executable]
# expr 2 + 2 + 2 [Math operations]
```

6

## **SEARCHING MAN PAGES:**

**\$ man -k nfs** [Useful for searching man pages by topic]

## **FINDING APPROPRIATE MAN PAGE TOPIC IF YOU DON'T KNOW COMMAND NAME:**

### **\$ apropos copy**

```
bcopy      (3) - copy byte strings
cp        (1) - copy files and directories
cpio      (1) - copy files to and from archives
dd        (1) - convert and copy a file
-----abridged-----
```

## **NAS & SERVER COMMAND MAN PAGES LOCATION:**

/nbsnas/man/cat1

## **UNIX FIND COMMAND:**

```
>find used with switches, powerful tool; >find -print filename [displays] ; >find -atime 5 [find files accessed 5 days ago]
# find / -print -name updategroup [searches entire root file system for file called "updategroup"]
# find -name "newfile" -print #find -user terry #find -mtime 1 [find files modified within last 1 day]
# find /usr/ron -size +10 -atime +30 -print [find files >than 10 blocks & accessed over 30 days ago]
# find /usr/ron -size -20 -mtime +15 -print [find files less than 20 blocks in size modified over 15 days ago]
# find /usr -name "pg5" -exec rm {} \; [finds file called 'pg5' in /usr directory and removes by executing "rm" command]
# find . -mtime -1 [Locating files that have changed timestamps within last day in current directory]
# find . -print |egrep httpd
# find /nas/cifs -name '*.db' -size +100kb -print [Finds files in /nas/cifs directory with .db extension and 100kb in size or more]
```

## **USING FIND TO FIND SPECIFIC UID IN FILE SYSTEM AND PRINT PATH TO FILE:**

**# /nasmcd/quota/slot\_2/fs1/find . -uid 32768 -print >/home/nasadmin/tm/32768.out &**

## **USING FIND COMMAND TO SEARCH FILES BY SIZE:**

**# find /nas -size +5000 -print**

Displays files over 5000 blocks(2.5MB) on the /nas filesystem

## **Using FIND to List Directory Structure in a Home Directory Folder and Output to File:**

**# find /nas/rootfs/slot\_3/engineering/raylau -exec ls {} \; >/home/nasadmin/raylau1 &**

**# find . -mtime -1 -print0 -exec cp -parents {} /dest \;**

One purpose of doing this is for checking total path lengths of a particular filesystem, especially for Tape Backup situations

## **USING FIND TO FIND INODE & OUTPUTTING PATH TO INODE:**

**# find . -inum <inode#> -print**

**# find /emcfind -inum 125228 -print >/inode1 &**

## **USING FIND TO LIST MTIMES:**

**# find . -mtime -1 -print0 -exec cp -parents {} /dest \;**

## **USING FIND TO FIND A NAME & OUTPUTTING PATH TO FILE:**

**# find /emcfind -iname 'WRL0516.tmp' -print >name2 &**

## **USING FIND TO LOCATE ALL FILES WITH ~ IN NAMES:**

**# find . ! -type d -depth -exec ls -al {} \; | egrep "\~" > /path/tilde.log**

**# find . -name \\*~\* -ls >/home/nasadmin/tilde.out &**

**Note:** Above command will output all directories & files with a tilde, as well as the timestamp from ls

## **FINDING SPECIFIC FILENAME FROM LINUX CS:**

**# find -iname edw\_prod\_vsaf\_vpi\_tlog\_200410110701.BAK**

## **FINDING FILES CREATED WITH FUTURE DATE & UPDATE WITH CURRENT TIMESTAMP:**

**PROBLEM:** Numerous files created or modified since a certain date are getting a year 2020 timestamp

```
$ ls -la *
-rw-r--r-- 1 root bin 19932947 May 10 2020 tcp.dump
-rw-r--r-- 1 root root 5 May 10 2020 temp
```

1. Create a template file with a future date in a directory on the CS where the find command will be run from—for example, a test file "date\_2019" with a December 12, 2019 timestamp:

```
# touch -t 201912121212.12 date_2019
```

```
# ls -la
-rw-r--r-- 1 root root 0 Dec 12 2019 date_2019
```

2. Use the template file as a time reference when running the find & use touch to update timestamp:

```
# nohup find /nas/quota/slot_2/root_vdm_3/Avr -newer date_2019 -exec touch {} \; &
```

3. Verify using ls -la of sample directory on a problem file system:

**/nas/quota/slot\_2/root\_vdm\_3/Avr:**

```
-rw-r--r-- 1 root bin 19932947 Oct 11 15:20 tcp.dump
-rw-r--r-- 1 root root 5 Oct 11 15:20 temp
```

## **RESETTING TIMES ON FILES:**

1. Start in directory of FS to check
2. Run command for the "creation" dates where X is the number of days BEFORE today  

```
# find . -atime X -fprint /tmp/creation_date_listing
```
3. Run command for the "modification" dates where X is the number of days BEFORE today  

```
# find . -mtime X -fprint /tmp/modification_date_listing
```
4. Examine the two files' dates:  

```
# cat /tmp/creation_date_listing
# cat /tmp/modification_date_listing
```
5. To change the dates:  

```
# find . -atime X -exec /bin/touch {} \;
# find . -mtime X -exec /bin/touch {} \;
```
6. Alternatively, update time to current time using following:  

```
# touch my_file.doc
```

**Note:** ‘touch’ command only updates inode information on file, does not change directory information

## **FINDING LARGE INODES:**

--Run “ls –ailR” in file system directory from control station mount to dm

--Find Location of Inode on File System using: 

```
#find . -inum 16823119 -exec ls -al {} \;
```

## **CREATING RECURSIVE LISTING OF ENTIRE DIRECTORY:**

```
# /eng/raylau/ls -Rail & [Creates Recursive listing of all directories and files]
```

## **USING LOCATE COMMAND TO FIND PATTERNS:**

```
# locate *[Jj]server' [Prints names of all files that end with Jserver]
```

## **SEARCHING A FILE LIST FOR WORDS:**

```
# xargs grep ndmp <file-list [Searches for all instances of ‘ndmp’ in the “file-list” file]
```

## **SEARCHING PASSWD/GROUP FILES FOR INSTANCES OF SIDs IN FIRST COLUMN:**

```
grep ^S-1-5-15 /nas/rootfs/slot_X/.etc/passwd
```

```
grep ^S-1-5-15 /nas/rootfs/slot_X/.etc/group
```

## **USING GREP TO SEARCH MULTIPLE FILES WITH MULTIPLE STRING VALUES:**

```
# egrep ‘tom | mary | sue’ /etc/{passwd,group,shadow} [Lists out all instances of Tom, Mary, and Sue]
```

```
$ /nas/server/slot_4 egrep ^514 camdisk*
```

```
camdisk:514:c49t2l0+556857258190+,c65t2l0+556857258300+:
```

```
$ server_devconfig server_3 -l -s -a | egrep "d52"
```

```
d52 c0t4l1 04B FA 0 On 000185704957 005B
```

```
d52      c16t4l1   13B FA 0 On 000185704957 005B  
d520     c49t2l6   03B FA 0 On 000185704957 025E  
d520     c65t2l6   14B FA 0 On 000185704957 025E  
d521     c49t2l7   03B FA 0 On 000185704957 025F  
d521     c65t2l7   14B FA 0 On 000185704957 025F
```

### **USING EGREP TO FIND MULTIPLE VALUES IN SINGLE FILE:**

```
$ server_devconfig server_4 -p -s -a | egrep "chain|val= 52"
```

```
chain= 49, scsi-49  
tid/lun= 2/6 type= disk sz= 13943 val= 520 info= 55685725E190  
tid/lun= 2/7 type= disk sz= 13943 val= 521 info= 55685725F190  
tid/lun= 2/8 type= disk sz= 13943 val= 522 info= 556857260190  
tid/lun= 2/9 type= disk sz= 13943 val= 523 info= 556857261190  
tid/lun= 2/10 type= disk sz= 13943 val= 524 info= 556857262190  
tid/lun= 2/11 type= disk sz= 13943 val= 525 info= 556857263190
```

```
# cat filesystems | grep "profile | 75: | ^9:"
```

**DELETING FILES/DIRECTORIES:** #rm [remove files] or #rmdir -p [remove directories & subdirectories] #rm test\* [same filenames]  
#rm -f -i -r [-f to force removal of write-protected files; -i for Y or N prompt; -r for all subdirectories; -R Solaris]  
#rm -i \* [delete all files in directory but prompts first!!] #rm -f [force deletion] #rm -R [remove directory & contents]  
#rm -Rf [super delete command]

### **VNON Errors:** 2.1.30.2 & below

Usually only occurs after a file has been deleted from Celerra FS. File is deleted but Directory entry was not properly cleaned up.

### **COPYING A FILE WHILE EMPTYING THE CONTENTS:**

```
# cp /dev/null export [copies over the file called ‘export’ with 0 bytes of data]
```

**CREATING FILES/DIRECTORIES:** #touch newfile #vi newfile #cat > newfile #cat >> newfile #cat newfile #more newfile #cat -n newfile [numbers each line] #cat test1 > test2 [copies file 1 to two] #file /etc/hosts

**Note:** ctrl + d will save a file created by “cat”

```
$cp -p old new [copies all permissions from file ‘old’ to file ‘new’] #cp -R old/ junk/
```

### **Combining Several Text Files into One:**

```
# cat file1 file2 file3 >concatenated.file [pipes results into new file]
```

### **APPENDING ONE FILE TO END OF ANOTHER:**

```
# cat bbb >> aaa
```

**SORTING FILES:** \$sort names [alphabetical sort of contents of file called ‘names’]

### **COMPARING FILE CONTENTS IN TWO DIFFERENT PATHS:**

**Example:** Comparing “netd” file of Primary Datamover & Standby Datamover

```
$ cat -n /nas/server/slot_7/netd
```

```
$cat -n /nas/server/slot_4/netd
```

### **UNIX TIMESTAMPS FOR FILES:**

\$ls -tl Lists out files in order of modification time

\$ls -lu Shows date that files were last opened or accessed

\$ls -la Shows last modification timestamp for files

\$ls -lc Shows creation date of file

### **BASH SCRIPT TO LOCATE TIMESTAMPS > THAN A SPECIFIC YEAR:** 2004 IN THIS EXAMPLE

```
#!/bin/sh  
i=0  
currentyear=2004  
$find . ! -type d -depth -exec ls -ul {} \; > /tmp/findlist num=`wc -l /tmp/findlist | awk '{print $1}'` while [ $i -le $num ] do  
    i=`expr $i + 1`  
    info=`head -$i /tmp/findlist | tail -1`  
    year=`echo $info | awk '{print $8}'`  
    filename=`echo $info | awk '{print $9}'`
```

```
echo $year | egrep ":" > /dev/null
if [ $? -ne 0 ]; then
    echo $filename
    if [ "$year" -gt "$currentyear" ]; then
        head $filename > /dev/null
    fi
fi
done
```

## **USING LIST COMMAND TO RECURSIVELY LIST OUT ALL INODES ON FILE SYSTEM:**

# ls -iaR

## **USING LIST COMMAND TO ASSESS HEALTH OF FS:**

# cd /nas; find . -ls >/dev/null

**Note:** I/O errors may be an indicator of file system issues

## **CREATING LISTING OF FILES IN VERY LARGE DIRECTORIES:**

1. Verify that file system "fs1" has available space (server\_df server\_2)

2. cd to / on CS and make a directory called "find"

#cd / #mkdir find

3. Mount fs1 to "find" mountpoint

#mount server\_2:/fs1 /find

4. cd to the directory path in question on the fs:

#cd /find/Valco/mars/cache/cache

5. Generate directory contents listing while gzipping to file:

# nohup ls -la | gzip >/find/list.out.gz &

## **CHARACTERS ALLOWED IN DOS NAMING CONVENTIONS:**

Letters A-Z; Numbers 0-9; ~ ! @ # \$ ^ & ( ) - \_ { } '

## **CHARACTERS ALLOWED IN UNIX NAMING CONVENTIONS:**

All ASCII characters except *ASCII Nul and Slash /*

Recommendation is to avoid the following characters within names: ! # & @ \$ ^ ( ) ' " ; | <> { } \* ? \[and spaces]

## **CREATING FILES OF SPECIFIC SIZES FOR TESTING:**

#mkfile 20m {k,b,m} file1 file2 file3 [makes a null file called "file1" at 20MB in size—b=bytes, k=kilobytes, etc]

### **Creating New Files Using the Line Editor [Stream Editor]: #ed newfile**

|      |                                  |  |
|------|----------------------------------|--|
| \$ed | \$a [to append to editor buffer] | \$ctrl + v to paste text or file into buffer |
| \$.  | [exits append mode]              | \$w newfile                                  |
|      |                                  | \$q [quit editor]                            |

## **SETTING ENVIRONMENTAL VARIABLES FOR LINUX CS—Red Hat 7.2:**

**Problem:** Might see an error when trying to execute commands—"NAS\_DB environment not defined"

**Fix:** Issue following command & then verify .bash\_profile file settings

1. # **NAS\_DB=/nas;export NAS\_DB**
2. Verify File: # cat /home/nasadmin/.bash\_profile
- # .bash\_profile

```
# Get the aliases and functions
if [ -f ~/.bashrc ]; then
    . ~/.bashrc
fi

# User specific environment and startup programs

PATH=$PATH:$HOME/bin

export PATH
```

unset USERNAME

**NAS\_DB=/nas**

**export NAS\_DB**

MANPATH=/usr/share/man:/usr/man:\$NAS\_DB/man

export MANPATH

PATH=\$PATH:\$NAS\_DB/bin

export PATH

/nasmcd/.emc\_login

## **APPENDING PATH STATEMENTS TO ENVIRONMENTAL VARIABLES:**

**# echo \$PATH**

/usr/local/bin:/bin:/usr/bin:/usr/X11R6/bin:/home/nasadmin/bin:/nas/bin:/usr/bin/env

**# PATH=\$PATH:/usr/bin/perl**

**Remote DialUp Session to Celerra:** Set your environmental variables to: #TERM=vt100;export TERM

**SETTING VI EDITOR:**

**# EDITOR=vi;export EDITOR**

## **LOGGING TERMINAL SESSION TO FILE:**

**\$ dtterm -l -If newlog &**

## **LINUX SUPPORTS IPCHAINS AS IP FIREWALL:**

IP Firewall Chains are enabled by default and can be configured or disabled via CLI.

**# /sbin/chkconfig --list ipchains**

ipchains 0:off 1:off 2:on 3:on 4:on 5:on 6:off

**# /sbin/service ipchains status**

Chain input (policy ACCEPT):

Chain forward (policy ACCEPT):

Chain output (policy ACCEPT):

**# /sbin/service ipchains stop | start | restart**

**# /sbin/service ipchains stop** →Temporarily stop service

Flushing all chains: [ OK ]

Removing user defined chains: [ OK ]

Resetting built-in chains to the default ACCEPT policy: [ OK ]

**# /sbin/chkconfig --level 2345 ipchains off | on** [to perm disable ipchains]

**# /sbin/ipchains -L** [Listing current firewall rules]

**# /sbin/ipchains -F** [Flushing current firewall rules that may be configured]

## **CONFIGURING IPCCHAIN RULES:**

**# /sbin/ipchains -A input -p icmp -i eth3 -j REJECT**

# /sbin/ipchains -L

Chain input (policy ACCEPT):

|        |      |       |          |             |            |
|--------|------|-------|----------|-------------|------------|
| target | prot | opt   | source   | destination | ports      |
| REJECT | icmp | ----- | anywhere | anywhere    | any -> any |

## **IPCHAIN FILES:**

**# cat /proc/net/ip\_fwchains**

|       |                                      |         |     |     |          |   |   |        |
|-------|--------------------------------------|---------|-----|-----|----------|---|---|--------|
| input | 00000000/00000000->00000000/00000000 | eth3    | 0   | 0   | 1        | 0 | 0 | 0      |
| 0     | 0-65535                              | 0-65535 | AFF | X00 | 00000000 | 0 | 0 | REJECT |

**# cat /proc/net/ip\_fnames**

/etc/sysconfig/ipchains

## **APPENDING OR INSERTING IPCCHAIN RULES:**

**#/sbin/ipchains -A input -p icmp -i eth1 -j REJECT** [Appends to end of ipchain rules]

**#/sbin/ipchains -I input 10 -p tcp -s 10.241.169.0/24 -dport 22 -i eth1 -j ACCEPT** [Inserts rule at line 10]

## **SAVING COPY OF FIREWALL CONFIG:**

**# /sbin/ipchains-save >/home/nasadmin/tm/fwall.txt**

## **RESTORING COPY OF FIREWALL CONFIG:**

**# /sbin/ipchains-restore </home/nasadmin/tm/fwall.txt**

**Important Note:** When configuring rules with IPChains, entries are parsed from top down and first match becomes effective rule.  
Place Global rules at the end of the file

**IPCHAINS INFO:** # man ipfw #man ipchains

### **SNARE [System iNtrusion Analysis and Reporting Environment]:**

Linux module that performs Control Station auditing—off by default for Celerra CS—kernel module, user-space audit daemon, and GUI reporting Tool (Snare)

# /sbin/chkconfig --list audit

audit 0:off 1:off 2:off 3:off 4:off 5:off 6:off

# /sbin/chkconfig audit on

# /sbin/service audit start

Installing Audit Module: Using /lib/modules/2.4.9-34.5406.EMC/kernel/drivers/add on/audit/auditmodule.o

Starting /usr/sbin/auditd:

SNARE audit daemon: version 0.90 starting up

### **EMC FTP Site:**

#ftp 168.159.216.19 Login: ftp Password: none needed for new FTP server

**Comments:** For “binary” files, always type “bin” at prompt. Type “ascii” before transferring text files. To watch evidence of transfer in progress, type “hash” at prompt. To ignore interactive mode, type “prompt” at command line. Use “put” or “get” or “mget \*” or “mput \*” commands to transfer up or down from FTP Server. Old FTP Server IP address was 168.159.4.20.

**FTP Commands:** cdup delete filename dir get remote lcd ls mkdir put *filename* pwd fmdir status mput mget

**Osm log:** Records FTP logins to Control Station. 40-50 FTP streams on a Celerra.

**Note:** If you are getting a “553 Permission Denied” error when trying to FTP from an NT client to the Control Station, set your transfer to “bin”; Also, do not FTP from the ‘root’ directory but from a subdirectory.

### **ALTERNATE FTP TOOL:**

# /usr/bin/ncftp 168.159.216.19

NcFTP 3.0.3 (April 15, 2001) by Mike Gleason ([ncftp@ncftp.com](mailto:ncftp@ncftp.com))

-----abridged-----

>cd /incoming/todd

> put \*

slog2.feb14: 2.20 MB 8.23 MB/s

slog2.gid32rebuild: 2.15 MB 8.90 MB/s

**Note:** Tool logs into ftp site automatically and also gives you transfer stats

### **VERIFYING FILE INTEGRITY USING VARIOUS CHECKSUM TOOLS:**

\$ cksum NAS3010.exe

3961016753 23199814 NAS3010.exe

\$ sum NAS3010.exe

14926 22657

# md5sum <filename> → Use to verify that file is the same if in different locations on the CS, for example

# md5sum clarion\_mgmt

1f682e1ea870e57b39a28d0db423dcaa clarion\_mgmt

# md5sum /nasmcd/sbin/clarion\_mgmt

1f682e1ea870e57b39a28d0db423dcaa /nasmcd/sbin/clarion\_mgmt

### **COMPRESSING DUMPS:**

\$ gzip slot3.dump.0211121824 [LINUX]

-rwxr-xr-x 1 nasadmin nasadmin 145053685 Nov 12 18:26 slot3.dump.0211121824.gz

### **USEFUL GZIP COMMAND TO VERIFY SIZE OF DUMP FILES:**

\$ gzip -l n5120102.exe.gz

|            |              |       |                   |
|------------|--------------|-------|-------------------|
| compressed | uncompressed | ratio | uncompressed_name |
| 5410362    | 18774464     | 71.1% | n5120102.exe      |

\$ gunzip -l 1781.gz

### **UNCOMPRESSING/COMPRESSING GZIPPED & TAR FILES:**

# gzip.bin -d filename.tar.Z # uncompress filename.tar.z #compress file.tar

### **UNZIPPING & UNTARRING A FILE:**

# /bin/gzip -d server\_profile.lin.tar.Z

server\_profile.lin.tar

### **UNCOMPRESSING ".gz" FILES IN LINUX:**

#/bin/gunzip compressed.gz

### **TARRING/UNTARRING FILES:**

# tar cvf tarmenow morefiles stillmore # tar xvf untar.me.tar  
\$ compress file1 \$ uncompress file1

### **EXAMPLE TAR & ZIPPING FILES TO DIRECTORY:**

\$ tar zcvf /nas/var/usrmap.tar.gz . [tars & zips all files in current directory to path specified]  
\$ tar zcvf /nas/var/usrmap.tar.gz usrmapping.cfg usrmapping\_control usrmapping\_svc \*.db

### **USING BZIP2 TO COMPRESS OR UNCOMPRESS FILES ON LINUX CS (similar to GZIP):**

# /usr/bin/bzip2 -d c.tar.bz | c.tar.bz2 [Use to uncompress files]

c.tar

# /usr/bin/bzip2 -z c.tar [Use to compress files]

c.tar.bz2

### **NAS XML:**

# nas\_xml -info:server -level:3

**Note:** Good command to obtain overall Celerra, CS, and DM hardware and software status information

# nas\_xml -info:volume -level:2

### **OTHER SOURCES OF CELERRA COMPONENT INVENTORY:**

Celerra Manager>Inventory page

# /nas/tools/.factory\_check get\_inventory

### **NAS XML COMMANDS:**

\$ /nas/bin/nas\_xml -info:fs

\$ nas\_xml -info:server

\$ nas\_xml -info:ALL

\$ nas\_xml -info:cifs

\$ nas\_xml -info:storage

\$ nas\_xml -info:volume

ALL yields an XML description of the entire system

server yields an XML description of Data Mover configurations

fs yields an XML description of Filesystem configurations

cifs yields an XML description of CIFS configurations

volume yields an XML description of Volume configurations

storage yields an XML description of Storage configurations

**\$ nas\_xml -table:filesystems**

1:root\_fs\_1:0:n:1:10::::0:::

2:root\_fs\_2:0:y:1:12:1::::0:::

----abridged, returns contents of filesystem file-----

**# date;nas\_xml -info:export -level:3;date** (to obtain list of server exports—quicker than server\_export)

Mon Mar 27 20:25:24 PST 2006

-----abridged-----

**Note:** If Swap “0K used” is “528776K used” or some other high value, then Control Station will begin shutting down processes and may act erratically, failover, etc.**UNIX PROCESSES--viewing & controlling:**

Unix uses two unique processes, 0 &amp; 1. 0 is a special process created whenever the system boots &amp; holds the data structure together as the swap process. Process 1 is spawned by 0 and is the init process. All other processes originate from process 1.

\$ps -ef [lists out processes] \$ps -ef | grep usrm \$ps -ef | grep 14688 [look at specific PID]

#kill -9 PID [to hard kill a process] \$kill PID \$ps -f [Full process listing] \$ps -u 1001 [or Username—lists processes run by that User or Process ID]

#fuser -u [shows users and processes that they are running] #finger /filesystem [shows who is using FS]

#who -r [current run level] -p [current active processes] -d [displays dead processes]

#rwho [login name, name of host, login time] #who -u [user, time, process, and port logged in to]

#who #w [Linux Redhat] #id

**# pkill -9 httpd** [Useful command--kills all httpd processes]**RUNNING JOBS IN BACKGROUND AFTER EXECUTING COMMAND:**

Step 1. Execute the script that you want to run

Step 2. To Place Job in Background: **#ctrl + Z** key then run **#bg** [places job in background]Step 3. To return Job to Foreground: \$jobs [identify which job # you wish to return to foreground]  
\$fg %1 [\$kill %1 --terminates job]**VIEWING PROCESSES ON CS:****# ps -auxmore**

**EXTENDING CONTROL STATION VOLUME LUNS 00 & 01:**

**Note:** NAS versions prior to 2.2.35.x had 2GB partitions, and 4GB partitions after 2.2.35.x. NAS 5.2.7.0 and higher installs create 11GB partitions for LUNs 00 & 01. There is currently no approved procedure to extend LUNS 0 & 1 to 11GB, though Eng is working on the creation of a procedure.

**INSTALLING SECONDARY CS IF RUNNING NAS 5.4 BUT LUNS 0 & 1 ARE STILL AT 4GB:**

See primus emc129785

1. Shutdown Secondary Control Station (if inserted) and remove from backplane

2. Login to the primary Control Station as nasadmin then su to root.

3. # mkdir /emc

```
# mount /dev/sdd3 /emc
# cd /emc/etc/rc.d/rc3.d
# cp -ip S95nas /root
```

4. # vi S95nas and go to line that shows "check\_control\_size" string--should reside around line number 1423 (this line number could vary by the NAS code). Comment out the line, then save and quit the vi session.

```
1421 celerra_S95 ()
```

```
1422 {
```

```
1423 # check_controllun_size
```

```
1424
```

5. # umount /emc

6. Reinsert CS1 into backplane and let boot

**Note:** If a previous attempt to install CS1 had caused the following error messages, then these messages should no longer be present:  
“Control LUN 0 is not large enough. It must be at least 11GBs”

7. Answer the questions to configure root password, keyboard type, timezone, date/time, primary internal network interface, backup internal network interface and external network interface.

8. After "Installing the EMC NAS standby package..." message will be displayed. Enter username (nasadmin by default) and password. Let the installation script finishes.

9. Run /nasmed/getreason and verify CS1 is running as a secondary Control Station.

10. If possible, run /nasmcd/sbin/cs\_standby -takeover to confirm the emcnassby functionality.

**CONTROL VOLUME PARTITION NAMES & LUNS:** Symmetrix Backends

|           |                    |          |         |
|-----------|--------------------|----------|---------|

| /dev/hda5 | 2.0G 555M 1.3G 29% | /nas     |   |
| /dev/ndf1 | 1.7G 96M 1.5G 6%   | /nas/var | →LUN 05 Backup files, dumps, logs       |

**CELLERRA CONTROL LUNS:**

LUN 00 →contains the DOS partition (NAS image & DM Config files), /nbsnas/dos & /nas/dos, located on /dev/nda1 on the backend—Server Logs, Dumpfiles, and DOS partition are located here. LUN 00 size now 11263

LUN 01 →ufslog partition, size 11263

LUN 02 →Linux CS0 partition, size 2047

LUN 03 → Linux CS1 partition, all systems except NS Series, size 2047

LUN 04 →contains /nbsnas partition (NASDB CS config files), located on /dev/nde1, size 2047

LUN 05 →contains /nbsnas/var partition (NASDB backups, dumps, log files), located on /dev/ndf1, size 2047

**INFORMATION STORED ON LUN0:**

→DOS boot partition and NAS image

→Server Logs

→Dumpfiles

## **BOOT AND ROOT DEVICE NAMES FOR CS0 & CS1:**

**CS0=/dev/sdc1 for boot & /dev/sdc3 for root**  
**CS1=/dev/sdd1 for boot & /dev/sdd3 for root**

## **COMMANDS TO VIEW FILES IN DIRECTORIES/SUBDIRECTORIES:**

**# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|

| 1.1G | ./dump       |
| 4.0k | ./log        |
| 16k  | ./lost+found |

**# du -s /etc**

**# /nas/var du -h --max-depth=1 -x |grep -i M** [grep only Megabytes]

|      |              |
|------|--------------|
| 16k  | ./lost+found |
| 16M  | ./backup     |
| 1.1G | ./dump       |
| 4.0k | ./log        |
| 1.1G | .            |

**# ls -larS**

|            |   |      |      |       |              |               |
|------------|---|------|------|-------|--------------|---------------|
| -rw-r--r-- | 1 | root | root | 7770  | Sep 19 12:16 | install.log   |
| -rw-----   | 1 | root | root | 7890  | Sep 26 09:50 | cron.1.gz     |
| -rw-r--r-- | 1 | root | root | 11624 | Sep 26 09:48 | messages.1.gz |
| -rw-r--r-- | 1 | root | root | 18666 | Sep 26 09:26 | lastlog.1.gz  |

**Note:** Sorts directory list by ascending Size

### **Linux Disk Usage:**

#du -sk foldername

## **CLEANING UP LINUX ROOT FS & SETTING LOGROTATION RULES:**

**SITUATION:** 97% full on root—cannot run compress command as it needs more space than is present to compress the /var/log/messages file [337MB]

**# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/sdc3  | 1.9G | 1.7G | 67M   | 97%  | /          |
| /dev/sdc1  | 7.6M | 5.7M | 1.5M  | 79%  | /boot      |
| none       | 250M | 0    | 250M  | 0%   | /dev/shm   |
| /dev/sde1  | 1.7G | 1.6G | 84M   | 95%  | /nas       |
| /dev/sda1  | 133M | 58M  | 75M   | 44%  | /nas/dos   |

```
/dev/sdf1      1.7G 884M 802M 53% /nas/var  
server_6:/    126M 13M 113M 10% /nasmcd/rootfs/slot_6  
server_12:/    1   1   0   0% /nasmcd/rootfs/slot_12
```

# ls -la messages

-rw-r--r-- 1 root root 337661092 Sep 26 07:22 messages

**SOLUTION—COPY FILES TO NULL & SETUP LOGROTATION RULES:**

**1. cp -i /dev/null messages**

```
cp: overwrite `messages'? y
```

**Note:** Root went from 97% to 78% full immediately. Repeat for other logs:

**# cp -i /dev/null pacct.27.gz**

```
# cp /dev/null lastlog
```

→To reduce /nas, deleted a 1GB dumpslot in /nas/log/toftp

**2. Edit /etc/logrotate.conf:**

--Changed default logrotate from 4 weeks to 3 weeks

--Enabled compressing of log files during the logrotate

--Implemented a logrotate scheme based on size as well and set this value to 1M

--tested the new scheme by running new logrotate via cron job

**#crontab -e**

**35 \* \* \* \* /etc/cron.daily/logrotate**

**3. Edit /nas/sbin/nasdb backup and comment out following three lines:**

```
# if [ "$dir" = "$NAS_DB/var/backup" ]; then  
#   cp -p ${1}.gz $dest >/dev/null 2>&1  
# fi
```

**Note:** Lines 484-486 on test system. This will stop nasdb\_backups from going into /home/nasadmin directory, but still leaves nsdb\_backups going to [/nas/var/backup](#)

**FILESYSTEM SIZES AFTER CHANGES:**

```
# df -h  
Filesystem      Size  Used Avail Use% Mounted on  
/dev/sdc3       1.9G  971M  832M  54% /  
/dev/sdc1       7.6M  5.7M  1.5M  79% /boot  
none            250M   0  250M  0% /dev/shm  
/dev/sde1       1.7G  550M  1.1G  33% /nas  
/dev/sda1       133M  58M  75M  44% /nas/dos  
/dev/sdf1       1.7G  768M  917M  46% /nas/var  
server_6:/     126M  13M  113M  10% /nasmcd/rootfs/slot_6  
server_12:/     1   1   0   0% /nasmcd/rootfs/slot_12
```

**LOGROTATE.CONF FILE:**

```
# cat /etc/logrotate.conf  
# see "man logrotate" for details  
# rotate log files weekly  
weekly  
# rotate logs if size grows to 1 megabyte  
size 1M  
# keep 3 weeks worth of backlogs  
rotate 3  
# create new (empty) log files after rotating old ones  
create  
# uncomment this if you want your log files compressed  
compress  
# RPM packages drop log rotation information into this directory  
include /etc/logrotate.d  
# no packages own lastlog or wtmp -- we'll rotate them here  
/var/log/wtmp {  
    monthly  
    create 0664 root utmp  
    rotate 1  
}  
# system-specific logs may be also be configured here.
```

## **PACCT FILES:**

Stop Process Accounting logging temporarily by running #/sbin/accton.

Permanently stop PACCT by editing /etc/rc.d/rc.sysinit as follows, deleting the /var/log/pacct\* files, and rebooting the CS:

```
# Turn on process accounting  
#if [ -x /sbin/accton ] ; then  
    action $"Turning on process accounting" /sbin/accton /var/log/pacct  
#fi
```

## **VIEWING & REMOVING NAS DATABASE LOCKS:**

**# od -d /nas/lock/db/\***

**# ps -ef |grep -i <pid>**

**Note:** Grep the first PID from the lefthand side of the output to find out what processes might be running that are locking the database. Be aware that NASDB backups also lock the database and can affect command completion, but DO NOT seem to take a lock on the db directory. Below example is when there are no processes in the db directory:

```
# od -d /nas/lock/db/*
```

od: /nas/lock/db/\*: No such file or directory

Step 1. Identify Processes Locking DB: **# od -d /nas/lock/db/\*** or **#cd /nas/lock/db #ls -la**

**Note:** Will list out processes locking NAS\_DB, if any. However, note that NAS\_DB Backups will also lock the database at different times during the backup, but without placing a lock on the /nas/lock/db directory

Step 2. Grep on Process ID: **# ps -ef |grep 'PID#'**

**Note:** Process will be in 2<sup>nd</sup> column of output from step 1

Step 3. Determine if Process can be killed, then kill it: **# kill -9 <pid#>**

## **FINDING CALLHOME LOCKS WITH XML SITES (NAS 5.3 & higher):**

**# ls -R |grep -i Lck**

```
get_backend_status.APM00042801790.lck
```

db..LCK

./nbsnas/lock/db..LCK:

dir..LCK

ls: ./proc/4436/fd: No such file or directory

dirsync.1716.lck

dirsyncch.1717.lck

**LCK..callhome**

tier2.lck

sympainlck

sympapislck

**Note:** With introduction of XML, running the /nas/sbin/ch\_stop will delete any callhome files in /nas/log/ConnectHome, but will not remove the lock identified above

**# cd /var/lock; ls -la**

```
-rw-r--r-- 1 root root      11 May  2 15:09 LCK..callhome  
drwxr-xr-x  2 root root    4096 May  2 12:32 subsys  
-rwxr-xr-x  1 root root      0 May  2 12:31 tier2.lck
```

## **PATTERN SEARCHES:**

**#ps -ef | grep root #grep -n user1 /etc/passwd #grep 'ksh\$' /etc/passwd #grep '^s' /etc/passwd**

**#find -print |egrep "trv" [finding instances of 'trv' using search string with find and egrep]**

**\$grep symm symmpdf [searches for string 'symm' in file "symmpdf"] \$grep -x homedirs technotes [exact matches only]**

**\$grep -i cifs cifsdoc [ignores case to search for "cifs" in file 'cifsdoc']**

**\$grep string filename [Greps for specified pattern in the file called 'filename'] \$grep -c hayes bankletter [Prints number matches to screen]**

**\$grep -v string filename [Prints all lines in filename that do not contain the specified 'string']**

**\$grep -i jan b\_days > my\_month [Pipe output of grep into a file]**

**\$server\_cifsstat server\_2 legrep -e [cpu]\*\*\*\*[server] [Greps for patterns within the command output]**

## **LIST COMMAND:**

**\$ls -laR [Lists a=all l=long list format R=list subdirectories recursively--Useful to touch all files in a filesystem, etc]**

\$ls -b Show Nonprinting characters in the output  
\$ls -tail  
ls -S List output of files by Size  
ls -R List recursively through subdirectories  
ls -nl List ownership of files by numeric UID/GID values rather than default names

**\$dir /home/nasadmin**

### **SORTING LIST OUTPUT BY NEWEST FILES LAST:**

**\$ls -ltr**

### **LISTING CONTENTS OF CURRENT DIRECTORY AND OUTPUTTING TO FILE:**

**#ls -l |awk '{print \$9}' >cwd.contents**

### **SYMBOLIC LINKS:**

Symbolic, or Soft Links, are special files whose contents are a portion of the name of another file—i.e., are pointers to another file. Hard Links have multiple directory entries for a single file inode number. Celerra supports only Symbolic Links that work “down” the directory structure, not “up”. Also, it cannot link to an absolute path.

### **SYMBOLIC LINK RULES FOR CELERRA:**

- Symbolic links resolved for Windows clients only if target is within same share
- Symbolic links that refer to target paths with parent directories using ‘..’ must use param shadow followdotdot=1
- In order to backup symbolic links for Windows, set param cifs acl.extacl=8
- Celerra does not support symbolic links that contain full pathnames or absolute links
- Celerra cannot refer up the directory path from a symbolic link

**param shadow followdotdot=1**

### **SYMBOLIC LINKS WITH NAS 5.2.13:**

Celerra now has the capability to access multiple file systems on a single DM through the use of Symbolic Links created on a single file system to other file systems. To allow Celerra to traverse symbolic links between file systems, enable the following parameter:

**param shadow followabsolutpath=1**

### **SUN SOLARIS:**

\$ls \*.c [lists files ending in ‘c’]  
\$ls -F [lists files]; \$ls/ [all files & Directories]; \$ls -ail {-la hidden files} {-lu last time accessed} {-li inodes}  
**ACL's:** #getfacl [displays ACL's] filename [or ls -l to show ACL info, reflected by the + sign]; \$ls -s [for size]  
#setfacl [Solaris only and not Celerra!]  
\$ls -R [recursive] #ls -F /etc/more or #ls -F |more \$ll bin [long list of files in bin directory]  
\$ls -r [lists files & directories in reverse order] \$ls -t [lists files in order last modified] \$ls -l |more  
**Wildcards:** \* Any string of characters ? Any one character [ ] Any character within brackets

### **First Character of ls -l output for each listing:**

-- = Regular File [Regular Files hold data in ASCII, binary, image, database, or other formats]  
d = Directory [Contains only one type of data—listings of file names with inode numbers]  
l = Symbolic Link [pointers or pathnames to regular files, directories, other links, device files; #ln -s]  
b = Block special device file [contain numbers that refer to major or minor devices; I/O by block size of 8k]  
c = Character special device file [I/O operations based on sectors of 512bytes]  
**Remote Logins:** #find .rhosts [/etc/hosts.equiv; /etc/ftpusers; & \$HOME/.rhosts files] #last [last user logged in]  
#cat /etc/nodename [file shows hostname] #csh also will provide hostname & brings up C-shell  
#./install [command used to install drivers]

### **VARIOUS SOLARIS COMMANDS:**

**# df -n**

**# uname -X**

System = SunOS

Node = eagle

Release = 5.9

KernelID = Generic\_117171-12

Machine = sun4u

BusType = <unknown>

Serial = <unknown>

Users = <unknown>

OEM# = 0

Origin#= 1

NumCPU = 1

# **prstat** (similar to Top)

### **SUN SOLARIS SYSTEM MANAGEMENT COMMANDS:**

```
# prtconf -v [Prints out the System configuration] # showrev -p [Current patches for the Solaris Version]
# pkginfo -i [Lists installed software packages] # pkgadd/pkgrm [Install/Uninstall software packages]
# devinfo [disk device information] # prvtoc <devicename> [Volume Table of Contents of device]
```

### **SUN SOLARIS LOGS:**

|                     |  |
|---------------------|--|
| /var/adm/messages   | [System Messages]                        |
| /etc/system         | [System kernel parameters]               |
| /etc/vfstab         | [List of mountable file systems]         |
| /kernel/drv/sd.conf | [list of available target ID's and LUNs] |

### **SUN SOLARIS PERFORMANCE:**

```
# truss -p <pid> -t <system call>
$ iostat -d
$ sar -d 15 15
```

### **USING DD TO CREATE SYSTEM LOAD:**

**#dd -f=/dev/zero of=/dev/rdsckntdns2 skip=8 bs=512 count=1000**

**PASSWD FILE ON SOLARIS SYSTEMS:** Comprised of Seven Fields [/etc/passwd /etc/group /etc/shadow]

**CommandLine:** #useradd                   **GUI:** #admintool [invokes GUI interface]

**EXAMPLE:** user1 : 2050 : 1005 : 100 : Comments Here : HomeDir : login\_shell

**Description:** user   /etc/shadow placeholder   UID   GID   comment field   Home Dir.   Login shell

**SUN SOLARIS STATISTICS:** \$iostat -d [with a variety of possible switches]

**Output of Extended Disk Statistics:** r/s=reads/sec w/s=writes/sec Kr/s=Kbytes read/sec Kw/s=Kbytes written/sec

Wait=aver # trans. waiting svc [queue length] actv=aver. # trans. being serviced svc\_t=aver.sve time in miliseconds

%w=percentage of time queue is not empty %b=percentage time disk is busy

\$sar -d 15 100 [reports disk activity every 15 seconds for 100 times]

### **Using Ping Command to Debug a Network Route Issue:**

Will record roundtrips on a network. Greater than several milliseconds could indicate a busy network.

\$ping sRv servername [s=1datagram per second R=record the route inside IP header v=verbose, lists any ICMP packets]

### **SETTING SPEED AND DUPLEX SETTINGS ON SUN SOLARIS HME NIC CARDS:**

**Step 1. Run the following Commands to Set 100MB Full Duplex on the HME Card:**

**Note:** This example assumes that “auto-negotiation” is “on”

```
#ndd -set /dev/hme instance 0
#ndd -set /dev/hme adv_autoneg_cap 0
#ndd -set /dev/hme adv_100T4_cap 0
#ndd -set /dev/hme adv_100fdx_cap 1
#ndd -set /dev/hme adv_100hdx_cap 0
#ndd -set /dev/hme adv_10fdx_cap 0
#ndd -set /dev/hme adv_10hdx_cap 0
```

**Step 2. Set the following Value on the Switch from the CommandLine:**

```
#ndd /dev/hme lp_autoneg_cap
```

**Step 3. Setting HME Card Speed and Duplex Values:**

```
#ndd /dev/hme link_speed 1 | 0 [1=100MB 0=10MB]
#ndd /dev/hme link_mode 1 | 0 [1=Full Duplex 0=Half Duplex]
```

### **CHECKING SUN SOLARIS HME CARD SPEED & DUPLEX SETTINGS:**

```
# ndd /dev/hme link_speed
# ndd /dev/hme link_mode
```

### **Configuring IP Address on Sun Solaris:**

```
# ifconfig hme0 192.10.3.8 netmask 255.255.255.0 broadcast 192.10.3.255
# ifconfig hme0 up | down [Interface Up or Down]
```

### **Configuring Gateway Address for Solaris: [Two Methods for Doing This]**

1. Commandline:                   #route add default 192.10.3.254
2. Create File:                   #vi /etc/defaultrouter [add IP address of Gateway—becomes permanent Gateway]

## **Verifying and Changing HME Interface Settings/Mode on the Sun Solaris 2.x Server:**

# ifconfig -a

```
lo0: flags=1000849<LOOPBACK,RUNNING,MULTICAST,Ipv4> mtu 8232 index 1 inet 127.0.0.1 netmask ff000000
hme0: flags=1000843<UP,BROADCAST,RUNNING,MULTICAST,Ipv4> mtu 1500 index 2 inet 152.62.37.193
netmask ffffff00 broadcast 152.62.37.255 ether 8:0:20:f5:41:3a
```

### **To Obtain HME Link Status:**

```
# ndd -get /dev/hme link_status [0:link down 1:link up]
```

### **To Obtain HME Link Speed:**

```
# ndd -get /dev/hme link_speed [0:10m 1:100m]
```

### **To Obtain HME Link Mode:**

```
# ndd -get /dev/hme link_mode [0:half duplex 1:full duplex]
```

### **To Change Duplex Settings Manually on Solaris:** /etc/system

```
#set hme:hme_adv_autoneg_cap=0
#set hme:hme_adv_100T4_cap=0
#set hme:hme_adv_100fdx_cap=0
#set hme:hme_adv_100hdx_cap=0
#set hme:hme_adv_10fdx_cap=0
#set hme:hme_adv_10hdx_cap=0
```

### **To Change Speed Settings Manually on Solaris:** /etc/rc2.d/S69inet

```
#ndd -set /dev/hme adv_autoneg_cap 0
#ndd -set /dev/hme adv_100T4_cap 0
#ndd -set /dev/hme adv_100fdx_cap 0
#ndd -set /dev/hme adv_100hdx_cap 0
#ndd -set /dev/hme adv_10fdx_cap 0
#ndd -set /dev/hme adv_10hdx_cap 0
```

## **SOLARIS 7 TCP ACK PARAMTER:**

tcp\_xmit\_lowat [Minimum value of TCP transmit buffers, default = 2048 (2k)]

## **SOLARIS NFS SHARES:**

Troubleshoot using the “share” command

|                   |  |
|-------------------|--|
| /etc/dfs/dfstab   | List of files to export for the Server   |
| /etc/dfs/sharetab | List of FileSystems exported   |
| /etc/rmtab        | FileSystems remotely mounted on the system, maintained by rpc.mountd           |
| /etc/vfstab       | List of files to mount on a Client   |
| /etc/mnttab       | List of FileSystems mounted on a Client [modified by mount and umount command] |

## **DEFAULT MOUNT FOR SOLARIS IS NFSv3 OVER TCP/IP:**

To change to NFSv2 Over UDP:

**\$mount -o vers=2,proto=udp server:/ts /mnt**

**Mounting Sun Client to DataMover:** Don’t forget to mount Celerra’s FS to a mountpoint that you can use!!!

1. First ensure that the File System is “exported” for NFS!

#mkdir /share1

From / mount the remote file system: # mount 193.1.21.173:/g1ufs1 /share1 [remote mntpoint & local mntpoint]

**Unmounting Sun from Celerra:** # umount -a /mntpoint or # umount /mntpoint

**Logging Onto Local Unix Machine as another user:** #exec login

## **RULE ON HARD vs. SOFT MOUNTS: If you are conducting Read-Writes to a Celerra FS, use Hardmounts!**

**Adding Devices in Solaris:** #devfsadm -c disk -c tape -c audio [etc] #devfsadm -i st #devfsadm -i dad #devfsadm -i sd

**Adding a New Disk Device:** #drvconfig -i dad [sd] #disks dad=ide sd=scsi

**Adding a New Tape Device:** #drvconfig -i st #tapes

**Logging In to Solaris from Root with Different Account:** #exec login login: todd password: nasadmin

**Continuous Ping from Solaris for Testing:** #ping -s 193.1.21.172

**Viewing Users on File Systems from Sun Client:**

```
#fuser -cu mnt_point [lists active processes] #fuser -ck mnt_point [Kill all processes accessing File System]
```

## **SETTING SUN SOLARIS CLIENTS TO NOT CACHE NEGATIVE GETATTR HITS:**

**param nfs:nfs3\_lookup\_neg\_cache=0**

**Note:** Functionality is similar to Celerra’s DNLC behavior in that if file lookups are not found in cache, a negative entry will be put in cache. Disable this behavior for NFSv3 on Solaris by using the above param. May help with issues related to Checkpoints.

## **TUNING SUN SOLARIS SYSTEMS FOR ENHANCED PERFORMANCE:**

## **GREATER READ PERFORMANCE:**

Step 1. Add the following lines to /etc/system and then reboot Server

```
set nfs:nfs_nra = 10  
set nfs:nfs3_nra = 10  
set nfs:nfs_max_threads = 24  
set nfs:nfs3_max_threads = 24  
set sq_max_size={ val }  
where { val } = 25 for each 64MB memory of client
```

## **GREATER STREAMS PERFORMANCE:** Change the following TCP/UDP parameters

```
ndd -set /dev/udp udp_recv_hiwat 65535  
ndd -set /dev/udp udp_xmit_hiwat 65535
```

### **ndd -set /dev/tcp tcp\_recv\_hiwat 65535 [Solaris TCP Window Size]**

```
ndd -set /dev/tcp tcp_xmit_hiwat 65535
```

**Note:** To make permanent, add to /etc/rc2.d script. Also, the sq\_max\_size and ndd settings are recommended for purely sequential workloads!

## **TUNING SOLARIS 2.8 CLIENTS FOR IMPROVED PERFORMANCE:**

```
tcp_xmit_hiwat=65536  
tcp_recv_hiwat=65536  
tcp_max_buf=4194304  
tcp_cwnd_max=2097152  
/etc/system:
```

Set maximum Read Ahead threads to 10 per process and up to 80 per client

Set queue buffer size to 200

## **SUN SOLARIS ETHERNET PARAMS:**

```
$pkginfo -l |grep -i gig [info about GB Ethernet card in use]  
$ndd -get /dev/ge \? [this will show you what settings are available]  
#/etc/power.conf [This file can be changed to automatically shutdown the Solaris]
```

## **IBM AIX SYSTEMS:**

```
#lscfg -pv [Displays configuration and vital stats]  
#lsps -a [snapshot of pagefile utilization levels]  
/etc/security/audit/config [Audit Files]
```

## **HP-UX 11.0:**

Unix Platform based on Unix System V Release 4

Network Traces: Use the 'nettl' utility

```
#sysdef [Analyzes current system and configuration parameters]  
#swlist -l PH* [displays installed HP-UX patches] #swlist -l bundle [OS Version & type]  
#ioscan [Scans system hardware] #lsdev -C disk [lists device drivers in system]  
/var/adm/syslog.log /stand/system
```

## **HP-UX TCP WINDOW SIZE:**

```
#ndd -get /dev/tcp $i  
tcp_recv_hwater_def 32768 [Max Receive Window Size]  
tcp_recv_hwater_lfp 65536 [Max Receive Window Size for fast links]  
tcp_recv_hwater_lnp 8192 [Max Receive Window Size for slow links]
```

## **CELERRA FTP/DATA MOVER FTP SERVICE:**

→Data Mover supports both NFS and CIFS for FTP, using either local /etc/hosts or NIS for NFS authentication, or CIFS authentication for CIFS. If a user logs in without the domain name format (domain\user), then the login uses Unix authentication. If the user logs in with domain\user account, and CIFS is running, then the login will attempt to use CIFS authentication.

→Default directory is root “/” for users logging into FTP, but access will not occur if they do not have permission to “/”

→Use defaultdir param to change working directory to a defined mountpoint on a file system

→Use the Celerra Homedir service to allow Users to ftp to their Home Directory

→For FTP CIFS Users using Celerra Homedir service, the following entry must also be made to the netd file:

**ftpd homedir**

**ftpd umask=027** (use this entry to change default umask for ftp users)

## **SERVER FTP & NAS 5.6.42:**

→Introduces the server\_ftp command and options, which allow for much easier configuration and changes to the FTP service on the Blade. Please note that FTP service changes will require that you first stop the service, do the change, then start the service.

**Restricting Users to Home Directory:**

# server\_ftp server\_2 -service -stop

server\_2 : done

# server\_ftp server\_2 -modify -homedir disable

server\_2 : done

# server\_ftp server\_2 -service -start

# server\_ftp server\_2 -service -status

server\_2 : done

State : running

→Default timeout for an active ftp session is 15 minutes

→Access-checking depends on the access-policy in effect, and whether a user is coming in from Unix/FTP client, or CIFS/FTP

→FTP also supports login with Anonymous or FTP user account, and requires that the “ftp” username be resolved from the local /etc/passwd file or from NIS—password is generally the username or the email address of the user—the passwd field for the entry must be disabled! (i.e., \*). The “home” directory of the FTP user will be what is defined in the passwd entry, or if not defined, and the ftpd defaultdir param is not changed, the default directory is “/” root. If FTP user has permissions to root, login will succeed—if not, login will fail.

**Note:** Normal behavior should be that ‘anonymous’, or ‘ftp’ user, or a cifs user, will not be able to log into “/” root unless perms are defined to allow it

**FTP vs. FTPS vs. SFTP (5.6.42):**

FTP authentication goes across the network unencrypted. FTPS authentication uses SSL security to pass user and password in encrypted format. SFTP uses the SSH protocol to encrypt data over the transport mechanism, and uses Public Key authentication and compression. The latter feature is available on the Control Station Linux O/S. Data Movers support only FTP and FTPS.

**CONFIGURING THE DATA MOVER FTP SERVICE FOR CIFS USERS (NAS 5.6.42+):**

**Note:** Setting up CIFS FTP is a little more complicated than NFS or Anonymous FTP. You would probably want to make sure the CIFS user is locked into a particular directory tree path, which requires setting up the Celerra HomeDir service with the autocreate user directory option, and setting the FTP HomeDir feature to “enable”. This will serve to map each CIFS FTP User to their own home directory, and they will not be able to ‘cd’ up the file system tree.

**Steps for configuring FTP for CIFS Users:**

1. Install the Celerra Home Directory Management snapin:

a) From the Celerra Application & Tools CD, install the "Celerra CIFS Management MMC Snapins" on a Windows platform [CelerraCifsMgmt.exe]

**Note:** Accept the default paths during the install, but on the "Select Components" screen, uncheck all boxes except for the "Home Directory Management" service

2. Enable the Home Directory service:

a) From the Programs or Administrative Tools section, open the "Celerra Management" program

b) Rightclick "Data Mover Management" and connect to the appropriate Data Mover using "Connect to Data Mover"

c) Rightclick the "HomeDir" section and "Enable" the service

**Note:** This starts the Home Directory service and creates a blank Home Directory map file /etc/homedir file

# server\_cifs server\_2 |grep Home

Home Directory Shares ENABLED, map=/etc/homedir

d) Use the Celerra Management HomeDir interface to add entries to the map file

**Example:**

# cat /etc/homedir

test.ftp.emc.com:\*:/fs3/ftp/cifs:create

**Note:** The first colon-delimited field represents the Windows Domain FQDN, the second field represents all “users” for the specified domain when using the “\*” wildcard, the third field defines the FTP Home Directory path, and the last field “create” serves to automatically create the User’s FTP directory upon first login to the FTP service

3. To lock CIFS Users into their own Home Directory, enable the FTP Home dir option:

# server\_ftp server\_2 -service -stop

server\_2 : done

# server\_ftp server\_2 -modify -homedir enable

server\_2 : done

FTPD CONFIGURATION

=====

State : stopped

Control Port : 21  
Data Port : 20  
Default dir : /  
Home dir : enable  
----output abbreviated-----

# server\_ftp server\_2 -service -start

server\_2 : done

**Note:** Setting -homedir enable makes sure that CIFS Users will not be able to navigate out of their own Home Directory. If sub-directories exist, the User would be able to navigate down the tree, provided they had NT permissions. Without the Homedir enable option set, a CIFS user could navigate up the file system path and even to the rootfs of the Data Mover, provided the User had the requisite NTFS permissions.

#### 4. Log into the Data Mover's FTP service using a fully qualified user name and password:

c:>ftp 192.1.10.27  
Connected to 192.1.10.27.  
220 server\_2 FTP server (EMC-SNAS: 5.6.43.8) ready.  
User (192.1.10.27:(none)): user@test.ftp.emc.com  
331 Password required for [user@test.ftp.emc.com](mailto:user@test.ftp.emc.com).  
Password:

230 NT User [user@test.ftp.emc.com](mailto:user@test.ftp.emc.com) logged in.

ftp >

#### 5. Configuring Celerra FTPS (FTP Secure, using SSL):

a) Create Server Certificate:

# server\_certificate server\_2 -persona -generate default -key\_size 4096 -cs\_sign\_duration 8 -cn "w2k.pvt.dns"  
server\_2 :

Starting key generation. This could take a long time...

done

### **CONFIGURING THE DATA MOVER FTP SERVICE FOR NFS USERS(Anonymous, etc.):**

1. Create an ftp user “ftp” with UID and GID values, but no password (i.e., :x:), by editing ./etc/passwd file on the Server, or by using a NIS entry

# /nas/sbin/server\_user server\_2 -add ftp

Creating new user ftp

User ID: 400

Group ID: 400

Comment:

Home directory: /fs3/ftp

Shell:

# cat passwd

SL7E10817000220000\_SL7E10817000220000:EFkc/WtYmB.S.:9000:9000:fDCZfJrevWsulnaQco0lkph9OV::ndmp\_md5

**ftp::!400:400::/fs3/ftp:**

2. Disable the password field for the user “ftp” either manually using a vi editor, or the following command:

# /nas/sbin/server\_user server\_2 -passwd -disable ftp

Changing password for user ftp

Removing password for user ftp

# cat passwd

**ftp::400:400::/fs3/ftp:**

**Note:** In testing NFS, it didn’t matter that the passwd value for ftp user was \*, !!, or just blank. The user was allowed to ftp in.

3. Define a home directory path in the “passwd” file for the FTP user as shown above, or by specifying a default directory with the FTP service

# server\_ftp server\_2 -modify -defaultdir /fs3/ftp

**Note:** A Home Directory can be specified either in the passwd/NIS file or using the –defaultdir command. If no home directory is defined, the working directory would be “/” on the Data Mover. If ftp has not been granted access permissions to “/”, then the login would fail, otherwise, the User would gain access to root. Normally, the FTP User will only be able to navigate downward on the file system, not upward, so having the default directory set is important.

4. Having the homedir value “disable” or “enable” made to difference to NFS user

### **FTP PARAMS:**

\$ .server\_config server\_2 -v "param ftpd"

| Name           | Location   | Current    | Default    |
|----------------|------------|------------|------------|
| ftpd.autostart | 0x03500458 | 0x00000001 | 0x00000001 |

```
ftpd.bounceAttackChk      0x035006d8 0x00000001 0x00000001
ftpd.cifsbypass          0x03500604 0x00000001 0x00000001
ftpd.defaultdir           0x035004d8 '/' '/'
ftpd.forceBinXfer         0x03500758 0x00000000 0x00000000
ftpd.longDirA             0x035408b8 0x00000001 0x00000001
ftpd.shortpathdir         0x03500698 0x00000000 0x00000000
ftpd.wildcharsInDir       0x03500658 0x00000000 0x00000000
```

### # server\_param server\_2 -f ftpd -l

```
server_2 :
param_name          facility default current configured
shortpathdir         ftpd     0      0
defaultdir           ftpd     /      /
wildcharsInDir       ftpd     0      0
bounceAttackChk     ftpd     1      1
```

### USING SERVER FTP:

#### # server\_ftp server\_2 -info

##### FTPD CONFIGURATION

```
=====
State          : running
Control Port   : 21
Data Port      : 20
Default dir    : /
Home dir       : disable
Keepalive      : 1
High watermark : 65536
Low watermark  : 32768
Timeout        : 900
Max timeout    : 7200
Read size      : 8192
Write size     : 49152
Umask          : 27
Max connection : 65535
```

##### SSL CONFIGURATION

```
=====
Control channel mode : disable
Data channel mode   : disable
Persona            : default
Protocol           : default
Cipher              : default
Control port       : 990
Data port          : 989
```

### CHANGING DEFAULT DIRECTORY FOR USERS LOGGING INTO FTP SERVICE:

#### # server\_param server\_2 -f ftpd -modify defaultdir -value /fs1/ftp

### DISABLING FTP SERVICE ON A DATAMOVER:

#### # server\_ftp server\_2

```
server_2 :
Error 2100: usage: server_ftp { <movername> | ALL }
               -info
               | -service { -status | -start | -stop }
               | -service -stats [-full | -reset]
               | -modify
```

### Verify that FTP service is running on Server:

#### # server\_netstat server\_2 -a | grep ftp

```
tcp *.ftp          0.0.0.0.0      LISTEN
```

Step 1. \$cd /nas/server/slot\_x

Step 2. Comment out the “ftpd” line in the “netd” file and reboot Data Mover, then verify

# server\_netstat server\_2 -a |grep ftp

### **CHANGING DEFAULT UMASK FOR FTP:**

1. #vi /nas/server/slot\_x/netd [Add following line to netd file]

**ftp umask=022**

### **FORCING DM TO TRANSFER IN BINARY MODE:**

**param ftpd forceBinXfer=1**

**Note:** Reboot DM after setting param. Default=0

### **SETTING DATA MOVER FTP TO LONG DIRECTORY LISTING MODE:**

**param ftpd listDirA=1**

**Note:** See AR47406

### **TROUBLESHOOTING TELNET/FTP:**

/etc/services [Linux--look for telnet entry--23/tcp]

/etc/inetd.conf [SCO--look for entry for telnet or ftp and make sure that it is uncommented]

/usr/sbin/in.telnetd [verify the file exists & permissions o.k.]

**Problem:** Some firewall implementations use an /etc/hosts.allow file to restricted Host connections from FTP or Telnet

### **TCP WRAPPER SERVICE:**

Available and configurable on Control Station using /etc/hosts.allow and /etc/hosts.deny files, works with inetd service. Always use at least one backup external IP address and both internal IP addresses in the hosts.allow file to prevent from being locked out.

### **EXAMINING TELNET SESSIONS ON A PARTICULAR HOST:**

**# netstat -a -n inet**

**Note:** Shows TCP connections and status of

### **DISABLING LINUX SERVICES ON DM:**

--Commenting out /nas/server/slot\_x/netd/#routed [Shuts off RIP service on DM]

--pax & ndmp port=10000 [Shut off if no local tape backup or ndmp in use]

--xattrp [Shutoff if not using EDM to backup CIFS attributes]

--rquotad action=start [Shutdown if quotas not in use]

--ftpd

--sysman [Shuts down snmp]

### **BEST WAY TO DISABLE SNMP DAEMON ON DATA MOVER:**

1. Remove “sysman” line from /nas/server/slot\_x/netd file

2. Reboot Data Mover

**Note:** There are sideaffects to running with SNMP disabled on the Data Mover. It disables the server\_netstat command, but more importantly, will prevent success NAS Upgrades, therefore, the daemon MUST be re-enabled prior to any NAS Upgrade.

### **IMPLEMENTING QUOTAS ON LINUX:**

1. #rpm -qa | grep quota

quota-3.09-1

2. #vi /etc/fstab and change ‘defaults’ to ‘usrquota,grpquota’

3. #mount -o remount /data

4. #touch /data/aquota.{user,group}

5. #quotacheck -cm /data

6. #quotaon /data

7. #edquota user1 [Using prototype: #edquota -p user1 user2]

8. Checking a User’s Quota: #quota user1

9. #edquota -t [establishing grace periods]

### **APACHE SYNTAX CHECKER:**

**# httpd -t**

### **TURNING ON TELNET/FTP SERVICES ON LINUX:**

1. Check /etc/services file and ensure Telnet/FTP are not commented out

2. **# /sbinchkconfig --list**

**# /sbin/chkconfig --list telnet**

- telnet off
- 3. Turn Telnet Service on:

**# /sbin/chkconfig telnet on**

- 4. Start Inet Services:

**# /sbin/service xinetd restart**

Stopping xinetd: [ OK ]

Starting xinetd: [ OK ]

**Note:** Using chkconfig method will configure service to restart automatically after reboots

## **VARIOUS SERVICES THAT CAN BE DISABLED ON LINUX:**

**Note:** /etc/services directory based on Red Hat 7.2

### **# Network services, Internet style**

```
systat      11/tcp    users
systat      11/udp    users

microsoft-ds 445/udp
kpasswd     464/tcp   kpwd     # Kerberos "passwd"
kpasswd     464/udp   kpwd     # Kerberos "passwd"
```

### **# UNIX specific services**

```
exec        512/tcp
talk        517/udp
```

**Note:** Above listing is just a sampling of contents listed in the /etc/services file

## **CELLERRA PORTS:**

### **IMPORTANT LINUX SERVICES AND PORT NUMBERS:**

|         |                  |                             |   |
|---------|------------------|-----------------------------|---|
| ssh     | Port 22/tcp      | Port state open             | Use /sbin/service sshd stop to stop service               |
| http    | Port 80/tcp      | Port state open             | Edit /nas/http/conf/httpd.conf file                       |
| http    | Port 8000/tcp    | Port state open             | Core Service for Celerra Monitor, WebUI—do not stop       |
| http    | Port 5080/tcp    | Port open                   | Core service, do not stop                                 |
| rpcbind | Port 111/tcp     | Port state open, aka sunrpc | Mandatory NFS Portmapper service—do not stop              |
| smux    | Port 199/tcp/udp | Port state open             | Mandatory snmpd service & ECC—do not stop                 |
| java    | Port 8009/tcp    | Port state open             | Core Java Service & ECC—do not stop                       |
| java    | Port 8010/tcp    | Port state open             | Core Java link Service & ECC, Celerra Monitor—do not stop |
| https   | Port 443/tcp     | Port open                   | Mandatory core service—do not stop                        |
| nas_mcd | Port 9823/tcp    | Port open                   | Master Control Daemon—Core Service—do not stop            |
| SMB     | Port 139/tcp     | Port open                   | Netbios Port 139—CIFS over netbios—can be stopped         |

|            |                      |                              |  |
|------------|----------------------|------------------------------|--|
| SMB        | Port 445/tcp         | Port open                    | Direct Hosted SMB over TCP on Port 445—CIFS services               |
| Nbt/wins   | Port 137/tcp         | Port open                    | Windows netbios name service, can be stopped                       |
| nbs        | Port 5033/tcp        | Port open                    | Core interconnection NS600 service, do not stop                    |
| rquotad    | Port 1024/tcp        | Port open                    | Quota daemon service, core service, do not stop                    |
| rpc.statd  | Port >1024/tcp/udp   | Port open                    | Dynamically allocated port. Close using /sbin/service nfslock stop |
| NIS        | Port 1038/tcp        |                              |  |
| Nlockmgr   | Port 1039/tcp        | [nfs & cifs lock management] |  |
| Mountd     | Port 1234/tcp        | Port open                    | Core service, mount daemon for nfs, do not stop                    |
| NFS        | Port 2059/tcp or udp | Port open                    | Core service, nfs daemon, do not stop                              |
| PAX        | Port 4658/tcp        | [Pax operation]              |  |
| NDMP       | Port 10000/tcp       | Port open                    | NDMP operation, core service, do not stop                          |
| Snmp       | Port 161/udp         | Port open                    | Core Celerra snmp service, do not stop                             |
| Mac        | Port >1024           | Port open                    | Core interconnection service, do not stop                          |
| Lockd      | Port >1024           | Port open                    | Core Celerra service, do not stop                                  |
| Statd      | Port > 1024          | Port open                    | Core Celerra service, do not stop                                  |
| Rcp        | Port 8888/tcp        | Port open                    | Celerra replicator service on Secondary side—can be closed         |
| Mgfs nfs   | Port 1020/udp        | Port open                    | Mgfs NFS Migration service, core service, do not stop              |
| Mgfs mount | Port 1021/tcp or udp | Port open                    | Core NFS Mgfs migration service, do not stop                       |
| Replicator | Port 8887/tcp        | Port open                    | Celerra IP ‘DR’ Replication service                                |
| iSCSI      | Port 3260/tcp        | Port open                    |  |

## **SETTING UP RSH REMOTE SHELL:**

Step 1. Create the “.rhosts” file in /home/nasadmin and enter client IP addresses:

```
#vi /home/nasadmin/.rhosts
192.10.4.4      root
192.10.4.5      nasadmin
localhost        nasadmin
```

Step 2. # chmod 600 .rhosts

Step 3. Turn on ‘rsh’ service: #/sbin/chkconfig rsh on

## **CREATING SSH KEYS IN USER’s HOME DIRECTORY:**

1. #su - user1
2. #ssh-keygen -t rsa -b 1024
3. #ssh-keygen -t dsa -b 1024

## **CREATING PUBLIC/PRIVATE ENCRYPTION KEYS ON LINUX CS:**

1. Generate the encryption key  
# ssh-keygen -t rsa  
Generating public/private rsa key pair  
Enter file in which to save the key ...
  2. Do not enter a passphrase, just hit enter key  
Enter passphrase (empty for no passphrase):
  3. Your identification has been saved in ...  
Your public key has been saved in ...
- Note:** Note the name and location of the public key that was generated—key ends in .pub
4. Copy appropriate public key to location on remote systems

## **CELERRA LINUX CS AND SECURE SHELL SERVICES (SSH—aka Secure Socket Shell):**

### **Note 1:** sshd runs on NAS 4.1 + by default

Celerra uses OpenSSH on the Linux Control Station. SSH uses RSA public key cryptography for connections and authentication and provides for secure encrypted passwords and communications between a Local and Remote Host using the SSHD Daemon. SSH works much the same as Telnet but is secure & encrypted (Telnet & FTP use plaintext communications) but is designed to replace “rlogin” and “rhosts”. SSH also automatically forwards the local host’s DISPLAY variable to the Client system so as to be able to execute an X term or other such program. Linux Redhat 6.2 & 7.2 Control Stations are configured with SSH by default.

### **Note 2:** rlogin and rlogind are similar to telnet and telnetd, with exception that rlogin does not require password to connect to host.

Rsh and remsh are similar to rlogin, requiring setup of .rhosts and hosts.equiv files.

→Default port for SSH is Port 22 (required for Celerra Manager, so do not change)

→/etc/ssh/sshd\_config is configuration file

→Root access via SSH is enabled by default, but can be disabled

**Step 1. Verify Default System Configuration File for SSH:**

# more /etc/ssh/sshd\_config

# \$OpenBSD: sshd\_config,v 1.48 2002/02/19 02:50:59 deraadt Exp \$

# This is the sshd server system-wide configuration file.

**Step 2. Verify SSHD Daemon (should be running by default):**

# ps -ef |grep sshd

root 904 1 0 Mar21 ? 00:00:00 /usr/sbin/sshd

# /sbin/chkconfig --list sshd

sshd 0:off 1:off 2:on 3:on 4:on 5:on 6:off

# /sbin/service sshd status

sshd (pid 904) is running...

**Step 3. Starting & Stopping the SSH Daemon/Service:**

# /sbin/service sshd start | stop | restart

Starting sshd: [ OK ]

**Step 4. Add Remote Hosts to Local "/etc/hosts" File:**

#vi /etc/hosts [Add entries to end of file!]

172.24.80.13 artmis

**Step 5. Login to Remote Host from Prompt :**

# ssh artmis

# ssh nasadmin@artmis

[Login as a different User: #ssh -l root artmis]

The authenticity of host 'artmis (172.24.80.13)' can't be established.

RSA key fingerprint is 88:ec:66:76:a1:13:ea:0f:d3:7e:18:ad:2f:a5:c9:3a.

Are you sure you want to continue connecting (yes/no)? Yes

Warning: Permanently added 'artmis,172.24.80.13' (RSA) to the list of known hosts.

root@artmis's password:\*\*\*\*\* [Enter Remote Host's Password here]

Last login: Wed Oct 30 14:44:47 2002

EMC Celerra / RedHat Linux Wed Oct 30 14:09:29 UTC 2002

server\_2 -

server\_3 -

**LOGGING INTO REMOTE HOST USING SSH:**

# ssh -l root 193.1.21.200

# ssh nasadmin@192.168.25

**DEFINING NAS\_DB ENV WHEN RUNNING CELERRA CMDS ON REMOTE CS USING SSH:**

# ssh cs0 "declare -x NAS\_DB="/nas"; /nas/bin/nas\_quotas -r -fs fs01

**CHANGING DEFAULT SSH-1 TO SSH-2 PROTOCOL:**

1. Edit /etc/ssh/sshd\_config file, changing following line:

#Protocol 2,1

2. Uncomment above line and change to this:

Protocol 2

3. Restart ssh: #/sbin/service sshd restart

**NAS 5.6 LONG LOGON TIMES USING SSH CLIENT:**

**Note:** emc221091 has an effective workaround for long delays when logging into the Control Station from a Remote SSH client, but the problem is really a remote host DNS resolution issue

**Workarounds for Long Logon Times:**

1. vi edit /etc/resolv.conf and remove domain & nameserver specific search entries (leave only “domain localdomain” on one line)

2. Or, vi edit /etc/nsswitch.conf and remove DNS from following line

#hosts: db files nisplus nis dns

hosts: files dns → Remove dns from this line

3. Or, vi edit /etc/ssh/sshd\_config file, change the following line, restart the sshd service:

#UseDNS yes → Uncomment the entry and edit as follows:

**UseDNS no**

# /sbin/service sshd restart

**KNOWN CELERRA LIMITATIONS:**

--boot.cfg file is limited in size to 512kb [Pre NAS 4.x code]

--UFSLOGSIZE is limited to (2) billion transactions; If log reaches more than 80% full, NFS threads are suspended until log reduced to 60% full—if it cannot flush these log entries within 60 seconds, DataMover will panic!

**Note:** Limitation fixed in 4.0**Cause:** High I/O conditions and/or poorly designed File Systems!UFSLOG "*Race Condition*"—occurs when there is thread contention in File System between one process and the single-threaded process that cleans up the ufslog entries.**"ufs log full" Panics:** This can occur when DART cannot flush metadata to file system due to extreme load on Celerra—by default, there are 8 threads allocated to flushing ufslog entries. To increase the number of threads for ufslog activity, change the following (3) params from (8) threads to (16) threads as a start, and possibly as high as (32) if required—consult with TS2 or Eng. before changing these values on your own, as this condition may no longer apply with latest NAS versions:

ufs.nFlushIno 0x01144654 0x00000008 0x00000008 →change to 16

ufs.nFlushDir 0x01144658 0x00000008 0x00000008 →change to 16

ufs.nFlushCyl 0x0114465c 0x00000008 0x00000008 →change to 16

**UFSLOG FLUSH CASE EXAMPLE OF PARAM CHANGES:**

param ufs syncInterval=10000

param ufs nFlushCyl=32

param ufs nFlushDir=32

param ufs nFlushIno=32

**CELERRA UID/GID LIMITATIONS:** 4 billion UIDs/65,534 GIDs on a single file system**PASSWD File:** 64k NIS Unix limitation**16 Cylinders per Cylinder Group:** Master Control SuperBlock is at offset 16, with alternate SuperBlock at offset 32**Basic Celerra Vol's:** Stripe 4-8 volumes in multiples of 512 bytes, at a width of 32,768 bytes, evenly across the Disk Directors.**Running Jobs In Background or Foreground in SCO or LINUX:**

Step 1. Execute the script that you want to run

Step 2. Place Job in Background: # ctrl + Z &amp; # bg [places job in background]

Step 3. Return Job to Foreground: # jobs [identify which job you wish to return to foreground] &amp; # fg %1 [# kill %1 kills job]

**CRONTAB UTILITY:**

System Daemon that executes commands at specific times

# crontab -l -u nasadmin

# /var/spool/cron/crontabs

# /var/spool/cron/nasadmin

# cat nasadmin

# DO NOT EDIT THIS FILE - edit the master and reinstall.

# (/tmp/crontab.4696 installed on Fri Feb 27 11:32:04 2004)

# (Cron version -- \$Id: crontab.c,v 2.13 1994/01/17 03:20:37 vixie Exp \$)

15 \* \* \* \* /home/nasadmin/scripts/ckpt\_refresh.sh

**Note:** Above is an example of where Cronjob resides for 'nasadmin'**Setup in Six columns:** \*Asterisks are used as Wildcards

| #minute to run  | hour | day of mnth | month of year | day of the week    | Command path         |
|-----------------|------|-------------|---------------|--------------------|----------------------|
| 0-59            | 0-23 | 1-31        | 1-12          | 0-7 [0 & 7=Sunday] |                      |
| <b>Example:</b> | 2    | *           | *             | *                  | /home/jar/bin/backup |

**Explanation:** Backup job will run at 2:30 every day of week all year**Example of NAS BackUp Cron Job:**

#var/spool/cron/crontabs/nasadmin

1 \* \* \* \* /nas/sbin/nasdb\_backup /nas /home/nasadmin 1 &gt;/dev/null 2&gt;&amp;1

**Explanation:** NAS Database Backup will occur at 1 minute after each hour, every day, all year**OTHER EXAMPLES:**

0,15,30,45 \* \* \* \* [Job runs every 15 minutes every hour of every day]

1 1 \* \* 0 [Job runs weekly on Sundays]

```
* */2 * * * [Run every 2 hours]  
* 0-23/2 * * * [Run every other hour]  
1-30 * * * * [runs only every minute 1-30]
```

#### **Running a Cron Job on Celerra:** Create and Name your Script File

```
$crontab -l [lists out cron jobs]  
$crontab -l > thm [Creates cron script into a file called ‘thm’]  
$vi the file ‘thm’ and add your scripting “15**** /home/nasadmin/chkdc.rel>/dev/null 2>&1” [15 = 15 minutes after each hour]  
$crontab thm [starts your scripted cron job]
```

#### **OTHER LOCATIONS FOR CRON JOBS/SCRIPTS:**

```
# cat /nas/site/cron.d/nas_sys [abridged]  
1 * * * * root /nas/sbin/root_cron >/dev/null 2>&1  
0-59/5 * * * * nasadmin /nas/sbin/get_backend_status APM00033402672 /nas/log/backend_status.APM00033402672.xml >/dev/null  
2>&1  
1 * * * * nasadmin /nas/sbin/nasdb_backup /nas /home/nasadmin 1 &>/dev/null  
0 2 * * 3 root /nas/sbin/nas_config -alertview -get >/dev/null 2>&1  
# cat /nas/site/cron.d/nas_user [abridged]  
10 6,10,14 * * 1-5 nasadmin /nas/RC_SCRIPTS/create_ckpts.wrapper -q >/dev/null
```

**Note:** This file contains scheduled checkpoint scripts as configured from WebUI

#### **CLARIION SYSTEM SCRIPTS:**

```
/nas/site/cron.d  
# cat nas_sys  
0-59/5 * * * * nasadmin /nas/sbin/get_data_mover_status server_2 5080 /nas/log/data_mover_status.server_2.xml >/dev/null 2>&1  
1 0-23/2 * * * * nasadmin /nas/sbin/get_data_mover_status -resume server_2 5080 /nas/log/data_mover_resume.server_2.xml  
>/dev/null 2>&1  
0-59/5 * * * * nasadmin /nas/sbin/get_backend_status APM00033500569 /nas/log/backend_status.APM00033500569.xml >/dev/null  
2>&1 (script uses /nas/opt/Navisphere/bin/navicli to make backend queries)  
2 0-23/2 * * * * nasadmin /nas/sbin/get_backend_status -resume APM00033500569 /nas/log/backend_resume.APM00033500569.xml  
>/dev/null 2>&1  
Note: Output files are in /nas/log
```

#### **NS SYSTEMS BACKEND CRON JOBS:** /nbsnas/site/cron.d

```
# cat nas_sys  
0-59/5 * * * * nasadmin /nas/sbin/get_backend_status APM00040303779 /nas/log/backend_status.APM00040303779.xml  
>/dev/null 2>&1  
2 0-23/2 * * * * nasadmin /nas/sbin/get_backend_status -resume APM00040303779 /nas/log/backend_resume.APM00040303779.xml  
>/dev/null 2>&1
```

**Note:** The above cronjobs are scheduled to run every 5 minutes on NS systems, the results of which are diff'ed to see if any changes have occurred—if changes have occurred, the script then invokes a sync command to sync up the Celerra and backend databases—the XML files are posted to the /nbsnas/log directory. Errors and events, such as trespassed luns, are posted to the sys\_log.

#### **LISTING CRON JOBS ON LINUX CONTROL STATION:**

```
# crontab -l [Lists Cron Jobs scheduled by Root]  
$ crontab -l [Lists Cron Jobs scheduled by Nasadmin]  
# crontab -e [Brings up Edit window—add new Cron Job entry here or comment out existing Job]  
# crontab -u nasadmin -l [Output cronjobs for User nasadmin or any other user specified]  
# /nas/sbin/nas_cron -l  
# ls /var/spool/cron [Lists User cronjobs that have been configured]  
# /usr/bin/atq [Run this to see if any Crontab actions are queued to run]
```

nasadmin root

**EXAMPLE:**

```
0-59 * * * * /home/nasadmin/dmstats.cron server_2 >/dev/null 2>&1
```

**Note:** Above Job runs every minute, every day of the week, and calls script “dmstats.cron”

#### **UPDATING CRON AFTER VI EDIT CHANGE:**

```
# touch /etc/crontab
```

## **CONFIGURING CRONJOBS TO SURVIVE NAS UPGRADES, ETC.:**

**Note:** Use the crontab file that runs the NAS DB Backups on the Celerra. Vi edit nas\_sys and add Cron job.

### **/nas/site/cron.d**

# cat nas\_sys

**1 \* \* \* \* nasadmin /nas/sbin/nasdb\_backup /nas /home/nasadmin 1 &>/dev/null**

0 4 1 \* \* root /nas/sbin/log\_config -d -c >/dev/null 2>&1

1 \* \* \* \* root /nas/sbin/root\_cron >/dev/null 2>&1

## **HOW TO SET DATAMOVER TO DEFAULT TO BINARY MODE: 2.2+ & above**

/nas/site/slot\_param [or by individual datamover /nas/server/slot\_x/param]

**param ftpd forceBinXfer=1** [Add this to the parameter file & reboot datamover]

## **DISABLING FTP ON DATA MOVER:**

Step 1. \$cd /nas/server/slot\_x

Step 2. Comment out the “ftpd” line in the “netd” file [this will work until next code upgrade]

## **Default Umask for Users Accessing Celerra Using FTP Service: umask=740**

**COPYING FILES FROM FLOPPY:** #doscp a:\script.txt / [copies script.txt file to default /home/nasadmin directory]

#doscp a:driver.tar. or #doscp a:.\*

**COPYING FILES TO LINUX:**

#mcopy -t msdosfile /home/nasadmin/unixfile

**COPYING FILES TO FLOPPY:**

#mcopy -t a:c4.cmd

## **REMOTE ACCESS TO CELERRA CONTROL STATION:**

### **USING RSH REMOTE SHELL TO CONNECT TO LINUX 7.2 CONTROL STATION:**

**Note:** The “rsh” service is no longer enabled by default for this version of Linux

Step 1. Using vi, create “.rhosts” file in /home/nasadmin and enter the client addresses:

192.10.20.3 root

192.10.20.4 root

localhost nasadmin

Step 2. Chmod file: #chmod 600 /home/nasadmin/.rhosts [-rw----- 1 nasadmin nasadmin]

Step 3. Turn on the ‘rsh’ Service: #chkconfig rsh on

**Note:** See man pages for more details: #man ruserok

## **CONFIGURING RSH/RCP FOR LINUX 7.2 CONTROL STATION:**

1. Turn RSH Service on:

**# /sbin/chkconfig --list rsh**

rsh off

**#/sbin/chkconfig rsh on**

2. #vi /etc/security & add “rsh” to last line of file or use # echo rsh >> /etc/security

3. #vi /etc/pam.d/rsh & comment out the last “auth” line:

**#auth required /lib/security/pam\_rhosts\_auth.so**

4. Connect to remote Control Station and copy Pre-Upgrade Check Script to local directory:

**# rcp -p 10.241.168.50:/home/nasadmin/upgrd-ckv9-9g.bin .**

## **INSTALLING SENDMAIL FOR LINUX CONTROL STATION 6.2 & 7.2:**

**Note:** Sendmail is turned off by default. EMC does not encourage the use of this Linux RPM on the Celerra CS.

### **Linux 6.2:**

1. Copy RPMs to Control Station’s root directory

sendmail-8.11.6-1.62.2.i386.rpm

sendmail-cf-8.11.6-1.62.2.i386.rpm

### **Linux 7.2:**

1. Copy RPMs to Control Station’s root directory

sendmail-8.11.6-23.72.i386.rpm

sendmail-cf-8.11.6-23.72.i386.rpm

2. Run command:

**#rpm -Uvh sendmail\*.rpm**

### **VERIFYING SENDMAIL SERVICE:**

**# ps -ef |grep sendmail**

```
root 2754 1 0 Feb26 ? 00:00:00 sendmail: accepting connections
smmsp 2762 1 0 Feb26 ? 00:00:00 sendmail: Queue runner@01:00:00 for /var/spool/clientmqueue
root 28576 14533 0 12:30 pts/0 00:00:00 grep sendmail
```

**# /sbin/chkconfig --list sendmail | --add sendmail** (to add service)

```
sendmail 0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

**# /sbin/service sendmail**

Usage: /etc/init.d/sendmail {start|stop|restart|condrestart|status}

**# /sbin/service sendmail status**

```
sendmail (pid 2762 2754) is running...
```

### **VERIFYING RPM PACKAGES ON NAS CD-ROM:**

1. Mount CD-ROM: # mount /dev/cdrom /mnt/cdrom

2. Run following command in the /mnt/cdrom/RedHat/RPMS directory: **rpm -qp -filesbypkg \*.rpm**

### **FINDING INFORMATION INSIDE AN RPM PACKAGE:**

**# rpm -ql emcnas --dbpath /var/sadm/pkg/emcnas/ | grep "version"**

### **LINUX 7.2 INSTALL:**

/dev/sde →NAS directory

/dev/sdf →VAR directory, both created using fdisk during install

### **CELERRA CONTROL STATION:**

**LINUX RED HAT 7.2:** Introduced with NAS 4.1.4.0, 2.4.7 kernel

--Services are controlled by /etc/rc.d/init.d scripts [init.d services]

--Services also controlled by xinetd [xinetd services]

--Also note that XWindows support has been removed [startx no longer opens an Xwindows session]

### **VERIFYING KERNEL VERSION:**

**# uname -r**

2.4.9-34.5405.EMC

**# cat /proc/version**

```
Linux version 2.6.9-42.5610.EMC (peacej@nasbuild9) (gcc version 3.4.4 20050721 (Red Hat 3.4.4-2)) #1 Tue Jan 8 18:36:46 EST 2008
```

**# nas\_version**

5.6.37-6

### **LINUX TRIVIA:**

# ch [Use tab + tab key to list out all commands starting with ch, etc.]

### **Changing Run Level at Startup to Level 5:**

# vi /etc/inittab [id : 5 : initdefault:]

# /usr/sbin/ntsysv #redhat-config-services [GUI to startup Linux Services] #redhat-config-xfree86 [Display & Video settings]

### **Determining if Partitions are EXT3 or EXT2:**

**# df -T \* #cat /proc/mounts #cat /etc/mtab**

**# df -T**

| /dev/sda1  | ext3  | 7746      | 3530    | 3816      | 49%  | /boot      |
| none       | tmpfs |           |         |           |      |            |

### **Drivers:**

Kernel drivers loading during bootup

Modules are loaded dynamically as needed [see /etc/modules.conf]

#sbin/lspci [List of controllers on system] #ls /proc/bus/pci #cat /proc/bus/pci/devices

### **Red Hat Installer:**

Bootable CD-ROM contains boot.iso file | 4 Boot Floppies contain bootdisk.img, drvnet.img, drvblock.img & pcmciaadd.img

### **Copying 1<sup>st</sup> Stage Installer from CD-ROM to Floppy:**

#cat bootdisk.img > /dev/fd0 #dd if=bootdisk.img of = /dev/fd0

### **EXTRACTING FILES FROM ISO IMAGE:**

```
#mkdir /iso  
#mount -o loop boot.iso /iso  
#ls /iso
```

### **LINUX NAMING CONVENTION FOR PARTITIONS AND MULTIPLE PHYSICAL DISKS:**

IDE: 0 /dev/hda /dev/hda1 /dev/hda2, etc.

IDE: 1 /dev/hdb /dev/hdb1 /dev/hdb2, etc.

SCSI: 0 /dev/sda /dev/sda1 /dev/sda2, etc.

SCSI: 1 /dev/sdb /dev/sdb1 /dev/sdb2, etc.

### **USING DISK DRUID DURING INSTALL:** Automatically configure or use manual Disk Druid utility

```
/boot 100M  
/ 256M  
/usr 1256M  
/var 400M  
swap 512M
```

### **GRUB LOADER [Grand Unified Bootloader]:**

/boot/grub/grub.conf

### **RESTORING MBR IF DAMAGED:**

**#/sbin/grub-install /dev/hda**

### **BOOTING TO SINGLE USER MODE ON LINUX RED HAT 7.3:**

1. At Grub screen where “linux” is the only word displayed, type “e” for edit, then select the middle line out of the three listed, and type “e” for edit:

**kernel /vmlinuz ro root=/dev/hda3 console=ttyS1,19200**

2. Add a single space and then the word “single” without quotes after 19200

3. After edit has been made, press ‘enter’ key, then “b” for boot

4. System will come up to Single User prompt:

Sh-2.05#

**Note 1:** Older versions of Linux may require following edit at end of kernel line: “s” →root=LABEL=/ s

**Note 2:** The above edit to get to Single User mode is only temporary and after reboot comes up to normal Run Level 3

5. Verifying runlevel on Linux: # /sbin/runlevel

### **ALTERNATE SYNTAX EDIT:**

**kernel /vmlinuz ro root=/dev/hda3 init 1 console=ttyS1,19200**

### **BOOTING SINGLE USER MODE ON CELERRA NS600 TO CHANGE ROOT PASSWD:**

At Lilo Prompt type: **linux single**

If root passwd needs changing, cd to bin directory and type: #passwd root

### **CONVERTING FILE SYSTEM FROM EXT2 TO EXT3 JOURNALING:**

1. Edit /etc/fstab to ‘ext3’

**#tune2fs -j /dev/hda6**

3. Reboot

4. Verify by running #df -T \*

### **FORMATTING PARTITIONS:**

**#mke2fs -T news /dev/hda8**

### **DISPLAYING AND SETTING THE IMMUTABLE ATTRIBUTE ON FILES:**

```
#lsattr file  
#chattr +i passwd [Setting this attribute allows no one to remove file] #chattr -i passwd
```

### **CREATING A SWAP FILE:**

#fuser -k /data [Removes any processes connected to /data]

#umount /data

#dd if=/dev/zero of=/tmp/nuswap bs=512 count=245678 [12MB file]

```
#mkswap /tmp/nuswap  
#swapon /tmp/nuswap  
#swapon -s  
#swapoff /tmp/nuswap  
#mkfs -j /dev/hda6  
#e2label /dev/hda6 /data  
#mount /dev/hda6 /data
```

### **CREATING USER AND GROUP ACCOUNTS:** (not allowed beginning with NAS 5.6)

```
#useradd user1; echo 'user1:password' |chpasswd [Creates and sets default password of 'password' for user1]  
#usermod -G group1, group2, group3 user1 [Adds User1 to the indicated Groups]  
#/nas/sbin/check_user [Enter passwd for user as test, returns 'Authenticated' if successful]  
#userdel -r accntname [deletes accnt from passwd and shadow files]  
#chage -l user1 [Lists out account properties for User1—use #chage user1 to change]  
#groupadd sales -g 104 [Adds new Group called Sales with GID of 104]  
#groupmod -g 105 sales [Changes GID of group 'Sales' to 105]
```

### **# chage tom**

```
Minimum Password Age [0]:  
Maximum Password Age [99999]:  
Last Password Change (YYYY-MM-DD) [2004-02-11]:  
Password Expiration Warning [7]:  
Password Inactive [-1]:  
Account Expiration Date (YYYY-MM-DD) [1969-12-31]:
```

### **CREATING USER PRIVATE GROUPS:**

1. #mkdir /data/{sales,mis}
2. #chgrp sales /data/sales;chgrp mis /data/mis
3. #chmod g+s /data/\* [Sets the setgid bit without affecting current permissions]
4. #chmod 2770 /data/\* [Sets setgid bit and gives RWX permissions to Owner and Group members and access denied to Other]

**Note:** Turns on Group Sticky bit for /data/\* directories. Files or subdirectories created will belong to user but assigned Group ownership of directory.

### **CREATING FILES FOR TEST PURPOSES:**

**#for i in \$(seq 1 100); do echo -n “file\${i}“; touch file\${i} 2>&1; done | less** [Loop script creates 100 files for testing User quotas]

**#dd if=/dev/zero of=bigfile bs=1M count=3** [Script to create large files quickly]

### **PRINTING SERVICE:**

```
#lpr -P printer [BSD] #lp -d printer [System V]  
#/sbin/service cups status [Common Unified Print Service]  
#printconf-gui #/etc/cups/cupsd.conf | printers.conf  
#lpadmin -p printer1 -E -v Dev [Adding printer]  
#lpadmin -d printer1 [Setting default printer]  
#lpadmin -x printer1 [Deleting printer]  
#redhat-config-printer  
http://localhost:631/
```

### **SETTING UP SMB SHARE:**

```
#smbmount //192.168.1.200/joker /joker -o mark=smbuser [Sharename Joker defined in /etc/samba/smb.conf]  
#smbclient //192.168.1.200/joker -u mark  
Password: redhat  
Smb:>cd get put [commands]  
#chkconfig --level 345 smb on  
#touch /etc/samba/smbpasswd #smbpasswd -a mark [User must exist in /etc/passwd first]  
#testparm
```

### **VERIFYING LIST OF AVAILABLE SERVICES WITH RED HAT 7.2:**

```
#/sbin/chkconfig --list [Run Level 3 = CLI Run Level 5 = GUI]  
#/sbin/service --status-all [Useful for Status of services and Mounts on the Control Station]
```

### **VERIFYING A SPECIFIC SERVICE WITH LINUX:**

**\$ /sbin/chkconfig --list sendmail**

```
sendmail 0:off 1:off 2:off 3:off 4:off 5:off 6:off
```

**\$ /sbin/service sendmail status**

sendmail is stopped

**#/sbin/chkconfig sendmail on**

**#/sbin/chkconfig sendmail restart**

Shutting down sendmail: [ OK ]

Starting sendmail: [ OK ]

#### **DEBUGGING SENDMAIL:**

**# sendmail -d0 </dev/null**

#### **HOW TO ENABLE "init.d" SERVICES ON RED HAT 7.2 CONTROL STATION:**

1. Turn the Service On: #/sbin/chkconfig atd on [Scheduler service for Jobs; /var/spool/st]

2. Start the Service: #/sbin/service atd start

#### **HOW TO ENABLE "xinetd" SERVICES ON RED HAT 7.2:**

1. Turn Telnet On: #/sbin/chkconfig telnet on

2. Start Service: #/sbin/service xinetd start

#### **HOW TO ENABLE SNMP SERVICE ON LINUX 4.0.18 CONTROL STATION:**

1. Turn SNMPD On: #/sbin/chkconfig snmpd on

2. Start Service: #/sbin/service snmpd start

#### **LIST OF LINUX SERVICES:**

**# /sbin/chkconfig --list**

#### **LINUX CONTROL STATION VOLUMES & BOOTUP PROCESS Red Hat 6.2:**

| Vol/Part. | Size     | Offset | Device/Mount | Mountpoint         |
|-----------|----------|--------|--------------|--------------------|
| TLUN 00 = | root_dos | 134MB  | 0            | /dev/sda1 /nas/dos |
| TLUN 02 = | sdc1     | 7MB    | 0            | /boot [CS0]        |
|           | sdc2     | 133MB  | 7mb          | /swap              |
|           | sdc3     | 1929MB | 140mb        | /                  |

TLUN 03 = same as above for CS1

**BootUp Process:** BIOS → Boot [tlun 00] → autoexec.bat [/nas/dos] → exec t2slot → cd ./slot\_0 (1) → boot exec boot.bat  
→ loadlin [boot dev=/dev/sdc1 root dev=/dev/sdc3] → Start Linux [/etc/rc.d/init.d from /etc/inittab]

#### **VERIFYING NAS VERSION USED IN BOOTUP ON DMs:**

**\$ cat /nas/dos[slot\_\*/boot.bat |grep gload**

gload \bin\nas.exe boot.cfg

gload \bin\518804.exe boot.cfg

#### **NAS DOS PARTITION: /dev/sda1 Lun 00**

Prior to NAS 2.2.25.6, the NAS DOS partition was mapped to /dev/sdb1

All subsequent NAS versions map NAS DOS to /dev/sda1

#### **CONDUCTING BYTE-for-BYTE READ ON LINUX PARTITION:**

**# dd if=/nas/rdf/5001 of=/dev/null** → might be useful to validate data integrity

#### **CELLERRA BOOT UP PROCESS EXPLAINED:**

→ Control Stations and Data Movers all boot initially into DOS using tlun t0l0.

→ After DOS loads, the /nas/dos/autoexec.bat file uses t2slot.exe -f to determine which slot is booting.

→ Autoexec.bat then runs the appropriate boot.bat file for the slot.

→ Data Mover slots load DART based on boot.bat:

\$ cat /nas/dos[slot\_2/boot.bat

gload \bin\nas15400.exe boot.cfg

→ Control Station slots load LINUX based on boot.bat:

\$ cat boot.bat

\bin\loadlin \bin\vmlinuz root=/dev/sdc3 boot=/dev/sdc1 initrd=/bin/initrd.img panic=1 max\_scsi\_luns=16

→ Both control stations will use same initrd.img & vmlinuz files, though use different root & boot partitions

/boot

lrwxrwxrwx 1 root root 25 Jun 4 10:21 initrd.img -> initrd-2.4.9-34.8.EMC.img

lrwxrwxrwx 1 root root 22 Jun 4 10:21 vmlinuz -> vmlinuz-2.4.9-34.8.EMC

-rw-r--r-- 1 root root 641942 Sep 19 2002 vmlinuz-2.4.9-34.5.EMC

### **IMPORTANT BOOT FILES IN /nas/dos/bin:**

```
gload.exe: MS-DOS executable (EXE)
initrd.img: gzip compressed data, deflated, last modified: Wed Jun 4 10:21:47 2003, max compression, os: Unix
loadlin.exe: MS-DOS executable (EXE)
nas.exe: 386 demand paged pure executable not stripped
t2slot.exe: MS-DOS executable (EXE)
vmlinuz: x86 boot sector
```

### **SAMPLE LILO.CONF FILE ON 5.1.15.3 CELERRA :**

**\$ cat /etc/lilo.conf**

```
boot=/dev/sda
disk=/dev/sda
bios=0x80
map=/boot/map
install=/boot/boot.b
prompt
timeout=50
default=linux
image=/boot/vmlinuz
    label=linux
    root=/dev/sda3
    initrd=/boot/initrd.img
    read-only
```

### **UPDATING THE LILO.CONF FILE:**

**#/sbin/lilo**

### **CHANGES WITH LINUX 7.2:**

Introduces the “ext3” Journaling FileSystem for Linux, which provides for better & more reliable recoveries after unclean shutdowns

#### **Ctrl + Alt + Delete:**

Performs clean shutdown & reboot equivalent to doing #/sbin/shutdown -t3 -r now

#### **BootUp Process:**

/dev/initrd [RO Block Device] takes over from vmlinuz kernel image and begins startup of Linux Kernel. If missing, Linux cannot boot and gives kernel panic error message. If present, /sbin/init will then execute and control rest of bootup process.

Printing [lp commands] functions no longer configured by default on Linux Control Station

### **LINUX BOOT.BAT FOR NAS 5.1 EAGLE & 5.5 NS SERIES:**

**# cat /nas/dos/slot\_0/boot.bat**

**\bin\loadlin \bin\vmlinuz root=/dev/sdc3 boot=/dev/sdc1 initrd=/bin/initrd.img panic=1 max\_scsi\_luns=16**  
(NAS 5.1)

**\bin\loadlin \bin\vmlinuz root=/dev/hda3 boot=/dev/hda1 initrd=/bin/initrd.img panic=1**  
**max\_scsi\_luns=16** (NAS 5.5)

### **LINUX GRUB BOOT LOADER:**

**Note:** Used by NAS 5.4? and higher. Replaces the older lilo.conf boot loader.

**# cat /boot/grub/grub.conf**

```
default=0
timeout=10
serial .unit=1 .speed=19200
terminal .timeout=10 serial console
title linux
    root (hd0,0)
    kernel /vmlinuz ro root=/dev/hda3 console=ttyS1,19200
    initrd /initrd.img
```

### **TMPWATCH UTILITY:**

Linux Control Station runs ‘tmpwatch’ utility each day at 4:02 a.m. that removes content of /tmp directory > than 10 days old. Run from /etc/cron.daily/tmpwatch

**Caution:** Do not mount Celerra Server to this directory on the Control Station!

## **LINUX CS0 INFORMATION ON CD-ROM DRIVE:**

1. Grep the “dmesg” file for Toshiba: **#cat /var/log/dmesg | grep -i toshiba**  
hda: TOSHIBA CD-ROM XM-6602B, ATAPI CD/DVD-ROM drive
2. **#/sbin/ide\_info /dev/hda**  
MODEL="TOSHIBA CD-ROM XM-6602B"  
FW\_REV="1017"  
SERIAL\_NO=""
3. #more /etc/fstab  
/dev/cdrom /mnt/cdrom iso9660 noauto,owner,kudzu,ro 0 0

**Note:** If no reference found in “dmesg” or “ide\_info”, the drive is not being seen by Linux and may be defective

## **NS40 CONTROL STATION CD-ROM:**

**# dmesg |grep CD**

hdc: DW-224E-C, ATAPI CD/DVD-ROM drive

**Note:** This is a TEAC CD/DVD Combo drive, as seen by the Model number, “DW-224E-C”, 24X Recordable, Readable, Rewriteable, 8X DVD-ROM

## **VIEWING CELERRA CONTROL VOLUMES:**

**Example: missing /nas/var directory**

**#/sbin/fdisk -l** [Partial output listed below]

```
Disk /dev/sda: 255 heads, 63 sectors, 529 cylinders
Units = cylinders of 16065 * 512 bytes
Device Boot Start End Blocks Id System
/dev/sda1 * 1 17 136521 6 FAT16
Device Boot Start End Blocks Id System
/dev/sdc1 * 1 4 32098+ 83 Linux
/dev/sdc2 5 69 522112+ 82 Linux swap
/dev/sdc3 70 264 1566337+ 83 Linux
```

**\$ more fstab**

```
LABEL=/ ext3 defaults 1 1
LABEL=boot /boot ext3 defaults 1 2
none /dev/pts devpts gid=5,mode=620 0 0
none /proc proc defaults 0 0
none /dev/shm tmpfs defaults 0 0
/dev/sdc2 swap swap defaults 0 0
/dev/cdrom /mnt/cdrom iso9660 noauto,owner,kudzu,ro 0 0
/dev/fd0 /mnt/floppy auto noauto,owner,kudzu 0 0

/usr/sbin/automount --timeout 1 /net/500 file /etc/auto.500 ,ro

crond (pid 1107) is running...

gpm (pid 1089) is running...

-----output abridged-----

## SERVER VOLUME COMMANDS:

\$.[server\\_config server\\_2 “volume info 239” “volume stripe 234 567”](#)

### How to Debug Services that Fail during Bootup on Linux or Solaris:

\$[var/log/dmesg](#) [Reboot and then look at the log created during bootup to inspect what services come up, etc]

#[dmesg |less](#)

#[tail -f /var/log/{dmesg,messages} -n0 \[nolines\]](#)

## LINUX OPERATION:

### LOCKING-DOWN LINUX CONTROL STATION SECURITY:

Disable the following Services by commenting out the desired line in /etc/services & rebooting CS:

|           |        |     |        |            |                |            |                                       |
|-----------|--------|-----|--------|------------|----------------|------------|---------------------------------------|
| #ftp      | stream | tcp | nowait | root       | /usr/sbin/tcpd | in.ftpd    | -l -a                                 |
| telnet    | stream | tcp | nowait | root       | /usr/sbin/tcpd | in.telnetd | <b>(Warning: Will disable telnet)</b> |
| #shell    | stream | tcp | nowait | root       | /usr/sbin/tcpd | in.rshd    |                                       |
| login     | stream | tcp | nowait | root       | /usr/sbin/tcpd | in.rlogind |                                       |
| talk      | dgram  | udp | wait   | nobody.tty | /usr/sbin/tcpd | in.talkd   |                                       |
| ntalk     | dgram  | udp | wait   | nobody.tty | /usr/sbin/tcpd | in.ntalkd  |                                       |
| #finger   | stream | tcp | nowait | nobody     | /usr/sbin/tcpd | in.fingerd |                                       |
| linuxconf | stream | tcp | wait   | root       | /bin/linuxconf | linuxconf  | --http                                |

Disable the following by changing capital “S” to small “s” in /etc/rc.d/rc3.d & rebooting CS:

|              |   |              |
|--------------|---|--------------|
| S80sendmail  | → | s80sendmail  |
| S99linuxconf | → | s99linuxconf |
| S14nfslock   | → | s14nfslock   |

## LINUX NETWORK INTERFACES:

### Linux Interface Statistics:

#[netstat -i # netstat -taupe](#)

Linux Interfaces:      #[sbin/ifconfig -a](#)

## RESTRICTING NUMBER OF CONCURRENT LOGINS TO LINUX CS:

Modify following file to set maximum logins: 0 = 1 user, 1 = 2 users, etc.

/etc/security/limits.conf

naslock hard maxlogins 0

## RED HAT INTERFACE TROUBLESHOOTING:

### LINUX CONTROL STATION FILES RELATED TO EXTERNAL NIC:

/etc/sysconfig/network-scripts/ifcfg-eth2 [Network Device param file]

/etc/inittab [Verify that “id :3 :initdefault” set to bring system up to Run Level 3]

#[cat /etc/inittab |grep -i initdefault](#)

# 0 - halt (Do NOT set initdefault to this)

# 6 - reboot (Do NOT set initdefault to this)

id:3:initdefault:

/etc/rc3.d/S10network [Verify that this script is set to startup NIC devices—reads ‘ifcfg-eth2’ file to set params]

lrwxrwxrwx 1 root root 17 Feb 23 20:23 S10network -> ./init.d/network

/etc/modules.conf [Verify spd/duplexing on bootup ; options de4x5 io=0→100; options de4x5 args='eth2:fdx' →full duplex]

/var/log/messages [Grep ‘eth2:media’ message\* to see how interfaces actually came up ; “100Mb/s full duplex”]

→Use ping and /sbin/route to verify connectivity and gateway

#### **INTERNAL NICs:**

Similar to above: ifcfg-eth0/ifcfg-eth1 files—use ping and /sbin/route and /nas/sbin/getboxmask –r to troubleshoot

### **USING NETCONFIG UTILITY:**

# netconfig --device-eth2

# /sbin/service network status | stop | start

### **VERIFYING WHAT MODULES ARE LOADED ON LINUX:**

# /sbin/lsmod

| Module        | Size   | Used by                   | Not tainted |
|---------------|--------|---------------------------|-------------|
| nfs           | 71680  | 0 (autoclean)             |             |
| lockd         | 48800  | 0 (autoclean) [nfs]       |             |
| sunrpc        | 60400  | 0 (autoclean) [nfs lockd] |             |

| tulip         | 35008  | 1 →External Interface     |             |
| 3c509         | 6976   | 2 →Internal Interfaces    |             |
| ext3          | 57888  | 4                         |             |
| jbd           | 35972  | 4 [ext3]                  |             |
| aic7xxx       | 112288 | 7                         |             |
| sd_mod        | 10460  | 7                         |             |
| scsi_mod      | 54284  | 3 [sg aic7xxx sd_mod]     |             |

**Note:** In this case, shows NIC drivers that are loaded

### **SETTING LINUX 7.2 CS EXTERNAL NIC (NAS 4.1-5.3) TO FULL DUPLEX:**

Step 1. Verify the current driver installed by examining the /etc/modules.conf file, looking for the entry for “eth2”

\$ more modules.conf

```
alias parport_lowlevel parport_pc
options scsi_mod max_scsi_luns=16
alias scsi_hostadapter aic7xxx
alias eth0 tulip
alias eth0 3c509
alias eth1 3c509
alias eth2 de4x5      [new driver that replaces the tulip driver]
options de4x5 io=0
```

**Note:** Check /var/log/messages file for following entry: “betacs0 kernel:eth2:media is 100Mb/s”

Step 2. Replace the “options de4x5 io=0” line with the following:

**options de4x5 args='eth2:fdx' de4x5\_debug=1 [Full Duplex setting, debug setting]**

Step 3. Reboot Control Station and check /var/log/messages file for following entry:

“betacs0 kernel:eth2:media is 100Mb/s full duplex”

**Note:** This now indicates that the Control Station NIC is operating at 100 Full Duplex

### **NS CELERRA CS SHOULD HAVE INTERNAL INTERFACES SET AUTO-NEGOTIATE:**

#### **EXAMPLE OF AUTO-NEGOTIATE:**

eth0: negotiated 100baseTx-FD flow-control, link ok

eth1: negotiated 100baseTx-FD, link ok

### **ONE METHOD OF FORCING FULL DUPLEX ON CONTROL STATION EXT. INTERFACE:**

Step 1. Add following line to /etc/modules.conf file:

**alias eth2 tulip options=5 full\_duplex=1**

Step 2. Reboot

### **STOPPING & STARTING EXTERNAL INTERFACE FOR LINUX CS:**

#sbin/service network stop

#sbin/service network start

**Caution:** Executing the “network stop” option may induce CS Failover & CallHome if CS1 is configured

#ifdown eth2 ifup eth2

### **VERIFYING EXTERNAL NIC DRIVER FOR NS600/NS700 SYSTEMS:**

# /sbin/lsmod

eepro100 20592 2

# cat /etc/modules.conf

alias eth0 eepro100

alias eth0:0 eepro100

alias eth1 eepro100 →External interface for NS systems

# /sbin/mii-tool

eth0: negotiated 100baseTx-FD flow-control, link ok

eth1: no autonegotiation, 100baseTx-HD, link ok

### **VERIFYING OR CHANGING SPEED & DUPLEX SETTINGS ON NS600/700—ETH0/ETH1:**

# /sbin/mii-tool -V

mii-tool.c 1.9 2000/04/28 00:56:08 (David Hinds)

**eth0: negotiated 100baseTx-FD flow-control, link ok**

**eth1: negotiated 100baseTx-FD flow-control, link ok**

#/sbin/mii-tool -v

**eth0: negotiated** 100baseTx-FD flow-control, link ok

product info: Intel 82555 rev 4

basic mode: autonegotiation enabled

basic status: autonegotiation complete, link ok

capabilities: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD

advertising: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD flow-control

link partner: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD flow-control

**eth1: negotiated** 100baseTx-FD flow-control, link ok

product info: Intel 82555 rev 4

basic mode: autonegotiation enabled

basic status: autonegotiation complete, link ok

capabilities: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD

**Note:** File configuration will be different if Secondary Control Station is configured, as in NS700 systems  
cluster\_if:xxxxxx

**SETTING FULL DUPLEX LINUX CS ETH0/ETH1/ETH3 INTERFACE:**

1. **# /sbin/mii-tool -F 100baseTx-FD eth1**

**# /sbin/mii-tool -V**

eth1: 100 Mbit, full duplex, link ok  
2. Add following line to end of /etc/rc.d/rc.local

**/sbin/mii-tool -F 100baseTx-FD eth1**

**Note:** If having issues setting eth3 to FDX, see primus emc124296, and add following to /etc/modules.conf file:  
alias eth3 e1000

**options e1000 Speed=0,0,100 Duplex=0,0,2**

**RESETTING AUTO NEGOTIATE & FLOW CONTROL FOR ETH0/ETH1:**

**# /sbin/mii-tool -A -r**

Invalid media specification '-r'.

restarting autonegotiation...

restarting autonegotiation...

**# /sbin/mii-tool -V**

**eth0: negotiated 100baseTx-FD flow-control, link ok**

eth1: negotiated 100baseTx-FD flow-control, link ok

**# /sbin/mii-tool -A 100baseTX-FD eth1** (Setting Autonegotiate without Flow Control)

restarting autonegotiation...

**# /sbin/mii-tool -V**

mii-tool.c 1.9 2000/04/28 00:56:08 (David Hinds)

eth0: negotiated 100baseTx-FD flow-control, link ok

**eth1: negotiated 100baseTx-FD, link ok**

**NAS 5.6 CS INTERFACE UTILITY:**

**# /sbin/ethtool eth3**

Settings for eth3:

Supported ports: [ TP ]

Supported link modes: 10baseT/Half 10baseT/Full  
100baseT/Half 100baseT/Full  
1000baseT/Full

Supports auto-negotiation: Yes

Advertised link modes: 10baseT/Half 10baseT/Full  
100baseT/Half 100baseT/Full  
1000baseT/Full

Advertised auto-negotiation: Yes

Speed: 100Mb/s

Duplex: Full

Port: Twisted Pair

PHYAD: 0

Transceiver: internal

Auto-negotiation: on

Supports Wake-on: umbg

Wake-on: d

Current message level: 0x00000007 (7)

Link detected: yes

**# /sbin/mii-tool eth3 -v**

eth3: negotiated 100baseTx-FD, link ok

product info: vendor 00:aa:00, model 56 rev 0

basic mode: autonegotiation enabled

basic status: autonegotiation complete, link ok

capabilities: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD

advertising: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD flow-control

link partner: 100baseTx-FD 100baseTx-HD 10baseT-FD 10baseT-HD

**Note:** Above is a comparison of the two tools. Ethtool allows one to make very specific and extensive param changes.

## **PROBLEM WITH NS CONTROL STATIONS WITH INCORRECT INTERNAL NIC SETTING:**

If Control Station internal settings are not set as in the following example, then it's possible that NAS Services, and NBS partitions, will not be properly started and mounted:

# /sbin/mii-tool -V

eth0: negotiated 100baseTx-FD flow-control, link ok

eth1: negotiated 100baseTx-FD, link ok → Normal and desired to have CS auto-negotiate

eth0: 100 Mbit, full duplex, link ok → This setting is not o.k.

## **SETTING LINUX 6.2 CS EXTERNAL NIC (NAS 2.2) TO FULL DUPLEX:**

Step 1. vi /etc/modules.conf file and add following entry for Tulip Card

**alias eth2 tulip options=3 full\_duplex=1 [100 Full Duplex]**

0=Auto; 1=10M; 3=100M

### **Configuring External Linux CS Interface for Auto:**

#vi /etc/conf.modules >>> alias eth2 tulip full\_duplex=1

### **Forcing Full Duplex 100baseTX on External Linux CS Interface:**

#vi /etc/conf.modules >>> alias eth2 tulip options=3 full\_duplex=1

## **SETTING DEFAULT GATEWAY ON LINUX:**

#/sbin/route add default gw 192.10.3.254 [good until next reboot]

# vi /etc/sysconfig/network GATEWAY=192.10.3.254 (example of default route line)

# /sbin/route delete default gw 192.1.4.1 [to delete a default gw]

## **SETTING OR CHANGING CONTROL STATION IP, HOSTNAME, etc.**

### **I. SET-UP TEMPORARY CONTROL STATION IP & ROUTE:**

# /sbin/ifconfig eth3 192.1.4.250 netmask 255.255.255.0 broadcast 192.1.4.255

# /sbin/route add default gw 192.1.4.254

### **II. USE CELERRA MANAGER TO MAKE NETWORK SETTINGS & HOSTNAME PERMANENT:**

1. Go to Celerra Home>Control Station Properties: Set Hostname, IP Address, Netmask, Gateway, and any other pertinent network information, then click Apply

2. Reboot Control Station and login via SSH

## **USING CLI TO CONFIGURE INTERNAL IP ON LINUX:**

Step 1. Determine Interface Name for Linux: #cat /etc/sysconfig/network

“Networking=Yes Forward\_IPv4=False Hostname: c7cs0

Gateway: 193.1.21.254 Gateway\_Dev=eth2 [this is CS0] NSO=193.1.21.1”

Step 2. #cd /etc/sysconfig/network-scripts #more ifcfg-eth2 [configure accordingly]

“DEVICE=eth2 IPAddr=193.1.21.170 Netmask=255.255.255.0 Broadcast=193.1.21.255 Onboot=Yes”

## **USING SYSCTL TO TUNE LINUX:**

The ‘System Control’ interface can be used to tweak system variables found in /proc/sys

/proc/sys/net → Networking

/proc/sys/fs → File Systems

/proc/sys/vm → Virtual Memory

## **SETTING UP LINUX CS FOR ROUTING/GATEWAY:**

By default, we do not enable ip\_forward prior to NAS 5.5.30, meaning that for multi-homed systems, packets will not be routed between physical interfaces. In order to route or create a gateway between different physical interfaces on the same system, enable IP Forwarding using the following:

### **Method I.**

# echo 1 > /proc/sys/net/ipv4/ip\_forward

**Method II.**

**# /sbin/sysctl -w net.ipv4.ip\_forward=1**

**Note:** The above methods do not make the change persistent on reboots, however.

**MAKING IP FORWARD PERSISTENT:**

1. Add following string to /etc/sysctl.conf file

net.ipv4.ip\_forward = 1

2. # /sbin/sysctl -p /etc/sysctl.conf or # /sbin/service network restart

3. Alternatively, edit the following file and set IP Forwarding to “true”, and reboot system:

/etc/sysconfig/network

FORWARD\_IPV4=true

**Note:** With NAS 5.5.30 and higher, we now enable ip\_forwarding by default

**CHANGING DEFAULT PRIVATE LAN IP ADDRESSES ON NS600/700 INTEGRATED or GATEWAY NS600G/700G:**

**Note:** Internal IP Address change would not be applicable for Gateway models for SPA or SPB as a Public IP Address is assigned for web management, but Internal IP Address scheme may need change on Control Station and Data Mover subnets.

**RULES & LIMITATIONS FOR CHANGING INTERNAL IP ADDRESSES:**

→Must change the private network for Celerra systems if the customer is already using the default subnet for public network

→Default subnets are 192.168.1 and 192.168.2

→New subnet with NS700G 4-Way 192.168.3.xxx for IPMI [Intelligent Platform Management Interface] connection between dual Control Stations only

→Cannot change last octet of CS or DM Internal IP addresses, only first 3 octets [i.e., 100, 2, 3, 200, or 201]

→Must use standard Class C subnet masks—255.255.255.0

→All Primary private IP addresses need to be on the same subnet

**Note:** External IP Address of CS must be on same subnet as SPA/SPB and set to auto-negotiate

**DEFAULT PRIVATE NETWORK ADDRESSES**

emcnas\_i0 192.168.1.100

emcnas\_i1 192.168.2.100

server\_2 192.168.1.2

server\_2b 192.168.2.2

server\_3 192.168.1.3

server\_3b 192.168.2.3

SPA 192.168.1.200

SPB 192.168.1.201

1. Stop NAS Services

2. #mount /nbsnas /nas /nas/dos /nas/var

3. Edit following files to change CS Subnet address: /nas/site/nas\_param site\_param cs\_aliases

4. Edit following files to change CS & DM addresses: /nas/server/slot\_2/ifconfig eof nbs.cs.ro nbs.cs.rw export

5. Regenerate Data Mover Boot.cfg File on DM\_2:

**#/nas/sbin/build\_config /nas/server/slot\_2 /nas/dos/slot\_2**

6. Unmount /nas/dos /nas/var /nas /nbsnas

7. Stop NBS Service: **#/sbin/service nbs stop**

8. #mount /nas

9. Change IP Address of SP-A

**# /nasmdc/sbin/navicli -h 10.241.168.52 networkadmin -get**

Storage Processor: SP A

Storage Processor Network Name: nyip2spa

Storage Processor IP Address: 10.241.168.52

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 10.241.168.128

**#/nas/sbin/navicli -h SPA networkadmin -set -name <new name> -address <new IP> -gateway <new gateway> -subnetmask <new mask>**

**Note:** Storage System reboots

10. Wait for SPA to come up, then ping new address to verify, repeat steps for changing IP on SPB

11. Edit CS Network Files to change IP Addresses;

**#vi /etc/sysconfig/network-scripts/ifcfg-eth0 | ifcfg-eth0:0**

**Note:** Broadcast address must end with 255

12. Restart Network Services to put new Address Scheme into effect: **#/sbin/service network restart**

13. Edit /etc/hosts to change all addresses to new values

14. Update CS with New IP of DM\_2:

**# /nasmcd/sbin/t2tty -c 2 "ifconfig el30 dev=fxp0l=<new IP> b=<new broadcast> n=255.255.255.0"**

**# /nasmcd/sbin/t2tty -c 2 "ifconfig el31 dev=fxp0l=<new IP> b=<new broadcast> n=255.255.255.0"**

15. Set HTTP port of DM\_2:

**# /nasmcd/sbin/t2tty -c 2 "mac allow=<cs IP> : <cs backup> httpport=5080"**

16. Ping SP-A, SP-B, Server\_2, and Server\_2b to verify changes

17. #umount /nas

18. Repeat Steps for Slot\_3, if required

19. Synchronizes Control Station view of backend with the Storage Array Subsystem:

**# nas\_storage -sync id=1**

**Note:** If this command fails, try moving the symapi\_db.bin file aside, run nas\_diskmark -all, and then nas\_storage -sync

20. Reboot data movers and verify by pinging

21. Restart NAS Services: **#/sbin/service nas start**

**Note:** Changing Server output to local console, and restoring logging to Server Log

**# /nasmcd/sbin/t2tty -c 2 "logsys add output console"**

**# /nasmcd/sbin/t2tty -c 2 "logsys delete output console"**

### **RUNNING SCRIPT FOR SCREEN CAPTURE ON LINUX CS:**

**#cd; script or #script filename** [Begins file capture of screen session to file ‘typescript’} –Use ctrl + d to end script session

### **EXAMINING SW PACKAGES INSTALLED ON LINUX CS:**

**# rpm -qa |more**

**# rpm -qa --last** [Displays latest rpm packages installed on CS in order]

-----abridged-----
```

### **CREATING LINUX BOOT FLOPPY ON CONTROL STATION:**

```
#/sbin/mkbootdisk `uname -r`
```

Linux Chat Windows: talk; write; wall

### **Using Stat Command for File & Inode Information:**

Example: # stat /etc/motd

### **DETERMINING SUPERBLOCK INFORMATION ON LINUX CS VOL's—Red Hat 7.2:**

Note: Example is for /nas/var directory & must be unmounted to run command

```
# /sbin/mke2fs -n /dev/sdf1
```

```
mke2fs 1.26 (3-Feb-2002)
Filesystem label=
OS type: Linux
Block size=4096 (log=2)
Fragment size=4096 (log=2)
231360 inodes, 461860 blocks
23093 blocks (5.00%) reserved for the super user
First data block=0
15 block groups
32768 blocks per group, 32768 fragments per group
15424 inodes per group
Superblock backups stored on blocks:
         32768, 98304, 163840, 229376, 294912
```

Comment: Mke2fs command is used to create an ext2 file system

### **DUMPING INFORMATION ON PARTITIONS:**

```
# /sbin/dumpe2fs /dev/sda1
```

### **EASY METHOD FOR RUNNING FSCK ON ROOT PARTITION:**

```
# touch /forcefsck
```

```
# reboot
```

### **RUNNING FSCK ON LINUX CONTROL STATION ROOT VOLUME:**

1. In Dual Control Station environments, log into CS1, unmount partition, and run command

```
# /sbin/e2fsck -f -y -v /dev/sdc3
```

Caution: Do not run this command without seeking a 2<sup>nd</sup> opinion!

2. Alternatively, if single Control Station, boot to single user mode, or unmount volume and run e2fsck

Comment: e2fsck is used to FS Check a linux second extended FS

## **RUNNING FSCK ON DOS PARTITION:**

```
# /sbin/fsck -t msdos -V -v -l /dev/nd1
```

## **CHANGING LINUX PART. TO EXT2 SO AS TO RUN FSCK:**

### **EXAMPLE:**

Control Station can see all NBS partitions, but cannot fsck /dev/nde1 (nbsnas)--error SIGSEGV

Feb 9 16:26:56 scosnas01 **kernel: EXT3-fs: invalid journal inode.**

Feb 9 16:26:56 scosnas01 mcd\_helper: : Failed to mount /nbsnas (32)

Feb 9 16:26:56 scosnas01 EMCServer: nas\_mcd: File system mount(s) failed - exiting

Feb 9 16:26:56 scosnas01 EMCServer: nas\_mcd: Slot 0 exiting

### **1. Verify File System partition info:**

```
# /sbin/dumpe2fs /dev/ndf1
```

dumpe2fs 1.26 (3-Feb-2002)

Filesystem volume name: <none>

Last mounted on: <not available>

Filesystem UUID: b19939df-f59d-4297-9b16-0764f88126aa

Filesystem magic number: 0xEF53

Filesystem revision #: 1 (dynamic)

Filesystem features: **has\_journal** filetype needs\_recovery sparse\_super

Filesystem state: clean

Errors behavior: Remount read-only

Filesystem OS type: Linux

### **2. Remove Journal File System type:**

```
# /sbin/tune2fs -O"!^has_journal" /dev/ndf1
```

tune2fs 1.26 (3-Feb-2002)

### **3. Verify:**

```
# /sbin/dumpe2fs /dev/ndf1
```

dumpe2fs 1.26 (3-Feb-2002)

Filesystem volume name: <none>

Last mounted on: <not available>

Filesystem UUID: 625050cd-4287-4cd0-8ec0-5587dcb4e0ea

Filesystem magic number: 0xEF53

Filesystem revision #: 1 (dynamic)

Filesystem features: filetype sparse\_super

### **4. FSCK File System:**

```
# /sbin/fsck /dev/ndf1
```

fsck 1.26 (3-Feb-2002)

e2fsck 1.26 (3-Feb-2002)

/dev/ndf1: clean, 2468/231360 files, 75301/461860 blocks

### **5. Recreate the Journal EXT3 File System Type:**

```
# /sbin/tune2fs -j /dev/ndf1
```

tune2fs 1.26 (3-Feb-2002)

Creating journal inode: done

This filesystem will be automatically checked every 20 mounts or 180 days, whichever comes first.

## **LINUX FILE SYSTEM DEBUG COMMAND:**

```
# /sbin/debugfs /dev/nde1
```

debugfs 1.26 (3-Feb-2002)

debugfs: stat <8>

Inode: 8 Type: regular Mode: 0600 Flags: 0x0 Generation: 0

User: 0 Group: 0 Size: 33554432

File ACL: 0 Directory ACL: 0

Links: 1 Blockcount: 65616

## **PROCEDURE TO USE WHEN FSCK'ing ROOT FILE SYSTEM ON LINUX:**

1. Boot from floppy & select “command prompt”
2. #cd /dev and type #mknod sda b 8 0 #mknod sda1 b 8 1 #mknod sda2 b 8 2 #mknod sda3 b 8 3
3. #fdisk /dev/sda & p to print out Partition Table

Ensure partitions look as follows: Then type q to quit

|           |    |     |         |    |            |
|-----------|----|-----|---------|----|------------|
| /dev/sda1 | 1  | 1   | 8001    | 83 | Linux      |
| /dev/sda2 | 2  | 18  | 136552+ | 82 | Linux swap |
| /dev/sda3 | 19 | 264 | 1975995 | 83 | Linux      |

4. Run FSCK: **#e2fsck -p /dev/sda3**

5. Mount Root: #mount /dev/sda3 /mnt

6. Verify size of “init” file: #cd /mnt/sbin;ls -la init [Size should be 25968 & file should be executable]

7. #cd / & umount: #exec umount /mnt

## **RUNNING FSCK ON NAS WHEN CS CANNOT MOUNT:**

**Note:** Stop NAS Services first

**# /sbin/fsck -t ext3 -y /dev/hda5**

fsck 1.26 (3-Feb-2002)

e2fsck 1.26 (3-Feb-2002)

/dev/hda5 has gone 189 days without being checked, check forced.

Pass 1: Checking inodes, blocks, and sizes

Error reading block 65659 (Attempt to read block from filesystem resulted in short read) while doing inode scan. Ignore error? yes

Pass 2: Checking directory structure

Pass 3: Checking directory connectivity

Pass 4: Checking reference counts

Pass 5: Checking group summary information

/dev/hda5: 6818/262144 files (1.5% non-contiguous), 154703/524112 blocks

**# /sbin/fsck -t ext3 -y /dev/hda5**

**Note:** Ran fsck again, and was clean

## **RUNNING FSCK ON CS0 FROM CS1:**

1. Power down CS0 #/nas/sbin/t2reset pwroff -s 0

2. Identify Root & Boot partitions on CS0: #cat /nas/dos/slot\_0/boot.bat

**CS0=/dev/sdc1 for boot & /dev/sdc3 for root**

**CS1=/dev/sdd1 for boot & /dev/sdd3 for root**

3. Run FSCK on boot & root partitions:

#/sbin/e2fsck -y -p /dev/sdc1

4. Mount root and boot partitions:

#mount /dev/sdc3 /mnt #mount /dev/sdc1 /mnt/boot #umount /mnt/boot

5. Powerup CS0: **#/nas/sbin/t2reset pwron -s 0**

## **FAILED 2.2 – 4.2 UPGRADE, RESULTING IN BAD JOURNAL FS:**

1. If CS1 is available, run following steps from CS1 against CS0’s Boot & Root File Systems

2. If running from CS0, unmount /nas partition first

3. Remove journal from device to FSCK:

**# /sbin/tune2fs -O ^has\_journal /dev/sdc3**

4. Run FSCK:

**# /sbin/e2fsck -f -y /dev/sdc3** [Run until fsck runs clean]

5. Mount Device:

#mount /dev/sdc3 /mnt

#mount [Run command to verify ext2/ext3]

6. Run command to create new Journal:

**# /sbin/tune2fs -j -c 60 /dev/sdc3**

7. #umount /mnt and verify that device reflects ext3 journaling

8. Repeat above steps for /boot file system if required

9. #cat /etc/fstab to verify ext3 journaling on both CS0 & CS1 side

10. Vi edit /etc/fstab to change file systems from ext2 to ext3

11. Verify internal IP address scheme

## **VERIFYING CONSISTENCY OF LINUX MOUNTPOINTS:**

**# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/sdc3  | 1.5G | 1.1G | 400M  | 72%  | /          |

```
/dev/sdc1      30M 4.3M 24M 15% /boot
server_3:/    126M 13M 113M 11% /mnt
/dev/sde1      1.7G 683M 1003M 41% /nas
/dev/sda1      133M 126M 7.7M 95% /nas/dos
/dev/sdf1      1.7G 61M 1.5G 4% /nas/var
```

### #df -T \*

Displays partition types

```
# /sbin/dumpe2fs /dev/sdc1
```

dumpe2fs 1.26 (3-Feb-2002)

Filesystem volume name: /boot

Last mounted on: <not available>

Filesystem UUID: ed10b020-1683-11d7-85c4-a44a2b288208

Filesystem magic number: 0xEF53

Filesystem revision #: 1 (dynamic)

Filesystem features: has\_journal filetype needs\_recovery sparse\_super

Filesystem state: clean

Errors behavior: Panic

Filesystem OS type: Linux

Inode count: 8032

Block count: 32098

Reserved block count: 1604

-----output abridged-----

## Opening Up Multiple "X-Term" Sessions on Linux Control Station from Commandline:

Alt + F1 or F2 keys to toggle between sessions

## Creating Files on Linux File System:

```
# dd if=/dev/zero of=jeff1 bs=1024 count=1000
```

## USING TAR TO ARCHIVE & UNARCHIVE FILES & DIRECTORIES:

```
# tar -cvf usrmap.tar * [Creates tar file of all unhidden files from current directory]
```

```
# tar -xvf usrmap.tar [Untars file in present directory]
```

```
# tar -tvf usrmap.tar [Use this command to list the contents of a Tar file]
```

## TARRING AND GZIPPING IN ONE OPERATION:

```
# tar -zcvf usrmap.tar.gz [Tarring up directory and zipping]
```

```
# tar -zxvf usrmap.tar.gz [Unzipping and untarring directory]
```

## EXTRACTING AN ARCHIVE FILE:

```
# tar -xf archive.tar
```

## TARRING SEVERAL FILES BUT NOT ALL:

```
# tar cvf /home/nasadmin/tartest.tar a b c
```

## TARRING ALL FILES FROM A DIRECTORY BUT NOT IN SUBDIRECTORIES:

```
# tar cvf autoupload.tar --exclude="*/\/*" autoupload/
```

Note: Will tar all contents of autoupload directory but no subdirectories

## TARRING ALL FILES IN A PARTICULAR DIRECTORY, INCLUDING SUBDIRS:

```
# tar cvf support_materials.070117_1616.tar fcs01.070117_1616/*
```

Note: Above command creates a support\_materials filename and tars all log files and directories underneath the fcs directory

## TAR SWITCHES:

-t Listing contents of tar file

-f append contents to existing tar file

-u append only newer files to existing archive

-v verbose

-x Extracting

-c Create an archive file

-f File=ARCHIVE

-z Zip or Unzip a gzip file at same time as tarring or untarring

-Z compress

## **SETTING UP NFS FTP SERVICE ON DATA MOVER:**

Step 1. #server\_user server\_2 -add -passwd ftpuser

User ID: 102

Group ID: 101

Home Directory: /home/nasadmin

New Passwd: xtra10

Retype New Passwd: xtra10

**Note:** This procedure encrypts the password and places the passwd file automatically onto the datamover for “ftpuser”

Step 2. FTP to the IP address and log in to test account

## **SETTING UP PASSWD FILE--Linux DataMover, using "server\_user" command:**

For NAS Versions 2.2+: Linux uses MD5 encryption, must use #/nas/sbin/server\_user utility

### **CREATING USER CALLED NDMP AND POPULATION DATA MOVER's ./etc/passwd FILE:**

# **/nas/sbin/server\_user server\_2 -add -md5 -password ndmp**

User ID: 102

Group ID: 101

Home Directory: /home/nasadmin

New Passwd: ndmpndmp →Min. passwd length 7 characters

Retype New Passwd: ndmpndmp

**Note:** This procedure encrypts the password and appends the entry to the passwd file on the datamover

## **SETTING UP USER ACCOUNTS ON LINUX:**

1. Create Account: # **/usr/sbin/adduser -u uid -g gid -G secondarygid -d /usr/user1 user1**

2. Set Environmentals: # **cp /home/nasadmin/.bash\_profile /usr/user1**

## **CREATING NEW USER ACCOUNT ON LINUX CS WITH NASADMIN PRIVILEGES:**

1. Create User Account: # **/usr/sbin/useradd**

2. Change Passwd: # **passwd newuser**

3. Assign ‘newuser’ to NASADMIN Group 201: # **/usr/sbin/usermod -G 201 newuser**

## **SERVER USER COMMAND OPTIONS:**

\$server\_user server\_x -l [Outputs what is in the passwd file]

\$server\_user server\_x -m username [Edit an existing user's passwd entry]

\$server\_user server\_x -a -p newuser

## **MISCELLANEOUS TOPICS:**

### **Using Telnet to Linux Control Station:**

Problem: Cannot connect using Telnet or takes a long time

Fix: 1. Add Hostname and IP address of Client to CS /etc/hosts file.

2. Check /etc/resolv.conf file for errant entry for Domain [delete entry]. What happens is that an incorrect entry causes session to timeout, at which point it went to its Default Gateway, and then found a Name Resolution.  
\$netstat -r will show the route table it uses

3. Other option is to edit /etc/rc.d/rc.local file and add to bottom of file: “/bin/ping -c 1 193.1.21.200””

## **CELLERRA WATCHDOG TIMER:**

**Note:** Celerra uses a single wdog thread for each physical data mover, to monitor all cpu tasks/processes. Purpose of the wdog time is to watch for runaway processes due to lost CPU, hung threads, sluggish threads, lock contention, long structures, looping structures, or memory corruption.

→wdog sleeps for 1 second, then checks all processes on all CPUs, then goes to sleep, and repeats the cycle, setting a memory flag status on each process to complete when done. If the process cannot be checked complete, then when the NMI Handler fires (every 4 seconds), and finds an incomplete check, it will panic the Server.

→NMI is a Non-Maskable Interrupt which checks the results of the WatchDog timer, every 4 seconds, and panics the DM if the processes have not been successfully checked by Watchdog

→Memory Flags are what is used by wdog timer when checking all processes

→Watchdog Timer below 5.2 code is set at 120 seconds

→Watchdog Timer for NAS 5.2 code and higher is set at 4 seconds, with 30 second variation during bootup

## **SETTING WATCHDOG TIMEOUT VALUE ON LINUX CONTROL STATION:**

**Note:** Control Station fibre HBA is sensitive to fibre channel connectivity and may reboot if Zone change or other activity occurs that might cause a temporary loss of connectivity to the fabric.

1. Edit /etc/inittab
2. wd:3:respawn:/nasmcd/sbin/nas\_watchdog -f /dev/raw/raw1 **-t 90** [Add value to increase timeout value to 90 secs]

## **DISABLING WATCHDOG ON DM:**

**# .server\_config server\_x -v “sched watchdog stop”**

**Note:** Watchdog Timers are used to monitor threads in progress—if threads are not making any progress, i.e., are stuck in a loop, the Watchdog could panic the Server, etc.

## **FINDING WWN OF FIBRE CONTROL STATION FOR QLOGIC & EMULEX:**

### **EMULEX:**

**# ls -l /proc/scsi**

```
dr-xr-xr-x 2 root root 0 Sep 18 08:40 lpfc
```

**# cat /proc/scsi/lpfc/0**

Emulex LightPulse LPFC Driver Version: 4.21g.EMC

HBA: Emulex LightPulse LP8000 1 Gigabit PCI Fibre Channel Adapter

SerialNum: 0000c9266446

Firmware Version: 3.82A1

Hdw: 2002506d

VendorId: 0xf80010df

Portname: 10:00:00:00:c9:26:64:46 Nodename: 20:00:00:00:c9:26:64:46

Link Up - Ready:

PortID 0x21900

Fabric

Current speed 1G

lpfc0t00 DID 021300 WWPN 50:06:01:60:10:60:05:10 WWNN 50:06:01:60:90:60:05:10

**# cat /proc/scsi/lpfc/1**

Emulex LightPulse LPFC Driver Version: 4.21g.EMC

HBA: Emulex LightPulse LP8000 1 Gigabit PCI Fibre Channel Adapter

SerialNum: 0000c9266449

Firmware Version: 3.82A1

Hdw: 2002506d

VendorId: 0xf80010df

Portname: 10:00:00:00:c9:26:64:49 Nodename: 20:00:00:00:c9:26:64:49

Link Down

**Note:** Above example shows HBA0 & HBA1 ports on CS0 for Emulex driver. Rules for CNS14 & CFS14 are that only HBA0 should be zoned to the backend, and to SPA for Clariion arrays. Port 1 should NOT be attached.

### **QLOGIC:**

**# ls -l /proc/scsi**

```
dr-xr-xr-x 2 root root 0 Sep 18 08:46 qla2x00
```

**# cat /proc/scsi/qla2x00/0**

QLogic PCI to Fibre Channel Host Adapter for ISP2100/ISP2200/ISP2300:

Firmware version: 2.02.03, Driver version 4.47.18.EMC.2

Entry Address = e0817060

Host adapter: loop state= <READY>, flags= 0x20e0001

----output abridged-----

SCSI Device Information:

scsi-qla0-adapter-node=200100e08b246706;

scsi-qla0-adapter-port=210100e08b246706;

scsi-qla0-target-0=50060482bc019584;

**# cat /proc/scsi/qla2x00/1**

QLogic PCI to Fibre Channel Host Adapter for ISP2100/ISP2200/ISP2300:

Firmware version: 2.02.03, Driver version 4.47.18.EMC.2

Host adapter: loop state= <DOWN>, flags= 0x2060000

-----output abridged-----

SCSI Device Information:

scsi-qla1-adapter-node=200000e08b046706;

scsi-qla1-adapter-port=210000e08b046706;

**Note:** CNS14 & CFS14 should not use Port 1, HBA1, to connect to Symm or Clariion backends. Link should be down for Port 1 and should NOT show any targets configured—see above for proper output and configuration.

**FINDING WWN OF DATAMOVER:**

**\$server\_log server\_3 | grep -i wwn**

2005-01-27 08:50:11: CAM: 4: FCP ONLINE HBA 0: S\_ID 690813 WWN: 10000000c939ed01

2005-01-27 08:50:17: CAM: 4: FCP ONLINE HBA 1: S\_ID 610813 WWN: 10000000c939ed02

**# .server\_config server\_2 -v "fcp show"**

FCP ONLINE HBA 0: S\_ID 690813 WWN: 10000000c939ed01 LP9000 2 GHz →**S\_ID** represents Data Mover WWN

FCP scsi-0: HBA 0: D\_ID 691113 FA-02cb: 5006048accef60e1 Class 3 →**D\_ID** represents WWN for Symmetrix FA

FCP scsi-16: HBA 0: D\_ID 691413 FA-15cb: 5006048accef60ee Class 3

FCP ONLINE HBA 1: S\_ID 610813 WWN: 10000000c939ed02 LP9000 2 GHz

FCP scsi-32: HBA 1: D\_ID 610e13 FA-15ca: 5006048accef60ce Class 3

FCP scsi-48: HBA 1: D\_ID 611513 FA-02db: 5006048accef60f1 Class 3

**STOPPING/STARTING BOX MONITOR/NASMCD ON LINUX CONTROL STATION:**

**#/etc/rc.d/rc3.d/S95nas stop [start]** [Linux Red Hat 7.2]

**#/etc/rc.d/init.d/nas stop | start** [Works with Red Hat 7.2]

**#/sbin/services nas start** [Permission denied on Red Hat 7.2]

**Caution:** This will unmount /nas, /nas/dos, & /nas/var File Systems!! Remount manually if you need to run commands!

**Verify:** nas\_mcd & boxm processes are stopped

**#ps -ef |grep nas\_mcd**

root 11348 1 0 10:45 ? 00:00:00 /nasmcd/nas\_mcd -h /nasmcd /nas/

**#ps -ef |grep boxm**

root 11855 11504 0 10:45 ? 00:00:00 /nas/sbin/nas\_boxmonitor /nas -i

**MOUNTING LINUX CS TO DM:**

**#mount -a -F nfs 172.19.32.10:/fs1 /mnt**

**#df -k** #cd /mnt #cp -f -R /. [forces a copy of all files into the current working directory]

**COPYING FILES FROM (1) DATAMOVER TO ANOTHER USING CONTROL STATION:**

**#mount 192.168.1.4:/ /mnt** [Mounting to Internal IP address of Servers 4 & 5]

**#mount 192.168.1.5:/ /mnt1**

**#cd /mnt/todd/folder1** #cp /mnt1/jeff1/\* . & [Copying contents from Jeff1 to folder1]

**Linux Device Tables:** /etc/fstab

**CD-ROM Directory:** /dev/cdrom

**Floppy Directory:** /fd0

**MOUNTING LINUX CONTROL STATION TO CD-ROM:**

**# mount /dev/cdrom /mnt/cdrom or #mount -ro /dev/cdrom /mnt/cdrom**

**Unmounting CD-ROM:** # umount -a /mnt/cdrom

**Mounting CD-ROM to Linux Control Station :**

**# mount -t iso9660 /dev/cdrom /mnt/cdrom** #cd /mnt/cdrom;ls

**# mount -rt iso9660 /dev/cdrom /mnt/cdrom**

**UPGRADING CELERRA USING USB FLASH DRIVE & ISO IMAGE ON NS40**

**USING USB FLASH DRIVE TO TRANSFER NAS ISO IMAGE TO CONTROL STATION:**

1. Plug USB Flash Drive into USB port on front side of Control Station [located underneath the serial port]

2. Run Fdisk to verify the discovered device type:

**# /sbin/fdisk -l**

/dev/sda1 1 992 999813+ 6 FAT16

**# df -h**

usbdevfs /proc/bus/usb type usbdevfs (rw)

3. Create mountpoint for USB device:

# **mkdir -p /mnt/usb**

4. Mount the Flash Drive to the Control Station

# **mount /dev/sda1 /mnt/usb**

5. Copy the ISO image from the Flash Drive to a partition with enough available space (about 550MB needed)

# **cd /mnt/usb**

# **cp emcnas5.5.31.6.iso /iso**

6. Unmount Flashdrive and physically remove from the Control Station

# **umount /mnt/usb**

### **MOUNTING NAS ISO IMAGE ON LINUX CONTROL STATION:**

1. Mount the ISO image to the mountpoint defined above [/mnt/usb]

# **mount -t iso9660 -o loop /iso/emcnas5.5.31.6.iso /mnt/usb**

2. Perform NAS Upgrade from the ISO image

# **cd /mnt/usb/EMC/nas;/setup**

**Note:** After upgrading Linux kernel, system will require a reboot. Perform steps 1-2 again after the system has rebooted.

### **MOUNTING LINUX FLOPPY DRIVE:**

# **mount -t msdos /dev/fd0 /mnt/floppy #cd /mnt/floppy;ls**

### **MOUNTING CS1 FROM CS0 FOR COPYING FILES BACK & FORTH:**

**Note:** Only prerequisite is that you know what the path is for the root “/” partition of the control station that you want to mount. Sdd3 & sdc3 are normal partition names for CS1 & CS0, respectively for Red Hat 7.2

# **mount /dev/sdd3 /mnt [Mounts root partition of CS1]**

# **mount /dev/sdc3 /mnt [Mounts root partition of CS0]**

**Permanently Mounting DataMover 'rootfs' to Linux Control Station:** #mount 172.19.31.4:/ /mnt

**Note:** Linux assumes the filesystem "type" [-t nfs] is "nfs" unless otherwise specified

Remember to "# umount /mnt" after you are completed

### **COPYING FROM FLOPPY:**

**Copying Floppy to Control Station:** # dd if=/dev/fd0 of=/tmp/floppy bs=1024 [copies contents of floppy]

**Copying from Control Station to Floppy:** # dd if=/tmp/floppy of=/dev/fd0 bs=1024

**Copying Files From Floppy to Control Station:** #cp \* /scripts

# mount [Floppy Mount Listed: “/dev/fd0 on /mnt type msdos (rw)”]

**Unmounting the Floppy Drive:** # **umount -a /mnt/floppy** [not real clean, gives error, but does umount]

### **FORMATTING FLOPPY DISK ON LINUX:**

# fdformat /dev/fd0H1440

# mformat a:

# mc当地 ks.cfg a:ks.cfg

### **LOGGING IN AS ROOT USING LINUX PROFILE:**

\$su -

### **LOGGING IN AS ROOT USER VIA MODEM CONNECTION:**

Add the following line to the /etc/security file

ttys0

### **RECOVERING ROOT PASSWD IF ACCESS TO LILO PROMPT ON LINUX CS:**

Step 1. Reboot Control Station and at LILO: screen, type “linux single” without quotes

Step 2. # passwd root

Step 3. Enter new root password and reboot: # shutdown -r now

### **RECOVERING ROOT ACCESS TO LINUX CS IF MISSING PASSWORD & NO LILO SCREEN:**

Step 1. Boot from linux floppy and insert Installation CD-ROM when prompted

Step 2. Select <alt--f2> option on list and it will bring you to a "bash#" prompt

Step 3. #mknod /dev/sdc3 8 35

Step 4. #mkdir /mnt

Step 5. #mount /dev/sdc3 /mnt

Step 6. #cd /mnt/etc

Step 7. #vi shadow file and delete the encrypted portion of the root user's password line [root : :] and save

Step 8. Reboot Control Station and login normally as User "nasadmin"

Step 9. \$su

    Password: newpasswd [Just type in a new password]

### **RESETTING ROOT PASSWORD ON LINUX CS:**

1. Press F5 key at end of HBA discovery on screen [Starting MSDOS...]

2. c:>rescue [Type "rescue" to enter Linux rescue mode]

3. #mkdir /mnt/tmp   #mount /dev/sdc3 /mnt/tmp [Mount root of linux to temporary mountpoint]

4. #cd /mnt/tmp/etc

5. #vi passwd and delete password field for nasadmin and root

6. Save and reboot CS

### **USING STRACE COMMAND ON LINUX TO TRACE COMMAND OUTPUT:**

# strace -F -o trace4 server\_export server\_4 [outputs file named "trace4" for server\_export command]

# strace -f -usrmapstart.out /etc/rc.d/rc3.d/S99usrmap start &

# strace -o /tmp/aaa -f server\_export server\_2 -p -u -P cifs -n testshare

### **EXTREMELY USEFUL DEBUG OF SHELL SCRIPTS ON LINUX:**

# /bin/sh -x nas\_version

```
+ ECHO=/bin/echo -e
+ get_kit
+ /bin/echo -e /nas
+ grep emctst
+ '[' 1 = 0 ']'
+ '[' -d /nas_standby ']'
+ kit=emcnas
+ PKG_DB=/var/sadm/pkg/emcnas
+ HOME=/root
+ export HOME
+ SQUERY=/bin/rpm --qf '%{VERSION}-%{RELEASE}' --dbpath /var/sadm/pkg/emcnas -q
+ LQUERY=/bin/rpm --dbpath /var/sadm/pkg/emcnas -qi
+ parse_args
+ '[' -d /nas_standby ']'
+ /bin/rpm --qf '%{VERSION}-%{RELEASE}' --dbpath /var/sadm/pkg/emcnas -q emcnas
5.1.9-4+ /bin/echo -e
```

**Comment:** Echoes result of script as it runs

### **NEW TOOL FOR SHOWING SERVER THREADS:**

Step 1. #cd /nas/tools

Step 2. #ln -s mac\_db \_mac\_db

Step 3. #./\_mac\_db server\_2

>show thread   >show thread /SMB030 [shows partial stack trace of code]

>quit

### **USING STRACE ON LINUX TO TRACE PROCESS:**

\$strace -o ch.trace -p <PID #>

### **USING WATCH COMMAND TO MONITOR COMMAND OUTPUTS:**

# watch -n 10 server\_sysstat server\_2

Every 10s: server\_sysstat server\_2                          Mon Jul 28 20:34:26 2003

server\_2 :

```
threads runnable = 3
threads blocked = 201
threads I/J/Z = 1
memory free(kB) = 189599
cpu idle_% = 99
```

**Note:** Command will execute every 10 seconds and output to screen continuously until interrupted [default = 2secs updates]

### **ADDING USERS/GROUPS TO LINUX CS:**

#**/usr/sbin/useradd -u 102 -g 101 -d /home/nasadmin -s /bin/bash -p xtra10 iisroot**

Explanation:      UID=102  
                  GID=101  
                  -d=Home Directory  
                  -s=shell type  
                  -p=password field  
Last Entry=new user "iisroot"

#**/usr/sbin/groupadd -g 101 officemax**

**Note:** These commands will update the respective /etc/passwd; /etc/shadow; /etc/group; and /etc/shadow files on the Control Station

### **NFS “CHOWN” OR “CHGRP” COMMAND FAILS TO EXECUTE:**

For Users other than “root”, symptoms are that Client Unix system Users try changing ownership on files located on a remote mount on the Celerra and receive message indicating that Users or existing Owners of files do not have rights to change them:

#### **EXAMPLE:**

\$imisd8:/home/damnypd2>**chown admin:admin test**

**test: Not owner**

Similar operation conducted from NFS Clients to HP-UX11 remote filesystem succeeds. By default Celerra supports POSIX file systems which do not allow the above "chown" or "chgrp" operations to succeed when issued by any User other than "Root".

To disable POSIX compliance and enable "chown" to work for non-root Users, add following param to DM and Reboot:

**param filesystem rstchown=0**

**Note:** Default Celerra value is rstchown=1

### **CHANGING USER/GROUP OWNERSHIP ON LINUX:**

```
# ls -la
-rw-rw-r-- 1 root    root      0 Mar 15 11:07 um_group
-rw-rw-r-- 1 root    root      0 Mar 15 11:07 um_user
# chown nasadmin:nasadmin um_group um_user
#ls -al
-rw-rw-r-- 1 nasadmin nasadmin   0 Mar 15 11:07 um_group
-rw-rw-r-- 1 nasadmin nasadmin   0 Mar 15 11:07 um_user
```

**Note:** Chown command changes ownership

### **Changing Group Permissions on Files for Whole Directories:**

Step 1. Changing Group Permissions from Group 555 to 8 on the /mnt directory

Step 2. #find /mnt -group 555 | xargs chgrp 8

Step 3. Update /etc/group file if required

### **CHANGING OWNERSHIP RECURSIVELY FROM SPECIFIED PATHPOINT:**

# **find /mnt/32bitfs01/0/GRPF-KPC-4-15-03/n4copy -user 543 |xargs chown 683**

# **find /mnt/32bitfs01/0/GRPF-KPC-4-15-03/n4copy -group 110543 |xargs chgrp 4196**

**Note:** Command executes find of all users with UID of 110543 in the specified path, then changes ownership to 4196

### **FINDING UIDs/GIDs AND DUMPING TO FILE FROM A FILESYSTEM:**

# find /mnt/32bitfs01/0/GRPF-KPC-4-15-03/n4copy -user | -group 4196 >/home/nasadmin/tm/n4copy.users

### **Changing NFS Permissions on a File, Directory, Mountpoint using chmod:**

Examples show how to “chmod” a DataMover Mountpoint called ‘chmod’:

# **chmod 644 chmod**

```
# ls -la
drw-r--r-- 2 root    root      512 Jul 11 14:09 chmod
# chmod 777 chmod
# ls -la
drwxrwxrwx 2 root    root      512 Jul 11 14:09 chmod
```

### **NAS 5.5 COMMAND TO GRACEFULLY SHUTDOWN CONTROL STATION & DATA MOVERS:**

# **/nasmd/sbin/nas\_halt now**

\*\*\*\*\* WARNING! \*\*\*\*\*

You are about to HALT this Celerra including all of its Control Stations

and Data Movers. DATA will be UNAVAILABLE when the system is halted.

Note that this command does \*not\* halt the storage array.

ARE YOU SURE YOU WANT TO CONTINUE? [ yes or no ] : yes

Sending the halt signal to the Master Control Daemon...: Done

Jul 31 08:15:10 nx4-2 EMCServer: nas\_mcd: Check and halt other CS...: Done

-----abridged-----

Jul 31 08:16:23 nx4-2 EMCServer: nas\_mcd: Halting all servers...

**Note:** Do not use this command if there are established IP Replication sessions as it will abort the sessions. Bug prevents complete shutdown of NS600/500/700 platforms—see AR122586.

## **DATAMOVER NAMING:** (2) files that deal with server names

**\$server\_name ALL**

**\$more /nas/server/servers**

1:server\_2:1000:1:2::0:2:

2:server\_3:1000:1:3::0:3:

3:server\_4:1000:1:4::0:4:

4:server\_5:1000:4:5::0:5:

5:server\_6:1000:1:6::0:6:

6:server\_7:1000:1:7::0:7:

**\$more /nas/server/slot\_x/hostname**

hostname server\_2 selfid=2

## **CHANGING SERVER NAME:**

**\$server\_name server\_4 coyote**

**Note:** This command correctly updates the "hostname" and "servers" file as referenced above. Keep in mind that the output of this command is from DM memory and could be different from the /nas/server/servers file and /nas/server/slot\_x/hostname file. If the output of server\_name shows a discrepancy, yet both the “servers” and “hostname” files are correct, then the name is being retained in memory and will be cleaned up during next reboot.

## **CELERRA COLLECTION SCRIPT REQUIRED FOR ESCALATIONS:**

NAS 5.3.20 & 5.4.18 contain the EE collection script in [/nas/tools/collect\\_support\\_materials](#) (current version 2.9.3)

**/nas/var/emcsupport/support\_materials\_APM00081800233.090513\_1019.zip**

For NAS issues requiring Clariion backend analysis, run the [/nas/tools/.get\\_spcollect](#) script and engage Clariion Support—puts the zipped file in /nas/var/log directory

Zipping all spcollect zip files in one SPCOLLECT.zip file and putting it in the /nas/var/log directory...

adding: SL7E1081700022\_SPA\_2009-05-13\_17-24-18\_21009f\_data.zip (stored 0%)

adding: SL7E1081700022\_SPB\_2009-05-13\_17-27-00\_21004a\_data.zip (stored 0%)

**Note 1:** The /nas/tools/.get\_spcollect script is found with NAS 5.4., 5.5., 5.6

**Note 2:** With the advent of the automatic log collection & transfer utility, now running with NAS Versions 5.5.21.4 or 5.4.25.1 and higher, the collect\_support\_materials script is invoked automatically for Celerra CallHome events, as is the panic dump collection.

See emc135846. Beginning with NAS 5.5.27.5, the Log Collection, and the Transfer feature, can be enabled or disabled from Celerra Manager. When the “transfer” feature is enabled, and a CallHome event occurs that triggers an Auto Log Collection & Transfer, the following text will be written to the CSI “SR” case, which is generated by the CallHome XML header file:

<![CDATA[Check FTP server host 168.159.216.19, in remote\_directory /incoming/APM00055103645 for possible log/dump uploaded as the result of this event

## **COLLECT SUPPORT MATERIALS COLLECTION DIRECTORIES:**

/nas/var/log and /nas/var/dump for all code versions prior to NAS 5.6

/nas/var/emcsupport and /nas/var/dump for NAS 5.6 and higher

## **COLLECT SUPPORT MATERIALS CHANGE VERSION 2.8 NAS 5.5.27.x:**

**Note:** With GrandNapa and version 2.8 the /nas/tools/collect\_support\_materials script will change from a tar.gz to .zip extension, the idea being to use better compression during the log collection process. This change should not seriously impact support folks, as the Surge escalation tool and Log Parsing Tool should be able to handle collections with either extension, but it will require additional knowledge about how to use Linux zip, unzip, zipgrep, and zipinfo utilities.

### **Example of Old vs New:**

**# tar -tzvf support\_materials\_ML2809000146.070309\_1003.tar.gz |grep -v "drw" |wc -l**

1081 (files)

-rw-r--r-- 1 root root 3760171 Mar 9 10:14 support\_materials\_ML2809000146.070309\_1003.tar.gz

**# zipinfo -t support\_materials\_ML2809000146.070309\_0940.zip**

1097 files, 24894903 bytes uncompressed, 3654736 bytes compressed: 85.3%

-rw-r--r-- 1 root root 3876712 Mar 9 09:51 support\_materials\_ML2809000146.070309\_0940.zip

### **USING UNZIP TO LIST FILES:**

**# unzip -l support\_materials\_APM00025002080.070213\_1508.zip |more**

Archive: support\_materials\_APM00025002080.070213\_1508.zip

Length Date Time Name

```
-----  
0 01-31-07 10:50 nyip2.070213_1508/nas/log/webui/  
24246 02-02-07 15:34 nyip2.070213_1508/nas/log/webui/ ipc.log  
125 02-04-07 03:34 nyip2.070213_1508/nas/log/webui/alert_log  
42933 02-02-07 15:34 nyip2.070213_1508/nas/log/webui/apl_sched.log
```

### **USING UNZIP TO EXTRACT ALL FILES:**

**# unzip support\_materials\_APM00025002080.070214\_0034.zip**

### **USING UNZIP TO EXTRACT SINGLE FILES OR TO PIPE:**

**# unzip -p support\_materials\_APM00025002080.070213\_1508.zip nyip2.070213\_1508/nas/log/cmd\_log**  
**>/home/nasadmin/tm/cmd\_log.feb13**

### **USING ZIPGREP TO FIND STRINGS OR PATTERNS IN ZIPPED FILES:**

**# zipgrep reboot support\_materials\_APM00025002080.070213\_1613.zip**

nyip2.070213\_1613/cmd\_outputs/server\_2.log:2006-08-29 12:46:39: ADMIN: 4: Command succeeded: param kernel autoreboot=600

### **USING ZIPINFO TO LIST FILES OR SEE TOTALS:**

**# zipinfo -t support\_materials\_APM00025002080.070214\_0034.zip**

1027 files, 28022755 bytes uncompressed, 3254373 bytes compressed: 88.4%

**# zipinfo -1 support\_materials\_APM00025002080.070214\_0034.zip |tail** (lists out filenames only)

nyip2.070214\_0034/cmd\_outputs/server\_viruschk-audit

nyip2.070214\_0034/cmd\_outputs/webui\_use

nyip2.070214\_0034/cmd\_outputs/chkconfig-list

## **CHANGING DEFAULT LOCATION FOR COLLECT SUPPORT LOGS:**

1. Export TMPDIR first                   # export TMPDIR=/nas/var

2. Then run collection script:        # /nas/tools/collect\_support\_materials

## **UPLOAD & RUN COLLECT SUPPORT MATERIALS SCRIPT:**

1. Upload to Control Station using rz or FTP

2. Untar file:

**# tar -xvf collect\_support\_materials.tar**

collect\_support\_materials.sh

3. Run script:

**# ./collect\_support\_materials**

**Note:** Some systems may have the /nas/tools/collect\_support\_materials file without the .sh extension, and latest version also drops the sh extension. Current version is 2.7 (faster, more verbose output, added commands to gather info on various features).

Running material collection script revision 2.2.2.

Collecting /nas/log/\*, and /nas/jserver/logs

Collecting output from server\_log

-----output abridged-----

Now running material collection script for longer running commands.

Collecting complete nas dir listing

Collecting output from nas commands

Collecting output from other CS commands

Zipping archive for single file output

Material Collection File:

/tmp/support\_materials.051027\_1158.tar.gz has been generated.

4. The support\_materials collection script is generated with a current date and placed in /tmp

**support\_materials.051027\_1158.tar.gz**

5. Download and ftp to Engineering, along with appropriate escalation email and details

**Note 1:** Older versions of collect\_support\_materials script produced a couple of different output files

-rw-rw-r-- 1 nasadmin nasadmin 80584 Nov 2 07:50 support\_cmds.051102\_0744.tar.gz

-rw-rw-r-- 1 nasadmin nasadmin 3096195 Nov 2 07:45 support\_logs.051102\_0744.tar.gz

**Note 2:** To redirect the output of the collect\_support\_materials script to an alternate location on the CS, do the following:

\$ export TMPDIR=/nas/var/log

\$ echo \$TMPDIR

/nas/var/log

**Note 3:** A more current way of running the collect while working on other things

# **nohup /nas/tools/collect\_support\_materials -q -d /nas/var/dump &**

## **NAS UPGRADES & INSTALLATIONS SECTION**

### **NAS UPGRADE PRECAUTIONS & STEPS:**

Checkpoints, TimeFinder/FS, NAS Family, LUN Trespass, Flare Code version, all should be considered before doing an Upgrade  
**Note:** Completed upgrades are in /nas/log/upgrade\* log—interrupted or incomplete upgrades will have a log in /var/tmp

### **UPGRADING CELERRA USING USB FLASH DRIVE & ISO IMAGE ON NS40**

#### **USING USB FLASH DRIVE TO TRANSFER NAS ISO IMAGE TO CONTROL STATION:**

1. Plug USB Flash Drive into USB port on front side of Control Station [located underneath the serial port]

2. Run Fdisk to verify the discovered device type:

# **/sbin/fdisk -l**

/dev/sda1 1 992 999813+ 6 FAT16

# **df -h**

usbdevfs /proc/bus/usb type usbdevfs (rw)

3. Create mountpoint for USB device:

# **mkdir -p /mnt/usb**

4. Mount the Flash Drive to the Control Station

# **mount /dev/sda1 /mnt/usb**

5. Copy the ISO image from the Flash Drive to a partition with enough available space (about 550MB needed)

# **cd /mnt/usb**

# **cp emcnas5.5.31.6.iso /iso**

6. Unmount Flashdrive and physically remove from the Control Station

# **umount /mnt/usb**

#### **MOUNTING NAS ISO IMAGE ON LINUX CONTROL STATION:**

1. Mount the ISO image to the mountpoint defined above [/mnt/usb]

# **mount -t iso9660 -o loop /iso/emcnas5.5.31.6.iso /mnt/usb**

2. Perform NAS Upgrade from the ISO image

# **cd /mnt/usb/EMC/nas;/setup**

**Note:** After upgrading Linux kernel, system will require a reboot. Perform steps 1-2 again after the system has rebooted.

#### **RUNNING NAS PRE & POST-UPGRADE SCRIPT:**

1. Download & install latest Celerra Procedure Generator file from CCA website (CelerraProcGen.exe)

2. Locate upgrd-ck script.zip file in c:\Program Files\EMC\NASCPG\Application\Modules\SCRIPTS

3. Unzip to retrieve User Guide document and the tar.gz PreUpgrade check script

**upgrd-ck-document10-36.doc**

**upgrd-ckv10-36.tar.gz**

4. Upload tar.gz script to /home/nasadmin on the Control Station and unzip/untar

# **tar xvzf upgrd-ckv10-36.tar.gz**

upgrd-ckv10-36.bin

5. Execute pre-upgrade check

/home/nasadmin/upgrd-ckv10-36.bin -v 1 |-vb 1 (to backup files)

6. Log file is written to /home/nasadmin/pre-upgrade.rpt

**Note:** Check report and resolve any errors

7. Perform NAS Upgrade activity

8. Run post-upgrade check

# **/home/nasadmin/upgrd-ckv10-36.bin -v 2**

9. Check /home/nasadmin/post-upgrade.rpt

#### **RUN NAS 5.5 ENGINEERING PRE-UPGRADE CHECK SCRIPT (PUHC):**

# **/nas/tools/check\_nas\_upgrade -pre**

Check Version: 5.5.22.5028

Check Command: /nas/tools/check\_nas\_upgrade

Check Log : /nas/log/check\_nas\_upgrade.Sep-05-11:04:51.log

**Checks-----**

**Note:** Later editions of NAS 5.5 now call on the check\_nas\_upgrade script during the NAS Upgrade (./setup) and will fail the upgrade until errors are corrected.

**# ./setup**

Setting up system, please wait...

Model: NS600G

Upgrading From Version: 5.5.24-2

Mon Jan 29 12:54:45 EST 2007

Checking Upgrade Requirements

Check Version: 5.5.80.0

Check Command: /nbsnas/var/log/pkg\_5.5.80.0/check\_nas\_upgrade

Check Log : /nas/log/check\_nas\_upgrade.Jan-29-12:55:03.log

**Checks-----**

Control Station: Checking if enough free space exists ns..... **Fail**

**# cat /var/tmp/upgrade.log.Mon\_Jan\_29\_12:59:19\_EST\_2007** [Logs output from check\_nas\_upgrade]

**Note:** The “checks.txt” file is the master checklist used during the check\_nas\_upgrade check operation

**NAS 5.6 UPGRADES:**

CD-ROM package contains a new upgrade command:

**/EMC/nas/install\_mgr –mode upgrade**

Lab Workaround for Unsupported Hardware NAS 5.6:

**/EMC/nas/install\_mgr –mode upgrade –allow\_upgrade\_on\_obsolete\_dm** (507 & 510 DM's)

**Note:** Upgrades from 5.4 and 5.5 to 5.6 requires a CD-ROM. Additionally, the CFS platform require the use of a boot floppy

**EXAMPLE OF UPGRADE TASKS FOR 5.6.43.5 (seen after 2<sup>nd</sup> .install mgr –m upgrade):**

====Time Estimate for All Tasks=====

|    |                                  | Estimated | Status    |
|----|----------------------------------|-----------|-----------|
|    | Time(Minutes)                    |           |           |
| 1  | Copyright Information            | 0         | completed |

==== Estimate

Estimated Time when Data Movers will be reset: 14:34

Estimated Time when NAS service will be restarted: 14:46

Estimated Time when upgrade will be complete: 14:57

=====

## **REMOTE UPGRADES NAS 5.6:**

RCM group performs many Celerra upgrades via remote connection

Primary utility on Linux Control Station is “screen”

# **screen** → Starts the screen terminal, after which, if you lost your connection and had to reconnect, you would use # screen -r to reconnect to the screen session

→ctrl + a, then c to create new screen window

→ctrl + a, then n to switch to next screen window (if multiple sessions)

# exit →Exits from screen program

## **NAS 5.6 INSTALL ISSUE WITH FLEET BACKEND:**

→Starting with NAS 5.6.39.5, Celerra Gateways support connectivity to Fleet Flare 28 arrays, but Celerra does not support IPv6 settings on the SP's until 5.6.43 storageAPI. AR129282 documents an issue where the Celerra cannot perform the backend discovery because the symapi cannot handle IPv6 network information--the SPs are set to IPv6 mode ‘automatic’ (DIMS292226). Changing the settings to “disabled” resolved the install issue:

**# /nas/sbin/navicli -h A\_APM00083701533 networkadmin -get -ipv6**

Storage Processor: SP A

Storage Processor IPv6 Mode: **Automatic**

Storage Processor IPv6 Address:

Storage Processor IPv6 Global Prefix:

Storage Processor IPv6 Link-local Address: fe80::260:1600:3b20:b9e

**# /nas/sbin/navicli -h 10.241.168.182 networkadmin -get -all**

Storage Processor: SP A

Storage Processor Network Name: SPA

Storage Processor IP Address: 10.241.168.182

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 10.241.168.128

Storage Processor IPv6 Mode: Disabled

Management Port Settings:

Link Status: Link-Up

Current Speed: 100Mbps/full duplex

Requested Speed: Auto

Auto-Negotiate: YES

Capable Speeds: 1000Mbps half/full duplex

10Mbps half/full duplex

100Mbps half/full duplex

Auto

**# /nas/sbin/navicli -h A\_APM00083701533 networkadmin networkadmin -set -ipv6 -disable**

**IPv6 Settings on SPs changed to Disabled:**

**# /nas/symcli/bin/symcfg discover -clarion**

This operation may take up to a few minutes. Please be patient...

**# /nas/bin/server\_devconfig server\_2 -c -s -a**

server\_2 : done

**# /nas/sbin/navicli -h A\_APM00083701533 networkadmin -get -ipv6**

Storage Processor: SP A

Storage Processor IPv6 Mode: **Disabled**

## **NAS UPGRADE ISSUES RELATED TO LARGE OBJECT COUNT OR HIGH CPU ON CLARIION:**

(aka, changing CLARiiON environmental values for slow polling systems)

See emc175499. Typically, when navi commands take a long time to respond, various functions such as NAS upgrades are subject to failure because of timeouts. Generally, this problem can be caused by high CPU activity on the array, or more recently, very high object counts on the array (>than 1000 objects). Traditional workarounds have included the –np switch, along with a script developed by Engineering to make sure all commands going to the backend used the “no poll” function.

**Two-part workaround:**

1. Connect to the array's /setup program via web browser and change the Communication Timeout default from 180 to 300 secs:

### **“Set Update Parameters”>Communication Timeout: 300**

2. Restart the Management Server on the array when prompted

3. From the same Control Station session where the upgrade will be run from, issue the following:

# **export NAVI\_TIMEOUT=300**

# echo \$NAVI\_TIMEOUT

300

**Note:** exporting the navi timeout value is only valid for the current shell session

4. Make sure a copy of classic\_navicli is present in /nasmcd/sbin, with 777 permissions

## **NAS 5.5 GATEWAY INSTALL USING KSNAS.CFG FILE (auto zone & storagegroup creation):**

### **Overview:**

→Need Procedure Generator to generate tailored NAS Installation document that produces a usable ksnas.cfg file

→Need NAS CD

→Need bootable system floppy disk to start install, along with ksnas.cfg file

**Note:** Obtain a copy of the latest Celerra Procedure Generator, install on desktop system, generate checklist of required information for “NAS Installation”, produce the NAS Installation Procedure, have NAS CD\_ROM available, create system floppy disk and copy ksnas.cfg file to the floppy disk for use during installation.

### **USING CELERRA PROCEDURE GENERATOR Version 1.2.3:**

1. Download executable file and install using defaults: doubleclick “NASProcGen.exe”

2. Open “PG” shortcut on desktop>select forward ‘hand’ icon and enter customer information

3. Choose either Hardware Change, Software Change, or NAS Installation

4. Select correct Celerra Model, Type, Data Movers, Factory racked, Primary Backend Type, file name, enter

**Note:** Above produces a questionnaire that can be used as a template to answer the questions needed by ksnas.cfg script

5. Re-open the file name that was produced in Step 4, select forward button, and generate NAS Installation document

### **PERFORM NAS INSTALLATION: NAS 5.5.22.5028**

1. Insert boot floppy, CD\_ROM, connect to CS with Serial cable Hyperterminal Session using 19200 defaults, COM1 or COM2, and Hardware FC ‘None’

2. Reboot Control Station and enter following at prompt:

### **boot: serialkickstart**

Select destructive install (no other option is really available), CS reboots and goes through Preinstallation checks

Package Installation of linux occurs and reboots using Grub loader

Starting EMC NAS Factory Installation

Detecting movers in cabinet: 2

Checking for existing System RG/LUN: Shared backend detected

System Raid Group will be setup on disks 0\_2\_0 0\_2\_1 0\_2\_2 0\_2\_3 0\_2\_4 (Bus 0, Enclosure 2, Disks 0-4)

RAID Group ID is 8

ALU IDs of System LUNs: 29 30 31 33 34 35

Waiting for LUNs to finish binding...

Rebooting Data Movers...

Mover in slot\_2 →Stages: NO STATE | DART LOADED | GENERIC SLOT CONFIG | DART CONFIGURING

Collecting Data Mover WWNs

Creating Zones...

Setting up Storage Groups on CLARiiON Backend...

Creating Storage Group: Celerra\_nyip2

3. NAS Installation proceeds

Starting EMC NAS installation

Creating the NAS Partition on /dev/nda1 with fdisk

Building the IDE NAS filesystem on /dev/hda5 with mke2fs

(Creates VAR & DOS Partitions next....)

## **FORCING POST UPGRADE NAS 5.6.45:**

→Generally speaking, POST & BIOS are flashed during the bootup process whenever a newer firmware version is detected.

Typically, firmware updates are provided in the NAS image.

→To force a system to update POST & BIOS

1. Edit boot.cfg to force post upgrade

```
# vi /nas/dos/slot_2/boot.cfg
flashupg post=upgrade bios=upgrade
Edit above line to read:
flashupg post=force bios=upgrade
2. Reboot server to force firmware update:
# /nasmcd/sbin/t2tty -C 2 "shutdown"
3. Verify:
# cat /nas/log/data_mover_resume.server_2.xml|grep "VERSION"
    <VERSION_INFORMATION BIOS_VERSION="03.80" POST_VERSION="Rev. 01.59" />
```

## **INSTALLING NAS WITH LUNS 0 & 1 AT 4GB vs. 11GB STANDARD: 5.5.28.1**

**Note:** Later code versions now enforce installations of Control Luns 0 & 1 at 11GB each, but for lab testing purposes, you can work around this and install at any desired size

1. Perform install as usual, with CD-ROM and floppy
2. After installation of Linux on CS, and right after configuring the CS interfaces and hostname, ssh into the CS
3. From ssh session, # cd /tftpboot/setup\_backend

**Note:** If this directory doesn't exist, extract from /nas/tools

```
# tar -xvf /nas/tools/tftpboot.tar.gz
```

4. Edit the system.pm file and change LUNs 0 & 1 from 11GB to desired LUN size:

```
# vi /tftpboot/setup_backend/system.pm
```

```
49 %systemLuns = ( $SYSTEM_LUN_ID_0, 11,
50     $SYSTEM_LUN_ID_1, 11,
51     $SYSTEM_LUN_ID_2, 2,
52     $SYSTEM_LUN_ID_3, 2,
53     $SYSTEM_LUN_ID_4, 2,
54     $SYSTEM_LUN_ID_5, 2);
```

5. Edit S95nas script in the following locations (same edit), also changing the 11GB size to 4 or 2GB:

```
# vi /etc/rc3.d/S95nas
```

```
1606 local GB_IN_BLOCKS=$[1024*1024*2]
1607 local LrgLunMinSiz=$[11*GB_IN_BLOCKS] # Minsize for Luns 0 and 1
1608 local SmlLunMinSiz=$[2*GB_IN_BLOCKS] # Minsize for Luns 2 3 4
```

```
# vi /mnt/source/EMC/nas/S95nas
```

6. Exit ssh session and continue with NAS Installation with serial session

## **NS40/NS80 INTEGRATED ADD ENCLOSURE or ADD BLADE PROCEDURES:**

### **NS40 INTEGRATED ADD BLADE PROCEDURE:**

An NS40 exists only in a Single or Dual Blade configuration. If the system is an NS41 Integrated, then a 2<sup>nd</sup> DM blade can be added. The actual steps for adding a Blade to an existing system are fairly simple. Internal Network switch cabling needs to be reconfigured for dual blades; Copper fibre channel cables need to be made between DM3 and the SPs; Celerra's Internal Network needs to be upgraded from a single blade configuration to a dual blade configuration; The new Blade contains its own Internal Management Switch (unlike the NSX/NS80 blades), which needs to be initialized so that the Celerra system and database are able to recognize the new Blade; And finally, a setup\_slot is required to setup the new Blade hardware on the Celerra.

#### **1. Internal Network Cabling Changes:**

Ethernet cable from lower management port DM3 to port labeled 2 on Control Station—eth2 (upper middle port)

Ethernet cable from upper management port DM3 to lower management port on SPB

#### **2. Fibre Channel Cabling Changes:**

DM blade 3 port BE 0 to SP A port 1 Fibre using copper SFP-to-SFP cable

DM blade 3 port BE 1 to SP B port 1 Fibre using copper SFP-to-SFP cable

#### **3. Upgrade the Internal Network:**

```
# /nasmcd/sbin/upgrade_to_dual_intnet
```

SUCCESS: Internal network upgrade succeeded. Please verify the sanity of  
the system and delete the directory /tmp/upgrade\_to\_dual\_net.23674.

**Note:** Above command stops & restarts NAS services—wait until nas\_mcd and boxmonitor processes are restored before continuing

#### **4. Verify that both internal networks are available and that Control Station has been reconfigured:**

```
# ping server_2
```

PING server\_2 (192.168.1.2) from 192.168.1.100 : 56(84) bytes of data.

64 bytes from server\_2 (192.168.1.2): icmp\_seq=0 ttl=255 time=154 usec

```
# ping server_2b
```

PING server\_2b (192.168.2.2) from 192.168.2.100 : 56(84) bytes of data.

64 bytes from server\_2b (192.168.2.2): icmp\_seq=0 ttl=255 time=184 usec

**# /sbin/ifconfig**

```
eth0    Link encap:Ethernet HWaddr 00:00:F0:9F:B3:74
        inet addr:192.168.1.100 Bcast:192.168.1.255 Mask:255.255.255.0
              UP BROADCAST NOTRAILERS RUNNING MULTICAST MTU:1500 Metric:1
eth2    Link encap:Ethernet HWaddr 00:00:F0:9F:53:07
        inet addr:192.168.2.100 Bcast:192.168.2.255 Mask:255.255.255.0
              UP BROADCAST NOTRAILERS RUNNING MULTICAST MTU:1500 Metric:1
```

**5. Remove the following directory from /tmp:**

**# rm -Rf upgrade\_to\_dual\_net.23674**

**6. Export NAS DB environmental variable:**

**# export NAS\_DB=/nas**

**7. Add new Blade's Mgmt Switch:**

**# /nas/sbin/setup\_enclosure -addMgmtswitches**

Discovered 1 Mgmt switch on Primary network and 1 Mgmt switch on Secondary network

Discover the following Mgmt switch ...

MgmtSwitch-B IP address = 192.168.2.50

MgmtSwitch-B MAC address = 00:60:16:0b:1b:a5

flashFirmware Completed

addMgmtswitches Completed

**Note:** If this fails with 0 Mgmtswitches in Secondary subnet B, run the t2net\_test command from the good switch on slot\_2 to reset the switch on slot\_3, which represents the Secondary subnet

**# /nas/sbin/t2net\_test -TyphPeercontrol**

Usage: t2net\_test -TyphPeercontrol {ipaddr operand}

where:- ipaddr = Mgmtswitch IP address

operand = 0(Peer Disable), 1(Peer Enable), 2(Peer Reset)

**# /nas/sbin/t2net\_test -TyphPeercontrol 128.221.252.50 2**

**Note:** Operand of 2 is used to reset the peer switch

**8. Verify that Secondary Switch was successfully added:**

**# /nas/sbin/setup\_enclosure -probeSystem**

Executing -probeSystem option

Discovering Primary subnet (A) ... OK

Enclosure ID = 0, BackplaneID 0 from IP 192.168.1.50

MgmtSwitch-A MAC = 00:60:16:0b:1a:ca, Peer MAC = 00:60:16:0b:1b:a5

F/W Version: Mgmtswitch=01.82, Bootblock=01.77

Discovering Secondary subnet (B) ... OK

Enclosure ID = 0, BackplaneID 1 from IP 192.168.2.50

MgmtSwitch-B MAC = 00:60:16:0b:1b:a5, Peer MAC = 00:60:16:0b:1a:ca

F/W Version: Mgmtswitch=01.82, Bootblock=01.77

**# /nas/sbin/enclosure\_status -e 0 -v**

DEVICE A DEVICE B

-----PRESENCE-----

00 60 16 0B 1A CA MAC 00 60 16 0B 1B A5

Scorpion Hardware Platform Scorpion

Present Peer Compute Blade Present

Present Compute Blade Present

Powered On Compute Blade Powered On

Present Power Supply A Present

Present Power Supply B Present (output abridged)

**9. If the switch was not properly added, try the following commands:**

**# /nas/sbin/setup\_enclosure -resetMgmtswitches or -initSystem force**

**10. Add the new Blade to the Celerra database & verify:**

**# /nas/sbin/setup\_slot -i 3**

**# nas\_server -l**

| id | type | acl  | slot | groupID | state    | name |
|----|------|------|------|---------|----------|------|
| 1  | 1    | 1000 | 2    | 0       | server_2 |      |
| 2  | 1    | 1000 | 3    | 0       | server_3 |      |

**Note:** With the later Celerra Integrated Models that use AccessLogix and Storage Groups (aka, NS20/NS40/NX4), you would use the /nas/sbin/setup\_slot -i -g 3 command to add the new host initiator records to the Storage Group

## **NS80 INTEGRATED ADD ENCLOSURE/BLADE PROCEDURE:**

An NS80 exists only in a 2, 3, or 4 Blade configuration. If the NS80 Integrated has only (2) Blades, when adding a 3<sup>rd</sup> Blade, the system would require Internal Network recabling, the addition of Fibre Optic fibre channel cables between the new Blade and the SPs, and a separate step to first add Enclosure 1 to the Celerra, followed by a step to add the 3<sup>rd</sup> or 4<sup>th</sup> blade, which aside from cabling requirements, requires a setup\_slot to recognize the new hardware on the Celerra. It is actually possible to have a 2<sup>nd</sup> Enclosure on an NSX or NS80 without a Blade, yet have the Internal Network cables cabled from the Enclosure Mgmt Switch A & B to the SPs A or B switch LAN port.

### **1.) Internal Network Cabling Changes:**

Example given is for going from a 2-blade system to a 3 to 4-blade system

--Move LAN cable from Port 4 on DM Encl 0 Switch A (the other end goes to the upper LAN port on SPA, Switch A, and is unchanged), to Port 4 on DM Encl 1, Switch A

--Move LAN cable from Port 4 on DM Encl 1, Switch B (the other end goes to the upper LAN port on SPB, Switch B, and is unchanged), to Port 4 on DM Encl 1, Switch B

--Connect new LAN cable from Port 0 on DM Encl 0, Switch A, to Port 3 on DM Encl 1, Switch A (daisychains Encl 0 & 1 together)

--Connect new LAN cable from Port 0 on DM Encl 0, Switch B, to Port 3 on DM Encl 1, Switch B (daisychains Encl 0 & 1 together)

### **2. Fibre Channel Cabling Changes:**

--Connect Port BE0 on DM 4 on Encl 1 to Port 2 on SPA using LC-to-LC fibre optic cables and SFP connectors

--Connect Port BE1 on DM 4 on Encl 1 to Port 2 on SPB using LC-to-LC fibre optic cables and SFP connectors

--Connect Port BE0 on DM 5 on Encl 1 to Port 3 on SPA using LC-to-LC fibre optic cables and SFP connectors

--Connect Port BE1 on DM 4 on Encl 1 to Port 3 on SPB using LC-to-LC fibre optic cables and SFP connectors

### **3. Add new Enclosure to System:**

/nasmcd/sbin/setup\_enclosure –addEnclosure

### **4. Add the new Blade to the Celerra database:**

/nas/sbin/setup\_slot –i 4

## ***NS80/NS40 INTEGRATED CONNECTION METHODS, INSTALLATIONS, INTERNAL NETWORK SETUP, & NDU UPGRADE PROCEDURES FOR SINGLE(NS41-only) & DUAL DM SYSTEMS***

### **NS40 NAS 5.5 INTEGRATED MODELS:**

#### **NS40 NAS Head with 4 Copper Ports and CLARiiON CX3-40 Backend:**

→Data Mover RoHS TLA Part # 100-561-998 for 1 or 2 blades

→Factory Sales Order Model # NS42C NS4xx NAS Head 100-520-605

→Field Install Sales Order Model # NS42C-A-FD NS4xx NAS Head 100-520-605

→BIOS version 3.48, Model: Sledgehammer: NAS, POST 01.30

→PROM information SAN/NAS Type (2): NAS, 1U-NAS 2DM CU CHASSIS, NS3-40 CU NAS 2

→Resume information for SPs:

# /nas/sbin/navicli -h 192.168.1.200 getresume |grep CX

Assembly Name: CX3-40 SAN/AUX

**Note:** As with the NSX models, there are no serial connections between CS & Data Mover blades (and no ctaptty logs either), meaning that the only way to observe or troubleshoot boot issues is via a local workstation connected directly to the maintenance Serial port of the Data Mover.

### **For NS40/NS80 Integrated Celerras, there are two possible configurations:**

#### **Factory-Installed systems:**

Hardware is pre-loaded with NAS software using factory-racked 40U EMC hardware. Factory-installed units are cabled into the environment, and after powering on, the Control Station can be configured with its External network address by using the InitWizard application on a Windows system that is plugged into the same network that the Control Station is cabled up to.

#### **INITWIZARD:**

The InitWizard is obtained from the Apps & Tools CD. Click InitWizard.exe and the Control Station Initialization Wizard appears. Click on Search tab and it searches the subnet via ARP broadcasts for any unconfigured Control Stations. Upon finding a CS, its MAC address is displayed. Click the “Configure” button and enter Hostname, IP Address, Netmask, Gateway, Finish. “Configuration completed successfully. Now you can access the Control Station over the network. Do you want to open a web browser and continue configuring the Control Station?” If you answer “Yes”, a browser bar opens—input the Control Station IP address. The wizard then runs through a cable check to validate the cabling—“Cable Check Passed”. Celerra Manager then launches. Configure Control Station>Call Home and then use the Wizards menu in Celerra Manager for further configuration, such as “Set Up Celerra”.

#### **CONTROL STATION INITWIZARD:** aka, iwd

When required, the IWD daemon runs on the Control Station to support the InitWizard and the new CSA wizard.

# ps -eaf|grep -i iwd

/nasmcd/sbin/iwd 040 R root 3429 3428 0 76 0 - 348 - 11:59 pts/0 00:00:00

/sbin/service nas\_ipinit stop | start | restart →Calls the /nasmcd/sbin/iwd executable

/sbin/chkconfig nas\_ipinit –list [is on by default]

**/var/log/messages** will log information regarding InitWizard starting and stopping

Jun 19 11:59:20 sludge1 iwd: InitWizard: the daemon has started.

Jun 19 11:59:20 sludge1 iwd: InitWizard: the daemon has terminated.

**Field-installed systems:**

These systems require assembly in the customer's racks, are designated with a model number, such as NS42C-A-FD, and require a completely fresh install. The Clariion SPs should already be configured with the correct SAN/AUX personality and have the correct internal IP address scheme and hostnames assigned, though the Setup Guide requests that the SP personality be verified during reboot, yet does not have User checking to ensure that SP IP Addresses are correctly set—the Celerra Procedure Generator will have the User verify each of the SP's Hostnames, IP & Gateway addresses.

**HEALTHCHECKING NS40/NS80 SYSTEM:**

**/nas/tools/auto\_checkup** → Version of PAHC tool that runs every 2 weeks per Cron entry in /nas/site/cron.d/nas\_sys

**Note:** PAHC checkup now runs once a week on Sunday

**/nas/bin/nas\_checkup** → CLI version of PAHC tool run On-demand from /nas/bin

**/nas/tools/dbchk -wvxpVs** [Switches available with latest NAS 5.5 code—not all switches may work on prior code]

**/nas/tools/dbchk -pvwx**

**/nas/tools/check\_clariion** (checks SP utilization and Disk IOPs on CLARiiON arrays)

**/nas/tools/check\_nas\_upgrade** [-pre -up -pro Upgrade check script]

**/nas/bin/nas\_storage -check -all**

**/nas/sbin/enclosure\_status -e 0 -v** → Overall system checkup of hardware components

**/nas/sbin/setup\_enclosure -checkCable**

**/nas/sbin/setup\_enclosure -checkSystem**

**/nas/sbin/setup\_enclosure -probeSystem**

**/nas/sbin/setup\_enclosure -readConfig**

**/nas/sbin/t2net\_test**

**/nas/sbin/t2net\_test -SetResumeProm**

**/nas/sbin/t2net\_test -GetResumeProm 2 38 150 30**

t2net\_test: Return values:

0000: 0x34 0x20 0x50 0x4f 0x52 0x54 0x20 0x46 0x49 0x42 4 PORT FIB

MgmtSwitch-A MAC address = 00:60:16:0b:1a:ca

F/W Version: Mgmtswitch=01.82, Bootblock=01.77

MgmtSwitch-B IP address = 192.168.2.50

MgmtSwitch-B MAC address = 00:60:16:0b:1b:a5

F/W Version: Mgmtswitch=01.82, Bootblock=01.77

## **INTERNAL MANAGEMENT SWITCH ISSUES:**

For dual blade systems, the Primary Management Switch A is cabled to Data Mover 2, and the Secondary Management Switch B is cabled to Data Mover 3. There are situations where the Internal Network cabling is incorrect, cables are bad, cables are removed, etc., that could lead to Mgmt Switch failures, as presented in the following example:

### **/nas/log/sys\_log**

May 2 10:16:33 2007 BoxMonitor:3:526 enclosure 0 failed to respond to ping at management switch A

May 2 10:17:41 2007 BoxMonitor:2:43 Slot 2 failed to respond to ping at server\_2

May 2 10:17:44 2007 BoxMonitor:2:43 Slot 3 failed to respond to ping at server\_3

May 2 10:20:50 2007 BoxMonitor:3:526 enclosure 0 failed to respond to ping at management switch B

May 2 10:21:55 2007 BoxMonitor:2:43 Slot 3 failed to respond to ping at server\_3b

May 2 10:21:55 2007 BoxMonitor:2:43 Slot 2 failed to respond to ping at server\_2b

**Note:** Log example shows that at one time, Mgmt Switch A & B were down, and the corresponding failure to ping the DM on the respective Primary or Secondary Network is logged

### **Manually Disabling Primary or Secondary Mgmt Switch Networks:**

**Caution:** The following commands should be used with extreme care as the Primary or Secondary Internal Network will be shutdown. Commands can be used for testing, etc.

### **# /nas/sbin/t2net\_test -TyphPeercontrol 192.168.1.50 0**

t2net\_test: Command succeed

**Note:** Disables the Secondary Management Switch & network—runs from switch in slot\_2 against its peer in slot\_3, and 0 means to disable

### **# /nas/sbin/t2net\_test -TyphPeercontrol**

Usage: t2net\_test -TyphPeercontrol {ipaddr operand}

where:- ipaddr = Mgmtswitch IP address

operand = 0(Peer Disable), 1(Peer Enable), 2(Peer Reset)

### **# /nas/sbin/t2net\_test -TyphPeercontrol 192.168.2.50 0**

t2net\_test: Command succeed

**Note:** This command disables the Primary Management Switch & network

### **# /nas/sbin/setup\_enclosure -probeSystem**

**Note:** Use the probeSystem command to see if the Primary or Secondary Mgmt Network is down, as in following example:

### **# /nas/sbin/setup\_enclosure -probeSystem**

Executing -probeSystem option

Discovering Primary subnet (A) ... OK

No Mgmtswitch is found on Primary subnet

Discovering Secondary subnet (B) ... OK

Enclosure ID = 0, BackplaneID 1 from IP 192.168.2.50

MgmtSwitch-B MAC = 00:60:16:0b:1b:a5, Peer MAC = 00:60:16:0b:1a:ca

F/W Version: Mgmtswitch=01.82, Bootblock=01.77

ZERO Mgmtswitch detection may due to one or more of the following cases:

- Miswired cabling on Mgmtswitches that causes switch looping

- Loose/bad cable between Enclosure ID# 0 and CS

- Bad Ethernet port on CS

- Bad Mgmtswitch

**Note:** The above causes of a Mgmt Switch failure should be verified prior to attempts to re-initialize the Switch. The failure can also be seen when adding a 2<sup>nd</sup> Blade to a single DM system, etc.

### **Re-initializing a failed Mgmt Switch after Blade Hardware Addition or Replacement, or Cable Replacement, etc:**

### **# /nas/sbin/setup\_enclosure -resetMgmtswitches**

**Note:** Command reboots Mgmt Switches in an attempt to recover

### **# /nas/sbin/setup\_enclosure -initSystem force**

**Note:** This command appears to rebuild the Enclosure and DHCP database, reboots both Switches, flashes the switch firmware (if needed), checks cabling, and does a discovery of the Mgmt Switches. Start with the –resetMgmtswitches first, then try –initSystem force if that fails.

Enclosure Status Commands:

### **# /nas/sbin/enclosure\_status -e 0 -v |grep -i compute**

Present Peer Compute Blade Present

Present Compute Blade Present

### **# /nas/sbin/enclosure\_status -e 0 -v**

DEVICE A DEVICE B

-----PRESENCE-----

00 60 16 0B 1A CA MAC ---

Scorpion Hardware Platform --- [output abridged]

**Note:** enclosure\_status command shows component failures in the system, but in the above example, does not show any components at all under the “DEVICE B” column, which also means that Mgmt Switch B (Secondary Network) is down or not initialized.

## **CHANGING SP HOSTNAME, IP ADDRESS, SUBNETMASK, GATEWAY ADDRESSES:**

### **# /nas/sbin/navicli -h 192.168.2.101 networkadmin -set -name spb -address 192.168.2.201 -subnetmask 255.255.255.0 -gateway 192.168.2.100**

**Note:** Running this command requires system reboot

## **UPDATING SP IP ADDRESS CHANGES IN CELERRA DATABASE:**

/nas/bin/nas\_storage –modify <APM> -network -spa | -spb xxx.xxx.xxx.xxx (Updates address in symapi db)

/nasmcd/sbin/mcd\_helper add\_SP\_info\_to\_hosts\_file (Updates /etc/hosts with new IP addresses)

/nas/site/sp\_info (File that stores SP IP addresses—update manually if necessary)

## **CHANGING SP IP ADDRESSES WITH NAS 5.5.31 AND ABOVE RUNNING PROXY ARP:**

### **# /nasmcd/sbin/clariion\_mgmt –modify –spa\_ip <new\_ip> -spb\_ip <new\_ip>**

→Changes SP IP addresses

→Updates /etc/hosts & /nas/site/sp\_info files

→Updates NASDB and SYMAPI.db with new addresses

## **OTHER COMMANDS THAT CHANGE OR IMPACT SP IP ADDRESSING:**

/nasmcd/sbin/clariion\_mgmt -stop (removes SP aliases (eth3:1, eth3:2), removes IPTables entries, reapplies old IP addresses & gateways on SPs for Napa 9 and above)

/nasmcd/sbin/clariion\_mgmt –start –spa\_ip xxx.xxx.xxx.xxx –spb\_ip xxx.xxx.xxx.xxx

## **NS40/NS80 INTEGRATED CLARIION IP ADDRESS SCHEME:**

# /nas/sbin/navicli -h 192.168.1.200 networkadmin -get

Storage Processor: SP A  
Storage Processor Network Name: SPA  
Storage Processor IP Address: 192.168.1.200  
Storage Processor Subnet Mask: 255.255.255.0  
Storage Processor Gateway Address: 192.168.1.100 (eth0 on Control Station)

# /nas/sbin/navicli -h 192.168.2.201 networkadmin -get

Storage Processor: SP B  
Storage Processor Network Name: SPB  
Storage Processor IP Address: 192.168.2.201 →Default IP for Integrated on SPB changed from 192.168.1.201  
Storage Processor Subnet Mask: 255.255.255.0  
Storage Processor Gateway Address: 192.168.2.100 (eth2 on Control Station)

### **NS42 INTERNAL MANAGEMENT SWITCH PORT CABLING—Dual DM configuration:**

- a.) Ethernet cable from lower management port DM3 to port labeled 2 on CS—eth2 192.168.2.100 Second. Mgmt (upper mid.port)
- b. ) Ethernet cable from lower management port DM2 to port labeled 10/100 on CS—eth0 192.168.1.100 Pri. Mgmt (lower left port)
- c. ) Ethernet cable from upper management port DM3 to lower management port on SPB
- d.) Ethernet cable from upper management port DM2 to lower management port on SPA

### **NS42 CS NETWORK CONFIGURATION & IMPORTANT FILES:**

# /sbin/ifconfig -a

eth0 inet addr:192.168.1.100 Bcast:192.168.1.255 Mask:255.255.255.0 →Primary Internal network (CS, DM, SPA)  
eth1 <not used>  
eth2 inet addr:192.168.2.100 Bcast:192.168.2.255 Mask:255.255.255.0 →Backup Internal network (CS, DM, SPB)  
eth3 inet addr:10.241.168.94 Bcast:10.241.168.255 Mask:255.255.255.0 →External Interface customer network

# cat /etc/sysconfig/network-scripts/ifcfg-eth0

ENCLOSURE-0\_MGMT-A\_MAC=00:60:16:0b:1a:ca  
ENCLOSURE-0\_MGMT-B\_IP=192.168.2.50  
ENCLOSURE-0\_MGMT-B\_MAC=00:60:16:0b:1b:a5

# cat /proc/sys/net/ipv4/ip\_forward

0 →By default, IP routing is disabled on the Control Station [But not after NAS 5.5.30 and higher—we enable it]

## **NS41 INTEGRATED INTERNAL MGMT SWITCH PORT CABLING—Single DM configuration:**

- a.) Ethernet cable runs from lower management port of SPB to the port labeled 2 on the Control Station switch (upper middle port)
- b.) Ethernet cable runs from lower management port of DM2 to the 10/100 port on CS0 (lower left port)
- c.) Ethernet cable runs from upper management port of DM2 to the lower management port on SPA

**Note:** With the NS41 system, both Primary & Backup Networks are now served from the same physical interface (eth0 & an alias called eth0:0). In this arrangement, eth2 does not service the Backup network for the Celerra, but instead is reconfigured with the 192.168.2.102 address, along with a special routing entry in /etc/sysconfig/static-routes, in order for the CS to communicate back & forth to SPB. All Primary & Backup network activity, with exception of SPB & eth2, are handled via eth0 or eth0:0.

## **NS41 CS NETWORK CONFIGURATION & IMPORTANT FILES:**

### **# /sbin/ifconfig -a**

```
eth0    inet addr:192.168.1.100 Bcast:192.168.1.255 Mask:255.255.255.0      →Primary Internal network (CS, DM, SPA)
eth0:0  inet addr:192.168.2.100 Bcast:192.168.2.255 Mask:255.255.255.0      →Backup Internal network alias (CS, DM)
eth1    <not used>
eth2    inet addr:192.168.2.102 Bcast:192.168.2.255 Mask:255.255.255.254 →SPB communications only (CS, SPB)
eth3    inet addr:10.241.168.94 Bcast:10.241.168.255 Mask:255.255.255.0      →External Interface customer network
```

### **# cat /etc/sysconfig/static-routes**

```
eth2 host 192.168.2.201 dev
```

**Note:** This entry must exist in order for proper communication to occur between CS & SPB. Under normal circumstances, you should be able to ping between CS to SPs and all internal networks, navicli commands should run against either SP, etc. This file is created only with an NS41 Integrated installation.

### **# cat /etc/sysconfig/network-scripts/ifcfg-eth0:0**

```
DEVICE=eth0:0

## **NS80 INTEGRATED INTERNAL MGMTN SWITCH PORT CABLING—(4) DM configuration:**

- a.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module A to port labeled 10/100 on CS—eth0 (lower left port)
- b.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module B to port labeled #2 on CS—eth2 (upper middle port)
- c.) Ethernet cable from upper Port 0 on DM Encl 0 Mgmt Module A to lower left Port 3 on DM Encl 1 Mgmt Module A
- d.) Ethernet cable from upper Port 0 on DM Encl 0 Mgmt Module B to lower left Port 3 on DM Encl 1 Mgmt Module B
- e.) Ethernet cable from lower right Port 4 on DM Encl 1 Mgmt Module A to upper Mgmt port on SP Mgmt module A (right side)
- f.) Ethernet cable from lower right Port 4 on DM Encl 1 Mgmt Module B to upper Mgmt port on SP Mgmt module B (left side)

### **Internal Network Cabling for NS80 (2) Blade Configuration:**

- a.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module A to port labeled 10/100 on CS—eth0 (lower left port)
- b.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module B to port labeled #2 on CS—eth2 (upper middle port)
- c.) Ethernet cable from lower right Port 4 on DM Encl 0 Mgmt Module A to upper Mgmt port on SP Mgmt module A (right side)
- d.) Ethernet cable from lower right Port 4 on DM Encl 0 Mgmt Module B to upper Mgmt port on SP Mgmt module B (left side)

### **Dual Control Stations:**

- g.) Lower right Port 4 Encl 0 Mgmt Module A to CS1 10/100 port
- h.) Lower right Port 4 Encl 1 Mgmt Module B to CS1 #2 port

## **VARIOUS CONNECTION METHODS TO NS40/NS80 INTEGRATED: CS, DM, SP**

### **CONNECTING TO NS40/NS80 INTEGRATED CS**

#### **I. CONNECTING TO CS USING SERIAL CABLE & HYPERTERMINAL:**

1. Connect null modem serial cable from Workstation COM1/COM2 to front serial port on the NS40/NS80 Control Station
2. Configure Hyperterminal connection for the Control Station using the following settings:  
Name of connection; Connect using: COM1 or COM2; Bits per second: 19200 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that Autodetect & ANSI are selected for terminal emulation)
3. Click on Hyperterm ‘Call’ icon to connect to Control Station & login at the prompt

#### **II. CONNECTING TO CS USING CROSSOVER ETHERNET CABLE TO EXTERNAL PORT ETH3:**

1. Temporarily remove External LAN cable from Public network and connect crossover cable from Workstation to external CS port eth3 (far left side of CS when viewed from rear) to create a private network
2. Configure an un-used IP address for the Workstation on the same network as the Control Station, & the internal network gateway:

**10.241.168.254** (example)

**255.255.255.0**

**192.168.1.100**

3. Verify connectivity from Workstation:

c:>ping 192.168.1.100 (Primary Internal Network CS0)

c:>ping 192.168.2.100 (Backup Internal Network CS0)

c:>ping 192.168.1.200 (SPA address)

c:>ping 192.168.2.201 (SPB address)

4. Open Internet Explorer Browser window for Celerra Manager or Navisphere

**192.168.1.100** or External IP Address (Celerra Manager, optionally use SSH Shell to run CLI)

**192.168.1.200** SPA (Navisphere Manager) or 192.168.2.201 SPB

**Note:** Both Celerra Manager & Navisphere Manager should show both SPs as managed when IP Forwarding is enabled

5. Enable IP Forwarding on Control Station via network connection:

# echo 1 >/proc/sys/net/ipv4/ip\_forward

# cat /proc/sys/net/ipv4/ip\_forward

1

## CONNECTING TO NS40/NS80 INTEGRATED DM

### I. CONNECTING TO NS40 BLADE USING SERIAL CABLE TO LAPTOP & HYPERTERM:

1. Connect serial cable from Workstation COM1/COM2 to DM upper serial maintenance port (indicated by wrench symbol) using special mini-DB9 cable (Part #038-003-084)

**Note:** Mini-DB9 cable is unique to NS40/NS80 Data Movers

2. Configure Hyperterminal connection for the Data Mover using the following settings:

Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that Autodetect & ANSI are selected for terminal emulation)

3. Click on ‘Call’ icon to connect to Data Mover: CONSOLE>

4. Set output to the console session and run direct commands to the Server:

**CONSOLE>logsys add output console**

**CONSOLE> version**

Product = EMC Celerra File Server

Version = T5.6.43.4 (CMB\_SLEDGEHAMMER 32-bit)

Debug = DEBUGOFF

BIOS = 3.58

POST = Rev. 01.50

1233070896: ADMIN: 6: Command succeeded: version

CONSOLE>ifconfig

5. Reset the console output to Log:

**CONSOLE>logsys delete output console**

**Note:** Reboot the Data Mover from the Control Station to watch the bootup process, or access F2 Setup/BIOS menu, or to access POST menu

### II. CONNECTING TO NS80 DM USING SERIAL CABLE & HYPERTERMINAL:

1. Connect from Workstation COM1/COM2 to Data Mover’s USB serial maintenance port (serial-to-USB adapter cable):

**Note:** Connect to righthand Management Module A’s USB port A (wrench symbol) using a Serial db9-to-USB connector, to connect to first blade in each enclosure (DM2, DM4, etc.). Connect to lefthand Management Module B’s USB port B (wrench symbol) using a Serial db9-to-USB connector, to connect to second blade in each enclosure (DM3, DM5, etc.).

2. Configure Hyperterminal connection for the Data Mover using the following settings:

Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that Autodetect & ANSI are selected for terminal emulation)

3. Click on ‘Call’ icon to connect to Data Mover: CONSOLE>

4. Set output to the console session and run direct commands to the Server:

CONSOLE>logsys add output console

CONSOLE> version

Product = EMC Celerra File Server

Version = T5.6.43.4 (HAMMERHEAD 32-bit)

Debug = DEBUGOFF

BIOS = 3.58

POST = Rev. 01.50

1233070896: ADMIN: 6: Command succeeded: version

CONSOLE>ifconfig

5. Reset the console output to Log:

CONSOLE>logsys delete output console

**Note:** Reboot the Data Mover from the Control Station to watch the bootup process, or access F2 Setup/BIOS menu, or to access POST menu

## CONNECTING TO NS40/NS80 INTEGRATED SP

### I. CONNECTING TO NS40/NS80 SPA/SPB USING SERIAL CABLE & HYPERTERMINAL:

1. Connect serial cable from Workstation COM1/COM2 to SP upper serial maintenance port (wrench symbol) using special mini-DB9 cable (Part #038-003-084)

2. Configure Hyperterminal connection for the Service Processor (SPA/SPB) using the following settings:

Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify ANSIW terminal emulation)

3. Click on ‘Call’ icon to connect to SP

4. Reboot SP to observe bootup and Resume PROM settings

**Note:** Above procedure is the same for CX3-80 SP’s, just be aware that SPB’s upper maintenance serial port is located on the lefthand side Management Module B, while SPA’s serial port is located on the righthand side Management Module A.

## **II. CONNECTING TO SP MANAGEMENT LAN ON NS40i OR SERVICE LAN ON NS80i:**

1a. Connect straight-through Ethernet cable from Workstation to the upper Management LAN port on SPA or SPB for NS40 Integrated

1b. Connect straight-through cable from Workstation to lower Service LAN port on Management Module A or Management Module B for NS80 Integrated

**Note:** The NS40 SP uses the lower Service LAN port on the CX3-40 array for the Internal Celerra network, while the NS80 uses the upper Management LAN port on the CX3-80 array for the Internal Celerra network. Please note that all CX3 arrays consider the bottom LAN port as the Service port, and the upper LAN port as the Management port. A BCM switch handles the internal network communications on the SPs, and is also why a crossover cable is not required.

2. Configure the Workstation to access the hard-coded CLARiiON System Network: 128.221.1 (same network SPA, SPB)

### **System IP Address SPA or SPB:**

**128.221.1.250 (SPA) 128.221.1.251 (SPB)**

a. Configure Workstation with following IP address:

My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

**128.221.1.249**

**255.255.255.0** (no gateway address or DNS settings)

b. Connect to bottom Service LAN port on left side Management Module B on CX3-80 or upper Management port on SPB for CX3-40 systems in order to communicate to SPA

c. Connect to bottom Service LAN port on right side Management Module A on CX3-80 or upper Management port on SPA on CX3-40 systems in order to communicate to SPB

**Note:** When connecting to the Clariion hard-coded System IPs on the CX3 arrays, communication to SPB is done via SPA’s Service or Management port on the CX3-40 and via Management Module A on the CX3-80. Similarly, communication to SPA is done via SPB’s Service or Management port on the CX3-40 array and via Management Module B on the CX3-80 array. Also, unlike the private Celerra network, which uses two different subnets, both SP’s use the same network when using the Clariion network.

3. Alternatively, configure the Workstation to access the default Celerra Internal IP network for either SPA or SPB:

### **Celerra IP Address SPA or SPB:**

**192.168.1.200 (SPA) 192.168.2.201 (SPB)**

a. Configure Workstation with following IP address & mask:

My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

**192.168.1.249 (SPA) 192.168.2.249 (SPB)**

**255.255.255.0**

b. Connect to the right side Management Module A on CX3-80 or SPA on CX3-40 system in order to communicate to SPA

c. Connect to the left side Management Module B on CX3-80 or SPB on CX3-40 system in order to communicate to SPB

**Note:** Unlike the default CLARiiON system IP Addresses, when connecting to the arrays using the Celerra’s Internal IP Address scheme, use the upper Management LAN port on SPA to talk to SPA, and the upper Management LAN port on SPB to talk to SPB for the NS40 system—use the left side Management Module’s lower Service LAN port to talk to SPB and the right side Management Module’s lower Service LAN port to talk to SPA for the NS80 system.

4. Verify connectivity from Workstation using Ping:

c:>ping 192.168.1.200 (SPA) or c:>ping 128.221.1.250 (SPA)

c:>ping 192.168.2.201 (SPB) or c:>ping 128.221.1.251 (SPB)

5. Open web browser and connect to Celerra Manager via IP Address:

192.168.1.100 (Primary network)

192.168.2.100 (Backup network)

**Note:** With the Internal Network scheme properly configured for either an NS42 or NS41 Integrated Celerra, both SPs should be reachable via CLI or Celerra Manager without the need for enabling IP Forwarding. Use Celerras>Tools>SSH Shell to open CLI session on Control Station from Celerra Manager.

6. Open web browser and connect to Navisphere Manager, or to the Setup program

192.168.1.200/setup (SPA) 192.168.2.201/setup (SPB)

128.221.1.250/setup (SPA) 128.221.1.251/setup (SPB)

**Note:** At the Navisphere Security popup window saying “Global Security is not initialized”, answer “No”. Without IP Forwarding enabled on the Control Station, the SP opposite the one to which the connection is made will show up as “(Unmanaged)”, and the connected SP may also display an array Fault with “client non-data stream error: TIMEDOUT”. This issue is seen primarily when running Flare versions 19 & 22 and is not seen with Flare 24.

7. Enable IP Forwarding on Control Station to resolve any connectivity issues within Navisphere Manager

# echo 1 >/proc/sys/net/ipv4/ip\_forward

# cat /proc/sys/net/ipv4/ip\_forward

1

**Note:** Once connected to the local internal Celerra network, a Web Browser session can be used to open either Celerra Manager or Navisphere Manager.

### **III. CONNECT TO CLARIION SYSTEM IPs TO VERIFY IP ADDRESS, HOSTNAME, GATEWAY:**

**Note:** Most Integrated systems should ship with CLARiiON SP's & Hostnames already configured for the Integrated Celerra environment. Use the default CLARiiON system IP addresses and the following procedure to verify or set the correct IP address, Hostname, and Gateway addresses for an Integrated Celerra using the /setup program.

1. Connect straight-through Ethernet cable from Workstation to the upper LAN port [Management] on SPA or SPB for CX3-40 and lower Service LAN port on Management Module A or Management Module B.

2. Configure the Workstation with a static IP of 128.221.1.249 or 128.221.1.254 & the following mask:

**Note:** Reserved IP Addresses for CLARiiON SP's are 128.221.1.250, 128.221.1.251, 128.221.1.252, 128.221.1.253, 192.168.1.1, & 192.168.1.2.

My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

- Use the following IP address:  
**IP address:** 128.221.1.249 or .254  
**Subnet mask:** 255.255.255.0

3. Verify connectivity from Workstation using Ping:

c:>ping 128.221.1.250/.251

4. Open web browser and connect to setup program on SPA/SPB, then confirm whether each SP has the correct IP Address, Hostname, & Gateway addresses for the Celerra environment:

**SPA: 128.221.1.250/setup**

**SPB: 128.221.1.251/setup**

5. Set proper IP Address, Hostname, and Gateway address on SPA, and wait until SPA reboots before continuing.

6. Connect to SPB/setup and repeat Step 5 process

7. For array management using Navisphere Manager (if Celerra Control Station is up), enable IP Forwarding so that both SP's can be managed

### **IV. CONNECT TO CLARIION SPs USING PPP (IP over Serial line) SESSION:**

**Note:** This connection method should be considered a last resort for a number of reasons. It's slow, it's time-consuming to setup, and it can lead to subsequent NAS Installation issues if the PPP connection is not properly disconnected.

1. Connect from Workstation COM1/COM2 to SPA/SPB upper serial maintenance port (wrench symbol) using mini-db9 cable

**Note:** For CX3-80 SPs, this port is located in the right side Management module for SPA, left side module for SPB

2. Create an IP connection between computers (Windows system & SPA) using IP over the serial interface:

**W2K:**

Start>Settings>Network and Dial-up Connections>Make New Connection>Next>Connect directly to another computer>Next>Guest>Next>Select a device (e.g., Communications Port (COM1))>Next>Create this connection: For all users>Next>provide a name for the connection and click 'Finish'.

**XP:**

Start>Connect To>>Show all connections>Create a New Connection>Next>Setup an advanced connection>Connect directly to another computer>Guest>Connection Name: SPA>Select a device (e.g., COM1)>Next>Create this connection for: Anyone's use>'Finish'.

3. The Connection window remains open--select Properties>Configure>set to 115200 with hardware flow control>click o.k. & then enter following:

**Connect To dialog box:**

**User name:** clarion

**Password:** clarion!

**Note:** Once authenticated and logged in, the system automatically assigns an IP & Route address of 192.168.1.2 for the workstation, with mask 255.255.255.255 for the WAN (PPP/SLIP) Interface, and uses 192.168.1.1 for SPA or SPB, depending on whether the serial port connection is to SPA or SPB.

4. Once the session is connected, open a Browser window and connect to SPA using its default system IP Address & setup program—answer “No” if prompted to create Domain Security on the CLARiiON:

**128.221.1.250/setup (SPA)**

**Note:** Since Navisphere & java are running over a serial connection, it will take time for Navisphere to connect. If the SP's are already configured for the Celerra environment, you would not need to run the /setup program and could instead simply connect to Navisphere using SPA or SPB's IP Address

5. For Integrated Celerras, configure the Hostname for SPA as “SPA”, enter the Celerra IP Address & Gateway information, click Apply Settings and the system will reboot:

Hostname: OEM-WF3HGVFERA0→Change to SPA

192.168.1.200 (IP address SPA)

255.255.255.0 (Mask)

192.168.1.100 (Gateway)

192.168.2.201 (Peer—SPB)

**Note:** The NS40/NS80 Celerra uses a different Internal IP network for SPB than that used for SPA

6. After SPA has completed its reboot, move the Serial cable to SPB's upper maintenance serial port (wrench symbol), reconnect the PPP session from the Windows system to the SP, and then open the Browser to connect to the default IP address for SPB so as to configure its IP address and hostname—remember to answer “No” when asked to enable Domain Security:

#### **128.221.1.251/setup**

Hostname: SPB

192.168.2.201 (IP Address SPB)

255.255.255.0 (Mask)

192.168.2.100 (Gateway)

192.168.1.200 (Peer IP Address SPA)

7. After SPB reboots, reconnect using the Web Browser and check for Privileged Users:

Highlight SPB>Properties>Check the Agent tab to verify whether any “Privileged Users” have been configured on the system. If Users are already configured, add the Celerra using: root@<CS\_External\_IP\_Address>

8. Reconnect the serial cable to SPA's maintenance port, connect via PPP session, then connect to Navisphere Manager on SPA using IP Address 192.168.1.200:

a.) Click Yes at the Warning – Security screen

b.) Enter IP Address & port to use for SPA in the Navisphere Connection screen

c.) Select No at the “Confirm: Navisphere Security” screen as we do not want to setup Clariion security

## **RESUME PROM ENCLOSURE SETTINGS FOR CX3 CLARiiON SPs & DATA MOVER BLADES:**

### **NAS:**

Resume PROM for Gateway or Integrated Data Movers should always be set to NAS

DHCP client is Enabled and allows for enclosure management

VLAN restrictions are Disabled to allow for daisy chaining of enclosures

### **SAN AUX:**

Resume PROM for Clariion SP's in most Integrated Celerra systems should be set to SAN AUX

**Note:** The exception to this rule is the NS80 Integrated system, which uses optical connectors, and SP's are set to SAN

DHCP client is Disabled in this enclosure configuration

VLAN restrictions are Disabled to allow dual Control Station configurations to work for Integrated NAS systems—no VLAN security set for Service vs. Public LAN ports

POST would stop blade from booting if SFP's were found in FE ports

### **SAN:**

Resume PROM for Gateway & NS80 Integrated Clariion SPs should be set to SAN

DHCP client is Disabled

VLAN restrictions are Enabled to keep Service LAN separate from Public LAN—i.e., VLAN security is set

POST would stop blade from booting if copper cables in FE ports are detected

## **VERIFYING & CHANGING RESUME PROM ENCLOSURE SETTING FOR NS40/NS80 AUX SPs:**

1. Connect serial cable from Workstation COM1/COM2 to SP upper serial maintenance port (indicated by wrench symbol) using special mini-DB9 cable (Part #038-003-084)

2. Configure Hyperterminal connection for the Service Processor (SPA/SPB) using the following settings:

Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that terminal emulation is set to Autodetect/ANSI)

3. Click on ‘Call’ icon to connect to SP

4. Reboot SP to observe bootup and Resume PROM settings:

BIOS 3 Release 6.1 POST Version 01.27

**Model: Sledgehammer: SAN AUX** (NS40Integrated)

**Model: Hammerhead: SAN** (NS80Integrated)

**Note:** Correct setting for Clariion SP in NS40 Integrated system is SAN AUX, while correct setting for NS80 Integrated would be SAN, due to direct optical connections between DMs and SPs. Normal setting would be SAN for NS40 Gateway models.

5. Use following steps if the correct SP personality is not set

a.) During the Extended POST sequence, where characters begin scrolling across the screen [ABCab...], use the “ctrl + c” keys (or Esc key if that does not work) to let POST complete, at which point a “.... Storage System Failure - Contact your Service Representative” message will display. Enter the POST password: SHIP\_it

**Note:** Original method used to interrupt POST was the “Esc” key—use the “esc” key only if the ctrl + c sequence does not work, say for an older platform, etc.

\*\*\*\*\*

\*WARNING: ABORTING EMC EXTENDED POST VIA ESC IS UNSUPPORTED \*

\* AND MAY CAUSE SYSTEM INSTABILITY. \*

\* PLEASE REBOOT AND USE THE CTRL-C ABORT MECHANISM. \*

\*\*\*\*\*

b.) At the POST Diagnostic Menu, select menu item (15) for Resume PROM Sub-Menu

**Note:** Menu item 22) for NS80

c.) Select 2) Set Resume and 5 XP\_Chassis

d.) Enter defaults until the SAN/NAS Type (5): SAN screen appears. Enter SAN AUX for NS40 systems, which is Type (3). Enter (1) for type SAN for NS80 systems, then enter 1 – Hammerhead for Family ID, if not already set to 1. Accept all other defaults.

**Note 1:** Enter SAN/NAS Type [0-Agnostic 1-SAN 2-NAS 3-SAN AUX] (0-3) [3] for NS40

**Note 2:** Enter SAN/NAS Type [0-Agnostic 1-SAN 2-NAS 3-SAN AUX 4-SAN SYMM] (0-4) [1] for NS80

e.) Exit menus to main Diagnostic Menu, select 1) Reset Controller to reboot SP, observe personality during reboot

f.) Reboot other SP and verify personality

## **VERIFYING & CHANGING RESUME PROM ENCLOSURE SETTING FOR NS40/NS80 AUX DM:**

**Note:** It's possible that a system may not have the correct RESUME setting for the DM blade in a CX3 system.

1. Connect to upper maintenance serial port on DM using special mini-db9 connector

**Note:** Connect to righthand Management Module A's upper leftmost USB port using a Serial db9-to-USB connector, to connect to first blade in each enclosure (DM2, DM4, etc.). Connect to lefthand Management Module B's upper leftmost USB port using a Serial db9-to-USB connector, to connect to first blade in each enclosure (DM3, DM5, etc.).

2. Open HyperTerminal application and configure for DM connection:

9600; 8; None; 1; None; Autodetect/ANSI

3. Reseat Data Mover and observe bootup:

Booting Extended POST

**Model: Sledgehammer: NAS (NS40)**

**Model: Hammerhead: NAS (NS80)**

**Note:** All NS40/NS80 Integrated or Gateway Data Movers should have their Enclosure personality set to “NAS”

4. If set to anything else, access the POST menu to update the Resume Prom using the following steps:

a.) When the following characters begin scrolling across the screen, press “ctrl + c” keys (or use “Esc” key if that does not work), which lets POST complete, then login to the POST menu using “SHIP\_it” or “DB\_key”—see following output:

*ABCab << Stopping after POST >>*

*DEabcdeFGHabcdIJKLMabcdeNOPabcQabcRabcSTUabVWXabYZAABBabcCCabcDDabcEEabcFFabGGHHIIJKKLLMMabcN  
NabcOOabcPPabcQQabRRabSSabTTabUUabVVabcWWXXYYZZAAABBCCCD*

*EndTime: 09/28/2009 19:23:48*

*.... Storage System Failure - Contact your Service Representative ...*

**<Type “SHIP\_it” here>**

b.) At POST Diagnostic Menu, select menu item (15) for Resume PROM Sub-Menu on NS40, or (22) for NS80

c.) Select 2) Set Resume and then 5 XP\_Chassis

d.) Enter defaults until the SAN/NAS Type (5): SAN screen appears. Enter [2] for NAS which is Type (2).

**Note:** Choices are [0-Agnostic 1-SAN 2-NAS 3-SAN AUX 4-SAN SYMM\*] (0-4) [ ]

e.) Exit menus to main Diagnostic Menu, select 1) Reset Controller to reboot SP, observe personality during reboot

f.) Disconnect

\*SAN SYMM choice is unique to NS80

## **NS42 CABLING:**

### **Internal Network Cabling for NS42:**

a.) Ethernet cable from lower management port DM3 to port labeled 2 on Control Station—eth2 (upper middle port)

b.) Ethernet cable from lower management port DM2 to port labeled 10/100 on CS—eth0 (lower left port)

c.) Ethernet cable from upper management port DM3 to lower management port on SPB

d.) Ethernet cable from upper management port DM2 to lower management port on SPA

**Note:** For NS42F Celerra, instead of lower port on SPs, will connect to Upper LAN port on SPs for c.) and d.) above

### **Fibre Channel Cabling from DM to SP on NS42:**

a. Data Mover blade 2 port BE 0 to SP A port 0 Fibre using copper SFP-to-SFP cable

b. Data Mover blade 2 port BE 1 to SP B port 0 Fibre using copper SFP-to-SFP cable

c. For dual blade systems, Data Mover blade 3 port BE 0 to SP A port 1 Fibre using copper SFP-to-SFP cable

d. For dual blade systems, Data Mover blade 3 port BE 1 to SP B port 1 Fibre using copper SFP-to-SFP cable

### **Fibre Channel Cabling from SP to DAE3P on NS42:**

a. SPA port BE0 to LCC A port Pri on first DAE3P [Encl 0 Loop 0] using SFP-to-HSSDC2 cable

b. SPB port BE0 to LCC B port Pri on first DAE3P [Encl 0 Loop 0] using SFP-to-HSSDC2 cable

- c. SPA port BE1 to LCC A port Pri on second DAE3P [Encl 0 Loop 1] using SFP-to-HSSDC2 cable
- d. SPB port BE1 to LCC B port Pri on second DAE3P [Encl 0 Loop 1] using SFP-to-HSSDC2 cable
- e. First DAE3P LCC A port Exp [Encl 0 Loop 0] to third DAE3P LCC A port Pri [Encl 1 Loop 0] using HSSDC2-to-HSSDC2
- f. First DAE3P LCC B port Exp [Encl 0 Loop 0] to third DAE3P LCC B port Pri [Encl 1 Loop 0] using HSSDC2-to-HSSDC2
- g. Second DAE3P LCC A port Exp [Encl 0 Loop 1] to fourth DAE3P LCC A port Pri [Encl 1 Loop 1] using HSSDC2-to-HSSDC2
- h. Second DAE3P LCC B port Exp [Encl 0 Loop 1] to fourth DAE3P LCC B port Pri [Encl 1 Loop 1] using HSSDC2-to-HSSDC2

#### **SPS Mini-DB9 serial to RJ12 Data Communications Cabling for NS42:**

- a. Mini-DB9 serial connection from SPB (bottom port) to SPS-B RJ12 jack
- b. Mini-DB9 serial connection from SPA (bottom port) to SPS-A RJ12 jack

#### **HSSDC2 & SFP CONNECTORS:**

HSSDC2 stands for High Speed Serial Data Cable 2, a copper fibre cable supporting 2.5Gbits/sec and having a smaller form factor than the HSSDC cable. HSSDC2 is generally used for connecting to the DAE3P or between DAE3Ps, and uses Copper FC Arbitrated Loop. SFP stands for Small Form-Factor Pluggable connectors, and can be either Copper Fibre or LC Duplex Fibre Optical, typically used for connecting to Hosts, such as CX3 series SPs and DMs.

### **NS42F CABLING:**

#### **Internal Network Cabling for NS42F:**

- a.) Ethernet cable from lower management port DM3 to port labeled 2 on Control Station—eth2 (upper middle port)
- b.) Ethernet cable from lower management port DM2 to port labeled 10/100 on CS—eth0 (lower left port)
- c.) Ethernet cable from upper LAN port DM3 to Upper Management LAN port on SPB
- d.) Ethernet cable from upper LAN port DM2 to Upper Management LAN port on SPA

#### **Fibre Channel Cabling from DM to SP on NS42F:**

- a. Data Mover blade 2 port BE 0 to SP A port 2 Fibre using fibre optic LC-to-LC SFP cable
- b. Data Mover blade 2 port BE 1 to SP B port 2 Fibre using fibre optic LC-to-LC SFP cable
- c. For dual blade systems, Data Mover blade 3 port BE 0 to SP A port 3 Fibre using fibre optic LC-to-LC SFP cable
- d. For dual blade systems, Data Mover blade 3 port BE 1 to SP B port 3 Fibre using fibre optic LC-to-LC SFP cable

### **NS80 CABLING:**

#### **Internal Network Cabling for NS80 (4) Blade Configuration:**

- a.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module A to port labeled 10/100 on CS—eth0 (lower left port)
- b.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module B to port labeled #2 on CS—eth2 (upper middle port)
- c.) Ethernet cable from upper Port 0 on Encl 0 Mgmt Module A to lower left Port 3 on DM Encl 1 Mgmt Module A
- d.) Ethernet cable from upper Port 0 on Encl 0 Mgmt Module B to lower left Port 3 on DM Encl 1 Mgmt Module B
- e.) Ethernet cable from lower right Port 4 on Encl 1 Mgmt Module A to upper Management port on SP Mgmt module A (right side)
- f.) Ethernet cable from lower right Port 4 on Encl 1 Mgmt Module B to upper Management port on SP Mgmt module B (left side)

#### **Internal Network Cabling for NS80 (2) Blade Configuration:**

- a.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module A to port labeled 10/100 on CS—eth0 (lower left port)
- b.) Ethernet cable from lower left Port 3 on DM Encl 0 Mgmt Module B to port labeled #2 on CS—eth2 (upper middle port)
- c.) Ethernet cable from lower right Port 4 on Encl 0 Mgmt Module A to upper Management port on SP Mgmt module A (right side)
- d.) Ethernet cable from lower right Port 4 on Encl 0 Mgmt Module B to upper Management port on SP Mgmt module B (left side)

#### **Dual Control Station Cabling:**

- g.) Lower right Port 4 Encl 0 Mgmt Module A to CS1 10/100 port
- h.) Lower right Port 4 Encl 1 Mgmt Module B to CS1 #2 port

#### **Fibre Channel Cabling from DM to SP on NS80:**

- a. Data Mover blade 2 port BE 0 to SP A port 0 Fibre using Fibre Optic multi-mode LC-to-LC cable (Optical SFP)
- b. Data Mover blade 3 port BE 0 to SP A port 1 Fibre using Fibre Optic multi-mode LC-to-LC cable
- c. Data Mover blade 4 port BE 0 to SP A port 2 Fibre using Fibre Optic multi-mode LC-to-LC cable
- d. Data Mover blade 5 port BE 0 to SP A port 3 Fibre using Fibre Optic multi-mode LC-to-LC cable
- e. Data Mover blade 2 port BE 1 to SP B port 0 Fibre using Fibre Optic multi-mode LC-to-LC cable
- f. Data Mover blade 3 port BE 1 to SP B port 1 Fibre using Fibre Optic multi-mode LC-to-LC cable
- g. Data Mover blade 4 port BE 1 to SP B port 2 Fibre using Fibre Optic multi-mode LC-to-LC cable
- h. Data Mover blade 5 port BE 1 to SP B port 3 Fibre using Fibre Optic multi-mode LC-to-LC cable

#### **Fibre Channel Cabling from SP to DAE3P on NS80:**

- a. SPA port BE0 to LCC A port Pri on first DAE3P [Encl 0 Loop 0] using SFP-to-HSSDC2 cable
- b. SPB port BE0 to LCC B port Pri on first DAE3P [Encl 0 Loop 0] using SFP-to-HSSDC2 cable
- c. SPA port BE1 to LCC A port Pri on second DAE3P [Encl 0 Loop 1] using SFP-to-HSSDC2 cable
- d. SPB port BE1 to LCC B port Pri on second DAE3P [Encl 0 Loop 1] using SFP-to-HSSDC2 cable

**Note:** Cabling schemes can vary greatly, depending on the total number of DAE2P/DAE3Ps, and on the types of drives in each enclosures. Refer to Clariion Setup Guide for more information. The above example shows Bus 0 to the 1<sup>st</sup> DAE3P and Bus 1 to the 2<sup>nd</sup> DAE3P. For an (8) DAE3P system with only two Buses, you might cable Bus 0/Loop 0 from SPA & SPB BE0 ports to LCC A & LCCB PRI, respectively, on the first DAE3P, then connect the next (3) DAE3Ps together via the EXP/PRI ports. Similarly, you

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
would then connect Bus 1/Loop 1 from SPA & SPB BE1 ports to LCC A & LCCB PRI, respectively, on the 5<sup>th</sup> DAE3P, then connect the other (3) DAE3Ps together via the EXP/PRI ports.

**SPS Mini-DB9 serial to RJ12 Data Communications Cabling for NS80:**

- a. Mini-DB9 serial connection from SPB (bottom port) to SPS-B RJ12 jack
- b. Mini-DB9 serial connection from SPA (bottom port) to SPS-A RJ12 jack

## **FRESH FIELD INSTALL--NS42 INTEGRATED SYSTEM NAS 5.5.27.5**

**Determine Factory vs. Field Install using the following verification steps:**

- I. Validate that the Clariion SP Resume PROM is set correctly (SAN AUX for NS40Integrated, SAN for NS80 Integrated)
- II. Validate that Clariion SP's are preconfigured to support the Celerra Internal Network (IP, Hostname, Mask, Gateway)
- III. Validate that Clariion array is preconfigured with Celerra Raid Groups/Luns
- IV. Perform Backend Cleanup of LUNs/Raid Groups if required
- V. Perform fresh install

**CELERRA NS42-FD FIELD INSTALLED INTEGRATED SYSTEM:**

1. After racking & cabling the NS42 array & Celerra hardware, power up the cabinet
2. Serially connect to SPA to verify the CLARiiON Resume PROM settings for the SP enclosure:
  - a. Connect serial cable from Workstation COM1/COM2 to SP upper serial maintenance port (indicated by wrench symbol) using special mini-DB9 cable (Part #038-003-084)
  - b. Configure Hyperterminal connection for the Service Processor (SPA/SPB) using the following settings:  
Name of connection: Connect using: COM1 or COM2; Bits per second: 9600 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify ANSIW terminal emulation)
  - c. Click on 'Call' icon to connect to SP
  - d. Reboot CLARiiON SPA, and during POST, verify that RESUME PROM values are set to SAN AUX

**Note:** An ICA's (Integrated Clariion Array) should display the following characteristic during the Extended POST

**Model: Sledgehammer: SAN AUX**

3. Use Ethernet cable to connect to SPA/SPB to verify whether the CLARiiON array has been preconfigured for NAS Installation  
**Note:** An Integrated system should ship with the array already preconfigured for the Celerra. The purpose of the following procedure is to verify that the backend SP's and Celerra Raid Groups/System LUNs have been properly configured, as well as to make the necessary changes if not.
  - a. Connect straight-through Ethernet cable from the Workstation to the upper LAN port [Management] on either SPA or SPB
  - b. Configure the Workstation with an unused IP address and mask value for SPA's network. Connect to either the Internal Celerra Network for SPA [192.168.1.0] or to the default Clariion Network for SPA [128.221.1.0], and verify/configure SPA:  
My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

|                              | Celerra Network (only when configured) | Clariion Network (hard-coded) |
|------------------------------|--|-------------------------------|
| <b>SPA Address:</b>          | <b>192.168.1.200</b>                   | <b>or</b>                     |
| <b>IP address (laptop):</b>  | <b>192.168.1.249 or .254</b>           | <b>128.221.1.250</b>          |
| <b>Subnet mask (laptop):</b> | <b>255.255.255.0</b>                   | <b>128.221.1.249 or .254</b>  |

c. Open web browser and connect to the setup program for SPA [192.168.1.200/setup or 128.221.1.250/setup] to confirm that IP, Hostname, Subnet Mask, & Gateway addresses are correctly setup for the Celerra environment.

**Note:** At the Navisphere Security popup window saying "Global Security is not initialized", answer "No".

d. If required, edit the following fields:

**IP Address:** **192.168.1.200**

**Hostname:** **SPA**

**Subnet Mask:** **255.255.255.0**

**Gateway:** **192.168.1.100**

e. Click the "Apply Settings" button and SPA will reboot

**Note:** Wait approximately five minutes for SPA to reboot and come back online, then proceed to next step to verify/configure SPB

f. Configure the Workstation with an unused IP address and mask value for SPB's network. Connect to either the Internal Celerra Network for SPB [192.168.2.0] or to the default Clariion Network [128.221.1.0], and verify/configure SPB:  
My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

|                              | Celerra Network (only when configured) | Clariion Network (hard-coded) |
|------------------------------|--|-------------------------------|
| <b>SPB Address:</b>          | <b>192.168.2.201</b>                   | <b>or</b>                     |
| <b>IP address (laptop):</b>  | <b>192.168.2.249 or .254</b>           | <b>128.221.1.251</b>          |
| <b>Subnet mask (laptop):</b> | <b>255.255.255.0</b>                   | <b>128.221.1.249 or .254</b>  |

g. Open web browser and connect to setup program for SPB [192.168.2.201/setup or 128.221.1.251/setup] to confirm that IP, Hostname, Subnet Mask, & Gateway addresses are correctly setup for the Celerra environment.

**Note:** At the Navisphere Security popup window saying "Global Security is not initialized", answer "No".

h. If required, edit the following fields:

**IP Address:** **192.168.2.201**

**Hostname:** **SPB**

**Subnet Mask:** 255.255.255.0

**Gateway:** 192.168.2.100

i. Click the “Apply Settings” button and SPB will reboot

**Note:** Wait approximately five minutes for SPB to reboot and come back online. Please note that unlike the hard-coded Clariion network scheme, which uses the 128.221.1 network for both SP’s, Celerra uses a different network for SPA (192.168.1) and SPB (192.168.2)

4. Configure the Workstation for the Internal Celerra network (192.168.1), and reconnect to SPA’s Management LAN port to verify whether the Clariion array has been preconfigured with Celerra Raid Groups/System LUNs

a. Open web browser and connect to Navisphere Manager using SPA’s IP Address: 192.168.1.200

**Note:** If a Navisphere Security popup window appears, “Global Security is not initialized”, answer “No”.

b. Note the Flare version (Array\_name>Properties>Software)

c. Check for pre-configured Celerra Raid Groups and system LUNs by expanding RAID Groups icon. Verify that LUNs 0-5 exist for RG 0 (system) and LUN 200 for RG 200 (Hot Spare)

**Note:** The presence of preconfigured Celerra Raid Groups/LUNs is a general indicator that the system is a Factory Install and should not require a fresh Field Install. However, if the preconfigured LUNs were not built with the shipped Integrated Celerra system, then the LUNs and Raid Groups would have to be destroyed before the Celerra could be installed.

d. For Fresh Installs only, delete the Celerra LUNs and Raid Groups. Unbind LUNs 0-5, then LUN 200, then rightclick RG 0 and select “Destroy”—repeat for RG200 Hot Spare

**Note:** Delete using Navisphere or Celerra CLI—if the RGs are not deleted, the fresh install process will fail because the Celerra install script will detect the Raid Groups (and Control Luns) and error out. For factory-install systems, the Raid Groups and Control Luns are pre-configured and should already exist, and you would not delete.

#### **Fresh Install Fails because System LUNs are already present:**

“Checking for existing System RG/LUN: Replacement Control Station Detected.”

“[FAILED]”

#### **e. DELETE CELERRA STORAGE GROUP, CONTROL LUNs, & RAID GROUPS USING NAVISPHERE:**

→Use straight ethernet cable & connect directly to SPB’s service LAN port (btm), configure workstation with IP address on 128.221.1 network, open web browser, enter default CLARiiON IP address for SPA for Navisphere: 128.221.1.250

- (1) Rightclick Celerra Storage Group>Connect Hosts>Select Hosts and remove
- (2) Rightclick Celerra Storage Group>Destroy
- (3) Navisphere>Expand SPA and highlight LUNs 0-5>Unbind
- (4) Navisphere>Unowned LUNS>LUN 200>Unbind
- (5) Highlight RAID Group 0>Destroy
- (6) Highlight RAID Group 200>Destroy [Continue with steps 7-10 for NS20/20FC/40/40FC complete backend cleanup]

**Note:** With the advent of CLARiiON Virtual Provisioning, supported by NAS 5.6.45, you may also need to delete ThinLuns and ThinPools from the Storagepool list

- (7) ctrl + shift + f12 messner for Engineering Mode:

Rightclick Array>Select Engineering Mode>Disable Access Logix

- (8) Navisphere (Engineering Mode)>Array>Properties>Software>select CelerraService>Uninstall

(9) Enter Clariion Setup Program (128.221.1.250/setup), change Gateway IP if necessary, on SPA, which requires reboot (then connect to SPA’s service port to access SPB and change Gateway IP address)

(10) Reconnect to SPA /setup program, choose the option “Reset all domain information and restart the Management Server” to “Destroy Security and Domain Information” on array, if required

#### **f. DELETE CELERRA CONTROL LUNs & RAID GROUPS USING CLI (Backend Cleanup Procedure):**

**Note:** If the /tftpboot/setup\_backend directories do not exist, unzip and untar the /nas/tools/tftpboot.tar.gz. Using a serial connection between Workstation and Control Station, open a HyperTerminal session to the Control Station to perform cleanup. The nas\_raid cleanup procedure is now an official procedure in all the NSxx Celerra Integrated Setup Guides, as well as the NS20 & NS40.

(1) Run the following to breakdown the array management setup:

**# /nasmcd/sbin/clariion\_mgmt -stop**

**Note:** If this fails, run the command again and add the –skip\_rules switch.

(2) Unset the NAS\_DB environmental variable prior to running cleanup:

**# unset NAS\_DB**

(3) Stop NAS Services:

**# /sbin/service nas stop**

(4) Remove Raid Groups and System LUNs—Raid Groups 0 & 200 are defaults:

**# cd /tftpboot/setup\_backend; ./nas\_raid -n ./bin/navicli -a 192.168.1.200 -b 192.168.2.201 -s cleanup**

Log will be created in the current directory →nas\_raid.log

System 192.168.1.200 is up

System 192.168.2.201 is up

Clariion Array: APM00063303725 Model: CX3-40 Memory: 4096

!!! WARNING !!!

The CLARiiON array connected to this Celerra control station contains an existing configuration.

This could include user data.

If you continue by selecting 'y' to cleanup the system at the next prompt all existing CLARiiON configuration will be destroyed and the system will have to be reinstalled.

Proceed with caution!

!!! WARNING !!!

Do you want to clean up the system [yes or no]?: yes

Cleaning Storage Group "Celerra\_emcnas\_i0"

Removing LUN .....

Removing diskgroup ..

Removing initiators ..

Removing storage group "Celerra\_emcnas\_i0"

Removing spares

Cleanup (200) ..

Access Logix disabled

Security domain removed

Done

(5) Verify:

**# /tftpboot/bin/navicli -h 192.168.1.200 getrg**

(6) Zero out drives—only systems below Flare 24—can take a long time to complete:

**# cd /tftpboot/setup\_backend; ./nas\_raid -n ./bin/navicli -a 192.168.1.200 -b 192.168.2.201 -s zero**

5. Verify CLARiiON Software Packages:

Rightclick array APM...>Properties>Software tab to verify array software:

FLARE-Operating-Environment 03.22.040.5.005 Commit required

AccessLogix - Active

NavisphereManager - Active

6. Allocate Write & Read Memory for SPs:

Rightclick Array>Properties>Memory tab, allocate 2048MB memory for Write Cache, then 968MB Read Cache for SPA, and 968MB Read Cache for SPB--this step automatically enables the Write cache on the system

**Note:** You will need to determine what the correct values are for Read Cache vs. Write Cache—the default CX3-40 system has 4096MB memory. Under Array Properties>Memory tab, configure the maximum write cache for the system, which in this example was 2048MB. Divide the remaining cache for Read cache on SPA & SPB. In general, the Clariion Best Practices guide recommends allocating as much memory as possible to Write cache, with the balance split as Read cache between the SPs, but keep in mind that specific customer environments may dictate different cache allocation values.

7. Verify Write & Read Cache Settings:

Array>Properties>Cache tab, ensure that Write cache is selected and that Read Cache for SPA & SPB are selected

8. Check for “Privileged Users” on the SPs:

Highlight SPA>Properties and check the Agent tab to verify whether any “Privileged Users” have been configured on the system. If Users are already configured, add the Celerra using: root@<CS\_External\_IP\_Address>

9. Disconnect any PPP sessions (if used) and reboot SPA to clear any potential contention with the Internal Celerra network

192.168.1.100—see emc151721

10. Establish Serial Connection between Control Station & Workstation by connecting a null modem DB9 female cable from COM port to front serial port on the NS40 Control Station

11. Create a Hyperterminal connection between systems using the following settings:

Start>Programs>Accessories>Communications>Hyperterminal>Name of connection>Connect using: COM1 or COM2>set Bits per second: 19200 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None>verify that Autodetect & ANSIW are selected for terminal emulation

12. Verify that NAS Version will be compatible with the Flare version running on the Backend—go to EMC Support Matrix, as found in eLab Navigator via the Powerlink portal. In this particular example, NAS 5.5.22.2 is the minimum code compatible with Flare 22 for the NS40 platform.

13. Create install floppy from CD-ROM for NAS 5.5.27.5 and commence the fresh NAS installation

```
# mount /dev/cdrom /mnt/cdrom  
# mount -t msdos /dev/fd0 /mnt/floppy  
# dd if=/mnt/cdrom/images/boot.img of=/dev/fd0 bs=1024
```

**Note:** Though the command comes back to the prompt immediately, keep in mind that the floppy has not yet been written to—the process will take a few minutes to complete

14. Commence Installation by inserting boot floppy and CD-ROM, then rebooting or powering on the Control Station

**Note:** Below Console outputs are informational and not comprehensive as to what takes place during the installation

a.) Type following at boot prompt:

boot: **serialinstall**

Loading initrd.img.....

Loading vmlinuz.....

Running install

Running Anaconda – please wait

b.) Destructive Linux installation: **Yes**

Pre Install

Package Installation (259 packages, takes about 10 minutes)

Complete

Installation is complete. Remove the boot media and press return to reboot.

c.) Remove boot media: **O.K.**

---

Starting EMC NAS Factory Installation

d.) Is this a Control Station Fresh Install? **Yes**

e.) At prompt, configure the Internal & External IP Addresses, Control Station hostname

The "emcnas" package install Succeeded.  
To run the new package login as <nasadmin>.  
Press Enter key to exit install :  
[ OK ]

## **NS42 INTEGRATED FLARE NDU UPGRADE PROCEDURE—LAN GUI METHOD:**

**Prerequisites:** Laptop has a copy of the Flare Upgrade package and the Navisphere Service Taskbar Version 6.24 installed.

1. Configure laptop or workstation with the following static IP address & click o.k. to save:

My Network Places>Properties>Local Area Connection 2>Properties>Internet Protocol (TCP/IP)>Properties:

- Use the following IP address:  
IP address: 192.168.1.95  
Subnet mask: 255.255.255.0  
Default gateway: 192.168.1.100

2. Connect an Ethernet cable (not a crossover cable) from the Laptop/workstation to the upper LAN port on SPA (Internal Network) & ping SPA

**Note 1:** If the connection to the SP fails, disable the DNS setting and reboot the laptop and try again

**Note 2:** The Service LAN port on SPA is actually a connection to SPB, and vice versa, while the Management LAN port on SPA is a direct connection to SPA, etc.

3. Connect to Celerra Manager via Web Browser using: <http://192.168.1.100>

4. Connect to Control Station using Celerras>Tools>SSH Shell, login, su to root, and perform the following activities:

- a.) Enable IP Forwarding on the Control Station for the NDU Upgrade procedure & verify:

**# echo 1 > /proc/sys/net/ipv4/ip\_forward**

**# cat /proc/sys/net/ipv4/ip\_forward**

1

- b.) Run Storage Check to verify backend connectivity:

**# /nas/bin/nas\_storage -check -all**

Discovering storage (may take several minutes)

done

- c.) Check for trespassed luns:

**# /nas/sbin/navicli -h 192.168.1.200 getlun -trespass**

**Note:** There are no trespassed LUNs if the output is blank

- d.) Verify SP IP & Gateway addresses to Celerra Internal Network:

**# /nas/sbin/navicli -h 192.168.1.200 networkadmin -get**

Storage Processor: SP A

Storage Processor Network Name: SPA

Storage Processor IP Address: 192.168.1.200

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: **192.168.1.100** (eth0 on Control Station)

**# /nas/sbin/navicli -h 192.168.2.201 networkadmin -get**

Storage Processor: SP B

Storage Processor Network Name: SPB

Storage Processor IP Address: 192.168.2.201

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 192.168.2.100 (eth2 on CS)

e.) Verify currently installed and committed Clariion Software:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -list**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.22.040.5.511

Commit Required: NO

Revert Possible: NO

Active State: NO

Is installation completed: YES

Is this System Software: NO

f.) Check for Clariion Faults:

**# /nas/sbin/navicli -h 192.168.1.200 getcrus**

SPE3 Enclosure SPE

Bus 0 Enclosure 0 LCC A State: Present

Bus 0 Enclosure 0 LCC B State: Present

Bus 0 Enclosure 0 LCC A Revision: 7.66

Bus 0 Enclosure 0 LCC B Revision: 7.66

Bus 0 Enclosure 0 LCC A Serial #: FCNBD063531833

Bus 0 Enclosure 0 LCC B Serial #: FCNBD063531839

**# /nas/sbin/navicli -h spa faults -list**

The array is operating normally.

g.) Verify that Clariion Statistics Logging is enabled:

**# /nas/sbin/navicli -h 192.168.1.200 setstats**

Statistics logging is ENABLED

**# /nas/sbin/navicli -h 192.168.2.201 setstats**

Statistics logging is ENABLED

**Note:** If not Enabled, run following command on each SP to Enable

**# /nas/sbin/navicli -h 192.168.1.200 setstats -on**

**# /nas/sbin/navicli -h 192.168.2.201 setstats -on**

h.) Verify Clariion IO disk and CPU load:

**# /nas/tools/check\_clariion**

CPU UTILIZATION (MUST BE LESS THAN 50% PER STORAGE PROCESSOR)

THIS WILL TAKE APPROXIMATELY 1 MINUTE(S).

CLARIION: APM00063303725:

SP A ..... 003.50% (PASS)

SP B ..... 000.64% (PASS)

DISK I/O LOAD (MUST BE LESS THAN 100 I/O OPERATIONS PER SECOND PER DISK)

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
THIS WILL TAKE APPROXIMATELY 4 MINUTES.

CLARIION: APM00063303725:

DISK 0\_0\_0 ..... 006 OPS/SEC (PASS)  
DISK 0\_0\_1 ..... 005 OPS/SEC (PASS)  
DISK 0\_0\_2 ..... 002 OPS/SEC (PASS)  
DISK 0\_0\_3 ..... 003 OPS/SEC (PASS)v

5. Use Celerra Manager to verify that Clariion IO/s are below 15,000 per second:

Celerra Manager>Celerras>Storage System>CLARiiON: review the graph

6. Using Control Station SSH session, complete the following steps:

a.) Disable Statistics Logging on each SP:

# /nas/sbin/navicli -h 192.168.1.200 setstats -off

# /nas/sbin/navicli -h 192.168.2.201 setstats -off

b.) Disable Clariion Write Cache & Verify:

# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 0

# /nas/sbin/navicli -h 192.168.1.200 getcache

|                       |          |
|-----------------------|----------|
| SP Read Cache State   | Enabled  |
| SP Write Cache State  | Disabled |
| SPA Write Cache State | Disabled |
| SPB Write Cache State | Disabled |

7. On the laptop/workstation, open the Navisphere Service Taskbar application & conduct the following actions to perform the NDU Upgrade:

a.) Connect to SPA by entering IP Address or Host Name in connection box:

Navisphere Service Taskbar>File>Connect>Select Storage System to Connect

Please enter the IP Address or Host Name of the target Storage Processor (SP)

**192.168.1.200**

b.) Software Assistant>Install Software>Welcome to the Install Software Wizard>Next

c.) On the Software Selection screen, browse to the location of the Flare Upgrade package and select>Next

d.) Software Selection screen unpacks and transfers files to the CLARiiON

e.) For the ‘Server readiness for software update’, if the High Availability check flags an issue, verify that the HA configuration is correct and then check off each box in the ‘Override HA Status’ column to continue>Next

f.) A number of Rule Checks are conducted, with results posted. If only Warnings are posted, and the details say that it is o.k. to continue after verifying each Warning or Info item, proceed with the next step.

**Note:** To enter Engineering mode with the NST tool, type Ctr + Shift + F12 and type SIR. Some failed rules is can be overridden by entering a password when running a mouse over the icon—password is “siw”.

g.) Keep the default 360 seconds setting in the ‘Non-disruptive Upgrade Delay’ screen>Next

h.) A Confirmation screen appears, select Next to continue

i.) For approximately the next hour, a ‘Software Maintenance Status’ screen will provide updates as to the progress of the Flare Upgrade, starting first with SPB, then finishing with SPA

j.) After the ‘Software Maintenance Status’ screen shows 100% completion, the ‘Post-install Tasks’ screen appears. If ready to do so, commit the newly upgraded Flare version, and click Finish.

k.) A ‘Registration Summary’ window appears, collects system statistics, and then presents the option to either Email the registration information or to Save the registration information to file—select the preferred choice in the ‘Select Transport’ screen and continue. If choosing to Save Registration, browse to a location on the laptop to save the file.

l.) A ‘Success’ screen completes the upgrade. Click ‘Finish’ to exit the NST application.

8. Complete Post-Install Steps from Celerra Manager SSH Session—log back into Celerra Manager if required--the SPA reboot does not seem to reset the network interface ports and the connection should survive.

Verify that Read & Write Cache are properly enabled—system will re-enable automatically after NDU is complete:

# /nas/sbin/navicli -h 192.168.1.200 getcache

|                      |         |
|----------------------|---------|
| SP Read Cache State  | Enabled |
| SP Write Cache State | Enabled |

# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 1

**Note:** Use above command to re-enable Write Cache if required, though the system should do this automatically

9. Verify that Statistics Logging is re-enabled—enable on each SP if required:

# /nas/sbin/navicli -h 192.168.1.200 setstats

Statistics logging is ENABLED

# /nas/sbin/navicli -h 192.168.2.201 setstats

Statistics logging is ENABLED

# /nas/sbin/navicli -h 192.168.1.200 setstats –on (Use to re-enable if required, and run on each SP)

10.) Manually check & trespass back any failed over Celerra LUNs:

**Note:** Since SPA was the last SP to reboot during the NDU process, SPA luns were trespassed to SPB

**# /nas/sbin/navicli -h 192.168.1.200 getlun -tresspass**

LOGICAL UNIT NUMBER 5

Default Owner: SP A

Current owner: SP B

LOGICAL UNIT NUMBER 0

Default Owner: SP A

Current owner: SP B

LOGICAL UNIT NUMBER 16

Default Owner: SP A

Current owner: SP B

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 16**

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 5**

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 0**

11.) Turn off IP Forwarding on the Control Station & Verify:

**# echo 0 > /proc/sys/net/ipv4/ip\_forward**

**# cat /proc/sys/net/ipv4/ip\_forward**

0

12.) Verify that new Flare version is committed:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -list |head**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.24.040.5.006

Commit Required: NO

Revert Possible: NO

Active State: YES

Is installation completed: YES

Is this System Software: NO

## **NS42 INTEGRATED FLARE NDU UPGRADE PROCEDURE—CS CLI METHOD:**

**Note:** This procedure was based on NAS 5.5.22.2 and upgrading from Flare 22 (03.22.040.5.005) to 03.22.040.5.511. Due to the differing subnets on SPA & SPB, it is recommended that the Flare NDU Upgrade be performed from the Celerra Control Station, though with IP Forwarding enabled, the Navisphere GUI can manage both SPs and the NDU Upgrade is possible using the Navisphere NST (Navisphere Service Taskbar) or Navisphere GUI when directly connected to the Internal Network.

1. Verify current CLARiiON software version and state:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -list**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.22.040.5.005

Commit Required: NO

Revert Possible: NO

Active State: YES

Is installation completed: YES

Is this System Software: NO

2. Upload Flare bundle to Control Station directory:

**/home/nasadmin/flare/cx3-40-bundle-03.22.040.5.511.pbu**

3. Run storage check to verify backend paths, etc:

**# /nas/bin/nas\_storage -check -all**

Discovering storage (may take several minutes)

done

4. Check for trespassed luns:

**# /nas/sbin/navicli -h 192.168.1.200 getlun -tresspass**

5. Verify SP Gateway addresses to Control Station Internal Networks:

**# /nas/sbin/navicli -h 192.168.1.200 networkadmin -get**

Storage Processor: SP A

Storage Processor Network Name: SPA

Storage Processor IP Address: 192.168.1.200

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: **192.168.1.100 (eth0 on Control Station)**

**# /nas/sbin/navicli -h 192.168.2.201 networkadmin -get**

Storage Processor: SP B  
Storage Processor Network Name: SPB  
Storage Processor IP Address: 192.168.2.201  
Storage Processor Subnet Mask: 255.255.255.0  
Storage Processor Gateway Address: **192.168.2.100 (eth2 on Control Station)**

**# /sbin/ifconfig -a**

```
eth0    Link encap:Ethernet HWaddr 00:00:F0:9F:B3:74
        inet addr:192.168.1.100 Bcast:192.168.1.255 Mask:255.255.255.0
              UP BROADCAST NOTRAILERS RUNNING MULTICAST MTU:1500 Metric:1
              RX packets:4337789 errors:0 dropped:0 overruns:0 frame:0
              TX packets:6321336 errors:0 dropped:0 overruns:0 carrier:0
              collisions:0 txqueuelen:100
              RX bytes:1248565640 (1190.7 Mb) TX bytes:3307255372 (3154.0 Mb)

eth2    Link encap:Ethernet HWaddr 00:00:F0:9F:53:07
        inet addr:192.168.2.100 Bcast:192.168.2.255 Mask:255.255.255.0

Bus 0 Enclosure 0 LCC B Serial #: FCNBD063531839

**# /nas/sbin/navicli -h 192.168.2.201 getcrus** (output abridged)

7. Verify that Statistics Logging is Enabled for both SP's & enable if not on:

**# /nas/sbin/navicli -h 192.168.1.200 setstats**

Statistics logging is ENABLED

**# /nas/sbin/navicli -h 192.168.2.201 setstats**

Statistics logging is ENABLED

**# /nas/sbin/navicli -h 192.168.1.200 | 2.201 setstats -on**

**Note:** To Enable statistics

8. Verify Clariion Front-End IO/s are below 15,000 per second:

a.) Using Celerra Manager>Celerras>Storage>Systems>CLARiiON CX3-40>System: Front-End I/O Requests Graph, with I/O statistics to the right of the graph: 0.0 I/O Req/sec.

9. Disable statistics logging for both SPs during the NDU process & Verify:

**# /nas/sbin/navicli -h 192.168.1.200 setstats -off**

# /nas/sbin/navicli -h 192.168.1.200 setstats

Statistics logging is DISABLED

# /nas/sbin/navicli -h 192.168.2.201 setstats –off

# /nas/sbin/navicli -h 192.168.2.201 setstats

Statistics logging is DISABLED

10. Verify CLARiiON IO disk load and CPU load:

# /nas/tools/check\_clariion

CPU UTILIZATION (MUST BE LESS THAN 50% PER STORAGE PROCESSOR)

THIS WILL TAKE APPROXIMATELY 1 MINUTE(S).

CLARIION: APM00063303725:

SP A ..... 000.65% (PASS)

SP B ..... 000.98% (PASS)

DISK I/O LOAD (MUST BE LESS THAN 100 I/O OPERATIONS PER SECOND PER DISK)

THIS WILL TAKE APPROXIMATELY 4 MINUTES.

CLARIION: APM00063303725:

DISK 0\_0 ..... 002 OPS/SEC (PASS)

DISK 0\_0\_1 ..... 003 OPS/SEC (PASS)

DISK 0\_0\_2 ..... 004 OPS/SEC (PASS)

DISK 0\_0\_3 ..... 001 OPS/SEC (PASS)

11. Disable CLARiiON Write cache

# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 0

# /nas/sbin/navicli -h 192.168.1.200 getcache

SP Read Cache State      Enabled

SP Write Cache State     Disabled

SPA Write Cache State    Disabled

SPB Write Cache State    Disabled

12. As Root User, enable IP Forwarding on Control Station for the Upgrade & Verify:

# echo 1 > /proc/sys/net/ipv4/ip\_forward

# cat /proc/sys/net/ipv4/ip\_forward

1

#### **Example of Flare Upgrade Failure if IP Forwarding is not set:**

**Note:** Following example shows results of NDU Upgrade attempt without first enabling IP Forwarding—fails because lack of route to SPB—IP Forwarding allows the Linux Control Station to serve as a router between the two internal networks

# /nas/sbin/navicli -h 192.168.1.200 ndu -install /home/nasadmin/flare/cx3-40-bundle-03.22.040.5.511.pbu -delay 360

Running install rules...

=====

Version Compatibility      : Rule passed.

Special Conditions        : Rule has warning.

Statistics Logging Disabled    : Rule failed.

Acceptable Processor Utilization    : Rule failed.

Redundant SPs            : Rule failed.

Host Connectivity        : Rule has warning.

No Trespassed LUNs      : Rule passed.

No Transitions           : Rule passed.

No System Faults        : Rule passed.

All Packages Committed    : Rule passed.

2 rule(s) have warnings.

3 rule(s) failed.

Detailed rule results:

=====

RULE NAME: Special Conditions

RULE STATUS: Rule has warning.

RULE DESCRIPTION: This rule is a warning to check for special conditions before installing software on the storage system.

RULE RESULT: Please check for the following conditions:

1. All attached servers are running failover software.

2. All attached VMWare ESX servers running pre v2.1.0 software should have I/O stopped

RULE INSTRUCTION: null

RULE NAME: Statistics Logging Disabled

RULE STATUS: Rule failed.

RULE DESCRIPTION: This rule verifies statistics logging is disabled on the storage system.

RULE RESULT: Statistics logging is enabled.

RULE INSTRUCTION: Statistics logging must be disabled before the install can proceed.

RULE NAME: Acceptable Processor Utilization

RULE STATUS: Rule failed.

RULE DESCRIPTION: This rule verifies each SP's utilization is low enough to accommodate an installation.

RULE RESULT: Cannot enable statistics logging on SP B. Verify SP B is operational.

RULE INSTRUCTION: Retry the installation when the storage system workload is expected to be low.

RULE NAME: Redundant SPs

RULE STATUS: Rule failed.

RULE DESCRIPTION: This rule checks for availability of dual SPs.

RULE RESULT: SP B: Error detected, SP is unmanaged.

RULE INSTRUCTION: All SPs must be operational for the installation to proceed.

RULE NAME: Host Connectivity

RULE STATUS: Rule has warning.

RULE DESCRIPTION: This rule checks for a path from each attached host to each SP.

RULE RESULT: During the installation, connectivity may be lost to following attached hosts:

50:06:01:60:C1:E0:1C:D0:50:06:01:68:41:E0:1C:D0 SP A Port 1

50:06:01:60:C1:E0:1C:D0:50:06:01:69:41:E0:1C:D0 SP B Port 1

50:06:01:60:C1:E0:1C:D0:50:06:01:60:41:E0:1C:D0 SP A Port 0

50:06:01:60:C1:E0:1C:D0:50:06:01:61:41:E0:1C:D0 SP B Port 0

RULE INSTRUCTION: Connectivity loss may be prevented if the storage system has 2 SPs, and each attached host has a path to each SP.

Pre installation rules have been run to ensure the success of this software upgrade. The above conditions have been detected that need to be corrected before running this command again. If this condition persists please contact your EMC Service representative.

13. Perform NDU Upgrade:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -install /home/nasadmin/flare/cx3-40-bundle-03.22.040.5.511.pbu -delay 360**

Item number: 0

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.22.040.5.511

Already Installed Revision 03.22.040.5.005

Installable YES

Disruptive upgrade: NO

Ndu Delay: 360 secs

The requested package(s) will be installed. Do you wish to proceed? : (y/n)? y

14. Tracking & Verifying Install Progress:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -status**

Is Completed: NO

Status: Preparing array Settings

Operation: Install

**# /nas/sbin/navicli -h 192.168.2.201 ndu -status**

Is Completed: NO

Status: Running check scripts

Operation: Install

**# /nas/sbin/navicli -h 192.168.2.201 ndu -status**

Is Completed: NO

Status: Installing software on secondary SP

Operation: Install

**# /nas/sbin/navicli -h 192.168.1.200 ndu -status**

Is Completed: NO

Status: Deactivating software on secondary SP

Operation: Install

**# /nas/sbin/navicli -h 192.168.1.200 ndu -status**

Is Completed: NO

Status: Activating software on secondary SP

Operation: Install

**# /nas/sbin/navicli -h 192.168.1.200 ndu -status**

Is Completed: YES

Status: Operation completed successfully

Operation: Install

**# /nas/sbin/navicli -h 192.168.2.201 ndu -status**

Is Completed: YES

Status: Operation completed successfully

Operation: Install

**Note:** At this point, FLARE has been installed but not yet committed

15. Post Install Steps:

a.) Verify that Read & Write Cache has been automatically re-enabled on both SPs:

**# /nas/sbin/navicli -h 192.168.1.200 getcache**

SP Read Cache State Enabled

SP Write Cache State Enabled

**# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 1**

**Note:** Use above command to re-enable Write Cache, though the system should automatically enable after NDU

b.) Verify & Enable Statistics Logging for both SPs, if required:

**# /nas/sbin/navicli -h 192.168.1.200 setstats -on**

Statistics logging is ENABLED

**# /nas/sbin/navicli -h 192.168.2.201 seststats -on**

Statistics logging is ENABLED

c.) Trespass Luns back to their Owner SPs using Celerra Manager>Celerras>Storage>Systems><clarion name>:System: Storage Processors: SP A Is Ready To Restore>Restore SP A

**Note:** Click on “Restore SP A” icon. It will restore LUNs for both SP’s, if both SP’s had trespassed luns.

d.) Alternatively, restore trespassed LUNs from the CLI:

**# /nas/sbin/navicli -h 192.168.1.200 getlun -trespass**

LOGICAL UNIT NUMBER 4

Default Owner: SP A

Current owner: SP B

LOGICAL UNIT NUMBER 5

Default Owner: SP A

Current owner: SP B

LOGICAL UNIT NUMBER 0

Default Owner: SP A

Current owner: SP B

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 5**

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 4**

**# /nas/sbin/navicli -h 192.168.1.200 trespass lun 0**

**# /nas/sbin/navicli -h 192.168.1.200 getlun -trespass**

**Note:** No output means that there are no trespassed luns on the backend

e.) Disable IP Forwarding on the Control Station & Verify:

**# echo 0 > /proc/sys/net/ipv4/ip\_forward**

**# cat /proc/sys/net/ipv4/ip\_forward**

0

f.) Commit the Flare Package to complete the NDU Upgrade & Verify:

**# /nas/sbin/navicli -h 192.168.1.200 ndu -list**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.22.040.5.511

Commit Required: YES

**# /nas/sbin/navicli -h 192.168.1.200 ndu -commit FLARE-Operating-Environment**

**# /nas/sbin/navicli -h 192.168.1.200 ndu -list**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.22.040.5.511

Commit Required: NO

**FLARE 24 PATCH 019 NS40 INTEGRATED NDU NAS 5.5.27.5:**

**# /nas/sbin/navicli -h 192.168.1.200 ndu -install /nas/var/dump/CX3-40-Bundle-03.24.040.5.019.pbu -delay**

**360**

Running install rules...

=====

Special Conditions: Rule has warning.  
Redundant SPs: Rule passed.  
All Packages Committed: Rule passed.  
No Trespassed LUNs: Rule passed.  
Statistics Logging Disabled: Rule failed.  
No Transitions: Rule passed.  
Acceptable Processor Utilization: Rule passed.

No Active Hot Spares: Rule passed.  
Version Compatibility: Rule passed.  
No Un-owned LUNs: Rule failed.  
No Active Replication I/O: Rule failed.  
No System Faults: Rule passed.  
Host Connectivity: Rule has warning.  
SP Event Log Verification: Rule failed.

**CORRECTIVE ACTIONS:**

→Disabled Statistics logging on both SPs  
**# /nas/sbin/navicli -h 192.168.1.200 setstats -off**

→Enabled IP Forwarding on Control Station

**# cat /proc/sys/net/ipv4/ip\_forward**

0

**# echo 1 > /proc/sys/net/ipv4/ip\_forward**

**# cat /proc/sys/net/ipv4/ip\_forward**

The requested package(s) will be installed. Do you wish to proceed? : (y/n)? y

**NS41 SINGLE DM FRESH INSTALL PROCEDURE:**

**I. Install Differences between Single vs. Dual Data Mover configurations:**

→Basic NAS Installation of the single DM NS41 Integrated is different than the NS42

→Internal network cabling different than with dual Data Movers

→Fibre Channel cabling scheme is the same, minus the 2<sup>nd</sup> Data Mover

→A single Data Mover system does not populate the /nas/server/slot\_2/start file with a uniqueid, though the nas\_checkup incorrectly classifies this as a problem for NAS 5.5.27.5 and higher. See AR92218

**NAS CHECKUP FLAGS “UniqueID” PROBLEM:**

If running a NAS 5.3 system, and a check\_nas\_upgrade is run in preparation for upgrading to NAS 5.5, the checkup will flag a check\_unique\_id failure because 5.3 does not support the t2tty –C command that is being used to check the ID. With 5.5, it is also possible to have a uniqueid failure for a single Data Mover system, as the nas\_checkup command considers this a problem and flags it as an issue. In either case, there is no real problem or harm in proceeding with an actual NAS upgrade. As for a workaround for single DM systems, you could just add the following line to the bottom of the start file with the proper ID from the server:

**# .server\_config server\_2 -v "uniqueid"**

1186684020: SYSTEM: 4: uniqueid: "50060160:41e05335"

**# vi /nas/server/slot\_2/start**

**uniqueid validate=50060160:41e05335**

**Sys log:**

Apr 1 03:33:02 2007 Checkup:3:123 Scheduled nas\_checkup discovered an error.

**Nas checkup Log:**

2007-04-01T03:32:46-0400 dm::check\_unique\_id: (Fail)

→SP's use the same Internal IP addressing scheme and gateway as for the NS42, but network cabling is different

→The key difference is how the Celerra Internal Network is constructed and how it operates

→With the NS42 system, the Control Station serves the Primary Internal Network from eth0 at 192.168.1.100, between Data Movers and SPA (this remains unchanged for the NS41 system)

→With the NS42 system, the Control Station serves the Backup Internal Network from eth2 at 192.168.2.100, between Data Movers and SPB

**Note:** With the NS41 system, both Primary & Backup Networks are now served from the same physical interface (eth0 & an alias called eth0:0). In this arrangement, eth2 does not service the Backup network for the Celerra, but instead is reconfigured with the 192.168.2.102 address, along with a special routing entry in /etc/sysconfig/static-routes, in order for the Control Station to communicate back and forth to SPB. All Primary & Backup network activity, with the exception of SPB & eth2, are handled via eth0 or eth0:0.

#### **Physical Cabling of Internal Management Ports for NS41:**

- a. )Ethernet cable runs from lower management port of SPB to the port labeled 2 on the Control Station switch (upper middle port)
- b. ) Ethernet cable runs from lower management port of DM2 to the 10/100 port on CS0 (lower left port)
- c.) Ethernet cable runs from upper management port of DM2 to the lower management port on SPA

#### **Fibre Channel Cabling for NS41:**

- a. Data Mover blade 2 port BE 0 to SP A port 0 Fibre
- b. Data Mover blade 2 port BE 1 to SP B port 0 Fibre

#### **NS41 CS Interface Configuration, Routes, and other Important Files:**

# **/sbin/ifconfig -a**

```
eth0  inet addr:192.168.1.100  Bcast:192.168.1.255  Mask:255.255.255.0      →Primary Internal network (CS, DM, SPA)
eth0:0  inet addr:192.168.2.100  Bcast:192.168.2.255  Mask:255.255.255.0      →Backup Internal network alias (CS, DM)
eth1  <not used>
eth2  inet addr:192.168.2.102  Bcast:192.168.2.255  Mask:255.255.255.254 →SPB communications only (CS, SPB)
eth3  inet addr:10.241.168.94  Bcast:10.241.168.255  Mask:255.255.255.0      →External Interface customer network
```

# **cat /etc/sysconfig/static-routes**

```
eth2 host 192.168.2.201 dev
```

**Note:** This entry must exist in order for proper communication to occur between CS & SPB. Under normal circumstances, you should be able to ping between CS to SPs and all internal networks, navicli commands should run against either SP, etc.

# **cat /etc/sysconfig/network-scripts/ifcfg-eth0:0**

```

ENCLOSURE-0\_MGMT-B\_MAC= →Mgmt B is not used with single DM configuration

**Note:** Output abbreviated to show only Enclosure 0

## II. Backend Prep Work prior to Installation:

**Note:** If this is a factory install, this section can be skipped. For all field installs or re-installations, use this section to check the existing configuration on the backend, then take the appropriate action to prepare the system for a “fresh” NAS installation

1. Use a standard Ethernet cable to connect directly to the upper Clariion ethernet port on SPA from a Windows system (set an unused IP address on the Workstation (as shown below), then open a Web Browser/Navisphere Mgr session to SPA (192.168.1.200).
2. Once connected to SPA, unbind all NAS LUNs, then destroy the Raid Groups--this step should not normally be necessary if doing a Fresh NS40 Install.

### Workstation IP when connecting to SPA's Upper Management LAN Port:

192.168.1.95

255.255.255.0

192.168.1.100

DNS→De-select any entries that may be set

## III. Proceed with NAS Installation:

1. Connect to the Control Station’s front serial port from a Windows station, then use Hyperterminal to connect:

### Hyperterm Settings:

19200/8/None/1/None (use ANSI & Autodetect for connection)

2. Insert NAS CD & Boot Floppy, reboot CS—wait for prompt, then enter: boot: **serialinstall**

3. Linux install is fast & done in about 15 minutes--make sure to select Fresh Install when it detects the linux image on the IDE drive

4. NAS Installation takes an hour or so, answer prompts as needed. The Bind Operation for the Raid Groups took 4/5 hours.

**Note:** Completed upgrades result in /nas/log/upgrade log—interrupted or incomplete upgrades will have log in /tmp

## **NS41 INTEGRATED SINGLE DATA MOVER FLARE NDU UPGRADE PROCEDURE:**

1. Connect to front Control Station serial port to Workstation COM1 using Serial cable and open a Hyperterm session

2. Connect directly to SPA's Management LAN port using straight-through ethernet cable to Workstation

a.) Open Browser session to Celerra Manager

b.) Open Browser session to Navisphere Manager

3. Verify backend paths:

### **# nas\_storage -check -all**

Discovering storage (may take several minutes)

done

4. Using Celerra Manager, verify that the Celerra system is healthy

5. Using Navisphere Manager, verify that the CLARiiON array is healthy

**Note:** You may notice that SPB appears "unmanaged" when connected to SPA. Apparently this is some anomaly in certain flare versions. After upgrading to Flare 24, both SP's are correctly displayed.

6. Perform CLARiiON Healthcheck using Navicli:

### **# /nas/sbin/navicli -h 192.168.1.200 getlun –trespss**

**Note:** Check for any trespassed Celerra LUNs and restore to default Owner before proceeding

### **# /nas/sbin/navicli -h 192.168.1.200 networkadmin -get**

Storage Processor: SP A

Storage Processor Network Name: SPA

Storage Processor IP Address: 192.168.1.200

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 192.168.1.100

### **# /nas/sbin/navicli -h 192.168.2.201 networkadmin -get**

Storage Processor: SP B

Storage Processor Network Name: SPB

Storage Processor IP Address: 192.168.2.201

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 192.168.2.100

### **# /nas/sbin/navicli -h 192.168.2.201 getcrus** (checked for failed components)

7. Verify that CLARiiON Statistics Logging is enabled:

### **# /nas/sbin/navicli -h 192.168.1.200 setstats**

Statistics logging is ENABLED

**# /nas/sbin/navicli -h 192.168.2.201 setstats**

Statistics logging is ENABLED

**8. Verify that CLARiiON Front-end I/O throughput is < than 15,000 I/O's/sec using Celerra Manager**

Celerras>Storage>Systems>CLARiiON CX3-40 APM00063303725

**Front-End I/O Requests:**

Use I/O counter to the right of the graph: 21.5 I/O Req./sec

**9. Disable Statistics Logging on both SPs:**

**# /nas/sbin/navicli -h 192.168.1.200 setstats -off**

**# /nas/sbin/navicli -h 192.168.2.201 setstats -off**

**10. Verify that CLARiiON Back-end I/O throughput passes:**

**# /nas/tools/check\_clariion**

CPU UTILIZATION (MUST BE LESS THAN 50% PER STORAGE PROCESSOR)

THIS WILL TAKE APPROXIMATELY 1 MINUTE(S).

CLARIION: APM00063303725:

SP A ..... 000.65% (PASS)

SP B ..... 000.65% (PASS)

DISK I/O LOAD (MUST BE LESS THAN 100 I/O OPERATIONS PER SECOND PER DISK)

THIS WILL TAKE APPROXIMATELY 4 MINUTES.

CLARIION: APM00063303725:

DISK 0\_0\_0 ..... 002 OPS/SEC (PASS)

DISK 0\_0\_1 ..... 003 OPS/SEC (PASS)

DISK 0\_0\_2 ..... 002 OPS/SEC (PASS)

DISK 0\_0\_3 ..... 001 OPS/SEC (PASS)

**11. Stop NAS Services and manually remount NAS Partitions:**

**# /sbin/service nas stop**

**# ps -ef |grep nas\_m**

**# ps -ef |grep boxm**

**# df -h**

**# mount /nbsnas # mount /nas # mount /nas/dos # mount /nas/var**

**12. Put CS interface eth0:0 down & verify:**

**# /sbin/ifdown eth0:0**

**# /sbin/ifconfig -a**

**Note:** eth0:0 should not be represented in the output after running the ifdown command

**13. Enable IP Forwarding on the Control Station & Verify:**

**# echo 1 > /proc/sys/net/ipv4/ip\_forward**

**# cat /proc/sys/net/ipv4/ip\_forward**

**1**

**14. Disable CLARiiON Write Cache & Verify:**

**# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 0**

**# /nas/sbin/navicli -h 192.168.1.200 getcache**

SP Read Cache State      Enabled

SP Write Cache State     Disabled

**15. Perform NDU and monitor Status from Control Station or Navisphere:**

**# /nas/sbin/navicli -h 192.168.1.200 ndu -install /home/nasadmin/flare/cx3-40-bundle-03.24.040.5.007.pbu**

**-delay 360**

Running install rules...

=====

Version Compatibility:      Rule passed.

Redundant SPs:            Rule passed.

-----abridged-----

Name of the software package:      FLARE-Operating-Environment

Revision of the software package:    03.24.040.5.007

Already Installed Revision        03.22.040.5.511

Installable                  YES

Disruptive upgrade:        NO

Ndu Delay:                360 secs

The requested package(s) will be installed. Do you wish to proceed? : (y/n)? y

**Note:** There is the possibility that the Rules Checking will prevent the NDU from proceeding. If absolutely certain that the Array is operating normally, add the "-skiprules" syntax to the end of the ndu -install command string

### # /nas/sbin/navicli -h 192.168.1.200 ndu -status

Is Completed: YES

Status: Operation completed successfully

Operation: Install

### 16. Post-Install NDU Upgrade Checks/Steps:

a.) Use Navisphere Manager or Navicli commands (getagent/getcrus/getcache/setstats, etc) to healthcheck CLARiiON backend

**Note:** Flare 24 has a fix so that both SPs will now register as “managed” when viewing the CLARiiON from Navisphere Manager

b.) Verify that Write Cache has been re-enabled on CLARiiON backend

### # /nas/sbin/navicli -h 192.168.1.200 getcache

SP Read Cache State Enabled

SP Write Cache State Enabled

**Note:** Write Cache automatically re-enables after a successful NDU

### # /nas/sbin/navicli -h 192.168.1.200 setcache -wc 1 -rca 1 -rcb 1

**Note:** Command to re-enabled Write Cache if necessary

c.) Trespass back any Celerra LUNs to their Owner SP, using either navicli trespass lun x or Celerra Manager:

### # /nas/sbin/navicli -h 192.168.1.200 getlun -tresspass

LOGICAL UNIT NUMBER 0

Default Owner: SP A

Current owner: SP B

### # /nas/sbin/navicli -h 192.168.1.200 trespass lun 0

d.) Re-enable Statistics Logging on both SPs:

### # /nas/sbin/navicli -h 192.168.1.200 setstats -on

### # /nas/sbin/navicli -h 192.168.2.201 setstats -on

### # /nas/sbin/navicli -h 192.168.2.201 setstats

Statistics logging is ENABLED

### # /nas/sbin/navicli -h 192.168.1.200 setstats

Statistics logging is ENABLED

e.) Commit flare version from navicli or Navisphere Manager & Verify:

### # /nas/sbin/navicli -h 192.168.1.200 ndu -commit FLARE-Operating-Environment

### # /nas/sbin/navicli -h 192.168.1.200 ndu -list

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.24.040.5.007

Commit Required: NO

f.) Disable IP Forwarding on the Control Station & Verify:

### # echo 0 > /proc/sys/net/ipv4/ip\_forward

### # cat /proc/sys/net/ipv4/ip\_forward

0

g.) Bring eth0:0 back online & Verify:

### # /sbin/ifup eth0:0

### # /sbin/ifconfig -a

eth0:0 Link encap:Ethernet HWaddr 00:00:F0:9F:B3:74

inet addr:192.168.2.100 Bcast:192.168.2.255 Mask:255.255.255.0

h.) Restart NAS Services & Verify:

### # /sbin/service nas start

### # ps -ef |grep nas\_mcd

```
root 3905 1 0 13:39 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root 4055 3905 0 13:39 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
```

### # ps -ef |grep boxm

```
root 5018 3905 0 13:40 ? 00:00:00 /nas/sbin/nas_boxmonitor /nas -i
root 5141 5018 0 13:40 ? 00:00:00 /nas/sbin/nas_boxmonitor /nas -i
```

-----both NAS & Box Monitor process output abridged for brevity-----

## **ADDING ARRAY ENABLERS:**

→Can be done using the NST/USM or via CLI

# /nas/sbin/navicli -h 10.241.168.179 ndu -install CompressionEnabler-01.01.5.001-fleet64\_free.ena -delay

**360**

Running install rules...

## **CHANGING PRIVATE IP ADDRESS NETWORK ON NS40 INTEGRATED CELERRA:**

**Note:** See current NAS 5.5 NS40 Integrated Setup Guide, but note that they forgot to include a section for changing SP addresses

1. Create /root/BACKUP directory
2. Copy /etc/hosts, /etc/sysconfig/network-scripts/ifcfg-eth\*, /etc/nas\_device.map, /etc/nas\_enclosure.map, /etc/encl\_dhcpd.conf, /etc/sysconfig/network & static-routes, /nas/site/nas\_param & slot\_param, and /nas/server/slot\_2/ files to /root/BACKUP
3. Stop NAS Services & manually remount NAS partitions
4. Update Secondary Network first:

**# /nasmcd/sbin/setup\_enclosure –changeSubnet 1 192.168.102.0**

**Note:** Runs CheckCable, updates ENCL\_DB & DHCPD\_CFG files, resets secondary management switches

5. Verify change:  
# /sbin/ifconfig eth2
6. Use following command to create updated files for Secondary network, review for accuracy, then copy over the original files:  
# cat /etc/hosts | sed 's/192.168.2./192.168.102./g' > /tmp/<filename>  
**Note:** Repeat process for /nas/site/nas\_param, /nas/site/slot\_param
7. Determine the list of files that require editing for each Data Mover slot, using following:  
**# fgrep -e ‘192.168.2.’ `find /nas/server/slot\_2/ -type f -maxdepth 1 |grep -v “tab\$”`**
8. Edit all files identified in Step 7 with the new subnet for the Secondary network  
[export, eof, nbs.cs.ro, nbs.cs.rw, ifconfig, etc.]
9. Export NAS DB and reboot the Server:  
# export NAS\_DB=/nas; server\_cpu server\_2 -r now  
**Note:** If system hangs, exit and reconnect to Control Station, then # ping server\_2b to verify backup network

10. Repeat sed replacement steps for the Primary network, review for accuracy, then replace original files:

**# cat /etc/hosts | sed ‘s/192.168.2./192.168.101./g’ > /tmp/<filename>**

**Note:** Repeat steps for nas\_param & slot\_param files

11. Manually unmount all NAS partitions  
**Note:** Use # /sbin/fuser -m /nbsnas and # kill -9 <pid> if needed to umount partitions
12. Stop NBS service:  
# /sbin/service nbs stop
13. Mount NAS: # mount /nas
14. Update Primary Network using setup\_enclosure command:

**# /nasmcd/sbin/setup\_enclosure –changeSubnet 1 192.168.101.0**

15. Verify using: # /sbin/ifconfig eth0
16. Umount NAS: # umount /nas
17. Restart Network Services: # /sbin/service network restart
18. Restart NBS Services: # /sbin/service nbs start
19. Remount all NAS partitions and re-export NAS DB
20. Perform Setup Slot on each Data Mover: # /nas/sbin/setup\_slot -i 2
21. Run Repair Command:

**# /nasmcd/sbin/setup\_enclosure –checkSystem autoRepair**

22. Restart NAS Services: # /sbin/service nas start
23. Change the Clariion IP Addresses using the following steps:
  - a. Using a straight-through Ethernet cable, and a valid IP on the 192.168.1 network, connect a Workstation to the upper LAN port on SPA
  - b. Open Web Browser on Workstation and access SPA’s setup program: 192.168.1.200/setup
  - c. Change SPA IP address to new subnet (Value in the last Octet must remain .200 for SPA & 201 for SPB)

**Note:** SP will automatically reboot. Wait until SPA comes back up before continuing.

  - d. Repeat above steps for SPB
  - e. From the Celerra Control Station, manually trespass luns back to their Owner SP using navicli  
# /nas/sbin/navicli -h <sp\_IPaddr> trespass lun x
  - f. Manually update the /etc/hosts file with the new Subnet addresses for SPA & SPB
  - g. Run # nas\_storage -sync <APM\_id> to update the symapi db with the revised SP IP addresses

**Note:** There was an issue where CS reboots would reset the SP addresses in the /etc/hosts file to the original values prior to the changes. The corrective action here would be to edit the /nas/site/sp\_info file and update the SP addresses to the correct values. See AR92483.

## **EXAMPLE OF sp\_info FILE:**

# cat /nas/site/sp\_info

192.1.4.214 A\_APM00071600514 SPA # CLARiiON SP

192.1.4.215 B\_APM00071600514 SPB # CLARiiON SP

### **REVERTING FLARE CODE WHEN FLARE HAS NOT YET BEEN COMMITTED:**

The process of reverting to the previous Flare version is fairly simple and straightforward, provided the Flare version that you upgraded to has not yet been committed. Rebooting an SP while in an “uncommitted” state does not revert the Flare version.

**Navisphere Manager>APM0063303725[CX3-40]>Properties>Software>FLARE-Operating-Environment**

**03.24.040.5.006 (Commit required):** Highlighted the Flare 24 uncommitted code, then selected “Revert” button and the system automatically goes back to the last running Flare version, which in this example was Flare 22 Patch 511.

### **USING CLI COMMAND TO REVERT FLARE (If not yet Committed):**

**# /nas/sbin/navicli -h 192.168.1.200 ndu -revert FLARE-Operating-Environment -delay 360**

Revert operation will revert

    FLARE-Operating-Environment

from both SPs with Ndu delay of 360 secs. Do you still want to continue. (y/n)? y

**# /nas/sbin/navicli -h 192.168.1.200 ndu -status**

Is Completed: NO

Status: Initializing

Operation: Revert

### **NAS ‘UPGRADE’ OF ENGINEERING CODE RELEASE FAILS (5.5.22.4028 to 5.5.22.5028):**

**# EMC/nas/setup**

Setting up system, please wait...

Model: NS600G

Upgrading From Version: 5.5.22-40130

Mon Jul 10 12:11:16 EDT 2006

./setup: Error: Downgrade detected. Attempt to downgrade NAS from version 5.5.22-40130 to version 5.5.22-5028 not permitted.

Run 'emcrpm --erase emcnas' to remove the previous package.

Solution: Create following file to allow for upgrade to succeed

**# touch /tmp/.allow\_downgrade**

### **NAS UPGRADE WHEN SYSTEM HARDWARE IS OUT OF REV: e.g., 507**

**# EMC/nas/setup –allow\_upgrade\_on\_obsolete\_dm**

**Note:** Purpose would be to upgrade to a code level that would support new hardware, for example

### **TROUBLESHOOTING UPGRADE ISSUES ON LINUX CONTROL STATION:**

**# rpm -qa** #rpm -qa lwc -l [Lists out Software Packages & is a good check to ensure that RPM database is o.k.]

**# rpm -a -q --last** [Lists out most recently installed packages by date]

**# rpm -qa “\*ftp”**

#### **ADDING LINUX PACKAGES:**

**# rpm -Uvh [ftp://192.168.0.254/pub/RedHat/RPMS/sendmail\\*](ftp://192.168.0.254/pub/RedHat/RPMS/sendmail*)**

#redhat-config-packages

#### **ADDING ERRATA TO ALL PACKAGES:**

**# rpm -Fhv [ftp://updates.redhat.com/current/en/os/i386/\\*.rpm](ftp://updates.redhat.com/current/en/os/i386/*.rpm)**

#### **UPGRADING KERNEL:**

1. **# rpm -ivh kernel-version.i386.rpm**

2. Reboot system and test new kernel

3. Set ‘default’ line in /boot/grub/grub.conf to 0 to load new kernel upon reboot

4. Remove old kernel if satisfied: #rpm -e old.kernel-version.i386.rpm

#### **REMOVING RPM’s:**

**# rpm -e xpdf**

#### **LOCAL RPM DATABASE:**

**/var/lib/rpm**

#### **QUERYING SPECIFICS OF A PKG:**

**# rpm -q zsh -i | -l #rpm -qa bash -i #rpm -qf /etc/imrc**

#### **EXTRACTING EXECUTABLES FROM ZIP TO LOCAL DIRECTORY:**

## **VERIFYING NASDB VERSIONS NAS 5.5+:**

**# /nas/sbin/nasdb\_tools/db\_status**

Current DB seems to be at version 3

**Note:** Command came into being to support RLL (Row Level Locking), introduced with NAS 5.5

## **DOWNLOADING & INSTALLING AN RPM PACKAGE ON LINUX CONTROL STATION:**

ftp://ftp.samba.org/pub/rsync/binaries/redhat/

ftp> mget rsync-2.5.7-1.i386.rpm

mget rsync-2.5.7-1.i386.rpm? y

**# rpm -i rsync-2.5.7-1.i386.rpm**

**# rsync**

rsync version 2.5.7 protocol version 26

## **REPAIRING EMCNAS RPM DATABASE ON CS DUE TO DESTRUCTIVE LINUX RECOVERY:**

### **Symptoms:**

**\$ nas\_version -l**

error: cannot open Packages index using db3 - No such file or directory (2)

**# ls -al /var/sadm/pkg/emcnas/**

```
drwxr-xr-x 2 root root 4096 Oct 13 19:16 install
-rw-r--r-- 1 root root 362 Oct 13 19:16 pkginfo
drwxr-xr-x 2 root root 4096 Oct 13 19:16 save
```

**Note:** 'Packages' file and others are missing

**Problem:** EMCNAS RPM database is corrupted and requires repair per the following steps—emc95561

1. Copy RPM from NAS 5.1.20.401 CD to /home/nasadmin on Control Station (or run directly from CD):

**# cp /mnt/cdrom/EMC/nas/emcnas-5.1.20-401.i386.rpm /home/nasadmin**

2. Restore emcnas RPM database using the following command on Control Station, specifying destination path and RPM source location:

**# rpm -U --justdb --force --nodeps --relocate /nas=/nas --dbpath /var/sadm/pkg/emcnas/ /home/nasadmin/emcnas-[0-9]\*.rpm**

3. Verify that database has been repaired:

**# ls -al /var/sadm/pkg/emcnas/**

```
-rw-r--r-- 1 root root 331776 Oct 14 13:01 Basenames
-rw-r--r-- 1 root root 24576 Oct 14 13:01 Dиримес
-rw-r--r-- 1 root root 12288 Oct 14 13:01 Group
drwxr-xr-x 2 root root 4096 Oct 13 19:16 install
-rw-r--r-- 1 root root 8192 Oct 14 13:01 Installtid
-rw-r--r-- 1 root root 12288 Oct 14 13:01 Name
-rw-r--r-- 1 root root 675840 Oct 14 13:01 Packages
-rw-r--r-- 1 root root 362 Oct 13 19:16 pkginfo
-rw-r--r-- 1 root root 12288 Oct 14 13:01 Providename
-rw-r--r-- 1 root root 8192 Oct 14 13:01 Provideversion
-rw-r--r-- 1 root root 12288 Oct 14 13:01 Requirename
-rw-r--r-- 1 root root 16384 Oct 14 13:01 Requireversion
drwxr-xr-x 2 root root 4096 Oct 13 19:16 save
```

**# nas\_version -l**

|                                |                                      |
|--------------------------------|--------------------------------------|
| Name : emcnas                  | Relocations: /nas                    |
| Version : 5.1.20               | Vendor: EMC                          |
| Release : 401                  | Build Date: Thu 15 Jan 2004 08:07:51 |
| AM CST                         |                                      |

| Packager : EMC Corporation     |                                      |
| URL : http://www.emc.com       |                                      |
| Summary : EMC nfs base install |                                      |
| Description :                  |                                      |
| EMC nfs base install           |                                      |

## **5.4 UPGRADE CHANGES:**

→ If rootfs size is not already 128MB, the upgrade will auto-extend to 128MB in size

→ root\_panic\_x partition will be created if it does not already exist (8MB)

→ Server Log has been increased from 1MB to 2MB and uses space from the work partition, root\_rdf\_channel

## **NAS UPGRADE USING NAS.EXE PATCH ONLY:**

**1. Login to Celerra, create directory for NAS Image, change to this directory:**

```
# mkdir /home/nasadmin/code;cd /home/nasadmin/code
```

**2. Connect to EMC FTP Server:**

```
# ftp 168.159.216.19 or #ftp ftp.emc.com
```

**3. At prompt, enter username of "ftp" or "anonymous" and then enter a valid email address as the password:**

```
Name (168.159.216.19:nasadmin): ftp
```

```
331 Guest login ok, send your complete e-mail address as password.
```

```
Password: joe@emc.com
```

**4. Set FTP transfer to Binary mode:**

```
ftp>bin
```

```
200 Type set to I.
```

**5. Change to the appropriate directory to obtain NAS Patch as outlined above & Verify presence of Patch:**

```
ftp> cd /outgoing/code
```

```
250 CWD command successful.
```

**Note:** Where "/outgoing/code" is an example of a patch for systems running NAS 5.1

```
ftp> ls -la
```

```
-r----- 1 g3 4920553 Jan 11 12:40 5120401.exe.gz
```

**6. Download Appropriate Gzipped NAS Version & Log off the FTP Server:**

```
ftp>get 5120401.exe.gz
```

```
ftp> bye
```

**7. Verify size of zipped NAS image and unzip:**

```
# ls -la /home/nasadmin/code/5120401.exe.gz
```

```
-rw-rw-r-- 1 nasadmin nasadmin 5423122 Jan 11 19:46 5120401.exe.gz
```

```
# gzip -d 5120401.exe.gz
```

```
# ls -la 5120401.exe
```

```
-rw-rw-r-- 1 nasadmin nasadmin 18913180 Jan 11 19:46 5120401.exe
```

**8. Determine NAS Version Running on Celerra for All Servers:**

```
# server_version ALL
```

```
server_2 : Product: EMC Celerra File Server Version: T5.1.18.804
```

```
server_3 : Product: EMC Celerra File Server Version: T5.1.18.804
```

```
server_4 : Product: EMC Celerra File Server Version: T5.1.18.804
```

```
# cat /nas/dos/slot_*/boot.bat
```

```
gload \bin\nas.exe boot.cfg
```

```
gload \bin\nas.exe boot.cfg
```

```
gload \bin\nas.exe boot.cfg
```

**9. Rename the current running "nas.exe" file located in the /nas/dos/bin directory:**

```
# ls -la *.exe
```

```
-rwxrwxr-x 1 root nasadmin 18701537 Dec 29 13:25 5118807.exe
```

```
-r-xr-xr-x 1 root nasadmin 42373 May 13 2003 gload.exe
```

```
-rwxrwxr-x 1 root nasadmin 32208 May 13 2003 loadlin.exe
```

```
-rwxrwxr-x 1 root nasadmin 18722612 Nov 20 13:12 5119504.exe
```

```
-rwxrwxr-x 1 root nasadmin 18722612 Jan 7 10:54 nas.exe
```

```
# mv /nas/dos/bin/nas.exe /nas51804.exe
```

**Note:** nas.exe is renamed to reflect the original Version Number of the patch.

**10. Run the following command to make sure that there is enough space (at least 20MB) in the /nas/dos directory to accomodate the new patch--you may need to remove older nas images:**

```
# df -h
```

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/sda3  | 1.9G | 1.2G | 607M  | 67%  | /          |
| /dev/sda1  | 7.6M | 3.5M | 3.7M  | 49%  | /boot      |
| none       | 251M | 0    | 250M  | 0%   | /dev/shm   |
| /dev/sdc1  | 1.7G | 649M | 1.0G  | 39%  | /nas       |
| /dev/sdb1  | 133M | 97M  | 37M   | 73%  | /nas/dos   |

**11. Copy the newly downloaded and unzipped patch into the /nas/dos/bin directory and rename it as "nas.exe":**

```
# cp -ip /home/nasadmin/code/5120401.exe /nas/dos/bin/nas.exe
```

```
-rwxrwxr-x 1 root nasadmin 18913180 Jan 11 20:15 nas.exe
```

**12. Verify Size and Permissions on nas.exe:**

```
# ls -la /nas/dos/bin/nas.exe
```

```
-rwxrwxr-x 1 root nasadmin 18913180 Jan 11 20:15 nas.exe
```

**13. Run server setup command to point all servers to the new "nas.exe" by updating the /nas/dos/slot \*/boot.bat gload utility:**

**# /nas/sbin/server\_setup ALL -L nas.exe**

**Note:** Where "nas.exe" is the new image.

**14. Verify that the correct image is being pointed to:**

```
# cat /nas/dos/slot_*/boot.bat  
gload \bin\nas.exe boot.cfg
```

**15. Reboot the Standby Data Mover first and Verify that the new NAS Version has Loaded:**

```
# server_cpu server_4 -r now  
# server_version server_4  
server_4 : Product: EMC Celerra File Server Version: T5.1.20.401
```

**16. To Load the New NAS Image, Failover the Production Data Mover to its Standby, then Failback:**

```
# server_standby server_2 -a mover  
# server_standby server_2 -r mover
```

**Note:** Repeat for each DM that requires the new image. Don't forget to reboot the primary data mover slot after failing the Server over to its Standby, before failing back.

**PROBLEMS WITH NAS 5.1/5.2/5.3 SOFTWARE/HARDWARE INSTALLS/UPGRADES:**

**UPGRADING TO NAS 5.3 PROBLEMS AND NAS 5.3 INSTALL ISSUES:**

**1. GENERIC NAS UPGRADE PROBLEMS:**

Problem: Missing "nas.exe" reference in boot.bat file. NAS 5.3 Upgrades needs to be able to run a script to help it identify the enclosure number for the data movers—this was necessary because we now have (4) Data Mover NS systems. In any event, the Upgrade creates a /nas/dos/slot\_99 directory, copies the boot.bat from slot\_2 to slot\_99 and creates a minimal boot.cfg to boot DM to reason code 14. Next part of the script issues resumeprom commands to verify enclosure\_id for DM\_2 only—once determined, DM reboots from its correct slot and upgrade completes (this is where the Upgrade will stall if the correct nas.exe cannot be located that contains the resumeprom commands). An enclosure\_id of 0 indicates slot\_2 or 3 and an id of 1 indicates slot\_4 or 5

**CTAPTTY Log Error:** -->/var/log/ctappty\$4.log [These logs are new to 5.3 & record DM boot process, for NS systems only]  
097961095: SYSTEM: 3: uniqueid: values do not match "LKE00040400134" vs "LKE00032400095"

**UPGRADE FAILURE SYMPTOMS—NAS 5.2.11 to 5.3.11:**

Waiting for a valid reason code on slot 2...14:done

Configuring Enclosure ID...:Failed

14:done

---

slot\_99 and Reason Code 14

**PXE BOOT & remove LKE line from /nas/server/slot\_x/start file:**

```
$ cat start  
uniqueid validate=LKE00035300071  
# .server_config server_2 -v "uniqueid"  
1175859583: SYSTEM: 4: uniqueid: "LKE00034200368"
```

**Note:** Above output from an NS700G with two Data Movers. The uniqueid is not used for single Data Mover systems, and is used for NS and NSX systems only as a way to properly identify enclosure IDs.

**Run setup\_slot to fix MAC Address & Serial Number issues:**

**Verify that SYMCLI was upgraded and is linked correctly:**

—following indicates that SYMCLI was not upgraded correctly:

```
# find / -name "symcli*" -print  
/nas/opt/emc/SYMCLI/V5.4.0/bin/symcli  
/nas/opt/emc/SYMCLI/V5.4.0/man/man1/symcli.1  
/nas/opt/emc/SYMCLI/V5.4.0/man/man1/symclient.1  
/nbsnas/opt/emc/WideSky/V5.3.0/bin/symcli  
/nbsnas/opt/emc/WideSky/V5.3.0/man/man1/symcli.1  
/nbsnas/opt/emc/WideSky/V5.3.0/man/man1/symclient.1
```

**2. DM's REMAIN IN STATE 3 LOADED NAS 4.2-to-5.2 UPGRADE:**

Data Movers remain in 'LOADED' state after NAS 4.2 to 5.2 Upgrade:

- Connect monitor to DM port and observe boot-up
- In this particular case, DM trying to locate its internal interface MAC address and cannot

**Solution:**

- Go to /nas/server/slot\_x/ifconfig & ifconfig.int files and remove following portion of the lines that reference internal interface MAC addresses: **mac=8:0:1b:43:b:63**
- Reboot data movers, should now come up to contacted state
- Conduct setup\_slot -i to complete proper backend discovery and initialization

**3. MPD CONVERSION FAILS TO COMPLETE:**

- a. Load NAS 5.2.18.2 or 5.3.11.403 or higher onto Standby Server
- b. Convert Standby server to a Primary
- c. Conduct FSCK/ALCHCK of file systems that will not convert
- d. Permanently unmount and remount affected file system to new Standby (Primary) Server
- e. Complete MPD conversion of affected file systems
- f. Mount file system back on original Server and reconfigure Standby Server

#### **4. AFTER NAS 5.3.11.4 INSTALL, SERVER COMMANDS FAIL:**

--one possible reason is that a configuration file contains an extra line at the end of the file [e.g., nas\_param file]

#### **5. NAS 5.2 GOLDEN EAGLE UPGRADE FAILS:**

If the root password on CS0 is changed using the WebUI, the password is DES encrypted. Normal passwd encryption uses MD5. If this situation has happened, when performing the NAS upgrade, upgrade will fail with “Password incorrect – please retry”. Change passwd back to MD5 encryption by using #passwd -S root

#### **6. UPGRADE 4.2-to-5.2 FAILS WITH WRONG NAS DEVICE.MAP:**

/etc/nas\_device.map.1.rev2--Upgrade script may overwrite the nas\_device.map file with incorrect information:

‘VERDSK=/dev/sde’—as in this example:

**CRITICAL FAULT:**

Inquiry failed for dev /dev/sde

**Solution:** Copy the nas\_device.map.1.rev1 file from the NAS Upgrade CD to /etc, contains ‘VERDSK=/dev/sdc’ [See emc97104]

#### **7. BIOS/POST INCOMPATIBILITY ISSUES 5.3 INSTALLS:**

##### **NS602G NAS 5.3 Install Failure:**

BIOS level of data movers was so old that the latest NAS code would not install correctly because the data movers could not boot from the backend DOS partition to complete the flash BIOS/POST upgrade. Workaround in this case was to take physical data mover and place into functioning down-rev 5.1 or 5.2 system and boot, which will flash upgrade—DM can then be used for the install on new system. Alternatively, order additional DM to replace with newer mover. In one case, the install completed on DM\_3, and DM\_3 was then used to complete the install on slot\_2—once completed, DM\_2 could be inserted in slot\_2 and setup\_slot completed.

**Note:** BIOS & POST version changes in mfg do not lead to purging of SPARES inventory—the auto-flash upgrade procedure is supposed to be able to handle this, even though we all know that it doesn’t. See AR’s 52344 & 54671.

#### **8. POST VERSION 3.37 CAUSES INSTALL FAILURES:**

Data Movers with POST version 3.37 cannot use port BE0 to boot from Backend, forcing a boot from BE1, and progressing to Reason Code 14 state, causing Install to fail. POST 3.38 or higher will resolve this problem.

#### **EXAMPLE BIOS/POST INCOMPATIBILITY FOR 5.3 INSTALLS:**

**Problem:** Down-rev BIOS & POST prevents NAS 5.3 Install from Succeeding

##### **Manual Flash Upgrade Procedure:**

→Insert problem Data Mover into functional 5.1 NS600 System

→Connect to Data Mover via HyperTerminal Session and wait for “FLASH UPGRADE UTILITY 5.7” screen to appear

##### **POST Upgrades first, followed by BIOS:**

C2\_POST.BIN <Rev. 02.30> <Rev. 03.12>

C2\_BIOS.ROM < 3.09 > < 3.26 >

→Let system reboot to complete flash upgrade, then remove hardware from system

→Installation on 5.3 system will now succeed

#### **9. NAS 5.3 FAILED INSTALL DUE TO PXE BOOT:**

##### **NAS 5.3 Install Failure on NS600G Symmetrix Backend:**

Data Mover\_2 fails to boot from the Backend using BE0, even though the POST & BIOS, Zoning, WWN’s, and Control Luns were correct. Makes sure BE0 logs into Switch and to the Clariion. In this situation, the setup\_slot starts the PXE services and the data mover will PXE boot if it cannot boot from Backend.

**Solution:** SSH to Control Station and kill the dhcpcd daemon so that PXE booting will not occur, then retry setup\_slot install.

#### **10. NAVISPHERE NOT REGISTERING DM PATHS TO SPs:**

In rare circumstances, some of the paths from the DM’s to the SP’s will get registered in Navisphere, but fail to complete the Fibre login when the first IO is sent from the DM to the CX. If this occurs, the fix would entail the following steps:

→Enter Engineering mode on Array using CTRL, SHIFT, F12 and use password “messner”

→Rightclick Storage Group for control luns, select ‘properties’>Hosts>Click Advanced

--Examine each DM for registered paths & check off the small box in front of the registered path statement on the paths not checked

--Update Navisphere and all 8 paths should register and login properly

→Navisphere Manager>rightclick SPA/SPB>properties>ALPA>verify that SCSI ID is set to 0 on all SP ports

#### **11. NAS 5.3 REASON CODE 14 ISSUES:**

- a. During DM upgrade, cannot boot from BE0—so PXE boots from IDE drive of CS0 and sits at reason code 14

**Causes:** Bad fibre switch, connection, zoning, speed settings across DM, Switch, BackEnd

- b. Unable to determine slot number (Review CTAP logs to see what slot number is being used on bootup)

c. Unable to bootup due to MAC address conflict (Do setup\_slot to correct MAC address)

d. Serial number conflict in config file (/nas/server/slot\_x/start)

**Correction:** Check start file serial # against /nas/log/data\_mover\_resume.server\_x.xml. If different, delete start file line and reboot

e. Examine CTAP logs for other indicators

f. NS700 or NS700G cannot establish enclosure ID number

**Causes:** Enclosure ID concept added for (4) DM NS Models—ensure DM's are booting from correct “nas.exe” image

g. Reason Code 14 on NAS Upgrade and Data Mover boots to c:\slot\_99 directory on Control Station:

CTAP Log shows error: Unable to determine slot number

**Note:** Upgrade script needs to be able to program the Enclosure ID number. If this cannot be determined, the t2slot.exe cannot determine its slot number and boots from slot\_99 by default.

#### **Possible Issues:**

a. Verify that data mover is pointing to nas.exe by checking boot.bat file

b. Verify that data movers 1 & 2 are pointing to correct Enclosure ID by running “resumeprom show”

**# .server\_config server\_3 -v "resumeprom show"**

NAS ENCLOSURE ID 0

**Note:** You may need to run the command via minicom session at the data mover’s CONSOLE>

c. Setting Enclosure ID’s to 0:

**# .server\_config server\_3 -v "resumeprom set xpeid=0"**

d. If all of these steps do not resolve the issue, go to FCCBOOT menu via serial session and do a Controller Reset on each DM

**“FCC Boot Sub-Menu”**

Select Option 1 to ‘Reset Controller’

## **12. NAS 5.2 to 5.3 UPGRADE FAILURE GOLDEN EAGLE CAB:**

Upgrade can fail if boot.bat is not updated properly

#### **Pre-Upgrade:**

\$ cat /nas/dos/slot\_2/boot.bat

gload -or c:\bin\nas.exe c:\slot\_2\boot.cfg

#### **After Upgrade:**

\$ cat /nas/dos/slot\_2/boot.bat

gload -or c:-m 2048 -or c:\bin\nas.exe c:\slot\_2\boot.cfg

## **13. DM FAILS TO BOOT PAST REASON CODE 3 AFTER NAS UPGRADE TO 5.3.14:**

AR56446 identifies issue with C compiler in which certain code was generated with different typecast, resulting in memory corruption problem for TOE 514 Data Movers. Using the following workaround allowed DMs to boot—fixed 5.3.18 & 5.4.17:

gload -or c:-m 2047 -or c:\bin\nas.exe c:\slot\_5\boot.cfg

## **NS SERIES ENCLOSURE ID:**

Enclosure ID of Data Movers is set during installation & is burned into eeprom, based on the serial connections to the DMs—tty4 & tty5 equate to Enclosure ID 0, while tty6 & tty7 equate to Enclosure ID 1. Furthermore, a pin on the backplane tells which data mover is in position A or B in the enclosure (0 or 1). The enclosure ID number, plus Hardware slot number from pin, are used to determine the slot number (setup\_enclosure utility in NSX). During upgrades, t2slot.exe is used to determine enclosure ID number for DM—if it cannot be determined, then data mover will boot a minimum config from slot\_99 and end up in Reason Code 14 status. In many cases, a setup\_slot can be run to correct issues. Check ctap logs for errors.

## **NAS 5.4/5.5/5.6/6.0 UPGRADE/INSTALLATION ISSUES:**

WORKPART MAGIC STRUCTURE BY CODE VERSION:

#### **NAS 5.3:**

workpart\_magic = 0xfacebeaf

#### **NAS 5.4 & 5.5:**

workpart\_magic = 0xbeaf0001

#### **NAS 5.6:**

workpart\_magic = 0xbeaf0002

**Note:** Please note that all 5.4 upgrades that do not complete have an upgrade.log in /var/tmp

#### **NAS 6.0:**

workpart\_magic = 0xbeaf0002

1. Installation with Symm backend may fail if data luns are presented. Data Movers will boot to RC4 ‘Dart Ready’ state by are unable to complete install when “camshowconfig” is run. See AR65121. Solution is to remove all data luns and use Control Luns and Gatekeeper luns only for install.

2. NAS 5.4 upgrades root\_log slices, which triggers workpart update. The workpart update fails to populate bind tables, meaning that they are then cleared and recreated. Can cause problems with systems with multiple backends or FA’s that use same target/lun for different volumes—scsi chains can become misaligned in new binding table.

3. Upgrade fails to complete (evidence is lack of upgrade log in /nas/log) and workpartition has been deleted:

**# /nas/sbin/workpart -r**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Work Partition Structure not found!

134

**Apply Primus EMC113946:**

1. Recover work partition:

**# /nas/sbin/workpart -o wpart**

134

**# /nas/sbin/workpart -r**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

workpart\_magic = 0xfacebeaf (workpart\_magic indicates system prior to 5.4)

dos\_slice.lba = 0x0

-----output abridged-----

2. Verify that workpartition is repaired:

**# /nas/sbin/check\_workpart\_and\_log\_slice\_consistency**

./check\_workpart\_and\_log\_slice\_consistency:

CRITICAL FAULT:

Error: Inconsistent workpart information

**Note:** If you get the above error, follow the rest of the steps outlined in Primus to complete NAS 5.4/5.5 upgrade

**# ./check\_workpart\_and\_log\_slice\_consistency**

Workpart layout is up to date, done

**# /nas/sbin/workpart -c**

Latest Version Workpart Layout Found!

134

## **UPGRADING NAS STORAGE API AFTER UPGRADE FAILURE NAS 5.4:**

**Note:** If NAS 5.4 upgrade fails with following message, download the latest nasStorageAPI and install

**Backend Storage Requirements Check Failed:**

-----  
INSTRUCTIONS: Upgrade NAS Storage API

1. Download nasStorageAPI from TS2 website (separate API required for primary CS and Standby CS)
2. Upgrade RPM: #rpm --upgrade nasStorageAPI-0.0-6.i386.rpm
3. Query to verify: **# rpm --query --info nasStorageAPI**

## **CREATING BOOT FLOPPY FROM NAS CD-ROM ON NAS 5.6 CONTROL STATION:**

**NAS 5.6 Mountpoint Changes on the Control Station:**

**/media/floppy**

**/media/cdrom** [for CD-ROM drives, ReadOnly]

**/media/cdrecorder** [for CD-RW drives, such as the NSX]

**Symptoms if using wrong mountpoints:**

**# mount -t msdos /dev/fd0 /mnt/floppy**

mount: mount point /mnt/floppy does not exist

**# mount /dev/cdrom /mnt/cdrom**

mount: mount point /mnt/cdrom does not exist

**NAS 5.6 Floppy Image Name Change on NAS CD-ROM:**

/mnt/cdrom/images/boot.img (NAS 5.5 or below)

/media/cdrom/images/floppy.img (NAS 5.6 and above)

**NAS 5.6 Boot Floppy Image:**

Since the floppy image contains no recognizable file system that Linux or Windows can detect, the only way to verify the boot floppy image is to use cksum

**Boot Floppy Creation & Verification Procedure:**

**1. Mount CD-ROM & Floppy on Control Station:**

**# mount -r /media/cdrom**

**# mount -t msdos /dev/fd0 /media/floppy**

**# mount**

```
/dev/hdd on /media/cdrom type iso9660 (ro,nosuid,nodev)  
/dev/fd0 on /media/floppy type msdos (rw)
```

**2. Create boot floppy system disk:**

```
# dd if=/media/cdrom/images/floppy.img of=/dev/fd0 bs=1024
```

1440+0 records in

1440+0 records out

**Note:** Eventhough the command prompt returns quickly, it takes a few minutes to complete the image write to the Floppy disk

**3. Use checksum to verify the image built to floppy vs. the image on the NAS CD Media:**

```
# dd if=/dev/fd0 of=/tmp/bootflop bs=1024
```

```
# ls -la /tmp/boot*
```

```
-rw-r--r-- 1 root root 1474560 Jan 31 14:36 /tmp/bootflop
```

```
# cksum /tmp/bootflop
```

```
1683387514 1474560 /tmp/bootflop
```

```
# cksum /media/cdrom/images/floppy.img
```

```
1683387514 1474560 /media/cdrom/images/floppy.img -->Checksums match on the file named "bootflop" vs. "floppy.img"
```

**4. Unmount Media from Control Station:**

```
# umount /media/floppy
```

```
# umount /media/cdrom
```

**CREATING BOOT FLOPPY FROM NAS CD-ROM (NAS 5.5 and below):**

1. # mount /dev/cdrom /mnt/cdrom
2. # mount -t msdos /dev/fd0 /mnt/floppy
3. # dd if=/mnt/cdrom/images/boot.img of=/dev/fd0 bs=1024

**Note:** Though the command comes back to the prompt immediately, keep in mind that the floppy has not yet been written to—will take a few minutes to complete

**CREATING LINUX BOOT FLOPPY FROM RUNNING LINUX SYSTEM:**

Insert diskette and issue command: **#/sbin/mkbootdisk `uname -r`**

**CREATING BOOT FLOPPY FOR NAS 4.X UPGRADE FROM CD-ROM ON WINDOWS:**

1. Requires having rawrite.exe program on the Windows system
2. Execute rawrite.exe and enter path to CD-ROM: c:>d:\images\boot.img
3. Enter diskette in a: drive, enter

**EXTRACTING FILES FROM CD-ROM:**

1. Mount CD containing NAS Version:  

```
#mount /dev/cdrom /mnt  
#cd /mnt/cdrom/EMC/nas  
#mkdir /nas/var/extract
```
2. Copy the RPM to the new directory & extract:  

```
#cp emcnas-5.1.18-3.i386.rpm /nas/var/extract  
#cd /nas/var/extract  
#rpm2cpio emcnas-5.1.18-3.i386.rpm | lcpio --extract --make-directories */nas/cifs* [*emcopy.exe* or *readme.txt*]
```
3. #cd /nas/var/extract/nas/cifs/usrmapperV3/linux [Check directories for desired files]

**EXTRACTING SINGLE FILE FROM NAS ISO IMAGE:**

1. FTP NAS ISO image to Control Station, or mount cd-rom (#mount /dev/cdrom)
2. Create mount point  

```
# mkdir /emc2
```
3. Mount ISO image using Linux loop device  

```
# mount /nas/var/temp/emcnas5.4.16.1.iso /emc2 -t iso9660 -o loop=/dev/loop0
```
4. Copy emcnas rpm to Control Station location  

```
# cd /nas/var/temp/EMC/nas  
# cp emcnas-5.4.16-1.i386.rpm /nas/var/temp
```
5. Extract the required file to /nas/var/temp using the following command.

```
#cd /nas/var/temp # rpm2cpio emcnas-5.4.16-1.i386.rpm | cpio --make-directories --extract *nas.exe*
```

```
# ls -al /nas/var/temp/nas/dosfs/bin
```

```
-rwxr-xr-x 1 root root 20667155 Aug 25 13:32 nas.exe
```

```
# umount /emc2
```

```
# rm /nas/var/temp/emcnas-5.4.16-1.i386.rpm
```

**EXTRACTING SPECIFIC PORTION OF NAS RPM TO REBUILD NAS CMD:**

**Note:** /nas/bin/nas\_cmd is invoked by numerous server commands, such as server\_df

```
#mount /dev/cdrom  
#cd /mnt/cdrom/EMC/nas  
#cp emcnas-5.4.19-4.i386.rpm /home/nasadmin  
#cd /home/nasadmin
```

**# rpm2cpio emcnas-5.4.19-4.i386.rpm | cpio -- extract --make-directories \*nas\_cmd\***

#### **EXTRACTING SINGLE FILES FROM RPM (ISO or CD-ROM):**

1. mount CD-ROM, ISO image, or place the .rpm file in a desired directory on the Control Station

**# mount /dev/cdrom # mount -t iso9660 -o loop emcnas5.4.17.5.iso /rpm**

2. Change to /nas/var/dump/pkg\_5.5.79.0 directory

3. Verify that file you want is in the RPM

**# rpm2cpio /nas/var/dump/pkg\_5.5.79.0/emcnas-5.5.79-0.i386.rpm |cpio -t |grep -i nas\_mcd.cfg**

```
./nas/sys/nas_mcd.cfg
```

4. Extract the file from RPM

```
# rpm2cpio /nas/var/dump/pkg_5.5.79.0/emcnas-5.5.79-0.i386.rpm |cpio -icduv *nas_mcd.cfg
```

```
./nas/sys/nas_mcd.cfg
```

**Note:** File will be extracted to the directory from which the command is run, and then to the path that the file exists within the RPM.  
In this example, the nas\_mcd.cfg file was extracted to the /nas/var/dump/pkg\_5.5.79.0/nas/sys directory.

#### **RESTORING NASDB FROM BACKUP:**

```
#uncompress nasdb_backup.x.tar.z [gzip -d for gz file]
```

```
#/nas/sbin/nasdb_restore /nas /nasdb_backup.x.tar
```

**Note:** Might need to conduct an FSCK on the restored file system.

#### **NASDB BACKUP & RESTORE:**

##### **BACKUP NAS DATABASE:**

**\$/nas/sbin/nasdb\_backup /nas /home/nasadmin**

##### **RESTORING NAS DATABASE:**

**# /nas/sbin/nasdb\_restore /nas /home/nasadmin/nasdb\_backup.x.tar** [Used to restore a backup copy of the NAS database]

**Example:**      uncompress nasdb\_backup.x.tar.z [or gzip -d for gz files]

```
/nas/sbin/nasdb_restore /nas /nasdb_backup.x.tar [May need to run fsck on restored file systems]
```

**Note:** NAS\_DB Backups do not currently backup SecMap or Internal Usermapper databases with 5.2 or 5.3

#### **NAS DB BACKUPS AFFECTS TIMEFINDER REFRESHES & OTHER PROCESSES:**

**Note:** There is a problem between nas\_db locking its database files and other processes not being able to complete because of this. Turns out that this is a regression issue and NAS 5.3 will contain fix to essentially not have the nas\_db backup lock the Celerra db.

##### **Workaround Fix:**

1. Stop NAS\_DB Cron Job before editing & comment out the Job:

```
# vi /nas/site/cron.d/nas_sys
```

```
#1 * * * * nasadmin /nas/sbin/nasdb_backup /nas /home/nasadmin 1 &>/dev/null
```

2. Edit nasdb\_backup Script to add “return 0” to following two areas in script:

```
# vi /nas/sbin/nasdb_backup
```

```
return 0
```

```
DIR=$1
```

```
DIR_LOCKED=$1$DIR_LOCK_EXT
```

3. Uncomment nasdb\_backup Job in cron.d directory

4. Reset Cron by doing: #touch /etc/crontab

**Note:** See AR59118 for more details about the fix. Fixed in NAS 5.3.17.0/5.4.15.0→nasdb\_backup script used to grab a lock while creating the SCCS archives. While holding this lock, all other administrative operations would not be permitted—was done to ensure consistency in the SCCS archive—this has found not to be required and is no longer done. One problem caused was that a SavVol extend might not be executed if the NAS\_DB had a lock, leading to SavVol full and inactive condition.

#### **MONITORING PROGRAM FOR NS SERIES SERIAL PORTS:**

**Note:** CTAP logs record the serial boot history of a data mover and is new to NAS 5.3—up to 11 logs per DM are kept

##### **Location:**

**/var/log/ctapptyS4.log** (Data Mover 2)

**/nas/sbin/ctap/ctapmon** →Program to monitors serial ports listed in /etc/ctapmon.conf

**# ps -ef |grep -i ctap**

```
root 30531 1 0 08:51 pts/7 00:00:00 /nasmcd/sbin/ctap_mon /dev/ttyS4
```

```
root 30539 1 0 08:51 pts/7 00:00:00 /nasmcd/sbin/ctap_mon /dev/ttyS5
root 30547 1 0 08:51 pts/7 00:00:00 /nasmcd/sbin/ctap_mon /dev/ttyS6
root 30555 1 0 08:51 pts/7 00:00:00 /nasmcd/sbin/ctap_mon /dev/ttyS7
```

# /nas/sbin/ctap/ctapmon -restart

# cat /etc/ctapmon.conf

```
/dev/ttyS4:/var/log/ctapttyS4.log →Data Mover_2
/dev/ttyS5:/var/log/ctapttyS5.log →Data Mover_3
/dev/ttyS6:/var/log/ctapttyS6.log →Data Mover_4
/dev/ttyS7:/var/log/ctapttyS7.log →Data Mover_5
```

**Note:** Logs contain information that may be useful in troubleshooting install/upgrade failures

#### **SAMPLE LOG OUTPUT:**

```
CONSOLE> rcq<0D>sib<0D>s reason_code=05 <0D><0A>
Fri Oct 15 17:05:56 2004
```

## **CELLERRA PRIMARY, SECONDARY, & IPMI INTERNAL NETWORKS**

Celerra uses a private IP communications network based on a Primary & Secondary network, for monitoring and control functions on the Data Movers, Control Station, and for Clariion SPs for Integrated systems. Additionally, there is a 3<sup>rd</sup> private network called IPMI, used only for those systems that use dual Control Stations (NSX, NS80, old CNS, CFS-14, etc)

### **CELLERRA INTERNAL IP NETWORKS ON CS:**

#### **SCO & LINUX Upgrades From SCO:**

192.1.1.100/192.1.2.100

#### **LINUX INSTALLS ABOVE 2.2.35.4:**

192.168.1.100/192.168.2.100

#### **NAPA 2 5.5.22.x SYSTEMS:**

Integrated SP addresses on SPB change from 192.168.1.201 to 192.168.2.201

#### **NOVEMBER 2007 NAS 5.5.31.x PRIVATE ADDRESS CHANGE—Current vs. New:**

#### **CURRENT CELERRA PRIVATE NETWORK SCHEME:**

Primary internal network IP: 192.168.1.100

Backup internal network IP: 192.168.2.100

Netmask: 255.255.255.0

IP address of storage processor A: 192.168.1.200

IP address of storage processor B: 192.168.2.201 (CX3-series Integrated NS)

IP address of storage processor B (NS350 Only & CX3-series NS): 192.168.1.201

Gateway IP address of storage processor A: 192.168.1.104

Gateway IP address of storage processor B: 192.168.2.104

IMPI network (NS80 only): 192.168.3.100; 192.168.3.101

#### **CELLERRA PRIVATE NETWORK SCHEME (NAS 5.5.32+):**

Primary internal network IP: 128.221.252.100

Backup internal network IP: 128.221.253.100

Netmask: 255.255.255.0

IP address of storage processor A: 128.221.252.200

IP address of storage processor B: 128.221.253.201

IP address of storage processor B (NS350 Only): 128.221.252.201

Gateway IP address of storage processor A: 128.221.252.104

Gateway IP address of storage processor B: 128.221.253.104

IMPI networks (NS80 only): 128.221.254.100 emcnasipmi; 128.221.254.101 emcnasotherIPMICS\_i3

**Note:** With the release of the NS20 for Napa 8, it was found that many customers were already using the 192.168.1/2 networks for their internal LAN, which conflicts with the default Celerra networks, resulting in the need to perform fresh reinstalls for systems that are being touted as factory-installed. As a result, the 128.221.252/253/254 networks will become the new default private networks for the Celerra. All systems shipped from Manufacturing as of 11/05/2007 will ship with the new defaults. As of NAS 5.5.32.x, the DART code will be updated to reflect the new Private Network scheme.

## **INTEGRATED SP ADDRESSES & GATEWAY FOR CONTROL STATION COMMUNICATIONS:**

#### **Pre-5.5.30 NS SYSTEMS USING CX3-ARRAYS:**

SPA 192.168.1.200

gw 192.168.1.100 → eth0 192.168.1.100

SPB 192.168.2.201

gw 192.168.2.100 → eth2 192.168.2.100

#### **NAS 5.5.30+ OLD INTERNAL IPs:**

SPA 192.168.1.200

gw 192.168.1.104 → eth0:1 192.168.1.104

SPB 192.168.2.201

gw 192.168.2.104 → eth2:1 192.168.2.104

**NAS 5.5.30+ NEW INTERNAL IPs:**

SPA 128.221.252.200

gw 128.221.252.104 → eth0:1 128.221.252.104

SPB 128.221.253.201

gw 128.221.253.104 → eth2:1 128.221.253.104

**NAS 5.5.30+ Proxy ARP:**

SPA 10.250.169.50

gw 10.250.169.1 → eth0:1 128.221.252.104 (remains configured on CS but is no longer applicable)

SPB 10.250.169.51

gw 10.250.169.1 → eth2:1 128.221.253.104 (remains configured on CS but is no longer applicable)

**CHANGING GET REASON CODE FROM CONFIGURED (4) TO CONTACTED (5):**

# /nas/sbin/setreason /nas 4 5 [Setting slot\_4 to ‘Sib’ Contacted State, 5--/nas required to define NAS\_DB path]

**CELLERRA FILE SERVER OPERATION:**

**DETERMINING DATAMOVER STATUS:**

# /nas/sbin/getboxmask -r [Shows DM’s powered on or not. Empty slot may mean DataMover removed]

# /nas/sbin/getreason [If both commands show the slot empty, then the DataMover is not plugged into backplane]

# /nasmcd/getreason [alternate command to obtain slot status]

# /nas/bin/nas\_server -l [Slot populated if a setup\_slot was performed—added to database & will still show if DM removed]

**Note:** Above command reads information from the /nas/server/servers directory

# /nas/sbin/t2adc

**Purpose:** pwr & voltage readings for DM; Will also show if a slot is physically empty

# nas\_server -a -i [Shows which DataMovers are Out\_of\_Service and which Slots are empty]

**Key Directories:** /nas/sbin and /nas/bin and /nas/server /nas/dos /nas/log /nas/sys etc Hosts Inet

**OBTAINING SLOT STATUS IF BOX MONITOR SHUT OFF OR FROM SECONDARY CS:**

# /nasmcd/getreason

**Note:** This command will return slot status even if Box Monitor is disabled or if you are telnetted into CS1 running as Secondary

**NAME RESOLUTION: Control Station and DataMovers**

**/etc/hosts File:** Normally configured on Control Stations and Sun Solaris servers, etc, but could have Hosts file for DM too.

Step 1. Mount the DataMover directly to the Control Station [#mount -F nfs server\_2:/ /mntpoint

Step 2. #ls -la to locate the .etc file

**Copying Hosts file from Control Station to DM:** \$cp /etc/hosts /tmp \$cd /tmp; #server\_file server\_2 -put hosts hosts

**Note:** use \$server\_file server\_x -put to copy files from your current directory to the default ./etc directory of the DataMover

**ORDER OF HOST NAME RESOLUTION ON DATAMOVER:** ./etc/hosts file; NIS Server; DNS Server

**HARDWARE OPERATIONS:**

**Removing a Production Data Mover from the database:**

**Example:** Removing slot\_5 on a CFS-14, with updates for NAS 5.6

**Caution:** There may be additional steps required for updating enclosure database information

Step 1. Verify that file systems are not in use before unmounting (nas\_fs –list):

# nas\_fs -list

Step 2. Permanently Unexport and Unmount all FileSystems

# server\_export server\_5 -u -p -a

# server\_umount server\_5 -perm -a

Step 3. If removing a primary Data Mover where a Standby has been configured, delete the standby relationship:

# server\_standby server\_5 -delete mover=server\_3 (where server\_3 is the Standby in this example)

Step 4. Permanently unmount the Root FileSystem:

# server\_umount server\_5 -p root\_fs\_5

Step 5. Leave the Data Mover running, in its slot, and run the following command:

# /nas/sbin/setup\_slot -d 5 [Will prompt that database will be deleted—select ‘Yes’]

Step 6. Rebuild SYMAPI Database using the following command:

**Prior to NAS 5.6:**

```
# mv /nas/symapi/db/symapi_db.bin /nas/symapi/db/symapi_db.old  
# /nas/sbin/nas_rdf –localinit  
# chown nasadmin:nasadmin symapi_db.bin
```

**NAS 5.6 or Higher:**

```
# server_devconfig ALL –c –s –a
```

Step 7. Conduct additional database cleanup:

```
# vi /nas/server/servers and remove the line for server_5  
# cd /nas/server;ls -la and remove link that refers to "slot_5 -->server_4"  
# rm slot_5  
# cd /nas/server/server_4, verify your location using ‘pwd’, then delete contents of /nas/server/server_4  
# rm -Rf *
```

**Note:** Due to an old Celerra system numbering anomaly, note that the /nas/server/server\_4 directory is actually for slot\_5. Exercise care when selecting the right slot vs. the right server directory!

Step 8. Verify that Root filesystem for Slot\_5 is unmounted:

```
#cat /nas/volume/filesys and verify that "n" is set, as shown below:
```

```
5:root_fs_5::0:10::n:1:18:::0:::0:0::
```

Step 9. Power down slot\_5 and remove the hardware

Step 10. If running NAS 5.6, and intending to move the Hardware to a new physical slot, make sure that nas\_cel –update id=0 is run to ensure that the Data Mover loopback interconnects are created

Step 11. Do system healthchecks:

```
# nas_storage –check -all  
# nas_checkup  
# /nas/sbin/setup_enclosure -checkSystem  
# /nas/sbin/enclosure_status
```

**REBOOTING, HALTING, USING T2RESET:**

```
#/nas/sbin/t2reset reboot -s 2 {slot # of DM}  
#/nas/sbin/t2reset pwoff {pwron} -s slot  
#server_cpu server_2 -r -monitor now  
#server_cpu server_2 -halt now  
#/nas/sbin/t2reset reboot -s 2  
# /sbin/halt  
# /nas/sbin/nas_halt now  
Perform a controlled halt of the Control Station(s) and Data Mover(s)
```

**RESETTING DM USING MOTHERBOARD CMD: #/nas/sbin/t2reset mother -s <slot\_#>**

**Note:** This command may be useful if DM is stuck in reason code 0 or 7, or if the comm. board is bad, for older CNS/CFS frames. Command issues a Tier 2 reset to the motherboard.

**WHY "T2RESET" vs. "SERVER CPU" COMMAND?**

1. Use the “t2reset” whenever you’ve edited the “boot.cfg” file, as in preparing to run an FSCK. The Server will reboot from the /nas/dos/slot\_x/boot.cfg and NOT rebuild the “boot.cfg” from /nas/server/slot\_x files as it normally does on reboot. The server\_cpu command invokes a build\_config which recompiles the boot.cfg based on the NASDB configuration files of the Data Mover slot.
2. Similarly, use the “server\_cpu” reboot command when you do want to rebuild the server’s configuration files [aka, “boot.cfg”], such as when the server won’t progress from “Status 4 configured” to “Status 5 contacted”. The Server rebuilds the “boot.cfg” from the files located in the /nas/server/slot\_x using build\_config.

**STOPPING NAS SERVICES:**

**#/sbin/service nas stop**

```
#ps -ef |grep boxm  
#ps -ef |grep nasmcd
```

**Note:** Do not try to stop NAS services while in any of the NAS partition directories

**SHUTTING DOWN/REBOOTING/CHANGING RUNLEVEL OF LINUX CONTROL STATION:**

**# sync;reboot | # reboot | # reboot -n -f** [Force, no sync reboot] | **# sync; sync;sync;init 6 | init 0 | # shutdown -r now**

## # /nas/sbin/nas\_halt now

Perform a controlled halt of the Control Station(s) and Data Mover(s)

## # /sbin/halt

### **Data Mover Reason Codes--BootUp:**

- 0 Data Mover performing BIOS check, then begins boot sequence
- 1 Data Mover passes SIB POST
- 2 Data Mover fails SIB POST
- 3 Data Mover booting EMC NAS
- 4 Data Mover in running state
- 5 Box monitor operational and Data Mover in normal running state
- 7 Data Mover Crash
- 9 Reboot

**NAS.EXE File:** \$/nas/dos/bin/nas.exe [/nas/dos/slot\_x contains gload.exe, boot.cfg; /nas/dos/bin contains nas.exe and misc. files]

**BOOT.BAT & BOOT.CFG Files:** \$/nas/dos/slot\_x/boot.bat & boot.cfg [DataMover configuration files]

## **CELLERRA NASDB**

### **NAS DATABASE:**

- Located in /nas/server directory and contains configuration information for each Data Mover, as well as general information for all Servers in the cabinet (servers & server\_setup files)
- Contains all files that combine to create the /nas/dos/slot\_x/boot.cfg file and complete Data Mover configuration on bootup
- Files contained in /nas/server/server directory allow server to mount file systems (camdisk; mount; mountpoint;ufs;volume)
- See /nas/sbin/build\_config script to see how NAS DB files are used to build the boot.cfg

### **CONTROL STATION DATABASE:**

- Located in /nas/volume directory, contains files common to all data movers regarding Storage volumes & file systems

## **CELLERRA ROWLEVEL LOCKING NAS 5.5 (Row Locking Files):**

- NAS 5.5 introduced RLL in order to support the DBMS database that will be put into service with NAS 5.6

- Row Locking done on /nas/volume/disks, volumes, filesystems, and slices files

## **/nas/sbin/nasdb\_tools**

```
# ls -la
-rwxrwxr-x 1 nasadmin nasadmin 1295 Jan 31 10:48 db_status
-rwxrwxr-x 1 nasadmin nasadmin 4583 Jan 31 10:48 downgrade_db
-rwxrwxr-x 1 nasadmin nasadmin 1685 Jan 31 10:48 downgrade_table
-rwxrwxr-x 1 nasadmin nasadmin 56223 Jan 31 10:48 fixdb3
-rwxrwxr-x 1 nasadmin nasadmin 2812 Jan 31 10:48 lock_cleanup
-rwxrwxr-x 1 nasadmin nasadmin 210143 Jan 31 10:48 lock_wrapper
-rwxrwxr-x 1 nasadmin nasadmin 5425 Jan 31 10:48 remove_lock_owners
-rwxrwxr-x 1 nasadmin nasadmin 5837 Jan 31 10:48 upgrade_db
-rwxrwxr-x 1 nasadmin nasadmin 1784 Jan 31 10:48 upgrade_table
```

## **# /nbsnas/sbin/nasdb\_tools/db\_status**

Current DB seems to be at version 3

**Note:** Above output reflects RLL with NAS 5.5.27.0

## **# /nas/sbin/nasdb\_tools/db\_status**

Current DB seems to be at version NO\_ROW\_LOCKING

**Note:** Output as seen from NAS 5.4 or earlier. An issue like this could be seen if upgrading from 5.4 to 5.5 and the upgrade did not complete the update of the NASDB.

→ NAS 5.5 contains Row Level Locking (RLL) in each db file to support auto fs extension and Thin Provisioning

### **ROWLOCK EXAMPLE FROM FILESYS, DISKS, & VOLUMES FILE:**

## **\$ head filesystem**

### **ROWLOCK:FILESYS:1:24:4::**

**Note:** The :24: field represents the last index number used in the last file entry. The last empty :: field would show a <pid> if the db was locked by another process

→ disks, volumes, slices, & filesystems files are all directly related and must match info posted in camdisk files

→ pools & profiles files are used by AVM to select disks during file system creation

## **\$ cat disks**

### **ROWLOCK:DISKS:1:8:8::**

```
1:root_disk::0:9::y:11263:APM00073801833:1:1:0000:7:  
2:root_ldisk::0:9::y:11263:APM00073801833:1:2:0001:7:  
3:d3::0:8::y:2047:APM00073801833:1:3:0002:7:  
4:d4::0:8::y:2047:APM00073801833:1:4:0003:7:  
5:d5::0:8::y:2047:APM00073801833:1:5:0004:7:  
6:d6::0:8::y:32767:APM00073801833:1:6:0005:7:  
7:d7::0:5::n:175473:APM00073801833:1:83:0010:7:  
8:d8::0:5::n:175473:APM00073801833:1:84:0011:7:
```

### \$ cat volumes

#### ROWLOCK:VOLUMES:1:84:6::

```
1:root_disk::0:41::y:4:0:1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,24,25,26,27,28,29,30,31,32,33,34,52:1:  
2:root_ldisk::0:23::y:4:0:35,36,37,38,39,40,41,42,43,44,45,46,47,48,49,50,51:2:  
3:d3::0:6::y:4:1:77:3:  
4:d4::0:6::y:4:1:78:4:  
5:d5::0:6::y:4:1:79:5:  
6:d6::0:6::y:4:1:80:6:  
---removed----  
83:d7::0:3::n:4:0::7:  
84:d8::0:3::n:4:0::8:
```

### **DB Status if Row Locking File missing with NAS 5.5:**

```
# ls -la /nas/volume/.row_locking_db_version*
```

**Note:** File not found

```
# /nas/sbin/nasdb_tools/db_status
```

Current DB seems to be at version NO\_ROW\_LOCKING

#### **Recreating & Setting Permissions on the Row Locking DB File:**

```
/nas/volume/
```

1. \$ echo -n "3" >/nas/volume/.row\_locking\_db\_version
2. \$ chmod 775 /nas/volume/.row\_locking\_db\_version
3. \$ ls -al /nas/volume/.row\_locking\_db\_version  
-rwxrwxr-x- 1 nasadmin nasadmin 1 < date time > /nas/volume/.row\_locking\_db\_version

#### 4. \$ cat .row\_locking\_db\_version

3

5. Verify:

```
# /nas/sbin/nasdb_tools/db_status
```

Current DB seems to be at version 3

### **DBCHK TOOL:**

```
/nas/tools/dbchk -wvxpVs [Not all switches are valid prior to NAS 5.5 code]
```

```
/nas/tools/dbchk.jar (Actual code for dbchk)
```

**Note:** dbchk was introduced in NAS 5.3 as a way to verify the relationship of db entries. Switches: w=warnings; v=verbose; x=extended checks; p=compare NAS\_DB to probe; V=volume consistency check; s=suggestion mode

### **NAS DB SIGNATURE FILES:**

→Each NAS\_DB file has a corresponding hidden signature file used to verify consistency and integrity of db files

Signature Files Found in Following Directories:

```
/nas/server  
/nas/server/slot_*  
/nas/server/vdm/  
/nas/site/  
/nas/sys/  
/nas/volume/
```

#### **EXAMPLE:** /nas/server/slot\_2/camdisk

```
-rw-r--r-- 1 nasadmin nasadmin 464 Jul 8 15:15 camdisk  
-rw-r--r-- 1 nasadmin nasadmin 13 Jul 8 15:15 .camdisk.sig  
# cat .camdisk.sig
```

1263787786:8: →Hash value, compared to bit value of original file, used to validate if file contents are valid

**Note:** If hash process detects problem, an error is logged in sys\_log. In above Hash value example, last colon-separated value “:8:” represents the last dvolume added to the database.

**GLOBAL PARAM DATABASE--Boot.Cfg File:**

Also known as the “Global Param Database” file. Location: */nas/dos/slot\_x*

**Note:** The boot.cfg is compiled from DART memory as it goes down for reboot. It contains information from the various configuration files located in the */nas/server\_slot\_x* directory

---

```
#verify_start

**REBUILDING THE BOOT.CFG FILE WITHOUT REBOOTING:**

**Comment:** Use this feature with extreme care; backup NAS\_DB first; save extra copy of boot.cfg file!!

In certain situations it becomes necessary to edit param files contained in the */nas/server/slot\_x* directory. Once the edits are done, you can execute the following command to rebuild the Server's "boot.cfg" file from the modified files:

**\$/nas/sbin/build\_config /nas/server/slot\_5 /nas/dos/slot\_5**

**\$/nas/sbin/build\_config -min /nas/server/slot\_7 /nas/dos/slot\_7**

**Note:** Use this second command to build a ‘minimum’ configuration for a DataMover that you are having problems trying to bootup

## **SERVER LOG EXAMPLE: NORMAL CPU BOOT-UP:**

```
2001-05-23 05:34:13: ADMIN: 4: Command succeeded: logsys add output disk=root_log_10 bufsz=256 [Beginning of reboot]

## NEW CELERRA DATABASE QUERYING SUBSYSTEM:

# nas\_disk -query:tags  
# nas\_fs -query:tags  
# nas\_volume -query:tags  
# nas\_slice -query:tags

**Note:** Run any of the above commands to see what type of Queries are available—following topics are available for FS queries:

## **AVAILABLE QUERIES FOR FILE SYSTEM TOPICS:**

Supported Query Tags for nas\_fs:

Supported Query Tags for CDMSConnections:

Supported Query Tags for CDMSThreads:

Supported Query Tags for Checkpoints:

Supported Query Tags for DefaultQuotas:

Supported Query Tags for Disks:

Supported Query Tags for ServerTable:

Supported Query Tags for GroupQuotas:

Supported Query Tags for ReplicationSessions:

Supported Query Tags for TreeQuotas:

Supported Query Tags for UserQuotas:

## **QUERYING SERVERS BY NAME & ID:**

# **nas\_server -query:\*** -format:'%s\n' -Fields:Name

server\_2

server\_3

**Note:** Example of query for list of all server names

# **nas\_server -query:\*** -format:'%s\n' -Fields:Id

## **QUERY EXAMPLES:**

\$ **nas\_cel -exec id=1 "nas\_fs -s fs04"**

total = 3223813 avail = 1755380 used = 1468433 ( 45% ) (sizes in MB) ( blockcount = 6704695296 )

volume: total = 3273777 (sizes in MB) ( blockcount = 6704695296 )

# **nas\_disk -query:\*** -Fields:'id,DiskType,StorageProfile,Protection' -format:'Disk id %s has %s, %s, type %s\n'

Disk id 1 has CLSAS, clarsas\_archive, type RAID5(4+1)

Disk id 2 has CLSAS, clarsas\_archive, type RAID5(4+1)

# **nas\_disk -query:\*** -Fields:'id,DiskType,StorageProfile,Protection' -format:'Disk id %s has %s, %s, %s type\n' |head

Disk id 1 has STD, symm\_std, 2-Way Mir type

Disk id 2 has STD, symm\_std, 2-Way Mir type

# /nas/bin/nas\_fs -query:\*

-format:"\n%-40s%q" -fields:name,disks -query:\*

-format:"%s" -fields:name

root\_fs\_1 root\_disk

root\_fs\_2 root\_disk root\_ldisk

## **QUERYING FILE SYSTEM ID & NAME:**

# **nas\_fs -query:Name==fs9** -format:'%s\n' -Fields:Id

# **nas\_fs -query:id==39** -format:'%s\n' -Fields:Name

## **OPERATOR DEFINITIONS:**

= having the pattern

== exact string match

=- integer minimum

=+ integer maximum

=\* any

=^ not having the pattern

=^= not an exact match

=^- not integer minimum, less than

=^+ not integer maximum, more than

=^\* not any

## **Example of Disks used by a Server:**

# **nas\_disk -query:servers=3 -fields:name,size** -format:'name=%L size=%L \n'

## **QUERYING FILE SYSTEMS USING NAS\_FS QUERY:**

# /nas/bin/nas\_fs -query:\*

-format:"\n%-40s%q" -fields:name,disks -query:\*

-format:"%s" -fields:name

>/tmp/filesystems.log

# tail /tmp/filesystems.log

-----abridged-----

d7

root\_avm\_fs\_group\_3 d7  
event\_log d38 d39 d40  
root\_avm\_fs\_group\_36 d38 d39 d40

## **CELERRA MANAGER/CELERRA MONITOR:** [http://172.24.80.64:8000/top\\_level.htm](http://172.24.80.64:8000/top_level.htm)

**Prerequisites:** Celerra Monitor is a Java client/server application consisting of “Java Server” on Control Station [/nas/sys/nas\_mcd.cfg] and Java applets that run on Client’s Web Browser. Cookies must be enabled since SSL is used between Browser and Control Station connections. Celerra Monitor is only available with the Advanced Edition of Celerra Manager.

## **CELERRA MANAGER BASIC vs. ADVANCED MANAGER:**

Celerra Manager Advanced Edition adds ability to manage multiple Celerra systems, use Manual Volume Management, and use the CDMS (Celerra Data Migration Services) feature.

### **CELERRA MANAGER 5.2 (WebUI):**

- Basic Edition=free & Advanced Edition requires license fees [NFS and/or CIFS and CDMS Data Migration with NAS 5.3]
- Interface emulates ECC “Highland” product & combines WebUI, Native Manager, & Celerra Monitor

### **NAVIAGENT ON LINUX:**

# /nas/sbin/naviagent -help

@(#)Navisphere Agent Revision 6.6.0.3.8 for Linux on 12/12/2003 01:21:32

# /nas/opt/Navisphere/bin/naviagent -help

@(#)Navisphere Agent Revision 6.6.0.3.8 for Linux on 12/12/2003 01:21:32

**Note:** NAS Upgrades can sometimes fail to upgrade these directories with the same files and Celerra Manager may stop working.

## **CHANGING CONTROL STATION HOSTNAME:**

### **Use Celerra Manager:**

Celerras>Control Station Properties>Hostname: new\_csname

**Note:** Updates the /etc/hosts and /etc/sysconfig/network files with new hostname. Logoff and log back on to see new hostname.

### **Changing Name Manually:**

1. Edit /etc/hosts file to new name
2. Edit /etc/sysconfig/network file to new name
3. Reboot or Logoff and log back onto CS
4. #/bin/hostname [Verify name changed—if not, use #hostname newname]

**Note:** Or, use commandline GUI programs called “linuxconf” or “/sbin/netconf” [Must change Hostname in Hostname section and in the Adapter section for eth3, then reboot CS]

## **TROUBLESHOOTING CELERRA MANAGER(WEBUI)/CELERRA MONITOR:**

### **CELERRA MANAGER:**

Celerra Manager is a web-based gui for remote administration (aka WebUI) & operates as a secure SSL Apache Web Server that listens for requests from Browsers—its purpose is to configure and administer the Celerra from a GUI interface. Users log into WebUI with an authentication token that requires ability of browser to use HTTP cookies (set Browser to accept cookies). Jakarta Tomcat consists of .jsp pages/servlets and forwards Browser requests received from Apache, to the WebUI application. NAS 5.2 and higher uses XML requests from WebUI to the JServer daemon for graph, file system, and data mover notification inquiries initiated from the WebUI. The APL Task Manager listens to emcapl socket to receive and process XML tasks created by the WebUI, and returns output to socket for Tomcat to retrieve and send to Web Browser. JServer is allowed to consume up to 230MB of CS RAM, while the WebUI is allowed up to 96MB memory. Control Station will consume physical memory, then all the page memory that is allocated—if it exceeds the total allocated memory, then processes that are using the greatest amount of memory are killed.

#### **Basic Edition:**

Basic management tasks and can use with only a single Celerra.

#### **Advanced Edition:**

Manage multiple Celerras; create & manage volumes on the backend; CDMS Data Migration feature; Celerra Monitor; MVM wizard to create sub-structure to build file system on top of; Notifications tab to set file system & DM resource notifications

## **ACCESSING CELERRA MANAGER PAGES DIRECTLY VIA BROWSER:**

**Note:** You can attempt to display JavaServer pages directly by entering the proper .jsp page in a Web Browser /nas/tomcat/webapps/ROOT [All Control Station .jsp pages are stored here]

<https://10.241.169.53/action/shareDisplay> [After logging in, CIFS Share page will be displayed]

## [https://<system\\_name>/action/filesystemDisplay](https://<system_name>/action/filesystemDisplay)

filesystemCheckPtProperties  
filesystemExtend  
filesystemNew  
filesystemNotificationProperties  
filesystemPredict  
filesystemProperties  
filesystemQuotaProperties  
filesystemStats

### **USING COMMAND LINE TO QUERY:**

\$ /nas/bin/nas\_server -query:name=server\_3 -fields:MemoryUsage -format:"%s\n"

54

# nas\_fs -query:id==37 -fields:Name,type -format:"%s %s\n"

EPWxtra2\_DR uxf5

**Note:** FSID is 37 for the above query--Queries can be run against different nas components, such as nas\_server, nas\_fs, nas\_xml, etc.

# nas\_storage -query:\* -fields:StorageProcessorTable -format:"%q" -query:\* -fields:Address -format:"%s," 192.168.1.200,192.168.1.201

192.168.1.200,192.168.1.201

**Note:** Command queries for SP IP Address confirmation

### **CELLERRA MONITOR V2.3:**

Celerra Monitor is a java-based client/server application used to monitor performance of Celerra Servers & Storage subsystems and is generally launched from within the WebUI window (NAS 5.2 +). Celerra Monitor runs as a Java Client/Server application launched from a Browser. The **Java Server** [poller] runs on the Control Station and a **Java applet** [application] runs on the Client's Web Browser. JServer API is known as Celerra XML API (aka xhmp)—XML is a session-based protocol used to encapsulate data carried to and from Control Station and Data Movers. Java archive files (.jar) are downloaded to Client browser from Control Station when connecting.

**Default Configuration used Celerra Manager>Tools>Celerra Monitor:**

/nas/http/htdocs/cmv2/cmv2.jnlp

### **CELLERRA XHMP PROTOCOL:** New feature with CFS 4.0 release—“XML Packet Messaging”

EMC W3C-compliant messaging protocol used for managing a Celerra using XML V2 to carry data messages and HTTP POST to communicate between Control Station & DM.

<http://10.241.168.51/schemas/xhmp/xhmp.htm>

Essentially, the XML API resides on the front-end of the Apache HTTP Server, receives Client Browser Request Packets using HTTP POST, passes to Apache JServer Servlet layer for parsing. All requests are sequential and Session-based. Replies are sent in Reply Packets & sent back to the Client.

### **XHMP OPERATION:**

**XML API V2:** Possible future replacement of JServer XML API V1

#### **Start & Stop:**

XML API V2 is started by configuration found in /nas/sys/nas\_mcd.cfg--start script is [/nas/sbin/start\\_xml\\_api\\_server](/nas/sbin/start_xml_api_server)

```
daemon "XML API Server"
executable  "/nas/sbin/start_xml_api_server"
optional    yes
canexit     yes
autorestart yes
ioaccess    no
```

In order to stop the XML API, comment out entries in nas\_mcd.cfg & shutdown using [/nas/sbin/hup\\_api](/nas/sbin/hup_api)

#### **Configuration & Ports Used:**

Configuration file is /nas/sys/xml\_api.conf, and contains port information for JServer, APL, & Indications Manager.

#### **Logs:**

→/nas/log/cel\_api.log XML API V2 Server log for User requests, APL requests & replies, & APL indications  
→/nas/log/webui/cel\_api.log XML API V2 servlet debug log  
→/nas/log/webui/cel\_api\_error.log XML API V2 servlet error log

#### **Processes:**

# ps fax |grep -i api

17476 pts/0 S 0:00 \\_ /bin/sh ./start\_xml\_api\_serve

# ps fax |grep java |grep -i xmxa180

```
2240 ? S 0:07 | \_ /usr/java/bin/java -server -Xmx180m -Xss10485
2337 ? S 0:00 | \_ /usr/java/bin/java -server -Xmx180m -Xss1
2339 ? S 37:10 | \_ /usr/java/bin/java -server -Xmx180m -
2342 ? S 0:00 | \_ /usr/java/bin/java -server -Xmx180m - [Multiple processes are running for java server]
```

### **ACCESSING CELERRA MONITOR DIRECTLY WITHOUT CELERRA MANAGER:**

1. Have JRE1.4.2 installed on Client computer
2. Use following URL to access Monitor & enter username & password at prompt:

**<http://172.168.2.20/cmv2/cmv2.jnlp>**

**Note:** This view shows Data Movers, Storage, File Systems, Volume Config, Alerts, System Log, OSM Log, & Graphs

### **BASIC THINGS TO CHECK OR DO WHEN TROUBLESHOOTING:**

- In all cases, you must first determine if this a WebUI or Celerra Monitor issue, or both. Always determine if the WebUI itself is operational and whether it is only Celerra Monitor that is not operational.
- If it is a WebUI issue, you must determine if a NAS Upgrade or other change has been done recently. If not, then the most likely problem is that the Apache & Tomcat processes are not recoverable except for a CS reboot—try to get customer to allow CS reboot.
- But more often than not it will be a Celerra Monitor. Again, determine if Monitor has ever been working correctly, and if so, whether an upgrade has just occurred.
- Obtain screen capture of problem from customer, if applicable
- Verify Browser and JRE versions in use and try access from a different Client and O/S [if possible]
- Verify that customer is not use a Proxy Server for the Web Browser [Uncheck ‘Use Proxy Server in Celerra Monitor’]

**Note:** If proxy does not consistently translate Client’s IP address, then Monitor will not operate correctly, especially if traffic is returning to Monitor with Proxy IP address but requests are being presented with Client’s real IP address.

→ Verify that Celerra Monitor is properly enabled via the #nas\_license –l output

```
advancedmanager online
```

### **MINIMUM SOFTWARE, JRE, & BROWSER REQUIREMENTS:**

→ Java Runtime Environment (JRE) 1.4.2 recommended, or higher on Client system [download from [java.sun.com/getjava](http://java.sun.com/getjava) to update Client system]. JRE 5.0 is available, but there are issues with this latest version.

→ Internet Explorer 6.0 SP2 is preferred

**Note:** Please note that Celerra Manager is not currently compatible with Internet Explorer 7.0—see Primus emc147371

→ Netscape 6.2.3 or higher, with 7.1 the preferred

→ Firefox 1.5 supported

→ Java Web Start package is required for Celerra Monitor & is included in the JRE package

→ Don’t used Proxy connections, may be unable to resolve hostname & IP address and login will fail

→ NAS 5.4 requires that Browsers accept all cookies, or else have CS in trusted site list

**Note:** If you are using a locale other than English, you must use JRE 1.3.1\_02-I to use Celerra Monitor!

### **BASIC CELMGR CELMONITOR TROUBLESHOOTING STEPS:**

#### **1. GET EXACT DESCRIPTION OF PROBLEM/FAILURE:** Check Primus & Logs

#### **2. VERIFY CONTROL STATION PROCESSES:** (**Apache/httpd, Tomcat, JServer, APL\_Task\_Mgr**)

**Note:** WebUI does NOT need JServer process to run, but does use JServer when polling the data movers for system information! JServer is a Server side process used for Celerra Monitor and also for graphs/resource notifications in WebUI.

**\$ ps -ef |grep -i jserv**

```
root 1816 1165 0 Jan06 ? 00:00:00 /bin/sh /nas/sbin/run_jserver
root 2867 2866 0 Jan06 ? 00:00:04 /bin/sh /nas/jserver/jexec
root 10408 10407 0 Jan06 ? 00:00:00 /nas/jserver/jserver_tail -f /na
root 10517 10515 0 01:14 ? 00:00:00 /nas/jserver/jserver_tail -f -c
```

**Note:** Above output reflects a correctly running JServer

**\$ ps -axlww |grep -i tomcat**

```
100 0 3134 1 9 0 284848 41084 wait_f S ? 0:15 /nas/http/webui/tools/j2sdk1.4.2_01/bin/java -server -
Djava.endorsed.dirs=/nas/tomcat/common/endorsed -classpath /nas/http/webui/tools/j2sdk1.4.2_01/lib/tools.jar:/nas/tom
cat/bin/bootstrap.jar -Dcatalina.base=/nas/tomcat -Dcatalina.home=/nas/tomcat -D java.io.tmpdir=/nas/tomcat/temp
org.apache.catalina.startup.Bootstrap start
```

**Note:** It is not unusual to see dozens of Tomcat processes running

**\$ ps -eafl |grep -i apache**

```
140 S apache 6897 2278 0 69 0 - 3297 semop Jan06 ? 00:00:01
/nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http/conf/httpd.conf
140 S apache 13167 2278 0 69 0 - 3287 semop Jan06 ? 00:00:01
```

**Note:** There may be dozens of httpd/apache processes running. Verify that the processes are running with a normal subroutine called “semop” or “semaphore operation”. If the processes are in a “wait\_if” state, could indicate a problem. Also check to ensure that the httpd daemon is running with proper configuration: -D HAVE\_PERL -D HAVE\_SSL You can verify its proper configuration by grepping for PERL from /nas/sbin/mcd\_helper file:

**\$ cat mcd\_helper |grep -i have\_perl**

\$SBIN/\$HTTPD -D HAVE\_PERL -D HAVE\_SSL \

**# ps fax |egrep httpd**

```
18504 pts/3 S 0:00 \ egrep httpd
17186 ? S 0:00 /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http (Parent HTTPD process)
17187 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
17188 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
```

**# ps -ef |grep task**

```
nasadmin 16275 1 0 11:40 pts/2 00:00:00 /nas/sbin/apl_task_mgr
root 29181 1165 0 13:42 ? 00:00:00 /bin/sh /nas/sbin/start_apl_task
root 29235 29181 0 13:42 ? 00:00:00 /bin/sh /nas/sbin/start_apl_task
nasadmin 29236 29235 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr
nasadmin 29239 29236 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr
nasadmin 29240 29239 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr
nasadmin 29242 29239 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr
```

**Note:** Above represents normal processes for APL Task Manager with NAS 5.3 and higher (4 apl\_task\_mgr processes)

**# ps axfw |less |grep -i jserv**

```
8446 pts/0 S 0:00 \ grep -i jserv
10721 ? S 0:00 \_ /bin/sh /nas/sbin/run_jserver
11852 ? S 0:12 | | \_ /bin/sh /nas/jserver/jexec
1021 ? S 0:00 | | \_ /nas/jserver/jserver_tail -f /nas/log/sys_log
20322 ? S 0:00 | | \_ /nas/jserver/jserver_tail -f -c +0 /nas/log/cmd_log
```

**# netstat -ant |grep 9824**

```
tcp 0 0 127.0.0.1:9824 0.0.0.0:* LISTEN
tcp 0 0 127.0.0.1:9824 127.0.0.1:37822 TIME_WAIT
tcp 0 0 127.0.0.1:9824 127.0.0.1:37827 TIME_WAIT
tcp 0 0 127.0.0.1:9824 127.0.0.1:37832 ESTABLISHED
tcp 0 0 127.0.0.1:37832 127.0.0.1:9824 ESTABLISHED
```

**Note:** Above output indicates that a Client has an established socket connection to the WebUI at port 9824

**# ps -ef |grep mac** [Verify presence of running mac threads]

```
root 3975 1928 0 2004 ? 00:01:43 [macstat <defunct>]
root 3988 1928 0 2004 ? 00:00:49 /nas/sbin/macstat 3 8033
root 446 1928 0 Mar11 ? 00:00:01 /nas/sbin/macstat 2 8032
```

**# top -n 3 -b ><filename>**

### **3. RUN NAS XML COMMAND TO EACH DM TO VERIFY XML FUNCTION:**

**# nas\_xml -info:server -level:3 2>&1 |more**

```
<CELERRA SRC='controlstation'>
<CELERRA_MANAGEMENT_UNIT NAME='0001877005320002' TYPE='Anaconda'
PRODUCT_NAME='Celerra CNS' SERIAL_NO='ml2805001458'
```

**Note:** If you do not get a screen stack failure trace, XML is working properly. Review errors if command does dump.

### **4. INVESTIGATE LOGS:**

#### **TOMCAT (/nas/tomcat/logs):**

/nas/tomcat/logs/mod\_jk.log [look here for Tomcat hangs and errors]

/nas/tomcat/logs/catalina\_log.2004-12-29.txt

# cat /nas/tomcat/logs/catalina.out [records stops and starts of Tomcat]

Mon Jan 10 11:28:31 EST 2005 Starting tomcat web server.

Starting service Tomcat-Standalone

#### **APACHE/HTTP (/nas/http/logs):**

/nas/http/logs/error\_log [Apache errors from browser transactions]

/nas/http/logs/access\_log [Browser transactions]

#### **JSEVER (/nas/jserver/logs):**

/nas/jserver/logs/error\_log.0 [Java exceptions]

/nas/jserver/logs/system\_log | system\_log.1 [main JServer log]

/nas/jserver/logs/jvm.out [timestamp on this file will show last successful start time of JServer]

/nas/jserver/logs/problem\_report.0 [Reports on issues with commands being run—new with NAS 5.4]

**Note:** The error\_log & system\_logs will not show a current timestamp if the JServer process itself cannot be started—this would be an indication of a major failure, perhaps related to a disk database consistency issue on the Celerra—tie the last timestamp date to a possible event that crippled the JServer. JServer will retry to start itself 3 times before going to sleep, and retrying again. JServer process itself is only allowed to consume up to 230MB RAM. Important to point out that JServer events are generally logged in the sys\_log or alert\_log, and NAS 5.5 has added more specific JServer event codes:

### # nas\_event -l -f JServer

```
id    description
0    Log Errors/Warnings into /nas/jserver/logs/system_log.x
101   Call Home - JServer failed to come up after 3 retries
102   Call Home - Generated debug file xxx from the core dump
103   Call Home - JServer reports nas_cmd errors
104   Call Home - JServer generated problem report zip file /nas/jserver/x.zip
105   Call Home - API Server failed to come up after 3 retries
1001  Crossed the Jserver file system usage threshold
1002  Dropped below the Jserver file system usage threshold
```

### SYSTEM LOG (/nas/log/sys\_log):

```
Jan 9 13:31:31 2005 JServer:4:0 "JServer stopped"
Jan 9 13:32:21 2005 JServer:4:0 "Polling of data mover in slot 2 has been restarted"
Jan 9 13:32:31 2005 JServer:4:0 "Polling of data mover in slot 3 has been restarted"
Jan 9 13:32:33 2005 JServer:4:0 "CLARiiON APM00042103183 poller has been restarted."
```

**Note:** Above output shows that JServer was stopped and then restarted normally.

Jan 4 11:03:46 2005 JServer:4:100 Failed to come up after 3 retries, shutting down

**Note:** Above message shows a JServer that is unable to start, as opposed to a JServer process that starts, then shuts down later

### API TASK MANAGER/WEBUI LOGS (/nas/log/webui):

#### **/nas/log/webui/apl\_tm.log** [Logs Starts & Stops of APL Task Mgr, also stack trace errors, Internal Errors]

2005-12-07 18:19:22.609 ATM> Starting APL indication manager with options:

```
port=9824
start_periodic_cleanup=True
save_task_files=False
run_as_daemon=False
default_expire_age=3:0:0:0
task_log_file=/nas/log/webui/apl_tm.log
scheduler_log_file=/nas/log/webui/apl_sched.log
indication_log_file=/nas/log/webui/apl_ind.log
iport=8886
jport=8887
```

**Note:** Above output from apl\_tm.log shows restart of Indications Manager after Control Station reboot. Indications Manager is new with NAS 5.4 and runs on Port 9824

/nas/log/webui/webui.log [Celerra Mgr internal errors can show up here, Java exceptions with source code messages]

/nas/log/webui/alert\_log [Event Notifications from WebUI or generated by the System]

**Note:** See /nas/http/webui/etc/web\_client\_eventlog.cfg for manually created WebUI event notifications

/nas/log/webui/apl\_sched.log [Log for Snapsure scheduling or WebUI initiated events]

/nas/tasks [Jobs in progress or incomplete]

/nas/tasks/schedule [Directory contains schedules created by WebUI, such as Checkpoints, etc.]

/nas/log/webui/webui\_syr.log [New log NAS 5.4 tracking actions taken with WebUI]

### **#cat /nas/site/task\_mngr.cfg**

port=9824 →Check to make sure that this emcapl socket port is defined correctly in /etc/services

start\_periodic\_cleanup=True

save\_task\_files=False

run\_as\_daemon=False

default\_expire\_age=3:0:0:0

task\_log\_file=/nas/log/webui/apl\_tm.log

scheduler\_log\_file=/nas/log/webui/apl\_sched.log

indication\_log\_file=/nas/log/webui/apl\_ind.log

iport=8886

jport=8887

### **# cat services |grep -i 9824**

emcapl 9824/tcp

### NAS 5.6:

```
# cat /nas/site/task_mgr.cfg
```

```
run_as_daemon=False
log_file=/nas/log/webui/apl_tm.log
port=9827
mgmtd_port=9824
save_task_files=False
default_expire_age=3:0:0:0
```

#### **INDICATIONS MANAGER LOGS:** (NAS 5.4)

The Indications Manager manages cache coherency for Celerra Manager for objects such as fs, shares, exports, tree quotas, checkpoints. When configuration changes occur, the APL Indications Manager will update its cache. NAS 5.5 adds more objects to cache.

```
/nas or /nbsnas/log/nas_log.al.indication
/nas or /nbsnas/sbin/indication_mngr
/nas or /nbsnas/sbin/start_indication_mngr
/nas or /nbsnas/site/indication_mngr.cfg
```

```
# cat indication_mngr.cfg
```

```
dport=9825
bport=9826
run_as_daemon=False
indication_log_file=/nas/log/nas_log.al.indication
```

#### **SYMAPI LOG:**

```
/nas/log/symapi.log [For issues related to backend, check this log to see what errors are occurring]
```

#### **CLIENT LOGS FOR CELERRA MANAGER:**

```
C:\Documents and Settings\<username>\Application\Java\Deployment\log→.plugin & .trace files
```

#### **XHMP API LOGS: (new with NAS 5.5)**

```
/nas/log/cel_api.log → Logs requests, replies, indications
```

```
/nas/log/webui/cel_api.log | cel_api_error.log → Servlet debug & error logs, respectively
```

### **5. INVESTIGATE FILES IN JSERVER DIRECTORY:**

```
# ls -la /nas/jserver
```

|                   |          |             |             |                       |   |
|-------------------|----------|-------------|-------------|-----------------------|---|
| -rw-r--r--        | 1        | root        | root        | 2 Jan 9 13:31         | CONTROL_STATION_SLOT  |
| -rw-rw-r-         | 1        | root        | sys         | 6756490 Sep 13 19:04  | emcaux.jar  |
| -rw-rw-r-         | 1        | root        | sys         | 2921 Sep 13 19:04     | esmif.jar   |
| <b>-rw-r--r--</b> | <b>1</b> | <b>root</b> | <b>root</b> | <b>13 Jan 5 15:26</b> | <b>fail_setup_logged</b> [Indicator of a JServer problem—delete file before restarting] |
| drwxr-xr-x        | 2        | root        | root        | 4096 Jan 6 17:07      | event_config  |
| drwxrwxr-x        | 2        | root        | sys         | 4096 Sep 13 19:04     | icons   |

| <b>-rw-r--r--</b> | <b>1</b> | <b>root</b> | <b>root</b> | <b>2 Jan 5 15:30</b>  | <b>jserver_retry</b> [Indicator of a JServer problem—delete file before restarting]     |
| lrwxrwxrwx        | 1        | root        | root        | 13 Jan 6 13:12        | jserver_tail -> /usr/bin/tail   |
| -rwxrwxr-x        | 1        | root        | sys         | 20233 Sep 13 19:04    | libj2c.so   |
| -rwxrwxr-x        | 1        | root        | sys         | 39589 Sep 13 19:04    | libj2sapi.so  |
| -rw-r--r--        | 1        | root        | root        | 0 Jan 9 13:31         | Linux   |
| drwxr-xr-x        | 2        | root        | root        | 4096 Oct 6 14:31      | logs  |
| drwxr-xr-x        | 2        | root        | root        | 4096 Nov 3 13:27      | odb   |
| -rw-r--r--        | 1        | root        | root        | 4 Jan 9 13:31         | SCHEMA_VERSION  |
| drwxr-xr-x        | 4        | root        | root        | 4096 Nov 3 13:27      | sdb   |
| drwxrwxrwx        | 5        | root        | sys         | 4096 Dec 6 18:22      | servlet   |
| -rw-r--r--        | 1        | root        | root        | 1 Jan 9 13:49         | timer_stamp   |
| -rw-rw-r-         | 1        | root        | sys         | 510088 Sep 13 19:04   | voyager.jar   |
| -rw-rw-r-         | 1        | root        | sys         | 1130741 Sep 13 19:04  | xerces.jar  |

**Note:** If possible, compare .jar (Java Archive) files to known good system

```
-rw----- 1 root root 8994816 May 29 02:12 debug_of_core.6925
```

#### **Debug of core Files:**

**Note:** NAS 5.4 introduces a feature that looks for JServer core dump files every 10 minutes. If it finds a core file, it parses it through the “gdb” utility to produce a “debug\_of\_core” file. Regular ‘core’ dumps are removed every 10 days and ‘debug\_of\_core’ files are removed every 28 days.

### **6. CORRECTIVE ACTIONS:**

→Reboot CS0 for WebUI issues, if allowed

→For JServer issues, cleanup any jserver\_retry files, kill off any sleep 1000000000 processes, kill off any residual JServer processes, clean JServer database, conduct fresh restart:

**# rm jserver\_retry**

**# kill -9 22415** [example of sleep 1000000000 process]

**# /nas/sbin/js\_kill -f**

**# /nas/sbin/js\_fresh\_restart**

→Kill Apache/httpd, Tomcat, and APL\_task\_mgr processes—conduct manual restart of httpd/apache & tomcat

## **GRACEFUL WAY TO STOP & RESTART TOMCAT & APL TASK MANAGER PROCESSES:**

**# /nas/http/nas\_ezadm/etc/script restart**

**Note:** See AR89253. Script is currently calling out wrong path to the /nas/http/webui/etc/config file. Edit the /nas/http/webui/etc/script file to correct the path:

**. /nas/http/webui/etc/config**

**# /nas/http/nas\_ezadm/etc/script restart &** [NAS 5.6.43]

[1] 2892

Stopping tomcat web server.

Stopping apl\_task\_mgr.

Starting apl\_task\_mgr.

Starting tomcat web server.

EventLog : will load /nas/http/webui/etc/web\_client\_eventlog.cfg... done

## **STOPPING & RESTARTING APACHE HTTPD DAEMON:**

1. Identify and Kill the master Apache httpd process:

**# ps fax |egrep httpd**

```
18504 pts/3 S 0:00 \_ egrep httpd
17186 ? S 0:00 /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http
17187 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
17188 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
```

**# kill 17186**

**Note:** Do not use kill -9 to stop the Apache httpd daemon

**# ps fax |egrep httpd**

```
18824 pts/3 S 0:00 \_ egrep httpd
```

2. Restart Apache httpd process using following command:

**# /nas/sbin/httpd -D HAVE\_PERL -D HAVE\_SSL -f /nas/http/conf/httpd.conf** [Restarts HTTPD/Apache Server]

3. Verify Apache process:

**# ps fax |egrep httpd**

```
19571 pts/3 S 0:00 \_ egrep httpd
19519 ? S 0:00 /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http
19521 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
```

**# /nas/http/webui/etc/tomcat restart** [Restarts Tomcat]

**# killall apl\_task\_mgr** [Stops apl\_task\_mgr—NAS\_MCD automatically restarts]

**Note:** Allow MCD to restart the apl\_task\_mgr processes

**#/nas/sbin/js\_cleandb**

**Caution:** Do not run the js\_cleandb without customer permission, as it deletes any historical performance statistics from the /nas/jserver/sdb directory. Older NAS versions also used to delete any customer alerts that have been setup, from the /nas/jserver/odb directory. AR67281 has been opened to see if current behavior of cleandb script can be changed. When running js\_cleandb with any GA version of NAS 5.5, it will prompt you whether you want to delete the statistical database information, and the alert configuration database. It does not remove Checkpoint schedules that have been created. More recently, AR85690 introduces two separate scripts, one to delete the statistical data, and one to delete customer notifications.

## **PRE-NAS 5.5 JS CLEANDB BEHAVIOR:**

**#/nas/sbin/js\_cleandb**

This script will clean Jserver database.

You will have to login as root to run this script.

All statistic history will be lost.

Do you wish to continue? [yes or no]: yes

Done.

**Note:** Prior to NAS 5.5, the js\_cleandb script would delete both statistical data and customer alerts!

### **CURRENT JS CLEANDB BEHAVIOR NAS 5.5.22.2:**

#### **# /nas/sbin/js\_cleandb**

This script will clean Jserver database.

You will have to login as root to run this script.

All statistic history will be lost.

Do you wish to continue? [yes or no]: yes

Warning - Deleting the JServer configuration data will remove also remove any user defined alert settings.

Do you wish to remove existing JServer configuration data? [yes or no]: no

Done.

**Note:** The wording is pretty confusing. If you select ‘Yes’ to the first question, it will delete the statistical data stored in the /nas/jserver/sdb directory. If you answer ‘No’ to the second question, it will KEEP the customer notifications/alerts that have been created in the /nas/jserver/odb directory—if you answer ‘Yes’ to both, it deletes both.

### **NAS 5.5.27.x JS CLEANDB CHANGES:** AR85690, fixed in GrandNapa, which will be NAS 5.5.27.x

**/nas/sbin/js\_cleandb** will delete only the historical statistical information data collected in the /nas/jserver/sdb directory

**/nas/sbin/js\_cleanconfig** will delete only the customer alerts/notifications that are stored in the /nas/jserver/odb directory

### **7. CONTROL STATION CHECKS:**

→ Verify Control Station hostname, interface configuration, and default routing are correct

[#uname –a #hostname #cat /etc/hosts #cat /etc/sysconfig/network #netstat -r]

#### **# uname -r**

2.4.9-34.5405.EMC

#### **# netstat -r**

Kernel IP routing table

| Destination | Gateway      | Genmask       | Flags | MSS  | Window | irtt | Iface |
|-------------|--------------|---------------|-------|------|--------|------|-------|
| 192.168.2.0 | *            | 255.255.255.0 | U     | 40 0 | 0      |      | eth0  |
| 192.168.1.0 | *            | 255.255.255.0 | U     | 40 0 | 0      |      | eth0  |
| 10.241.0.0  | *            | 255.255.0.0   | U     | 40 0 | 0      |      | eth1  |
| 127.0.0.0   | *            | 255.0.0.0     | U     | 40 0 | 0      |      | lo    |
| default     | 10.241.169.1 | 0.0.0.0       | UG    | 40 0 | 0      |      | eth1  |

### **8. WEBUI/CELERRA MONITOR ESCALATIONS:**

→ Run Eng. support script to gather necessary logs:

**#/nas/tools/collect\_support\_materials** [Bundles up log files and puts in /tmp; with NAS 5.6, logs are placed in /nas/var/emcsupport directory]

→ Provide NAS Version

→ Provide screenshot example of Client error seen by customer

→ Provide synopsis of issue and output of JServer processes and any errors noted in sys\_log

→ Determine if this is a new issue or never worked, and whether a code upgrade occurred

→ Verify Client Browser [i.e., IE 6.0, Netscape 6.2.3] and JRE versions [JRE 1.4.2 minimum]

### **9. VERIFY CONTROL STATION PARTITION USAGE:**

→ If the Control Station partitions are at 100%, Celerra Manager may not run without errors, as in following example:

#### **Key Symptom:**

#### **# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/hda3  | 2.0G | 779M | 1.1G  | 41%  | /          |
| /dev/hda1  | 30M  | 2.7M | 26M   | 10%  | /boot      |
| none       | 251M | 0    | 250M  | 0%   | /dev/shm   |
| /dev/nde1  | 1.7G | 479M | 1.1G  | 100% | /nbsnas    |
| /dev/hda5  | 2.0G | 393M | 1.4G  | 21%  | /nas       |
| /dev/nda1  | 133M | 37M  | 96M   | 28%  | /nas/dos   |
| /dev/ndf1  | 1.7G | 77M  | 1.5G  | 5%   | /nas/var   |

**Note:** With /nbsnas at 100%, Celerra Manager returned following error: “Query Celerras All. Internal Error: Missing response from Celerra Manager agent” or “Internal Server Error....Apache 1.3.27 Server at 192.168.32.123 Port 443.”

**Key Message:** Feb 9 11:18:30 2005 JServer:4:0 "FS Usage exceeds 80%. DbMgr has been suspended [See Primus emc101854]

**Resolution:** Unfortunately, it can be difficult cleaning up files from /nbsnas because of the “dirstync” process that is tasked with keeping /nas and /nbsnas in sync. Stop NAS services before cleaning up /nbsnas & /nas directories.

### **NBSNAS 100% FULL:**

### **DELETING FILES FROM BOTH /NAS & /NBSNAS:**

1. Run #df -h
2. Stop NAS Services
3. Remount /nbsnas /nas /nas/dos /nas/var
4. Delete necessary files from /nas first, then same files from /nbsnas
5. Start NAS Services
6. #df -h to verify

**Note:** For example, if you need to cleanup JServer files, you would have to delete from both locations, /nas & /nbsnas

## **PROBLEM WITH WEB MANAGER UNABLE TO COMMUNICATE WITH APL MANAGER:**

### **Symptoms:**

/nas/log/webui/webui.log

Catching an exception in task [[15649](#)]

Class / Object Routine Nature of exception Effect

CLARIION\_DISK\_GROUP is\_spindle\_type\_ata have\_spindles:

<41252DE8> Precondition violated. Fail

/nas/log/webui/apl\_tm.log

ERROR 2005-05-04 13:24:55,272 [COMMON]: Empty response XML from APL for task Query file systems All:All

### **Celerra Manager File System Query:**

Internal Error: Missing response from Celerra Manager agent

**Workaround NAS 5.3:** (NAS 5.4 uses nas\_storage -check or server\_devconfig -create to force discovery)

1. Determine path to use for creating a temp gatekeeper file:

# nas\_disk -i id=1  
server = server\_2      addr=c2t0l0

2. Take the first path (c2t0l0), and make a temp gatekeeper file in /nas/dev

# touch /nas/dev/c0t0l0s2 (s2 specifies server\_2)

3. Run discover command:

# /nas/symcli/bin/symcfg discover –clariion

4. Remove the temp gatekeepr file:

# rm /nas/dev/c0t0l0s2

5. Verify results using:

# nas\_storage -i -a

**Cause of Problem:** Inconsistency in symapi database causes Celerra Manager error outlined above

## **UNABLE TO LAUNCH CELERRA MANAGER – Internal Server Error:**

Generally Apache or Tomcat issue after logging into Celerra Manager. Restart Apache and Tomcat. Check webui.log & mod\_jk.log.

### **INTERNAL ERROR – Celerra Manager Agent not Responding:**

Generally APL Task Mgr issue. Check for task processes, sys\_log, netstat –ant lgrep 9824

## **UNABLE TO LAUNCH CELERRA MONITOR – Connection refused HTTP Status 503:**

JServer processes not running.

### **NAS AGENT FOR ECC (CNN):**

ECC uses a NAS agent for discovering & polling (every 15 minutes) various information about the Celerra and its data movers, which uses xhmp queries to obtain Control Station-generated nas\_xml output. Information is then displayed in the ECC StorageScope GUI.

### **NAS LICENSE:**

# nas\_license -l

|                 |        |             |

## **REPLACING JAR FILES FOR JSERVER ISSUES Pre-5.5 Code:**

1. Copy replacement jar file to CS /nas/jserver
2. #chmod 664 emcaux.jar

3. Stop JServer: #/nas/sbin/js\_kill -f
4. Remove any /nas/jserver or /nbsnas/jserver\_retry files, and sleep 1000000 processes
5. Start JServer: #/nas/sbin/js\_fresh\_restart

### **REPLACING JAR FILE FOR JSERVER ON NAS 5.5.28 CODE:**

1. # cd /nas/j\_lib
2. # mv emcaux.jar emcaux\_ori
3. Copy new jar file into this directory
4. # chown root:sys emcaux.jar
5. # chmod 664 emcaux.jar
6. Restart JServer  
/nas/sbin/js\_shutdown  
/nas/sbin/js\_kill  
/nas/sbin/js\_fresh\_restart

### **OVERVIEW OF CELERRA MANAGER (WEBUI) ARCHITECTURE:**

#### **MASTER CONTROL DAEMON (MCD) & MCD HELPER SCRIPT:**

Overall management and control of Celerra Manager. MCD starts and maintains APL Task Manager, JServer, & Trimmer Logs while MCD Helper script starts Apache and Tomcat applications.

#### **WEBUI:**

WebUI creates XML documents that describes ‘tasks’ to be performed, and posts the document to the socket used by APL Task Manager, defined by emcapl in /etc/services. Default port for emcapl is 9824. Requests for JServer are sent as XML documents over HTTP to establish session with JServer.

**webui\_syr.log** → Log used for System Reporting (SYR) of statistics for Celerra Manager

#### **APL TASK MANAGER (APpliance Layer):**

Runs as daemon started by MCD using /nas/sbin/start\_apl\_task\_manager. Listens on port 9824 (emcapl socket defined in /etc/services) for XML tasks generated by WebUI. Processes XML tasks and returns results to socket in XML format for Tomcat to retrieve and forward to Browser. Most tasks logged to /nas/log/webui/apl\_tm.log & /nas/tasks/JID number (Job ID number).

#### **Stopping & Restarting APL Task Manager:**

```
# killall apl_task_mgr [NAS MCD will automatically restart]  
# ps -ef |grep task  
nasadmin 16275 1 0 11:40 pts/2 00:00:00 /nas/sbin/apl_task_mgr  
root 29181 1165 0 13:42 ? 00:00:00 /bin/sh /nas/sbin/start_apl_task  
root 29235 29181 0 13:42 ? 00:00:00 /bin/sh /nas/sbin/start_apl_task  
nasadmin 29236 29235 1 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr  
nasadmin 29239 29236 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr  
nasadmin 29240 29239 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr  
nasadmin 29242 29239 0 13:42 ? 00:00:00 /nas/sbin/apl_task_mgr
```

**Note:** Above reflects normal apl\_task\_mgr processes

#### **APL INDICATION MANAGER:**

New with NAS 5.4, the Indication Manager manages Browser cache coherency for Celerra Manager for objects such as volumes, file systems, shares, exports, tree quotas, checkpoints.

**apl\_ind.log** → Log used by APL Indications Manager for object caching

**ipc.log** → Internal log for Indication communication

#### **JSERVER:**

Runs as daemon on CS under nas\_mcd control and serves as server side process for Celerra Monitor, started by /nas/sbin/run\_jserver. Client side application is launched using .jar files which are downloaded to the client when launching Celerra Monitor (/nas/http/htdocs/cmv2). The JServer API is known as Celerra XML or XMHP. When invoked, Jserver polls data movers, file systems, and storage systems for status, configuration, and performance statistics, sending information to WebUI via XML documents using HTTP. Although the Polling interval defaults to 5 minutes, you can set to a different value from Celerra Manager, though the historical data only captures a minimum of 5 minutes. Most logs found in /nas/jserver/logs directory. Live graph displays, file system info, and Data Mover notifications are all processed via XML requests to the JServer daemon. JServer polling intervals are set via Celerra Monitor, and now Celerra Mgr with NAS 5.4. Default data retention for polling information on components is 1 week, configurable up to 26 weeks, and file system usage & capacity is hard-coded at 12 weeks. Configuration changes are updated every 20 minutes and recorded in the /nas/jserver/sdb/dbmgr\_persist file. JServer also monitors and acts on messages given by the Indications Manager.

#### **JSERVER STARTUP:**

→ nas\_cmd queries are conducted in DART to gather configuration info

→ Storage API queries are made to update backend information

## **WHICH NAS COMPONENTS USE JSERVER?**

- Celerra Monitor
- Celerra Manager
- ECC Solutions Enabler
- XML API v1 Server [JServer & APL APIs for 3<sup>rd</sup> Party applications]

## **STATISTICS & NOTIFICATION INFORMATION:**

### **/nas/jserver/odb**

File System and Data Mover usage notification settings are stored in this directory as binary information

### **Stopping & Restarting JServer:**

**#/nas/sbin/js\_kill -f**

**#/nas/sbin/js\_fresh\_restart**

**# ps -ef |grep -i jserv**

```
root  21034 1165 0 Jan09 ?    00:00:00 /bin/sh /nas/sbin/run_jserv
root  21305 21304 0 Jan09 ?    00:00:01 /bin/sh /nas/jserver/jexec
root  21810 21809 0 Jan09 ?    00:00:00 /nas/jserver/jserver_tail -f -c
root  21845 21844 0 Jan09 ?    00:00:00 /nas/jserver/jserver_tail -f /na
```

**Note:** Above output reflects normal JServer processes

### **DUMPING DEBUG OUTPUT OF JSERVER:**

**#/nas/sbin/js\_kill -debug**

**#cat /nas/jserver/logs/jvm.err**

Full thread dump Java HotSpot(TM) Server VM (1.4.2\_04-b05 mixed mode):

```
"com.emc.cs.Timer" prio=1 tid=0x08197fb8 nid=0x784b in Object.wait() [bcbff000..bcbff908]
```

```
at java.lang.Object.wait(Native Method)
- waiting on <0x45c963c8> (a java.lang.Object)
at com.emc.cs.Timer.waitInternal(Timer.java:251)
- locked <0x45c963c8> (a java.lang.Object)
at com.emc.cs.Timer.run(Timer.java:179)
```

**Note:** Output may give indication of what process is hanging

## **SYSLOG TRIMMER:**

Part of nas\_mcd.cfg script, checked every 24 hours and backed up when exceeding 1000 lines—4 backup versions kept.

## **APACHE WEB SERVER:**

Serves as secure HTTP Web Server when using SSL, listens to browser requests, and requires session token (HTTP cookie) for user authentication, generated by CS after user logs on. Browser requests are sent and retrieved to WebUI via Apache using Jakarta Tomcat. Apache version 1.3.27.

### **Stopping & Restarting Apache/HTTP:**

#### **/nas/sbin/mcd\_helper**

**#kill <master http pid>** [Kill all httpd processes & verify that Apache & HTTP processes are stopped]

**#/nas/sbin/httpd -D HAVE\_PERL -D HAVE\_SSL -f /nas/http/conf/httpd.conf** [Use this to restart Apache/http]

**# ps -eafl |grep -i apache**

```
140 S apache 13258 27562 0 69 0 - 3238 do_sel 12:58 ? 00:00:00
/nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http/conf/httpd.conf
140 S apache 13331 27562 0 69 0 - 3247 semop 12:59 ? 00:00:00
/nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http/conf/httpd.conf
```

**Note:** There may be dozens of Apache and HTTP processes running on a system

**# ps -eafl |grep -i http**

```
/nas/http/webui/tools/j2sdk1.4.2_01/bin/java -server -Djava.endorsed.dirs=/nas/t
040 S root 22686 22681 0 69 0 - 69725 rt_sig 14:53 pts/2 00:00:00
/nas/http/webui/tools/j2sdk1.4.2_01/bin/java -server -Djava.endorsed.dirs=/nas/t
040 S root 22687 22681 0 69 0 - 69725 rt_sig 14:53 pts/2 00:00:00
```

## **JAKARTA TOMCAT:**

Tomcat supports web browser requests using the Apache Web Server (WebUI jsp pages and applets/servlets). Version 4.0.4 NAS 5.2, and 4.1.29 for NAS 5.3. Tomcat-Apache mod\_jk module version 1.2.5 is used as the communication pipe between Apache & Tomcat

### **Stopping & Restarting Tomcat:**

**/nas/sbin/mcd\_helper**

**# /nas/http/webui/etc/tomcat restart**

**# ps -axlww |grep -i tomcat**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
100 0 22679 1 9 0 278900 85816 wait\_f S pts/2 0:15 /nas/http/webui/tools/j2sdk1.4.2\_01/bin/java -server -Djava.endorsed.dirs=/nas/tomcat/common/endorsed -classpath /nas/http/webui/tools/j2sdk1.4.2\_01/lib/tools.jar:/nas/tomcat/bin/bootstrap.jar -Dcatalina.base=/nas/tomcat -Dcatalina.home=/nas/tomcat -D java.io.tmpdir=/nas/tomcat/temp org.apache.catalina.startup.Bootstrap start

**Note:** There may be dozens of Tomcat processes running

#tail -20 /nas/tomcat/logs/catalina.out [Example of normal Tomcat startup in log]

Mon Jan 10 14:53:29 EST 2005 Starting tomcat web server.

tomcat start: http ready to go

Starting service Tomcat-Standalone

Apache Tomcat/4.1.29

### **How to Set Linux Hostname to Make Celerra Manager Work:**

Updating Hostname on Box: vi \$/etc/HOSTNAME [Linux] or vi /etc/nodename [SCO] vi /etc/hosts file #set name celctrl01

**Caution:** Must be logged in as "root" and use 'linuxconf' or 'netconf' GUI program to change Hostname permanently!

Updating Hostname on External Interface Card: #linuxconf or #netconf or edit directly; #/etc/sysconfig/network "Hostname"

### **CELERRA MONITOR:**

Celerra Monitor is a java-based client/server application used to monitor performance of Celerra Servers & Storage subsystems.

Celerra Monitor runs as a Java Client/Server application launched from a Browser or Desktop Windows or Unix machine. The **Java Server** [poller] runs on the Control Station and a **Java applet** [application] runs on the Client's Web Browser.

#### **ACCESSING CELERRA JSERVER API HELP FILES:**

<http://10.241.169.43/schemas/xhmp/xhmp.htm> [Celerra Control Station]

#### **PURPOSE:**

**File System Statistics:** File System I/O performance history, HWMarks, Alerts, Inode Usage, predictive monitoring of fs capacity

**DataMover Statistics:** DM Configuration, NFS, CIFS, TCP Stats, CPU & Memory Usage, alerts.

**Storage Backend Stats:** Director Performance Stats\*

\***Note:** This statistic is not yet available with CLARiiON platforms [NAS 5.1 or lower]

→Used to view Run Time, Logs, configure Polling times for data collection

→Status Monitor provides flashing icon for system problems

→Data export capability to CSV export to files

### **USING CELERRA MONITOR WITH MULTIPLE SYMMS ATTACHED TO A SINGLE CELERRA:**

Step 1. Run \$/nas/bin/nas\_symm -l [Outputs Serial Numbers of Symmetrixes]

Step 2. Run \$/nas/bin/nas\_symm -i serialnumber [Verifies SymAPI is parsing through the GateKeeper to the respective Symm]

Step 3. Run \$server\_devconfig server\_x -p -s -a

#### **Check to see if Gatekeepers are properly recognized:**

tid/lun= 0/15 type= disk val= -99 info= 5266470B4050 diskerr= -1 [Correct entry for a GateKeeper]

tid/lun= 0/15 type= disk sz= 3 val= -1 info= 52667202E010 [Incorrect entry]

**Caution:** Celerra Monitor will not see 4-Port FA's at this level of code [fixed in 4.0 +]

### **TROUBLESHOOTING CELERRA MONITOR:**

**Browser Error:** 404 Not Found. The requested URL...was not found on this server. [Java Server is not starting]

Resolution? Ensure /etc/hosts and /etc/nodename are identical!

**Processes on CS:** \$ps -ef | grep java lagent lmacstat

**/nas/jserver/sdb/control\_station/data\_movers/1/cifs\_stats:**

Check for evidence that Stats are populating the Data Mover directories—if not, Jserver is not working

#### **VERIFY HTTP.CONF FILE: #ps -ef |grep http**

a. Telnet to port 8000; Type GET and check default HTM page

b. If connection refused may indicate bad "httpd.conf"

c. Copy good "httpd.conf" over: \$cp /nas/http/conf/httpd.conf /etc/httpd/conf/httpd.conf

## **CONTROL STATION MEMORY UTILIZATION HIGH DUE TO JAVA PROCESSES:**

```
$ ps -axuw grep java
root 10306 0.2 4.5 170348 23500 ? S 2002 30:50 /usr/java/bin/i38 [4.5=% Memory Utilization for PID 10306]
6/green_threads/java -classic -Xmx128M com.objectspace.voyager.system.Main 8010
-r -q -b com.emc.cs.Initiator 8010 8000 /nas 1 2
root 11436 0.0 3.2 180228 16852 ? S 2002 9:23 /usr/java/bin/i38
6/native_threads/java -Xss1048576 com.emc.cs.symmpoller.SymmAgentSapi
```

## **STOPPING & RESTARTING JSERVER:**

1. Remove any `/nas/jserver/jserver_retry` if present
2. `#kill -9 sleep 1000000` if required
3. **`#/nas/sbin/js_kill -f`**
4. Startup using **`#/nas/sbin/js_fresh_restart`**
5. Grep for jserver processes:

```
# ps -ef |grep -i jserver
root 24027 869 0 20:16 ? 00:00:00 /bin/sh /nas/sbin/run_jserver
root 24167 24103 0 20:16 ? 00:00:00 /bin/sh /nas/jserver/jexec
root 25294 24103 0 20:19 ? 00:00:00 /nas/jserver/jserver_tail -f -c
root 25350 24103 0 20:19 ? 00:00:00 /nas/jserver/jserver_tail -f /na
```

## **ADDITIONAL JS START & CLEANUP OPTIONS:**

### **`#/nas/sbin/js_cleandb`**

This script will clean Jserver database.

You will have to login as root to run this script.

All statistic history will be lost.

Do you wish to continue? [yes or no]: yes

Done.

### **`#/nas/sbin/js_fresh_restart`**

### **`# ps -ef |grep js`**

```
root 11258 1 0 09:06 ? 00:00:00 /bin/sh /nas/sbin/js_start
root 11457 28660 0 09:06 ? 00:00:00 /bin/sh /nas/sbin/run_jserver
root 11588 11392 0 09:06 ? 00:00:00 /bin/sh /nas/jserver/jexec
```

**Creating Large Celerra Monitor Database for Analysis:** `#/nas/jserver/sdb` [move to another location & softlink to it]

**Changing Default Passwd "user" & "root":** `/nas/http/esteem`

## **Three Key Measurements that Celerra Monitor Can Provide:**

- 1.) Assessing activity on a FileSystem basis—not read via any CLI commands
- 2.) View Input/Output activity for a specific DataMover interface
- 3.) CPU & RAM usage for system

## **USING CONSOLE UTILITY:**

→Special utility used by Support & EE to view & manage different NAS processes, such as Tasks, Databases, Events, Logs, etc.

### **`/nas/tools/console`**

1) Create link to the console utility

```
# cd /nas/tools
```

```
# ln -s console _console
```

2) Run the console utility

```
# ./_console
```

console 127.0.0.1 6666

Commands:

```

HouseKeeping  120
CicSender     240

```

**Command {Enter "exit" to quit} >> cic.dump**

```

Default connection timeout: 20
Default response timeout: 100
Default async timeout: 900

```

### **CELERRA PARAMETERS:**

→ param tuning is done using /nas/site/slot\_param or /nas/server/slot\_x/param file to make changes outside the default values  
 → See server\_param command for outputting & setting param values NAS 5.3 +  
 → Note that NAS 5.4 + has begun hiding many parameters from view, though they may still exist  
 → NAS 5.3 + are now beginning to port commands to xml output, removing the output limitation—not all commands ported yet

### **DATA MOVER PARAM FILES:**

**/nas/server/slot\_x/param    /nas/server/slot\_x/paramtab    /nas/site/slot\_param** (Global param file)

**Note:** During Server reboot, the last param settings applied are from the local /nas/server/slot\_x and if different than the /nas/site/slot\_param, will override the global param value

### **EXAMPLE OF HIDDEN PARAM & FULLDESCRIPTION OPTION NAS 5.5:**

```

# .server_config server_2 -v "param cifs wins.Refresh" -->Hidden cmd, won't output current value
1143835291: SMB: 3: cifs.wins.Refresh must be <= 3600 sec and >= 30 sec
1143835291: ADMIN: 3: Param-attached function failed.

# .server_config server_2 -v "param fulldescription cifs wins.Refresh" -->Outputs current & default values in hex
cifs.wins.Refresh 0x01fd8798 0x00000384 0x00000384
1143835301: ADMIN: 4: Command succeeded: param fulldescription cifs wins.Refresh

```

**\$ server\_param server\_2 -facility usrmap -list**

```

server_2:
name          facility default  current  configured
maxgid        usrmap 2147483647 2147483647
minuid        usrmap    16      16
maxuid        usrmap 2147483647 2147483647
mingid        usrmap    16      16

```

### **USEFUL COMMANDS TO DUMP PARAMETERS AND VALUES:**

**.server\_config server\_6 -v 32768 “param”**

**Note:** NAS 5.2 and higher has increased the buffer output for .server\_config commands to 32k from 16k

**# .server\_config server\_2 -v "param cifs verbose" | grep mac** → New with Cognac release, shows more than 5.5  
 cifs.macOS INT 0x09efd718 0 0 (0,4294967295) FALSE REBOOT 'NA'

**.server\_config server\_6 “help” “fcp bind help” “wins help” “ds help” “secmap help” “help /s”**

**.server\_config server\_3 -v "help /s"**

**.server\_config server\_2 "printstats all"**

### **SERVER CONFIG COMMANDS & PARAM SETTINGS: NAS 5.5**

#### **CONTROL STATION HISTORY LOG:**

\$more /home/nasadmin/.sh\_history [command history log from root shell]

#[/home/nasadmin/.bash\\_history](#) → Current Linux command history file for root user #history **#history -c** [Clear History log]

## **CELERRA TROUBLESHOOTING LOGS/CELERRA LOGS:**

### **I. CONTROL STATION LOGS:**

Most of the important Control Station logging for Celerra activities is located in /nas/log directory, though Celerra Manager, and its associated components, are logged in various directories. Additionally, some important tasks, such as NAS Upgrades, or SRDF failover activities, are logged in /tmp directory until the operation is completed. Linux-related logging is located in the traditional /nas/log directory. The Control Station runs a nas\_eventcollector daemon that retrieves events from a memory buffer and uses ReportEvent and PostEvent to post to the nas\_eventlog, which is turn gets recorded to the sys\_log.

#### **/nas/log directory:**

install.log: NAS install log **upgrade.5.3.15-3.Apr-15-17:54.log:** NAS Upgrade log

**nas\_log.al** Successful commands **nas\_log.al.err** Cmds that err **nas\_log.al.trace** (Eiffel dump location)

**sys\_log:** Control Station log of Hardware Events—this is what Call\_Home utility uses **sympapi.log** (sympapi events)

**osmlog:** /var/adm/log/osmlog **setup\_clariion2.log** (clariion setup log) **nas\_rdf.log** (rdf issues) **cmd\_log cmd\_log.err**

**nas\_log.al.rll**

#### **Callhome Logs:**

\$ /nas/log/callhome.phone\_calls [Prior to NAS 5.5.31--Callhome information, times & numbers of calls made]

\$ /nas/opt/connectemc [NAS 5.5.31 and higher]

#### **/var/log directory:**

messages file

dmesg file

boot.log file

### **II. CELERRA MANAGER/JSERVER LOGS:**

→ see Celerra Manager section for complete list of logs for APL Task Mgr, Tomcat, Apache, JServer, etc.

JServer events are posted in the sys\_log and the alert\_log, not the Server Log

### **III. SERVER LOGS—DART:**

DART uses a logmsg facility to post events into the Server Log, and a logEvents facility to post events into a memory buffer that gets checked by the NAS Event Collector daemon via MAC/XML interface (?)

## **TROUBLESHOOTING USING THE SERVER LOG:**

### **REAL SERVER LOG vs. HISTORICAL LOG:**

**RealTime Server log:** *format* is always \$server\_log server\_2 and shows information since last reboot, or in case of a failover or panic, information from point of failure to present time on the Standby Server if running as the Primary Server

**Historical Server log:** *format* is always \$server\_log server\_2.faulted.server\_5 -a -s and shows all historical information up to the point of panic or failover.

## **USING SERVER LOGS TO TROUBLESHOOT PANICS OR FAILOVERS:**

**Scenario:** Primary Server\_2 panics & fails over to Standby Server\_5

- Step 1. Locate Hostname in **historical server\_log**: \$server\_log server\_2.faulted.server\_5 | grep hostname  
[Locate section where server\_5 renamed itself server\_2]
- Step 2. Locate Panic Info in sys\_log: \$grep panic /nas/log/sys\_log  
[Obtain TimeStamp{CS0} for Panic in question; 2001-04-26 07:30:05]
- Step 3. Note diff. in CS0 & Server Dates: \$date \$server\_date ALL
- Step 4. **For Historical Events for Server 2:** \$server\_log server\_2.faulted.server\_5 -a -s |more /2001-04-26 07:30:05
- Step 5. **For RealTime Events for Server 2:** \$server\_log server\_2  
[Observe that Standby Server\_5 is running as Server\_2 in Slot\_5]

#### **Using Logs to Focus in on Data Mover Problem:**

Step 1. Use Control Station “Sys\_log” to ID problems and obtain timestamps of events, etc

Step 2. Go to appropriate Server\_log \$server\_log server\_2 -a -s | more

Step 3. Run this Server Log Command to view Log “live”: \$server\_log server\_2 -s -f

**Note:** DataMover reboots are logged in the “sys\_log”

**TAILING SERVER LOG TO OBSERVE ‘REALTIME’:** [Contains Log info since last server reboot]**\$server\_log server\_2 -s -f**

-f switch keeps log open -s switch applies date/timestamp

**Using Server Log Command to Open the Archival Logs:**

\$server\_log server\_2 -a -s

**CREATING SCRIPT TO SAVE SERVER LOG CONTENTS USING CRON JOB:**

1. Create following script on Control Station and chmod 777—make sure you create folder in which the logs will be collected, and insert the folder name in the script—in this example, the script will create log files in /nas/var/slog:

```
#!/bin/sh
DMname=server_2
NAS_DB=/nas
export NAS_DB
$NAS_DB/bin/server_log $DMname -s -a > /nas/var/slog/log.$DMname.`date '+%y%m%d%H%M'`
```

2. Create Cron Job to run every 5 minutes, or set the interval as desired

**0-59/5 \* \* \* \* /nas/var/slog/logscript.log &****Note:** Cronjob example creates a new server\_log with timestamp every 5 minutes**CFS ENTRIES IN SERVER LOG:**

CFS=Common File System, the software layer that resides between the NFS &amp; CIFS protocol and the filesystem.

**OPENING SERVER LOG AND OUTPUTTING CONTENTS INTO FILE:**

**Purpose:** Since the total size of Server Log is limited to 1 MB it is useful to pipe the Server Log into an open file so as to capture debugging information:

**\$server\_log server\_3 -f -s > s3log.log & [\$jobs #fg %1 ctrl + c]****SERVER LOG SIZE INCREASED TO 2MB WITH NAS 5.4:****Note:** NAS 5.4.5.0 increased Server Log to 2MB from 1MB—see AR47260--root\_rdf\_channel volume.**NAS 5.3 WORKPART MAGIC & SERVER LOG SLICE SIZE:****# /nas/sbin/workpart -r**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

workpart\_magic = 0xfacebeaf      --&gt;0xfacebeaf = pre-5.4 workpart\_magic

-----  
log\_slices[0].size = 0x7ff      -->0x7ff = 2047 decimal \* 512 = 1048064 (1MB)**# /nas/sbin/rootnas\_volume -i root\_rdf\_channel**

id = 41

name = root\_rdf\_channel

acl = 0

in\_use = False

type = slice

slice\_name = root\_log\_1

slice\_of = root\_disk

offset(MB) = 391

**size (MB) = 1**

disks = root\_disk

**NAS 5.4/5.5 WORKPART MAGIC & SERVER LOG SLICE SIZE:****# /nas/sbin/workpart -r |head**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

workpart\_magic = 0xbeaf0001      --&gt;0xbeaf0001 = 5.4/5.5 workpart\_magic

-----  
log\_slices[0].size = 0xffff      -->0xffff = 4095 \* 512 = 2096640 (2MB) Server Log**-rw-r--r-- 1 root root 2328452 Dec 28 15:22 slog2.2mb**

# /nas/sbin/rootnas\_volume -i root\_rdf\_channel

```
id      = 165
name    = root_rdf_channel
acl     = 0
in_use   = False
type    = slice
slice_name = root_rdf_channel
slice_of  = root_disk
offset(MB) = 391
```

**size (MB) = 2**

```
disks   = root_disk
```

# /nas/sbin/rootnas\_volume -s root\_rdf\_channel

```
total = 2 avail = 2 used = 0 ( 0% ) (sizes in MB)
```

## NAS 5.6 WORKPART MAGIC & SERVER LOG SLICE SIZE:

# /nas/sbin/workpart -r | head

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

```
workpart_magic      = 0xbeaf0002
log_slices[0].size  = 0x1fff → 0x1fff = 8191 * 512 = 4193792 (4MB) Server Log
```

## OUTPUTTING RAW SERVER LOG WITH LOG SLOT:

\$ /nas/sbin/log\_slot -r slot\_2.logfile 2

Creating raw log dump file "slot\_2.logfile".

Dumping slot 2 raw log to "slot\_2.logfile".

## Looking at Correct Log for the Primary and Faulted-Over DataMover:

1. For events prior to the Panic on Primary Server\_2:

\$server\_log server\_2 -s -f

2. For events after failover, while faulted over to the Standby Server\_4:

\$server\_log server\_2.faulted.server\_4

## SETTING SMB DEBUG LOGGING ON DM:

1. Turning on Debug Logging: #.server\_config server\_x "logsys set severity SMB=LOG\_DEBUG"

2. Turn off Debug Logging: #.server\_config server\_x "logsys set severity SMB=LOG\_PRINTF"

## VERIFYING THE CURRENT LEVEL OF DEBUG LOGGING FOR CATEGORIES:

# .server\_config server\_2 -v "logsys get severity SMB"

1158591814: LIB: 4: Server log severity for facility SMB is 4

## SERVER LOG CATEGORY PRECEDENCE NUMBERS/CLASSIFICATION CODES:

### Existing DART Logging Severity Levels:

0 = LOG\_EMERG or LOG\_EVENT

0=Emergency, system unusable

1 = LOG\_ALERT

1=Alert, take action

2 = LOG\_CRIT

2=Critical, critical condition

3 = LOG\_ERR

3=Error, error condition (old default logging level)

4 = LOG\_PRINTF or LOG\_WARNING or LOG\_STAT

4=Warnings (this appears to be the new default logging level)

5 = LOG\_NOTICE or LOG\_DEBUG or LOG\_DBG1

5=Notice, normal, but significant messages

6 = LOG\_DBG2 or LOG\_INFO

6=Info, informational messages

7 = LOG\_DBG3

7=Highest debug level messages

### Proposed CCMD Logging Levels:

0 = Emergency → LOG\_EMERG=0

0=Emergency, system unusable

1 = Alert → LOG\_ALERT=1

1=Alert, take action

2 = Critical → LOG\_CRIT=2

2=Critical, critical condition

3 = Error → LOG\_ERR=3

3=Error, error condition (old default logging level)

4 = Warning → LOG\_WARNING=4

4=Warnings (this appears to be the new default logging level)

5 = Notify → LOG\_NOTICE=5

5=Notice, normal, but significant messages

6 = Info → LOG\_INFO=6 [or LOG\_PRINTF or LOG\_STAT]

6=Info, informational messages

7 = Debug → LOG\_DEBUG=7

7=Highest debug level messages

## BACK-END STATISTICS:

`$server_config server_2 -v "printstats scsi full" or "printstats scsi full reset" [resets stats buffer to zero]`

### **PRINTSTAT SCSI OUTPUT DEFINED:**

**`$ .server_config server_2 -v "printstats scsi"`**

io count 82344, time 221553637 usecs, ave 2690

tot time on nexus queue 1741478392 usecs, ave 21148

ctr0: maxqueued 360, maxpend 33, byteCount 603410320, busy 29286206695, idle 4611494911468 = 99%

io count 82344 -->Number I/O's since last reboot

time 221553637 usecs -->Time used to perform 'io count' totals

ave 2690 -->Average time to complete one i/o

maxqueued -->Max number of i/o's queued--queue depth is 8/lun (Clariion) and 1/hyper (Symmetrix)--number indicates chain

maxpend -->Number of pending I/O's to luns on indicated chain--pending, not queued I/O

byteCount -->Ticker value for bytes processed

busy -->Ticker value for the time of actual work down chain

Idle -->Idle value is usually near 99% but can be lower as I/O increases and decreases--represents amount of time chain fulfills request.

**Assessing Celerra-to-Symmetrix Performance:** Writes to the Symm from the Celerra

**`$server_config server_2 -v "printstats scsi"`**

**`$server_config server_2 -v "printstats filewrite"`**

### **CELERRA SERIAL NUMBER:**

**`# /nas/sbin/serial`**

APM00024300875

**`# cat /nas/sys/callhome.config`**

modem phone number:9999999

site name:35021551

serial number:APM00024300875

**`# expect -f /nas/sbin/encl_mon.exp resume server_2 5080 |grep RESUME_INFORMATION_MIDPLANE`**

IDS exp7 1 RESUME\_INFORMATION\_MIDPLANE

<RESUME\_INFORMATION\_MIDPLANE EMC\_PART\_NUMBER="005047766" EMC\_ARTWORK\_REVISION=""  
EMC\_ASSEMBLY\_REVISION="A13" EMC\_SERIAL\_NUMBER="APM00024300875" VENDOR\_NAME="" L  
OCATION\_OF\_MANUFACTURE="Apex, NC USA" YEAR\_OF\_MANUFACTURE="2002" MONTH\_OF\_MANUFA  
CTURE="10" DAY\_OF\_MONTH\_OF\_MANUFACTURE="28" ASSEMBLY\_NAME="XPE NAS CHASSIS" WORL  
D\_WIDE\_NAME\_SEED="006006aa" />

**`# nas_xml -info:server |grep SERIAL_NO`**

PRODUCT\_NAME=Celerra NS600G' SERIAL\_NO='APM00024300875'

**`$ /nas/sbin/get_data_mover_status -resume server_2 5080 /tmp/dm2_resume.xml`**

### **HOW /nas/sbin/serial COMMAND DERIVES CELERRA SERIAL NUMBER:**

#### **I. CELERRA IP SYSTEMS (e.g., NS500, 700, etc.):**

**1. /nas/sbin/serial command determines "Celerra IP" system**

a) Gets Data Mover Resume information from Server\_2

→From serial script: \$NAS\_DB/sbin/get\_data\_mover\_status -resume server\_2 5082 \$dm\_file

b) Sed & Greps for EMC\_SERIAL\_NUMBER from the RESUME\_INFORMATION\_MIPLANE xml field

**`# cat /nas/log/data_mover_resume.server_2.xml`**

<RESUME\_INFORMATION\_MIDPLANE EMC\_PART\_NUMBER="005048417" EMC\_ARTWORK\_REVISION=""  
EMC\_ASSEMBLY\_REVISION="A03" EMC\_SERIAL\_NUMBER="APM00042403637"

c) Outputs Celerra Serial number

**`# /nas/sbin/serial`**

APM00042403637

#### **II. HAMMERHEAD/SLEDGEHAMMER SYSTEMS (NS20, NS40, NX4, NSX, NS-120, etc.):**

**1. /nas/sbin/serial command determines "Celerra Hammerhead" | "Celerra SledgeHammer" system**

a) Gets Enclosure Resume information from Enclosure\_0

→From serial script: \$NAS\_DB/sbin/get\_enclosure\_status -resume 0 \$encl\_file

b) Sed & Greps for EMC\_SERIAL\_NUMBER from the RESUME\_INFORMATION\_MIPLANE xml field

**`# cat enclosure_resume.enclosure_0.xml`**

<?xml version="1.0"?>

<EnclosureResume EnclosureID="0">

```
<RESUME_INFORMATION_MIDPLANE
  EMC_PART_NUMBER="100-520-327    "
  EMC_ARTWORK_REVISION="   "
  EMC_ASSEMBLY_REVISION="A05"
  EMC_SERIAL_NUMBER="APM00071601776 "
```

c) Outputs Celerra Serial number

```
# /nas/sbin/serial
```

```
APM00071601776
```

### III. FOXGLOVE SYSTEMS (NS-960/NS-G8):

**Note:** Beginning with Foxglove, the EMC\_PRODUCT\_SERIAL\_NUMBER becomes the system serial number, as found in the enclosure\_resume\_enclosure\_0.xml 'RESUME\_INFORMATION\_MIDPLANE' field, and also on the PSNT tag hanging on the back of DME0. This is the serial number used to install the system in CSI and is the serial number used by the Celerra when it calls home. The serial and nas\_connecthome commands should list this serial number.

#### 1. /nas/sbin/serial command determines "Celerra Foxglove" system

→From serial script: serial=`get\_db\_psn`

a) Gets PSN (Product Serial Number) from /etc/product\_numbers.db file

```
# cat product_numbers.db
```

#Product Numbers Database file

#This file contains the Product Serial Number(PSN) and Product Part Number(PPN).

Version=1.0

**PSN=FNM00083800203**

PPN=900-525-001

b) If the PSN is not available from the product\_numbers.db file, defaults to using Enclosure\_0's default serial number (NOT the PSN number):

→From serial script:

```
$NAS_DB/sbin/get_enclosure_status -resume 0 $encl_file
```

```
serial=`sed -n '/<RESUME_INFORMATION_MIDPLANE/,/\/>/p' $encl_file | grep EMC_SERIAL_NUMBER
```

**Note:** It's important to repeat that the EMC\_SERIAL\_NUMBER in the RESUME\_INFORMATION\_MIDPLANE represents the Serial number of the actual Enclosure\_0 midplane, and NOT the Product Serial Number that is found on the PSNT tag and inputted by the factory into the Enclosure\_0 RESUME PROM

#### # cat enclosure\_resume.enclosure\_0.xml

```
<?xml version="1.0"?>
```

```
<EnclosureResume EnclosureID="0">
```

```
<RESUME_INFORMATION_MIDPLANE
```

```
  EMC_PART_NUMBER="100-520-839    "
```

```
  EMC_ARTWORK_REVISION="   "
```

```
  EMC_ASSEMBLY_REVISION="A01"
```

**EMC\_SERIAL\_NUMBER="FNM00083800197 "** →Enclosure serial number, not the PSN

```
  EMC_PRODUCT_PART_NUMBER="900-525-001    "
```

**EMC\_PRODUCT\_SERIAL\_NUMBER="FNM00083800203 "** →Real PSN number

c) Outputs Celerra PSN Serial number (Same as written on the PSNT Tag)

```
# /nas/sbin/serial
```

FNM00083800203 →Actual PSN number as derived from PSNT tag and factory installation

d) Output from Serial command when product\_numbers.db file is missing or PSN field blank

```
# /nas/sbin/serial
```

FNM00083800197 →Enclosure serial number

**Note:** It's worth commenting that with the release of the Foxglove system, the traditional "EMC\_SERIAL\_NUMBER", as read in the Data Mover or Enclosure\_0 RESUME information, is no longer the system Celerra Serial number, and instead represents the physical serial number used for enclosure\_0. Instead, the EMC\_PRODUCT\_SERIAL\_NUMBER (PSN) is now considered the top-level system serial number and is the "Celerra Serial number".

#### CELERRA SERIAL NUMBER & CONNECTHOME ISSUE:

**Note:** See emc211169 for an issue where the system serial number reported has changed to display the serial number for Data Mover enclosure 0, both for the /nas/sbin/serial output and in the connecthome.config file. This occurs only for older 'fish' NS Series (NS500, NS350, NS600, NS700) that upgrade from NAS 5.5 or earlier 5.6 codes to NAS 5.6.42.5 or above. See AR140547. This issue was fixed in NAS 5.6.45.

The Celerra Serial number is referenced in the /nas/sys/connecthome.config file on all systems using the ConnectHome feature:

```
# cat /nas/sys/connecthome.config |grep Serial
```

```
celerraSerial:FNM00083800203
```

```
# /nas/sbin/nas_connecthome -modify -serial_number
```

Serial number automatically detected

Ok

**Note:** The system will automatically detect the Celerra Serial number from the product\_numbers.db or enclosure resume file and write the serial number to the connecthome.config file

# /nas/sbin/nas\_connecthome -info|head

ConnectHome Configuration:

Encryption Enabled = no

Dial In :

Enabled = yes

Modem phone number =

Site ID = 117900

Serial number = FNM00083800203

### **REPAIRING SERIAL NUMBER ON FOXGLOVE SYSTEMS:**

# /nas/sbin/serial -get

Error 255: serial

```
-get { -psn | -ppn } [ <enclosure_id> ]
| -db_check
| -repair
| -c <Serial Number>
```

/var/log/serial.log

### **REPAIRING PPN ON GALILEO SYSTEMS:**

#### **Scenario:**

During the install, the PPN for VG2 was inadvertently used for the VG8 hardware. Although the model correctly reported itself, the PSN number was wrong.

# /nas/sbin/serial -db\_check

Error 28: PPN is inconsistent between the db file and the enclosures

#### **Corrective Actions:**

- 1) First step is to connect to the serial port of either Blade 2 or Blade 3 in Enclosure 0
- 2) Boot the blade, access the POST program [passwd=SHIP\_it], select 2) Set Resume, then edit the following field with the correct PPN number for a VG8:

Enter Product PN (16 characters)[900-567-004]: 900-567-005

3) Reboot blade

4) Update the Enclosure Resume status file:

# /nas/sbin/get\_enclosure\_status -resume 0 /nas/log/enclosure\_resume.enclosure\_0.xml >/dev/null 2>&1

5) Vi edit the /etc/product\_numbers.db file and enter the correct PPN

6) Reboot CS and verify that the product\_numbers.db retains the edited values

### **CELLERRA CALLHOME (Pre-NAS 5.5.31):** Modem Number & Site info in "callhome.config" file

#### **File Path= /nas/sys/callhome.config:**

- |  |  |
|--|--|
| Step 1. Verify CallHome Configuration: | #more /nas/sys/callhome.config   |
| Step 2. Stop CallHome Service:         | #/nas/sbin/ch_stop [Stops any current CallHomes & clears callhome buffers]   |
| Step 3. Modify CallHome.Config:        | #/nas/sbin/ch_cfg  |
| Step 4. Modify Fieldwatch Numbers:     | #/nas/sbin/ch_dd [/nas/sys/callhome.dial_dir]  |
| Step 5. Test CallHome:                 | #/nas/sbin/ch_test [Tests callhome]  |
| Step 6. Running Modem Test:            | #/nas/sbin/modemtst  |
| Step 7. Enabling or Disabling Dial-In: | #/nas/sbin/ch_pm [Must run this after running "modemtst", which disables Dial-In!] >on [for Enabling Dial-In for "ttyS0"] >off [for Disabling Dial-In for port monitor "ttyS0"]] |

### **XML CALLHOME PAYLOAD DIRECTORY NAS 5.2:**

/nas/log/ConnectHome

# ls -la

```
-rw-r--r-- 1 root root 2468 Jun 22 09:26 RSC_ML2805001493_062204_092650000.xml
```

### **CALLHOME PROCESS FOR CLARIION BACKEND EVENTS:** see primus emc125099

The naviagent is running on the control station to monitor backend events. For any informational/warning/error/critical events generated from the Backend, the naviagent will call syslog() function with a specific event message [Note that this new naviagent has changed message format to syslog() function]. Once an event is generated, the syslog() function will direct the message to the Control Station's syslogd daemon, which will then simultaneously redirect the messages to /var/log/messages & /nasmcd/event\_fifo, based on the contents of the configuration file located in /etc/syslog.conf. Another Control Station process, called /nas/sys/navilog\_mon, monitors for any backend events posted to /nasmcd/event\_fifo, and upon finding events, will then post the

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
message to /nas/log/sys\_log. The problem here is that /nas/sys/navilog\_mon could read the redirected message from  
/nasmcd/event\_fifo but could not parse it correctly because the new naviagent has added four additional fields in the event message.

#### **ORIGINAL NAVIAGENT FORMAT (6.16.2.0.0):**

Jan 2 14:32:48 ns600-1 EV\_AGENT[5161]: Time Stamp 01/03/06 00:32:09 Event Number a07 Severity Critical Error Host ns600spa Storage Array APM00023700164 SPA Device Bus 1 Enclosure 0 Disk 2 Description CRU Powered Down

#### **NEW NAVIAGENT FORMAT (6.19.0.4.14):**

Dec 21 03:26:15 cs\_kama EV\_AGENT[5073]: Time Stamp 12/21/05 03:25:06 Event Number **0xa07 ExtCode1 0xa07 ExtCode2 0xa07** Severity Critical Error Host OEM-2MYA58ZGAQT Storage Array CK200054201137 SPA Device Enclosure 0 Disk 9 SoftwareRev 6.19.0 (4.14) Unknown Error 2.19.0.500.5.016 Description CRU Powered Down

**Note:** Issue fixed with NAS 5.3.24.1 & 5.4.21.2

**# /nas/sbin/naviagent -help**

@(#)Navisphere Agent Revision 6.19.0.4.14

### **TEMPORARILY DISABLING CALLHOME EVENTS WHILE CONDUCTING MAINTENANCE:**

1) Create file to prevent ch\_monitor process from performing CallHome:

**# touch /nas/tmp/CallHomeTESTING**

**Note:** Above applies to NAS 5.3.19.0, 5.4.17.0, 5.5.3.0 only. Use # touch /nas/log/ConnectHome/TESTING for other versions.

2) Perform the maintenance activity: maintenance, upgrade, hardware replace, etc.

3) Clear CallHome queue and remove the CallHomeTESTING file:

**# /nas/sbin/ch\_stop**

**Note:** For NS systems, go to /nbsnas/log/ConnectHome directory & manually delete XML files

4) Verify that the file (CallHomeTESTING or TESTING) was deleted—remove manually if required

### **CALLHOME EVENTS NAS 5.4:**

CPU Blade faults, Management Switch faults, Power Supply, Fan faults, slot boot errors, Voltage, Fan, Temp alarms, APC UPS faults

#### **CALLHOME CONFIG FILES:**

**Configuring:** #/nas/sbin/ch\_cfg

**Stop Service:** #/nas/sbin/ch\_stop

**Start Editor:** #/nas/sbin/ch\_dd [R to revise the table. Modify Fieldwatch numbers]

**Conduct Test:** #/nas/sbin/ch\_test {if successful, then test from Remote Dial-In}

**Useful Log:** Call Home event.dir

### **CALL-IN UTILITY:**

**Default Settings:** No parity; 8 data bits; 1 stop bit; speed 9600bps Default Terminal is ttyS0 enabled, ttyS1 disabled.

**Note:** To set correct emcnas command set path; #set path =\$path: /nas/bin: /nas/sbin export PATH

#### **DISABLING CALL-IN UTILITY:**

**#/nas/sbin/ch\_dialin\_disable ttyS0 | ttyS1** ['enable' to reactivate]

**Modem Daemon:**

#top esc + M → Look for modem process: /sbin/mgetty -x 0

### **CALL HOME EVENTS FOR NAS 5.5:**

**# nas\_event -list -a callhome**

| facility      | id | description                                |

May 12 21:00:00 2006 NaviEventMonitor:**3:3** Backend Event Number 0x957 Host OEM-XOO25IL9VL9 Storage Array  
APM00041700339 SPA Device

Bus 1 Enclosure 1 Disk 12 SoftwareRev 6.19.0 (4.14) Unknown Error 2.19.0.701.5.027 Description Uncorrectable Sector

**Note:** First number represents Severity, second number is the EventID for the facility called “NaviEventMonitor”. Use # nas\_event -list -f -i to obtain the list of facilities.

**USING SERVER SYSSTAT:** Operating System statistics by kernel thread; free memory; free CPU time

\$server\_sysstat server\_2 server\_3 :

|                          |  |
|--------------------------|--|
| threads runnable = 2     | [number processes running and not waiting for I/O] |
| threads blocked = 170    | [number processes running and waiting due to I/O]  |
| threads I/J/Z = 1        | [threads in zombie status, not an error!]          |
| memory free(kB) = 419998 | [free memory]                                      |
| cpu idle_% = 99          | [processor idle time in %]                         |

**SCO Control Station Statistics:** \$sar -u 5 5 or \$sar -u 1 5 [Provides STATS on CS0 CPU activity, et al for SCO 2.1.3]  
\$sar -d 15 10 [Provides disk activity report every 15 seconds for 10 times]

**Linux CS Statistics:** \$top and \$vmstat commands

**Quick Way to See if DataMovers Have Panic Information Logged:**

\$egrep -i panic /nas/log/sys\_log [/nas/log/eventhome]

## **CELERRA DUMP FILES/PANICS:**

**Note:** DataMover “panics” create memory ‘dump’ files that can be extracted and used for analysis by Engineering. Default location for writing dumps to CS is /nas/var/dump [5.3 & 5.4 only]. When dumpfiles are not automatically written to the CS, there are still retained in slots on LUN 0 backend. These dumps can be forced from the slot by using the dump\_slot utility. Dump files are actually written to LUN 0 on disk. For the Celerra backend, there are three full, dedicated dump\_slots that are used for full panic dumps, with a total capacity of 3.1GB each, though with current 5.4 code, a typical dump is 1.6GB. There are also (2) partial dump slots that can capture up to 4MB of data, per Data Mover. Please note that with AR44489, NAS Versions 5.2.22.0, 5.3.16.0, & 5.4.12.0, panic dumps are no longer automatically extracted and written to the Control Station, /nas/var/dump, but must be deliberately and manually extracted using the dump\_slot utility. Dumps are generated directly by DART when the panic() function is called, and written directly to one of the available dump\_slots on LUN 0 of the backend. The Control Station is not involved in this process. If the Server loses connectivity to backend, then the panic dump cannot be written to LUN 0, so panic handler will not be updated, but a sys\_log entry should still be generated.

## **NAS 5.5 DUMP SLOT SIZES:**

# /nas/sbin/workpart -r

|                        |                                 |
|------------------------|---------------------------------|
| workpart_magic         | = 0xbeaf0001                    |
| full.dumps[0].size     | = 0x300004 = 3,145,732 or 3.1GB |
| full.dumps[1].size     | = 0x300004                      |
| full.dumps[2].size     | = 0x300004                      |
| dump_slices[0][0].size | = 0xffff = 4096 or 4MB          |
| dump_slices[0][1].size | = 0xffff                        |

**Note:** Celerra can write a total of (3) full 3.1GB dumps to the backend LUN 0 and (2) Partial 4MB dumps for each Data Mover slot. Cognac will remove one of the partial dump slots on each DM. Compressed dumps will be introduced with GrandNapa release. Crash header will show if dump is compressed or not and normal dump\_slot commands will still apply. Eng. recommends gzipping any dumps prior to FTP. Can transfer nas\_crash and dump\_slot binaries from newer code to older systems.

→Use #/nas/sbin/& -v -F utility to mark the 'dump' partition for cleanup of Full Dumps

→Use #/nas/sbin/dump\_slot -d /tmp/slot2.dump -v -F 2 [use to extract dump from 2<sup>nd</sup> full dump slot]

→Use #/nas/sbin/dump\_slot -v to cleanup partial dumps

→Use #/nas/sbin/nas\_crash -F 0 | 1 | 2 to see the panic headers of any existing dumps in the full slots

## **ZEROING OUT DUMP SLOTS SO THAT NEW PANICS CAN BE WRITTEN TO BACKEND:**

### **1. Verifying current dump\_slot Status:**

# /nas/sbin/dump\_slot -v -F -x

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

Checking LBA 0xf3800 for Full Dump...

Tue Feb 14 08:19:31 2006 UTC

Product: EMC Celerra File Server

Uptime: 006 days, 21:03:52

Version: T5.5.18.2

IP Address: 192.168.2.2

Host Name: server\_2

Checking LBA 0x3f380a for Full Dump...

Checking LBA 0x6f3814 for Full Dump...

**Note:** Output indicates that a dumpfile exists in the first dump\_slot position but that no dumps have been written to the other (2) dump\_slots

**2. Verify whether the dumps are valid or invalid, or use to dump to CS partition:**

**# /nas/sbin/dump\_slot -v -F**

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

Checking LBA 0xf3800 for Full Dump...

\*\*\*\*\*

DART Slot 2, Full Dump 0 Found @ LBA 0xf3800 (997376)

Dump info:

DART Slot 2

magic = 0xfacedead

dump\_lba = 0xf3805

dump\_type = 0x3

dump\_chunks = 0x30000

dump\_chunksz = 0x2000

DART panic message: >>PANIC in file: ../../dskdump.cxx at line: 1450 :

to see if ip rep survives

DART stack trace:

0xd6617a80: 0x13d047 waitForReboot+0x8b

0xd6617aa0: 0x13d24f fault\_dump+0x67

0xd6617ac0: 0x13d14f PANIC+0x2b

0xd6617ad0: 0x830c04 \_Z11paniccfgcmdR6Option+0x178

0xd6617c10: 0x161765 \_ZN11cfgcmd\_desc6invokeEPKcPP11CCMDMessageii+0

0xd6617c80: 0x1fb25e \_Z10xml\_cfgcmdP7macDataRP8CCMD\_Msg+0x30e

0xd6617cd0: 0x1f7652 \_ZN17macCCMDCommand\_DB6invokeEPKcP7macDataRP8C

0xd6617d00: 0x1f7b76 \_Z17mac\_CCMDDocParserP7macDataRP8CCMD\_Msg+0x20

**Note:** Run dump\_slot -v -F to view panic header and also to verify the magic value of the dump\_slot. When the magic value is something other than 0, a dump\_slot exists and has not yet been marked for overwrite.

**3. Use the following command to zero out the magic values for each dump\_slot, thereby enabling the Celerra to overwrite the dump\_slots with new panic dumps:**

**# /nas/sbin/dump\_slot -c 0**

**# /nas/sbin/dump\_slot -c 1**

**# /nas/sbin/dump\_slot -c 2**

**Note:** The above command does not return a success or failure message, though each dump\_slot becomes marked for overwrite (deletion).

**4. Verify Dump\_slot -c Results:**

**# /nas/sbin/dump\_slot -v -F**

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

Checking LBA 0xf3800 for Full Dump...

Dump info FOUND:

Dart Slot = 2

magic = 0

dump\_lba = 0xf3805

dump\_type = 0x3

dump\_chunks = 0x30000

dump\_chunksz = 0x2000

No Full Dump Found

**Note:** Magic value is set to zero and "No Full Dump Found" is indicated this time--system is now able to overwrite any existing dumps if a new panic occurs. Please note that as in past behavior, until the slot is actually overwritten by a new panic dump, the contents of the existing dump still exist on disk and can be extracted to the Control Station.

## **GZIPPING DUMP FILES ON PARTITIONS WITH LITTLE FREE SPACE:**

```
# cat slot3.dump0 | gzip -9 -c >/nas/var/dump/slot3.dump.gz &
```

```
/dev/ndf1      1.7G  1.4G  354M  79% /nas/var  
# ls -la  
-rwxr-xr-x  1 root  root  1154796032 Feb  9 17:30 slot3.dump0  
-rw-r--r--  1 root  root   29032448 Feb  9 17:41 slot3.dump.gz
```

## **CHECKING FOR FULL DUMP SLOT PANICS:**

```
# /nas/sbin/dump_slot -v -F -x
```

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.  
DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

## **NAS 5.4 CONTAINS (3) FULL DUMPSLOTS FOR MEMORY DUMPS:**

**Note:** As seen from /nas/sbin/workpart -r output

|                    |            |
|--------------------|------------|
| full.dumps[0].lba  | = 0xf3800  |
| full.dumps[0].size | = 0x300009 |
| full.dumps[1].lba  | = 0x3f380a |
| full.dumps[1].size | = 0x300009 |
| full.dumps[2].lba  | = 0x6f3814 |
| full.dumps[2].size | = 0x300009 |

## **AUTOREBOOT AFTER PANIC:**

```
param kernel autoreboot=600
```

**Note:** Amount of time in seconds that DART will wait after panicking, before rebooting

## **DEFAULT LOCATION OF DART AUTOMATIC & MANUAL DUMPS:**

```
/nas/var/dump
```

**Note:** NAS 5.3.6.0 & 5.4.1.0 changed manual dump\_slot behavior from putting dump in /nas/log to /nas/var/dump, but later versions write dumps to LUN 0 dump\_slots on backend only and do not extract to /nas/var.

**DEPOSIT DUMP TO ALTERNATE LOCATION ON CS: /nas/var/dump /dev/sdf1**

```
$/nas/sbin/dump_slot -v -F -d /nas/var/dump/dump_slot.2
```

**Note:** Later NAS versions write panic dumps automatically to /nas/var/dump, but the default location when using /nas/sbin/dump\_slot would still output dump to /nas/log, creating potential problems with the /nas partition filling up. NAS 5.3.6.0 & 5.4.1.0 now use

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
/nas/var/dump as the default location when using the dump\_slot command manually. NAS 5.2.22.0, 5.3.16.0, & 5.4.12.0 no longer writes the dump to /nas/var/dump by default, just to the backend dump\_slot.

### **WATCHDOG PANICS:**

Watchdog panics mean that something in the system was in a deadlock or a never-ending state

### **NMI EXCEPTION PANICS:**

NMI is a “Non-Maskable Interrupt” that exists so that the processor can be interrupted no matter what. This is only necessary when there are certain hardware errors that require immediate shutdown so as to stop the system from further damaging itself. An uncorrectable memory error would be an example.

### **COMPRESSING DUMPS:**

```
$compress -v slot3.dump.0203121420      [536873472]      [SCO]  
slot3.dump.0203121420.Z                  [200161175]  
$ gzip slot3.dump.0211121824            [LINUX]  
-rwxr-xr-x 1 nasadmin nasadmin 145053685 Nov 12 18:26 slot3.dump.0211121824.gz
```

### **MANUALLY COLLECTING PANIC DUMPS:** [/nas/var/dump    /nas/log]

#### **Step 1. Locate the Dump Slot Files:**

```
# ls -l /nas/log/slot*          [SCO]  
-rwxrwxr-x 1 nasadmin nasadmin 109731331 Nov 17 09:31 /nas/log/slot4.dump0.1171.Z  
#ls -la /nas/var/dump*        [LINUX SYSTEMS]  
-rwxr-xr-x 1 root  root  529574400 Nov 12 18:26 slot3.dump.0211121824
```

#### **Complete 536MB Dump File:**

```
-rwxrwxrwx 1 nasadmin root  536873472 Mar 12 14:22 slot3.dump.0203121420
```

#### **Step 2. Ensure there is enough room to Uncompress Dumpfile:** #df -k

```
/dev/sdd1    1818352 123640 1602340 7% /nas/var
```

#### **Step 3. Uncompress the Dump File:**#uncompress /nas/log/slot4.dump0.1171.Z & [Run as bg process--takes about 15 min]

```
# jobs  
[1]+ Running      uncompress /nas/log/slot4.dump0.1171.Z &
```

**Note:** #fg %1 to bring background job to foreground; use ctrl + c to end job

#### **Step 4. # wait** [Displays prompt when background job is completed]

```
# ls -al slot*  
-rw----- 1 root  root  209350656 Nov 19 16:02 slot4.dump0.1171  
-rwxrwxr-x 1 nasadmin nasadmin 109731331 Nov 17 09:31 slot4.dump0.1171.Z
```

#### **Step 5. View Dump Header using Nas Crash:**

```
# /nas/sbin/nas_crash slot4.dump0.1171 -i [Always use -i switch!]
```

-----  
DART time of dump: Sat Nov 17 12:37:00 2001

Product: Symmetrix Network File Storage

0x3800c: 0x19171e _start_11Mac_Initial+0x26
```

DART panic/fault current cpu registers:

```
edi   =     0    esi   = 1362db  
ebp   = 37ed0    oldEsp = 37ebc  
ebx   = fffe    edx   =     1  
ecx   =     4    eax   =     0  
eflags = 202
```

**Step 6. Take snapshot of Server Log 20 lines before and 10 lines after Panic**

```
#server_log server_4 -a -s > slog4.log
```

**Step 7. Compress the dump file: #compress -v slot3.dump0 [slot3.dump0.Z]**

[or use gzip to compress]

**Step 8. FTP the “slot dump” and ProComm “capture file” to Engineering using TFTP process**

**Step 9. Clean up DUMP Files from Celerra:**

```
#/nas/sbin/dump_slot -v -F [full dumps] | -v [partial dumps]
```

Creating dump file "/nas/log/slot4.dump0"

```
#/nas/var/dump      #/nas/log
```

**Note:** Answer Yes to all questions except if you want to "Continue Y/N" make selection

**(Old Method—see new dump\_slot -c procedure) CLEANING UP DUMPFILE SLOTS ON CELERRA:**

**1. Log into system and verify current partition usage on the Control Station:**

```
$ df -h
Filesystem      Size Used Avail Use% Mounted on
/dev/sdc3        1.4G 710M 697M 51% /
/dev/sdc1        30M  4.0M 24M 14% /boot
none            251M  0 250M 0% /dev/shm
/dev/sde1        1.7G 1.1G 581M 66% /nas
/dev/sda1        133M 78M 55M 59% /nas/dos
/dev/sdf1        1.7G 886M 799M 53% /nas/var
```

**Note:** Default directory for writing dumps is /nas/var/dump—newer 5.4 dumps require 1.6GB space

**2. Go to /nas/var/dump directory and delete any old dump files that might be taking up the space:**

```
$ ls -la
-rwxrwxr-x  1 nasadmin nasadmin 111550995 Sep 20 10:48 slot2.dump0.gz
$ rm *
```

**3. Verify space on Control Station:**

```
# df -h
Filesystem      Size Used Avail Use% Mounted on
/dev/sdc3        1.4G 710M 697M 51% /
/dev/sdc1        30M  4.0M 24M 14% /boot
none            251M  0 250M 0% /dev/shm
/dev/sde1        1.7G 1.1G 585M 66% /nas
/dev/sda1        133M 78M 55M 59% /nas/dos
/dev/sdf1        1.7G 48M 1.5G 3% /nas/var -->Now have enough space to write a full panic dumpfile
```

**4. Now we can begin the tedious process of cleaning up each memory slot:**

**Option 1:** For systems below NAS Version 5.3, use following syntax to redirect the dumpfile to /nas/var/dump. Failure to do so can fill /nas to 100% and cause file system corruption:

```
#/nas/sbin/dump_slot -v -F -d /nas/var/dump/dump_slot.2 (directing dumpfile to specific location and assigning name to the dump)
```

**Option 2:** For NAS 5.3 and higher, use following command to extract dumps:

```
# /nas/sbin/dump_slot -v -F
```

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

**5. From the crash header above, determine if dumpfile is needed or not (i.e., check the date and size to see if it's a keeper)**

**6. Delete dumpfile from /nas/var/dump and repeat step 4. to extract any other full dumps that might be written to memory.**

**7. After full dumps have been extracted, erased from the memory slot, and deleted, run the following command to extract any "partial" dumpfiles that might exist.** Follow same procedure as in steps 4-5 and repeat until all slots are empty:

#/nas/sbin/dump\_slot -v -d /nas/var/dump/dump\_slot\_partial.2 (NAS 5.2 or below)

#/nas/sbin/dump\_slot -v (NAS 5.3 or higher)

## **FORCING DUMP & REDIRECTING TO ALTERNATE DIRECTORY:**

#/nas/sbin/dump\_slot -d /home/nasadmin/slot3.dump0 -v -F [ -d switch redirects to specified path]

**Note:** Make sure you give the dump a name when specifying the new location or the script won't work!

## **GZIPPING DUMPFFILE:**

#cat slot3.dump0 | gzip -9 -c > /nas/log/slot3.dump0.gz &

**Note:** This procedure will allow you to gzip a large dump in a partition that would not normally be able to conduct a gzip due to the partition being nearly filled.

## **COLLECTING DUMP FILES ON DATAMOVERS:**

**Checking for DumpFiles:** #ls -l /nas/log/slot\* [this is where slot\_x.dump0 would be if dumps had occurred]  
#/nas/log /slot2.dump0

**Dump Summary Info:** \$/nas/sbin/nas\_crash slot2.dump.9906231630 -i >slot\_2.dump1 #more slot\_2.dump1

**Collecting Dump:** #/nas/sbin/dump\_slot -v -F [Polls all slots on DM's & finds dumps. Prompts for extraction or not]  
a.) Do You Wish to Save Dump? Yes  
b.) Do you Wish to erase this Dump from the DART Disk? Yes {**Note:** Doesn't actually remove dump, frees mem slot}

## **FORCING PANIC DUMPS FROM LUN 0 DUMP SLOTS:**

#/nas/sbin/dump\_slot -v -F

## **PANIC DUMPS & THE CFS 4.0 SERVER:**

Due to the increase in Memory for the 510 DataMovers, dump files have changed to a new "sparse" format  
If using a 2GB system disk config, the default is for (1) 1GB dumpslot  
If using a 4GB system disk config, the default is for (3) 1GB dumpslots  
**Note:** System can be reconfigured for (1) 3GB dumpslot if necessary

## **EXTRACTING DUMPS DIRECTLY FROM DUMP SLOT & UPLOADING TO EMC FTP SERVER:**

**Note 1:** With NAS 5.4 there are (3) full 1.6GB dump\_slots that are shared between the Data Movers. When a Data Mover panick occurs, the memory from the DM is written to one of the full dump\_slots, if available, or to (2) partial dump\_slots for each Server, to backend Control LUN 0. Because of the recent NAS 5.4 increase in dump size, there is generally not enough native free space available to extract the 1.6GB dump to /nas/var/dump. The following procedure and /nas/tools/ftp\_dump tool can be used to transfer dumps directly from dump\_slots to an FTP Server directory, precluding the need to output dumps to the Control Station first.

**Note 2:** AR44489 stopped the autosaving of panic dumps to the Control Station partition—all dumps need to be manually extracted with NAS Versions 5.2.22.0, 5.3.16.0, 5.4.12.0.

Note 3: The FTP Dump utility will no longer be supported in NAS 5.6

### **1. Configure an ftp.cfg transfer file in /nas/tools directory with the following information:**

# cat /nas/tools/ftp.cfg

host ftp.emc.com

user anonymous

pass ftp\_ftp@emc.com

**Note:** Host can be in form of hostname or IP Address. Email address needs to be in format "user\_name@emc.com" to be a valid password entry

### **2. Execute the following command to list out the various dates associated with Full Dump Slots:**

# /nas/sbin/dump\_slot -v -F -x

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

Checking LBA 0xf3800 for Full Dump...

Sun Dec 18 18:49:17 2005 UTC

Checking LBA 0x3f3805 for Full Dump...

Sat Dec 17 18:51:41 2005 UTC

Checking LBA 0x6f380a for Full Dump...

Sat Dec 17 19:33:52 2005 UTC

**Note:** Identify the dump date that is relevant and note the LBA partition information for use when extracting dump

### **3. Execute the script to find and transfer the desired dump to the EMC FTP Site:**

**Note:** Since there may be a number of dumps available, ranging in age from current to old dumps, a decision will need to be made on which ones to extract and transfer, and which ones not to extract.

#/nas/tools/ftp\_dump -f ftp.cfg

Please enter the remote-directory: /incoming/ftp\_dmp

Partition 0 starts at 0x1, size 273042 (0x42a92) blocks.

DART Work Partition Layout found @ LBA 0x43000 (134MB boundary)

Checking LBA 0xf3800 for Full Dump...

**Do you wish to save this dump anyway? [y or n] y**

\*\*\*\*\*

DART Slot 2, Full Dump 0 Found @ LBA 0xf3800 (997376)

DART panic message: >>PANIC in file: ../dskdump.cxx at line: 1437 :

Server\_2 PANICKED

DART stack trace: -----output abbreviated-----

**Do you wish to save this dump? [y or n] y**

Dump size is 660834816 bytes. A dump file of this size will be created.

**Do you wish to continue? [y or n] y**

Creating dump file "/nas/var/dump/29797.dump".

**Dump file "/nas/var/dump/29797.dump" already exists. Overwrite it? [y or n]: y**

**Note:** A process file 29797.dump is created in /nas/var/dump during the dump transfer from dump\_slot to FTP Server directory, and then erased after the operation is completed. This process file works in 4k chunks—a minimum of 4k of freespace is required in the /nas/var/dump directory for this procedure to work:

prw-r--r-- 1 root root 0 Jan 9 13:41 29797.dump

prw-r--r-- 1 root root 4096 Jan 9 13:42 29797.dump

**Dump to file "/nas/var/dump/29797.dump" complete.**

**Do you wish to erase this dump from the DART disk? [y or n] y**

**4. At this point, the dumpfile has been transferred to FTP Server and the dump\_slot marked for deletion of the old dump**

**5. Answer following questions below, to either transfer other dump files, or to complete the current activity:**

Checking LBA 0x3f3805 for Full Dump...

**Do you wish to save this dump? [y or n] n**

**dump saved as 29797.dump @ /incoming/ftp\_dmp**

done.

**6. Dump file has been transferred to FTP site /incoming/ftp\_dmp:**

-r----- 1 u3 g3 660834816 Jan 17 19:02 29797.dump

## **SPLITTING BINARY DUMP FILES INTO SEGMENTS IN ORDER TO FTP TO EMC:**

Step 1. Prior to splitting a Binary Dump File, run the following command to obtain a CheckSum of the File

(Checksum number will be used after the files are concatenated back together to verify the integrity of the final Dump File):

**#/usr/bin/cksum slot6.dump.0208261933 [or #sum /var/dump/]**

**3661864574 268184064 slot6.dump.0208261933**

[3661864574 is the CheckSum of the Original Dump File]

Step 2. From a directory on Control Station that has adequate space, run the split command:

**\$/nas/var/split -b 250000000 /nas/log/slot6.dump.0208261933**

**Note:** This command will split the binary dump file into 250MB segments that are named “xaa, xab, xac,” etc. This eliminates the original slot6.dump filename and deposits the segments in the directory from which the command was run.

Step 3. Gzip the segments #gzip \* [xaa.gz, xab.gz, xac.gz]

Step 4. FTP the zipped files to EMC, unzip, then concatenate the binary files together again [\$gzip -d xaa ]

**\$cat xaa xab xac >slot6.dump.0208261933**

Step 5. Verify the integrity of the binary file:

**#/usr/bin/cksum slot6.dump.0208261933**

**3661864574 268184064 slot6.dump.0208261933**

## **GZIPPING DUMP USING CAT COMMAND TO REDUCE SIZE OF DUMPFLE:**

1. #cd /nas/var/dump

2. Zip dump to location with adequate room: **#cat slot2.dump0 | gzip -9 -c > /home/nasadmin/slot2.dump0.gz &**

3. Upload file to FTP Site & send to Engineering

## **ANOTHER METHOD FOR GZIPPING DUMP TO SPECIFIC DIRECTORY:**

1. #mkfifo /tmp/fifo

2. #cat /tmp/fifo lzip > /nas/var/dump/slot2.dump0.gz &

3. #/nas/sbin/dump\_slot -s -d /tmp/fifo -v -F

4. #rm -Rf /tmp/fifo

## **STABILIZING DM's IN "Rolling Panic" SITUATIONS:**

1. Stop NAS Services, if time permits, to stop the annoying CallHome messages on screen:

**#/sbin/service nas stop**

2. Verify that Box Monitor and nas\_mcd are no longer running:

**#ps -ef |grep boxm**

**#ps -ef |grep -i nas\_mcd**

3. Manually remount file systems on Control Station:

**# mount /nbsnas # mount /nas # mount/nas/dos #mount/nas/var**

4. Identify panicked slot and obtain Server Log:

**# nas\_server -l**

**# /nas/sbin/getreason**

**# /nas/sbin/log\_slot -s -a 2 >s2log**

5. Look for cause of panic in the log. Rolling panics are often caused by a corrupted file system that cannot be remounted by the Data Mover during bootup. Look for evidence of file system corruption, FSTOOLS activity for fsck's, in the log.

**Note:** NAS 5.4 should be able to handle corrupted file systems better and allow for the Server to bootup without the corrupted file system mounted, conducting autofsck, etc.

6. Once identified, make a copy of the /nas/server/slot\_x/mount file, then vi edit and delete the offending file system line entirely from the mount file:

**#cp -ip mount mount\_ori**

**# vi mount** (edit the file & remove following line using dd to delete the line)

**uxfs rw /fs31 359=1283 rw**

**Note:** If DM continues to panic, find the corresponding “359=1283” entry in the ufs file and remove this entry

**# cat ufs**

file recover ufs 73=131072 14=5 122=18 36=16 357=1282 **359=1283**

**Note:** Remove the highlighted entry, which is for file system /fs31 or volume # 359

7. Use **# server\_cpu server\_x -r now** to reboot server. This will rebuild the Server configuration based on the current state of its database files, and therefore not attempt to mount the offending file systems.

#### **ADDITIONAL COMMENTS:**

→ In some situations, Checkpoints can cause the Rolling Panic scenario to occur, and may require a permanent unmount and deletion of the Checkpoints associated with a particular file system. Again, the Server Log should be the first place to check to identify the source of the rolling panics

→ In other situations, IP Replication file systems can also cause rolling panics. Determine the offending file system, then comment out the respective ipfsclone line from the panicking server's netd file

→ In rare cases, a newly implemented Server Param entry may be the cause of the rolling panic and would need to be removed

→ An alternative method of commenting out file systems would involve making a copy of the appropriate /nas/dos/slot\_x/boot.cfg file and editing the boot.cfg as in following example, followed by **#/nas/sbin/t2reset reboot -s 2**. The T2reset command will boot the server based on the current state of the boot.cfg file:

file recover ufs 73=131072 14=5 122=18 36=16 357=1282 **359=1283 (remove this entry)**

#file mount ufs rw /fs31 359=1283 rw

### **EXAMPLES OF FILE SYSTEM RELATED PANICS:**

#### **IO FAILURE PANIC:**

>>PANIC in file: ../../volume.cxx at line: 214 :

IO failure despite all retries/failovers

---

#### **READ BLOCK FAILURE PANIC:**

>>PANIC in file: ../../ufsio.cxx at line: 340 :

readBlock failed

---

#### **BAD MAGIC PANIC:**

finishTake: bad magic in CG

#### **Corresponding Server Log Entry specifies problem file system:**

2004-08-23 15:58:38: UFS: 3: bad magic num 8c3a5178 in cylinder group at blk 6ac0030

2004-08-23 15:58:38: CFS: 3: **Unmounting fs 56**: Reason: finishTake: bad magic in CG

---

#### **MANGLED DIRECTORY ENTRY PANICS:**

DART panic/fault message: mangled directory entry

#### **Corresponding Server Log Entry:**

UFS: 3: fs /mnt02: bad dir ino 615176 at offset 7658: mangled entry

>>PANIC in file: ./ufsdir.cxx at line: 184 :

UFS\_DirHashIter::getEntry: mangled entry

### **VARIOUS SERVER LOG ENTRIES FOR FILE SYSTEM PANICS:**

UFS: 3: Partially truncated inode 292588 in fs 77

You can recover the storage for this file by running fsck at a convenient time

UFS: 3: bad magic num b1a3ca0f in cylinder group at blk c9a0030

UFS: 3: Corrupted file: ino 522768, fsid 75, size 100000000001

UFS: 3: fs /fs2: bad dir ino 1515984 at offset 192: mangled entry

CFS: 3: Unmounting fs 19: Reason: mangled directory entry

STORAGE: 3: readBlock() : Volume 156 Bad Block Index 233293f01067406870: UFS: 3: readBlock failed, err 16

>>PANIC in file: ./ufsinode.cxx at line: 894 : Oversized file: need to run fsck

DART panic/fault message: mangled directory entry

>>PANIC in file: ./ufsio.cxx at line: 340 : readBlock failed

### **CASE STUDY TO FIND FILE SYSTEM BASED ON TARGET & LUN INFO FROM LOG ONLY:**

1. In certain cases, you may see only the following entries in the Log just prior to a panic, and may need to do some detailed work to find out what the offending file system name is. In the following example, all that is recorded is the Target 11 & Lun 14.

#### **Server Log:**

2005-09-27 12:20:03: CAM: 3: FCP I/O Error: c16t11114: CamStatus 04 ScsiStatus18

2005-09-27 12:20:03: CAM: 3: FCP I/O Error: c0t11114: CamStatus 04 ScsiStatus 18

2. Grep the camdisk file to find the “d” volume & device that matches up with Target 11, Lun 14.

# egrep t11114 /nas/server/slot\_7/camdisk

**68:c0t11114+556812~~2E2~~031+,c16t11114+5568122E2201+:** (Line 68 is d68 & device is 2E2)

3. Use following commands to determine file system name:

# nas\_disk -i d68

clnt\_volume = stv9

#nas\_volume -i stv9

clnt\_volume = mtv3

# /nas/sbin/rootnas\_volume -i mtv3

**clnt\_filesys= prodFO\_fs**

# nas\_fs -l

20 y 1 0 231 prodFO\_fs 1 (FSID is 20 and Volume # is 231)

### **HOW TO VERIFY IF A PANIC IS IN PROGRESS:**

**\$ps -ef |grep recover\_slot** [If this process is running, a panic is in progress & you must let it play out]

### **GENERATING SERVER PANIC:**

**\$server\_config server\_x “panic for a 0 percent cpu condition”**

### **FORCING SERVER PANIC USING MAC\_DB TOOL:**

1. Create link to MAC\_DB Utility in /nas/tools directory:

**# ln -s /nas/tools/mac\_db \_mac\_db**

2. Open MAC\_DB on Server\_3:

**# /nas/tools/\_mac\_db server\_3**

**macdb>**

3. Obtain List of Memory Registers by running "Show Thread" command:

**macdb> sh thr**

Dummy at 35f6010: State = IDLE

---output abridged-----

logXmlS at dd8cc448 0: Waiting for Condition at 211a910

logXmlS at dd8cc4fc 0: Waiting for Condition at 211a910

logXmlS at dd8cc5b0 0: Waiting for Condition at **211a910**

4. Select a memory register from something that appears innocuous—consult with TS2!:

**macdb> sh thr 211a910**

**Note:** System hangs at this point, indicating a reboot

5. Use ctrl + C to exit from the macdb> prompt

6. Grep for Panic Dump Recovery Process, check /nas/var/dump, or run dump\_slot utility to see if dump was written:

### # ps -ef |grep recover

```
root      9  1 0 Apr19 ?    00:00:00 [mdrecoveryd]
root   24152 1583 0 07:02 ?    00:00:00 /bin/sh /nas/sbin/recover_slot /
nasadmin 24410 24152 3 07:02 ?    00:00:00 /nas/sbin/slot_recover 3
```

### # /nas/sbin/dump\_slot -v -F -x

**Note:** If first attempt does not panic Server, continue using 'sh thr' command with different Memory addresses until successful  
7. Remove \_mac\_db link from /nas/tools directory

### **ANOTHER METHOD TO PANIC A TOTALLY HUNG DM:**

1. Obtain the server\_xml.tar.gz file from Kore: /pub2/utils
2. Push file to Celerra Control Station & copy to newly created directory
3. #tar -zxpvf server\_xml.tar.gz
4. #chmod 700 \*

### 5. #./server\_xml server\_x cfgcmd

**Note:** This will create a server panic and can be used with NAS 5.2, 5.3, 5.4

### **YET ANOTHER METHOD TO PANIC HUNG DATA MOVER:**

### # /nas/sbin/t2tty -c 2 "panic hung mac thread issue"

#### **How to Capture Screen Inputs and Displays on the Linux Control Station:**

**#cd; script** [Begins file capture of screen session to file ‘typescript’} –Use ctrl + d to end script session

**STARTING LINUX SCREEN SCRIPT CAPTURE:** \$script /tmp/aaa [starts script session in /tmp directory with filename “aaa”]

### **CELERRA EVENTS:**

\$nas\_event -l -f MasterControl | BoxMonitor [This command lists events for each ‘facility’]

**\$ nas\_event -l -f -i** [Lists the facilities on the Celerra: AAF; VideoService;BoxMonitor;MasterControl]

\$/nas/bin/nas\_event -list -f UFS [Lists all events for UFS facility such as Quota warnings]

**\$ /nas/bin/nas\_event -list -f CFS** [Lists all events for CFS facility]

\$/nas/bin/nas\_event -list -f SVFS [lists Checkpoint Save Volume Events]

### # nas\_event -list -k panick

facility id description

BoxMonitor 300 Slot 00 panicked

BoxMonitor 301 Slot 01 panicked →output abridged---list of all panic events

\$/nas/bin/nas\_event -list -k quota [Lists all quota-related events]

\$nas\_event -l -a callhome [Lists all events that generate CallHomes]

\$/nas/bin/nas\_event -L /nas/site/event.cfg

**\$ /nas/bin/nas\_event -L -info** NAS Events that are loaded on the Control Station

\$/nas/bin/nas\_event -list -a mail [Lists all events for mail action]

**\$ nas\_event -l -a trap** [Viewing SNMP Trap Events]

**# nas\_event -list -a -info** [Lists all possible actions for Celerra]

action

udprpc

exec

terminate

trap

callhome

logfile

**# nas\_event -list -a <list above possible actions here to get output>**

### **OUTPUTTING ALL NAS 5.6\6.0 EVENTS TO FILE:**

```
$ export NAS_DB=/nas ; /nas/bin/nas_event -l -c -i \| awk '/^[*][0-9]+/{print $1}' \| xargs -n1 -i bash -c \ "export COMP={} ; /nas/bin/nas_event -l -c {} -i \| awk '/^[*][0-9]+/{print $1}' \| xargs -n1 -i /nas/bin/nas_event -l -c \$COMP -f \{\} -id" \| fgrep -v 'DEBUG(7)' >events.out
```

**Note:** Event categories for 5.6 are DART; CS\_CORE; XML\_API; & CS\_PLATFORM

### **NAS EVENT SEVERITY CODES:**

1 = Alert  
2 = Critical  
3 = Error  
4 = Warning  
5 = Notice  
6 = Info  
7 = Debug

### **SYS LOG EXAMPLES:**

### **LIST OF EVENTS FOR A FACILITY WITHIN A COMPONENT:**

**# nas\_event -l -c DART -f DBMS**

```
DART(1)
```

|--&gt; DBMS(122)

BaseID Severity Brief\_Description

1 ALERT(1) The environment database of the VDM might be corrupted and a recovery procedure must take place  
 2 CRITICAL(2) Only \${freeblocks,3,%llu} free blocks in the root file system (fsid \${fsid,2,%u}) of the VDM \${vdm,8,%s}.  
 3 ALERT(1) The root file system (fsid \${fsid,2,%u}) of the VDM \${vdm,8,%s} is full. There are only \${freeblocks,3,%llu} free blocks.

**# nas\_event -l -c CS\_PLATFORM -f NaviEventMonitor**

CS\_PLATFORM(6)

|--&gt; NaviEventMonitor(138)

BaseID Severity Brief\_Description

1 INFO(6) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.  
 2 WARNING(4) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.  
 3 ERROR(3) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.  
 4 CRITICAL(2) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.  
 5 DEBUG(7) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.  
 10 ALERT(1) CLARiiON Event Monitor daemon terminated unexpectedly.  
 100 ALERT(1) Disk \${dname,8,%s} has been cache-compromised.  
 101 CRITICAL(2) Disk \${dname,8,%s} has been trespassed.  
 200 INFO(6) Device group \${name,8,%s} on \${BACKEND\_NAME,8,%s} is \${condition,8,%s}.  
 201 ERROR(3) \${BACKEND\_NAME,8,%s} \${name,8,%s} is \${condition,8,%s}.  
 202 ERROR(3) Device group \${name,8,%s} on \${BACKEND\_NAME,8,%s} is \${condition,8,%s}.  
 203 WARNING(4) Device group \${name,8,%s} on \${BACKEND\_NAME,8,%s} is \${condition,8,%s}.

**LIST OF POSSIBLE ACTIONS FOR EVENTS:****# nas\_event -list -a -info**

action

terminate

trap

exec

logfile

**LIST OF EVENTS FOR A PARTICULAR ACTION:****# nas\_event -list -a callhome|head**

DART(1)

|--&gt; CFS(27)

BaseID Severity Brief\_Description

4 WARNING(4) File system size threshold (\${size,5,%u}%) was crossed for (fs \${fsname,68,%s})

DART(1)

|--&gt; DRIVERS(36)

BaseID Severity Brief\_Description

6 ERROR(3) SlicNicDevice: TOE \${deviceName,45,%s} panic detected. The TOE core image is being saved to \${filename,8,%s}'.

**# nas\_event -list -a callhome →CS\_PLATFORM for facility NaviEventMonitor BaseIDs**

CS\_PLATFORM(6)

|--&gt; NaviEventMonitor(138)

BaseID Severity Brief\_Description

4 CRITICAL(2) CLARiiON event number 0x\${navi\_event\_str,8,%s} \${desc,8,%s}.

100 ALERT(1) Disk \${dname,8,%s} has been cache-compromised.

**# nas\_event -list -a trap|head**

DART(1)

|--&gt; FSTOOLS(40)

BaseID Severity Brief\_Description

1 CRITICAL(2) The file system utility, fsck, started on file system id: \${id,22,%u} for type: (\${type,8,%s}).

2 INFO(6) FsId: \${id,5,%u} Fsck Started (\${type,8,%s}).

3 CRITICAL(2) FsId: \${id,5,%u} Fsck Succeeded

4 INFO(6) FsId: \${id,5,%u} Fsck Succeeded

5 CRITICAL(2) FsId: \${fsid,5,%u} Fsck Failed

6 INFO(6) FsId: \${fsid,5,%u} Fsck Failed

**NOTIFICATION ACTIONS CS CAN MAKE FOR EVENTS:**

Logging event to file

Sending email message  
Generating SNMP trap  
CallHome  
Running a script  
Sending RPC message to Host  
Terminating processing of an event

## **FACILITIES WITHIN NAS 5.5:**

# **nas\_event -l -f -i**

```
id facility
140 UPSMonitor
139 LocalHardwareMonitor
138 NaviEventMonitor
137 NASDB
135 JServer
131 BoxMonitor
129 MasterControl
111 DPSVC
108 REP
102 FCP
101 ACLUPD
96 DHSM
93 USRMAP
91 SNAPSURE_SCHED
86 CHAMIIENCMON
84 VMCAST
83 RCPD
81 VC
77 VRPL
75 MGFS
70 SVFS
64 UFS

36 DRIVERS
27 CFS
26 CAM
24 ADMIN
```

## **NAS EVENTS WITHIN EACH FACILITY 5.5:**

# **nas\_event -list -f VC**

```
id description
0 Normal state
1 High water mark reached
2 Low water mark reached
3 No Virus Checker server available
4 No Virus Checker server; stop CIFS
5 No Virus Checker server; stop virus checking
6 File not checked
7 Virus Checker server online
8 Virus Checker server offline
9 Filesystem scan started
10 Filesystem scan terminated
11 Filesystem scan aborted
12 File has been deleted by the Virus Checker engine
```

13 File has been renamed by the Virus Checker engine  
14 File has been modified (cleaned) by the Virus Checker engine  
15 Virus Checker stopped  
16 Virus Checker started

**# nas\_event -list -f UFS**

id description  
0 I18N OK  
1 I18N - Out of Inodes  
2 I18N - Cannot balloc  
3 I18N - Recovery failed, filesystem not mounted  
4 Soft quota (warning limit) crossed  
5 Hard quota limit reached/exceeded  
6 Directory translate status message  
7 Skip auto fsck for corrupted filesystem at mount  
8 Gid map file is not present  
9 Gid map file is full  
10 Directory translate major error  
11 Crossed the root filesystem inode threshold  
12 Crossed the filesystem inode threshold  
13 Dropped below the root filesystem inode threshold  
14 Dropped below the filesystem inode threshold  
15 Filesystem size incorrect in superblock

**# /nas/bin/nas\_event -l -f VMCAST**

id description  
1 Filesystem Copy over IP done  
2 Filesystem Copy over IP failed  
3 Volume Copy over IP done  
4 Volume Copy over IP failed  
5 Filesystem Copy over IP interrupted, unmount  
6 Filesystem Copy clean up done  
7 Filesystem Copy convert failed  
8 Filesystem Copy clean up failed  
9 Resync Copy failed. Full Copy started

**INTERPRETING NAS EVENT FACILITY, SEVERITY, & EVENT ID FROM SYS LOG:**

**# nas\_event -l -f CAM** →All Event IDs for the Facility CAM

id description  
0 CAM OK  
1 CAM I/O path has failed  
2 CAM I/O path is inaccessible  
3 CAM command timeout  
4 CAM hung I/O  
5 CAM internal error or bad request  
6 CAM I/O path is again normal  
7 CAM I/O error

**Event Severity Levels for Celerra:** Lower the number, the greater the Severity

0 Emergency  
1 Alert  
2 Critical  
3 Error  
4 Warning  
5 Notice  
6 Info  
7 Debug

**Sys log examples:**

Nov 3 15:38:14 2006 **CAM:3:1** Slot 2: 1162586223: WARNING: Scsi-48 hba FAILED! →Facility CAM, Severity 3, EventID 1  
**(IO path failure)**

Nov 3 15:53:14 2006 **CAM:3:7** Slot 2: 1162587155: I/O Error: c16t115 Irp 0xde185904 CamStatus 0x84 SessStatus 0x02 Sense 0x03/0x11/0x00 →Facility CAM, Severity 3, EventID 7 (IO Error)

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Nov 1 12:31:36 2006 **CAM:3:2** Slot 2: 1162402259: Warning: Scsi-16 hba is INACCESSIBLE. →Facility CAM, Severity 3,

**EventID 2 (Inaccessible path)**

**3:1 →Severity 3 Error, Event ID 1**

**3:7 →Severity 3 Error, Event ID 7, etc.**

## **DECIPHERING NAS EVENTS FROM THE MASTER EVENT FILE:**

**Note:** Typically, each NAS Event generation requires a facilitypolicy line and a disposition line

**# cat /nas/sys/nas\_eventlog.cfg**

# CAM

#

**facilitypolicy 26, 4 →Facility 26 is the ID assigned to CAM, as seen in nas\_event -l -f -i, 4 is the Event Severity**

disposition range=0-7 severity=0-4, logfile "/nas/log/sys\_log"

disposition **range=7-7 severity=0-3, callhome materials** →range=list of CAM events, 0-3=severity level, and ‘callhome materials’ is the action to take—in this case, only (1) CAM Event generates CallHome events for Event Severity 0-3, which is a CAM I/O Error

## **POSTEVENTS:**

**\$/nas/sbin/postevent**

postevent v0.1

usage: postevent <-f ev\_facility> <-s ev\_severity> <-i ev\_ID> [ev\_text]

Posts an ev\_ID with ev\_text to the nas\_eventlog facility as if it came from ev\_facility with ev\_severity. The nas\_eventlog will dispose of the event based on instructions in the file nas\_eventlog.cfg

-f Facility under which to log the event (e.g. Box Monitor = 131).

-i Event ID.

-s Severity to assign this event.

- 1 - Alert
- 2 - Critical
- 3 - Error
- 4 - Warning
- 5 - Notice
- 6 - Info
- 7 - Debug

## **EXAMPLE OF POSTING AN EVENT TO SYS LOG:**

**\$/nas/sbin/postevent -f 84 -s 4 -i 1 "Slot 2: 1099502624: Group:77\_CK2000433012710000 FSID:76 noconvert Copy done (t:11120531190117096)"**

**Note:** Obtain “1099502624” from date command: \$date +%

## **TESTING DEFINED CELERRA EVENTS & CALLHOMES:**

**# .server\_config server\_2 "logtest event facility=CAM severity=LOG\_EMERG eventid=7 message=toast"**

**Note:** If successful, will output the event in both sys\_log and server\_log, and if the event qualifies as a CallHome event [# nas\_event -list -a callhome], then the system will generate a CallHome.

Sys\_log → Nov 15 16:00:36 2006 CAM:0:1 Slot 2: 1163624407: toast

**# .server\_config server\_2 "logtest server facility=CAM severity=LOG\_EMERG eventid=7 message=toast"**

**Note:** If successful, this outputs only to the Server Log

2006-11-15 16:00:33: ADMIN: 4: Command succeeded: logtest server facility=CAM severity=LOG\_EMERG eventid=7 message=toast

## **POSSIBLE ACTIONS THAT CAN BE TAKEN:**

**# nas\_event -l -a -i**

action

udprpc

exec

terminate

trap

callhome

mail  
logfile

## **CELERRA NAS EVENTS: /nas/sys/nas\_eventlog.cfg [Caution: Do not edit this file!]**

DataMover & Control Station Internal operating events are logged in this file. Internal events contain the name of the Celerra facility, the "High Water mark" severity of the event [1-7], the Event ID number, short description of event, and System action being taken.

## **CONFIGURING ADDITIONAL CELERRA EVENTS:**

Celerra supports additional custom-defined Events. Events are added by creating a new event.cfg file and loading it to the existing event files. For example, an event.cfg file contains a line for "facility policy" that describes facility ID & severity level. Also contains lines for "disposition" describing Event ID ranges & actions to be taken.

### **EXAMPLE:**

Step 1. Create "event.cfg" file using appropriate format [see other examples below]

Step 2. Place this file in the /nas/site directory

**\$/nas/bin/nas\_event -L /nas/site/event.cfg**

Step 4. Verify that new Event file has been added: **\$/nas/bin/nas\_event -L -info**

### **Loaded config. files:**

1: /nas/sys/nas\_eventlog.cfg

2: /nas/http/webui/etc/web\_client\_eventlog.cfg

**Note:** #nas\_event -L -info reads file /nas/site/nas\_eventlog.cfg

Step 5. \$cat /nas/sys/nas\_eventlog.cfg [should see reference to new 'event.cfg' file]

Step 6. To Unload an Event File: **\$/nas/bin/nas\_event -Unload /nas/site/event.cfg**

## **CELERRA FAILS TO CALL HOME OR LOG ENTRIES IN SYS LOG:**

**PROBLEM:** nas\_eventlog.cfg file is no longer "loaded" or is corrupted. Without a properly loaded nas\_eventlog.cfg file, Celerra cannot post events to the sys\_log, which is used to trigger CallHome events.

**sys log:** no current entries being logged at all

### **/var/log/messages**

Feb 27 00:01:53 emc\_cs02 EMCServer: ReportEvent: daemon "Event Log" unexpectedly exited (status = 256)

Feb 27 00:02:26 emc\_cs02 EMCServer: ReportEvent: "Event Log" respawning too fast: disabled for 5 minutes

Feb 27 00:05:20 emc\_cs02 get\_datamover\_status: Data Mover server\_3 is not responding "messages" [readonly] 8216L, 855559C

### **Nas Event Log shows as not loaded:**

**\$ nas\_event -L -i**

Loaded config. files:

1: /nas/http/webui/etc/web\_client\_eventlog.cfg

### **Nas Event Log with corrupted entries:**

# cat nas\_eventlog.cfg (Shows corrupted entries)

1:export "/" anon=0 access=192.168.1.100:192.168.2.100:192.168.1.101:192.168.22:

/nas/http/webui/etc/web\_client\_eventlog.cfg::

## **RELOADING NAS EVENTLOG.CFG FILE:**

### **1. Unload all NAS Events that are listed in output of #nas\_event -L -i:**

**# nas\_event -U /nas/sys/nas\_eventlog.cfg**

Config file (/nas/sys/nas\_eventlog.cfg) not loaded

# nas\_event -U /nas/site/cwm\_notify.cfg

Config file (/nas/site/cwm\_notify.cfg) not loaded

# nas\_event -U /nas/http/webui/etc/web\_client\_eventlog.cfg

Config file (/nas/http/webui/etc/web\_client\_eventlog.cfg) not loaded

### **2. Verify that all files are unloaded:**

**# nas\_event -L -i**

Loaded config. files: <none>

### **3. Stop NAS Services:**

**4. Manually remount: /nas /nbsnas /nas/dos /nas/var**

**5. Edit the /nas/site/nas\_eventlog.cfg to add the correct entries back to the file:**

**# vi /nas/site/nas\_eventlog.cfg**

1:/nas/sys/nas\_eventlog.cfg:

2:/nas/http/webui/etc/web\_client\_eventlog.cfg:

3:/nas/site/cwm\_notify.cfg:

**6. Restart NAS Services & verify that nas\_mcd & box monitor restart**

**7. Verify NAS Event processes:**

**# nas\_event -L -i**

Loaded config. files:

- 1: /nas/sys/nas\_eventlog.cfg
- 2: /nas/http/webui/etc/web\_client\_eventlog.cfg
- 3: /nas/site/cwm\_notify.cfg

**\$ ps -eafl |grep -i nas\_event**

```
/nas/sbin/nas_eventcollector -I 10
040 S root 11054 10991 0 69 0 - 7728 nanosl Mar02 ? 00:00:00 -->Number of nas_eventcollector processes running
/nas/sbin/nas_eventcollector -I 10
100 S root 14136 10460 0 69 0 - 1453 do_pol Mar02 ? 00:00:00
/nas/sbin/nas_eventlog /nas nas_eventlog.cfg
040 S root 14138 14136 0 69 0 - 1453 do_pol Mar02 ? 00:00:00 -->Number of nas_eventlog.cfg processes running
/nas/sbin/nas_eventlog /nas nas_eventlog.cfg
140 S root 14141 14138 0 69 0 - 1453 rt_sig Mar02 ? 00:00:0
```

**CELERRA SNMP: /nas/sys/emccelerra.mib**

An "SNMP Community" is configured with the DataMover or Control Station as the "SNMP Agent" and "SNMP Managers" running on PC or Unix Workstations. SNMP Agent recognizes users by community name. Because SNMP communications are 'plain text', it's recommended that SNMP implementations be conducted on trusted networks. SNMP uses UDP ports 161/162.

**THREE TYPES OF SNMP MESSAGES:**

Get requests from SNMP manager for information from remote devices

Set request from SNMP manager to modify configuration of remote devices

Trap messages from SNMP agent located on remote devices for notification and monitoring of events

**TROUBLESHOOTING FILES & SNMPD SERVICE:****/nas/site/trap.config****/sbin/service --status-all |grep snmpd****# snmpwalk -Cc -c public server\_x****TRANSLATING EMCCELERRA MIB:****# snmptranslate -Tp -m ./emccelerra.mib**

```
+--emcCelerra#(0)

      |
      +-+R-- INTEGER celEventFacility(1)
      +-+R-- INTEGER celEventID(2)
      +-+R-- INTEGER celEventSeverity(3)
      +-+R-- String celEventDescr(4)
      Textual Convention: DisplayString
```

**CONTROL STATION EVENTS:** The Control Station SNMP Agent sends "traps" back to Management Station when predefined "events" occur. These events are logged in an "event log" in /nas/log/sys\_log. Additional "traps" can be defined in a customized version of the event log via a "trap.cfg" file, which supplements, but does not replace, the existing "nas\_eventlog.cfg" file.

**CONFIGURING SNMP EVENTS ON CONTROL STATION:****CreatingTraps and Eventlog Configuration Files**

Step 1. Set SNMP Manager: #vi /nas/site/trap.cfg and add following:

“snmpmanager 193.1.21.210 ; communityname comics”

Step 2. Set DNS configuration for Email: #vi /etc/resolv.conf

**nameserver 192.168.1.200**

**search example.com**

Step 3. Create Event Log & Assign Policy Statements: #vi /nas/site/new\_eventlog.cfg

**Caution:** Do not modify the original /nas/site/nas\_eventlog.cfg file

Step 4. Load Eventlog File : #nas\_event -L /nas/site/new\_eventlog.cfg

## **CONFIGURING CELERRA FOR SNMP TRAPS FOR FILESYSTEM ISSUES:**

1. Set the FileSystem threshold on the Data Mover by adding the following to /nas/server/slot\_x/param and rebooting the Server:

**param file fsSizeThreshold=80** [notify at 80% full]

2. Create a new config file called /nas/site/fs\_eventlog.cfg that contains the following:

**# vi /nas/site/fs\_eventlog.cfg**

#CFS High Water Mark Event Control

facilitypolicy 27, 7

disposition range=1-1, mail "root@Celerra\_CS0"

disposition range=1-1, trap "/nas/site/trap.cfg 11"

**Note :** 27 = CFS facility, 7 = Event severity code, 1-1 means events 1 thru 1, equating to ‘crossed fs threshold’, 11 is the newly assigned trap number from the emccelerra.mib file, and “root@Celerra\_CS0” is an example of an email address for notification.

3. Edit the /etc/resolv.conf file so as to setup the CS DNS Client and allow for email notification:

domain mydomain.com

search localdomain

nameserver 192.10.20.10

4. Edit /nas/site/trap.cfg so that it contains the following configuration setup:

snmpmanager 192.168.1.100; communityname public

**Note:** IP address of SNMP manager that will receive traps; “public” = community name used for authenticating with SNMP Mgr

5. Modify the Celerra MIB by editing the /nas/sys/emccelerra.mib file and adding to the bottom of the file with the following syntax, first checking to see what the next available trap number is--in this case, 11 is the next trap number to be assigned:

celCFS TRAP-TYPE

ENTERPRISE emcCelerra

VARIABLES { celEvent }

DESCRIPTION

“Trap message will be sent when a file system exceeds the threshold.”

::= 11

6. Using HP OpenView, or some other SNMP Management Program, recompile the Celerra MIB by choosing “Options -> Load/Unload MIBs:SNMP”

7. Ensure Control Station Hostname and email Domain name are correctly registered in the /etc/hosts file:

# Do not remove the following line, or various programs

# that require network functionality will fail.

127.0.0.1 localhost.localdomain localhost

172.24.96.82 Celerra\_CS0 Celerra\_CS0.mydomain.com

**Note:** mydomain.com is the domain that has the mail server--substitute with your domain information

8. Load the new config file:

**# /nas/bin/nas\_event -L /nas/site/fs\_eventlog.cfg**

9. Verify:

**# nas\_event -L -i**

**# nas\_event -l -a mail**

**# nas\_event -l -a trap**

10. Test the new Trap:

**# /nas/sbin/nas\_snmptrap /nas/site/trap.cfg -m /nas/sys/emccelerra.mib -f 10 -f 2 -i 1 -s 4 -d**

**# /nas/sbin/nas\_snmptrap /nas/site/public.cfg -m /nas/sys/emccelerra.mib -r 10 -f 131 -i 8 -s "test trap fan 1 error"**

11.Add cron tab for snmp\_trap\_full\_fs

#crontab -l >nas.cron

#vi nas.cron

5,10,15,20,25\*\*\*\* /home/nasadmin/SNMP/snmp\_trap\_full\_fs 1>/dev/null 2>&1

30,35,40,45,50,55\*\*\*\* /home/nasadmin/SNMP/snmp\_trap\_full\_fs 1>/dev/null 2>&1

## CONFIGURING TRAP FOR FILESYSTEM USAGE THRESHOLD:

- ```
1. Specifying recipient of snmp Trap: #cat /nas/site/trap.cfg  
snmpmanager localhost; communityname public  
2. Start Trap Daemon on CS0: #!/usr/sbin/snmptrapd -P &  
3. Shell Script for >than 90% Full FS:  
#!/bin/sh  
SERVER=server_2  
FILESYSTEM=fs02  
HWM=90  
CAP1=`/nas/bin/server_df $SERVER | egrep $FILESYSTEM | awk '{print $5}'`  
CAP2=`echo $CAP1 | sed 's/%//'`  
MESSAGE="Filesystem $FILESYSTEM on $SERVER exceeds $HWM, totals $CAP1"  
if [ $CAP2 -ge $HWM ]; then  
/nas/sbin/nas_snmptrap /nas/site/trap.cfg -m /nas/sys/emapcelerra.mib -r 4444 -i 5555 -s 6666 -d capacity_of_fs02_is_over_$CAP1  
4. When triggered, Filesystem event will be sent to snmptrapd daemon
```

## **VIEWING SNMP TRAP EVENTS:**

**\$ nas event -l -a trap**

Trap messages consist of the Name of the Celerra facility for the 'event'; the High Water Mark event severity, from 1-7; the Event ID number; Description of Event; and System-defined action to be taken [defined in \$NAS\_DB/site/trap.cfg]

**SNMP DIRECTORIES:** /nas/site      /nas/sys

/nas/site [trap.cfg and eventlog.cfg files] /nas/sys [trap.cfg; nas eventlist; nas eventlog.cfg--events; emccelerra.mib--MIBs]

## **ISSUING TEST SNMP TRAPS:**

```
#/nas/sbin/nas_snmptrap /nas/site/2031806010public.cfg -m /nas/sys/emccelerra.mib -r 10 -f 131 -i 8  
-s "emc test trap for fan 1 error"
```

#### **INFORMATION FOR 5.5 and 5.6 WHEN TESTING SNMP TRAPS AB109619:**

1. Kill the default UPS snmptrap service  
**# killall snmptrapd**
  2. Perform SNMP Trap testing
  3. Reboot CS after testing to restore UPS snmptrap service, or issue following:  
**# /usr/sbin/snmptrapd -c /nas/sys/snmptrapd.conf -p 162 -u /var/run/snmptrapd.pid >/dev/null 2>&1 &**

#### **CELLERRA SNMP: Only MIB II supported**

## SNMP CONFIGURATION:

**\$ server snmp server 4 -community**

server 2 : public [Default com

**SNMP CONTACT NAME:**

---

```
$server_snmp server_4 -syscom
```

## **SNMP AGENT LOCATION:**

\$Server\_snmp server\_4 -location location name

## **SNMP EVENTS & TRAPS:** /nas/site/trap.cfg

Two ‘facilities’ issues traps: **Box Monitor 131** & **Master Control Daemon 1**

Other facilities also exist, such as Call Home, D

- SEVEN PREDEFINED CELERRA TRAPS**

  - 1. DataMover Reboot
  - 2. Missing Control Station heartbeat/serious fault
  - 3. Celerra Hardware failure
  - 4. Stale Reason Code
  - 5. DataMover panic
  - 6. Failure to ping both DM internal interfaces
  - 7. Automated Archive Facility Error

**Note:** In the case that one of these (7) predefined "events" occur, a trap message will be sent that includes the Facility Name, Event ID, Severity, and Text description of event.

## **CELERRA EVENTLOG CONFIG FILE:**

**/nas/sys/nas\_eventlog.cfg** [Celerra "binding" file that correlates internal events to the predefined system traps]

**Warning:** Never Edit this file if adding new Events to Trap as this file controls Celerra CallHome Events!!!]

## **CHECKING FACILITIES AND TRAPS:**

### **LISTING SNMP FACILITIES:**

**\$nas\_event -l -f -i**

**\$nas\_event -l -f UFS**

### **USE FOLLOWING KEYWORD TO FIND EVENTS FOR QUOTA, FILESYSTEM, etc.:**

**\$nas\_event -l -k quota**

```
facility id description
USRMAP 7 Usermapper filesystem quota exceeded
UFS 4 Soft quota (warning limit) crossed
UFS 5 Hard quota limit reached/exceeded
```

**# nas\_event -list -k filesystem**

```
facility id description
USRMAP 7 Usermapper filesystem quota exceeded
SVFS 3 Source filesystem restore done
UFS 3 I18N - Recovery failed, filesystem not mounted
UFS 7 Skip auto fsck for corrupted filesystem at mount
UFS 11 Crossed the root filesystem inode threshold
UFS 12 Crossed the filesystem inode threshold
UFS 13 Dropped below the root filesystem inode threshold
UFS 14 Dropped below the filesystem inode threshold
NDMP 1 Create a checkpoint for the backup filesystem and mount it
NDMP 2 Unmount the checkpoint for the backup filesystem and delete it
CFS 1 Crossed the filesystem size threshold
CFS 3 Dropped below the filesystem size threshold
CFS 4 Crossed the root filesystem size threshold
CFS 5 Dropped below the root filesystem size threshold
```

### **LISTING SNMP TRAPS:**

**\$nas\_event -l -a trap**

### **DETERMINING WHAT EVENT.CFG FILES ARE LOADED ON CS0:**

**#nas\_event -L -info**

Loaded config. files:

- 1: /nas/sys/nas\_eventlog.cfg
- 2: /nas/http/webui/etc/web\_client\_eventlog.cfg
- 3: /nas/site/mail\_events.cfg

### **Seven Default System Actions:**

|           |                               |                        |
|-----------|-------------------------------|------------------------|
| SNMP Trap | Sent to SNMP Manager          | \$NAS_DB/site/trap.cfg |
| UDPRPC    | RPC message to specified host |                        |
| Exec      | Execute a procedure           |                        |
| Terminate | Shutdown process              |                        |
| Callhome  | Call Home to EMC              |                        |
| Mail      | Send email                    |                        |
| LogFile   | Log an entry                  |                        |

**Action Listings:** #nas\_event -l -a -i      #nas\_event -l -a callhome      #nas\_event -l -f BoxMonitor [MasterControl]

### **SAMPLE TRAP.CFG FILE:**

```
#snmp trap configuration file
#snmpmanager 128.154.11.20 ; communityname public
#snmpmanager host1 ; communityname public
```

### **SAMPLE NASEVENTLOG.CFG FILE:**

```
# Test configuration file
#
defaultpolicy 7
```

```
disposition , logfile "/nas/log/sys_log"
facilitypolicy 0x10, 3
    disposition range=1-100 severity=2-2, mail "user@host"
    disposition range=50-100 threshold=6 resetafter=20, logfile "/nas/lo
g/sys_log"
        disposition range=5-5, callhome immediate
        disposition range=5-5, trap "/nas/site/trap.cfg 2"
facilitypolicy 17, 4
    disposition range=1-5, terminate
    disposition range=6-100 threshold=4 rearm=2, exec "/usr/bin/xxx"
    disposition range=80-99, udprpc "1,706001,1@remote.domain.com"
#
# For now all Dart log messages use facility 128
#
facilitypolicy 128, 4
    disposition , logfile "/nas/log/sys_log"
        disposition , mail "user@remote"
        disposition , udprpc "1,706001,1@remote"
#
# Master Control
#
facilitypolicy 129, 4
    disposition range=0-1000, logfile "/nas/log/sys_log"
    disposition range=6-10, callhome immediate
    disposition range=6-7, trap "/nas/site/trap.cfg 2"
#
# BoxMonitor
#
facilitypolicy 131, 7
    disposition range=0-1000 , logfile "/nas/log/sys_log"

    disposition range=1-1, trap "/nas/site/trap.cfg 2"
    disposition range=3-15, callhome immediate
-----abridged-----
```

## **CREATING ADDITIONAL CELERRA EVENTS:**

Step 1. Copy the /nas/sys/nas\_eventlog.cfg to /nas/site/new\_eventlog.cfg

Step 2. Edit file to add new traps but leave facilitypolicy and disposition

Step 3. Load new file: **\$/nas\_event -L /nas/site/new\_eventlog.cfg**

## **LINUX SNMPWALK:** [Other Unix hosts use 'getmib']

/usr/bin/snmpwalk -V UCD-snmp version: 4.1.1 -H config files -h help files  
SNMP GET NEXTS requests are used to query community tree for information.

## **OUTPUTTING DATA MOVER OIDs:**

```
$ /usr/bin/snmpwalk -Cc server_2 public
$ /usr/bin/snmpwalk -Cc server_2 public at
$ /usr/bin/snmpwalk -Cc server_2 public tcp
$ /usr/bin/snmpwalk -Cc server_2 public ip
# snmpwalk -v 1 -c public server_2 system
```

SNMPv2-MIB::sysDescr.0 = STRING: Product: EMC Celerra File Server Project: SNAS Version: T5.6.37.5

SNMPv2-MIB::sysObjectID.0 = OID: SNMPv2-SMI::enterprises.1139

SNMPv2-MIB::sysUpTime.0 = Timeticks: (172213913) 19 days, 22:22:19.13

SNMPv2-MIB::sysContact.0 = STRING: nasadmin

SNMPv2-MIB::sysName.0 = STRING: server\_2

SNMPv2-MIB::sysLocation.0 = STRING: here

SNMPv2-MIB::sysServices.0 = INTEGER: 72

## **USING SNMPWALK ON LINUX:**

```
# /usr/bin/snmpwalk -Cc -c public server_5 |grep ifMtu
```

interfaces.ifTable.ifEntry.ifMtu.1 = 9000

```
# /usr/bin/snmpwalk -t 10 192.168.10.10 public [Where 10 is timeout value of command]
```

**OTHER DIRECTORIES:** /usr/share/snmp/snmpd.conf lsnmpd.local.conf | mibs [list of all mibs]

## **SNMPD DAEMON:**

The snmpd daemon binds to a port, receives SNMP Management request, collects requested information, performs requested operation, and returns to requestor.

## **SNMP TRAP DAEMON:**

**Note:** Works as an SNMP application that receives and logs snmp trap messages that are sent to ‘SNMP-TRAP’ Port 162

### **STARTING SNMPTRAPD:**

**#/usr/sbin/snmptrapd -P &**

```
#ps -ef |grep -i snmp
root 1396 1 0 Dec24 ? 00:00:00 /usr/sbin/snmpd -s -l /dev/null
root 15187 15149 0 18:26 pts/0 00:00:00 /usr/sbin/snmptrapd -P
```

### **TRAPPING CONTROL STATION SNMP EVENTS TO A SPECIFIC LOG or MESSAGES FILE:**

**# /usr/sbin/snmptrapd -P >/home/nasadmin/snmp.log 2>&1 &**

**# /usr/sbin/snmptrapd -P -o custom\_events\_messages &**

### **DEFAULT SNMP PORT FOR AGENT:** Port=161 for Agent

**Verify Port: # netstat -a -p |grep snmp**

**Comment:** SNMP is one of the basis of many Celerra Commands, such as "nfsstat", "netstat", etc

### **TURNING ON SNMP:**

**#/nas/sbin/chkconfig snmpd on** [Configures SNMP daemon to start on bootup]

**#/etc/rc.d/init.d/snmpd start** [or #/sbin/service snmpd start]

### **CONFIGURING NAS EVENTS ON LINUX:**

1. Edit the /nas/site/trap.cfg file create an entry similar to the one below:

**snmpmanager 192.168.4.253 ; communityname public**

2. Turn on the SNMP daemon on the control station (as root), the daemon will start by default at boot up.

**/sbin/chkconfig snmp on**

3. Verify which snmp traps are set for nas\_events, (most events that would be desirable are set by default)

**nas\_event -l -a trap**

4. Use the following command (as root) to start the snmpd:

**/etc/rc.d/init.d/snmpd start**

**NOTE:** It is possible to use the control station to verify operation by setting the control station to be the snmp manager in the trap.cfg file, and then starting another process to catch the traps. By issuing the following command it is possible to log all snmp activity to a log file, provided the control station is identified in the trap.cfg file as the SNMP manager. This should only be used to verify functionality.    /usr/sbin/snmptrapd -P >/home/nasadmin/snmp.log 2>&1 &

### **NAS EVENT LOGGING PROCESSES:** NAS 5.2

NAS\_MCD controls the NAS Event Collector and Logging mechanism that generates messages to sys\_log and nas\_eventlog:

**/nas/sys/nas\_mcd.cfg**

**daemon "Event Log"**

```
executable  "/nas/sbin/nas_eventlog"
optional    no
autorestart yes
ioaccess   no
cmdline    "/nas/nas_eventlog.cfg"
eventlogger yes
```

**daemon "Event Collector"**

```
executable  "/nas/sbin/nas_eventcollector"
optional    no
autorestart yes
ioaccess   no
cmdline    "-I 10"
```

**#/nas/sbin/nas\_eventcollector** runs as a daemon that catches events and posts to /nas/log/sys\_log. There is a problem where a cloned eventcollector process may die without the parent process recognizing a problem, and leads to zombie status of the eventcollector. Proper operation is that parent nas\_eventcollector should recognize a problem and then kill off all processes, at which point the NAS\_MCD will restart the processes cleanly. See AR47104. End result of this problem is that events may not get logged, and processes such as Checkpoint SavVol extensions, may fail as well.

**# ps -axuww |grep nas\_event**

```
root 1833 0.0 0.1 5924 892 ? S Dec22 0:00 /nas/sbin/nas_eventlog /nas nas_eventlog.cfg
root 1834 0.0 0.1 5924 892 ? S Dec22 0:00 /nas/sbin/nas_eventlog /nas nas_eventlog.cfg
root 1835 0.0 0.1 5924 892 ? S Dec22 0:39 /nas/sbin/nas_eventlog /nas nas_eventlog.cfg
root 1836 0.0 0.1 5924 892 ? S Dec22 0:00 /nas/sbin/nas_eventlog /nas nas_eventlog.cfg
root 1838 0.0 0.1 31948 936 ? S Dec22 0:00 /nas/sbin/nas_eventcollector -I 10
root 1841 0.0 0.1 31948 936 ? S Dec22 0:00 /nas/sbin/nas_eventcollector -I 10
# ls -la /proc/1833
lrwxrwxrwx 1 root root 0 Dec 30 11:07 exe -> /nas/sbin/nas_eventlog
```

## **CONFIGURING SNMP MAIL EVENTS ON CELERRA:**

Step 1. Create Map file called “mail\_events.cfg” and place in /nas/site directory

### **Contents of Mail Events Map File:**

```
#  
facilitypolicy 129, 4  
    disposition range=6-7, mail "nasadmin@sun1"  
# BoxMonitor  
#  
facilitypolicy 131, 7  
    disposition range=1-1, mail "nasadmin@sun1"  
    disposition range=3-15, mail "nasadmin@sun1"  
    disposition range=18-21, mail "nasadmin@sun1"  
    disposition range=38-39, mail "nasadmin@sun1"  
    disposition range=43-43, mail "nasadmin@sun1"  
    disposition range=57-58, mail "nasadmin@sun1"  
    disposition range=60-60, mail "nasadmin@sun1"  
    disposition range=100-315, mail "nasadmin@sun1"
```

Step 2. Load Map file to control station:

**\$/nas/bin/nas\_event -L /nas/site/mail\_events.cfg**

EventLog: will load /nas/site/mail\_events.cfg...done

Step 3. The following mail message was received when a test datamover panic was done:

**\$ mail**

```
From root@jessica Mon Mar 20 16:57:22 2000
From: root@jessica
To: nasadmin@sun1
Date: Mon, 20 Mar 2000 21:58 GMT
Subject: EMCServer Event
Message-ID: <38d69f220.e64@jessica>
Content-Length: 58
Mar 20 16:58:57 2000 BoxMonitor:2:302 Slot 2 has panicked
```

Step 4. Issue the following command to determine what events emails will be sent for:

**#nas\_event -l -a mail**

```
facility id description
AAF 4 Not much tapes left available
MasterControl 6 unexpected daemon exit
MasterControl 7 Control Station heartbeat missing
BoxMonitor 1 EPP did not initialize
```

Step 5. To unload the current email events configuration so that changes can be made:

**#/nas/bin/nas\_event -U /nas/site/mail\_events.cfg**

## **MODIFYING CELERRA MIBs FOR NEW TRAP EVENTS:**

1. #vi /nas/sys/emccelerra.mib & add new Trap Event at bottom of file, using the next available Trap number:

```
celCFS TRAP-TYPE
ENTERPRISE emcCelerra
VARIABLES { celEvent }
DESCRIPTION
    "Trap message will be sent when a file system exceeds the threshold."
 ::= 11
```

**Note:** Once modified, the “emccelerra.mib” file needs to be recompiled into the SNMP Manager Program

## **TROUBLESHOOTING SNMP/CELERRA NAS EVENTS:**

1. Is Event File loaded? \$nas\_event -L -info
  2. View Server Log. If Event not recorded, event is not being issued.
  3. View Eventlog.cfg to ensure that Facility, Severity, Disposition Range, Severity Range, Trap numbers are setup correctly
  4. Verify IP Address & Community name of trap.cfg and ping IP Address
  5. Conduct Mail Test on CS0: #mail -s test "joeblow@emc.com"
  6. Manually initiate trap: #/nas/sbin/nas\_snmptrap /nas/site/trap.cfg -m /nas/sys/emccelerra.mib -r 8 -d test
- Note:** Would need to check on SNMP Manager (HP OpenView, etc) to see if Trap is received
7. Manually initiate Trap to CS0: #/usr/sbin/snmptrapd -P
- Note:** Requires IP address of CS0 in Trap.cfg file and should output to screen
8. I18N Events are not yet supported
  9. SNMP Events are usually a 1-time notification, but with NAS 4.x and above, the following Events are now routinely duplicated:  
Checkpoint; File System Full; Soft/Hard Quota
  10. Following is an Example of Server Log Duplicate Event Entries being Logged:  
2002-11-09 23:11:29: LIB: 6: last message repeated 1 times

## **MAX SIZE OF SNMP QUERY FOR DART IS 494 BYTES:**

If data mover receives SNMP queries > than 494 bytes in size, following message is logged:

LOG\_SYSLOG: 4: SNMP AGENT: Too big message – discarded

**Note:** NAS 5.0.9.1

## **SNMP INQUIRIES CREATE ANNOYING SYS LOG/SERVER LOG ENTRIES:**

Modprobe: Can't locate module block-major-22

**Solution:** Vi edit /etc/modules.conf and insert following entry for each offending module

**alias block-major-22 off**

## **DATA MOVER FAILOVER:**

### **DATA MOVER HARDWARE FAILOVER RULES:**

- Standby Server should contain same amount of memory and CPU as Primary [SnapSure, Celerra Replicator are memory hogs]
- 507 DM can only failover to another 507, 510, or 514, provided network interface rules are met
- 510 DM can only failover to another 510 or 514, provided network interface rules are met
- 514 DM can only failover to another 514, provided network interface rules are met

#### **Interface Rules:**

- Primary & Standby Servers must share a similar “ana”, “ace”, or “cge” interface in order to failover
- Can failover from copper ana interface to Standby with copper cge interface if cge is set to auto
- Copper cannot be used to failover to Fibre and vice versa

#### **Storage Rules:**

- Fibre SW can be replaced by Fibre SW or SCSI and vice versa
- Fibre AL can only failover to another Fibre AL system [NS600G]
- Standby Server must be able to probe and see the same devices that the Primary Server sees

#### **Tape Rules:**

- NDMP backups from a Standby Server are not supported
- 507 DM uses one FC-SW HBA for disks and a SCSI HBA for tape backup [not to be used for Disk storage]
- 507 DM does not support dual FC-SW HBA's
- 510 & 514 with dual FC-SW HBA's, the 2<sup>nd</sup> HBA can only be used for connecting to tape devices via Switch

#### **Common Error for this: "hardware components mismatch"**

- DataMover cannot Failover or Assume duties of a ‘failed’ server if Control Station is not operational
- Prior to “Failing Back”, ensure that the original server is up & running at Status 5 & not in a reset 0 state--reboot original server & check for Status 5

## **DATA MOVER STATUS & STANDBY SERVERS:**

### **CREATING STANDBY SERVER 3 for PRIMARY SERVER 2:**

**\$ server\_standby server\_2 -c mover=server\_3 -policy auto**

server\_2 : server\_3 is rebooting as standby

**# nas\_server -l**

|    |      |      |      |         |          |      |
|----|------|------|------|---------|----------|------|
| id | type | acl  | slot | groupID | state    | name |
| 1  | 1    | 1000 | 2    | 0       | server_2 |      |

2 4 1000 3 0 server\_3

**Note:** Type 1 indicates a Primary NAS Server, Type 4 indicates a Standby Server

**EXAMPLE: FAILING OVER PRIMARY (server 2) TO ITS STANDBY SERVER (server 3):**

**# server\_standby server\_2 -a mover**

server\_2 : operation in progress (not interruptible).....

server\_2 : going offline

server\_3 : going active

replace in progress ...done

failover activity complete

commit in progress (not interruptible)...done

server\_2 : renamed as server\_2.faulted.server\_3

server\_3 : renamed as server\_2

**# nas\_server -l**

id type acl slot groupID state name

1 4 1000 2 2 server\_2.faulted.server\_3

2 1 1000 3 0 server\_2

**Note:** nas\_server output shows if Data Movers are failed over to Standby server. In this example, the Primary Server\_2, who's normal slot is slot\_2, is “faulted” and failed over to its Standby server in slot\_3. Keep in mind that regular commands issued to the server will still produce the correct output, but that the Data Mover’s actual database is located in slot\_3 while failed over.

**DELETING STANDBY RELATIONSHIP & CREATING PRIMARY NAS SERVER:**

**# nas\_server -l**

id type acl slot groupID state name

1 1 1000 2 0 server\_2

2 4 1000 3 0 server\_3

**# server\_standby server\_2 -d mover** [removes server\_3’s Standby relationship from server\_2]

server\_2 : done

**# server\_setup server\_3 -type nas**

server\_3 : is rebooting as type nas

**Note:** You cannot use setup\_slot -init to convert a Standby Server to a Primary. Only server\_setup can do this.

**# nas\_server -l**

id type acl slot groupID state name

1 1 1000 2 0 server\_2

2 1 1000 3 0 server\_3

**\$ nas\_server -a -i** (shows data mover type, nas or standby; shows standby relationships; shows actual server status)

id = 1

name = server\_2

acl = 1000, owner=nasadmin, ID=201

type = nas

slot = 2

member\_of =

standby = server\_3, policy=auto

status :

defined = enabled

actual = online, active

id = 2

name = server\_3

acl = 1000, owner=nasadmin, ID=201

type = standby

slot = 3

member\_of =

standbyfor= server\_2

status :

defined = enabled

actual = online, ready

**\$ server\_standby ALL -v mover** (shows if standby relationship has been defined)

server\_2 : ok

server\_3 : ok

**# server\_standby ALL -v mover** (No standby relationships defined)

server\_2 :

Error 4003: server\_2 : standby is not configured

server\_3 :

Error 4003: server\_3 : standby is not configured

## **DATA MOVER FAILOVER MECHANISM:**

When data mover fails over to standby, the Standby Server inherits the MAC addresses, IP addresses, and any physical interface settings that are set, such as speed, duplex, link negotiation, etc. [Configure Switch ports of Standby with same settings as Primary]. After failing over to Standby, Standby sends one gratuitous ARP broadcast so that the Switch can learn the new location of the MAC address, thereby updating its CAM Tables with the new source MAC address, mod/port number, and VLAN number. This also serves to update client ARP tables on local VLANs.

## **CHANGING DATA MOVER FAILOVER TIMEOUT VALUE:**

# cat /nas/server/slot\_2/bmparms

ScanInterval:5: →Scan Interval is number of secs between checks by Box Monitor of DM progress during failover

StaleReasonThresh:49: →Number of times Box Monitor will use the ScanInterval to check failover progress before aborting

#FailedPingThresh:10:

#wait\_ready:162:

**Note:** Change “StaleReasonThresh” value to a max. of 120, which translates as  $120 * 5 = 600\text{secs} / 60 = 10\text{ minutes}$ . This value dictates on how long Control Station will wait for Data Mover to failover before aborting the failover. Please note that after any changes are made to the bmparms file, stop and restart Box Monitor to read-in the new changes. Also, setup\_slot and NAS Upgrades may change the file settings back to system defaults!

## **FAILOVER ACTIONS DURING SERVER PANICS:**

→Current code requires that panic dump completes before restarting services on failing over to Standby Server

→Cognac will allow failover to begin after panic handlers have written recovery data to disk, & compress dumps to disk

1. DART panic, panic handlers run, dump written

2. CS Box Monitor kicks off recover\_slot after panic, waits for handlers or dump complete, forks off to slot\_recover

3. Slot\_recover changes faulted DM boot.cfg to minconfig, feeds DM config to standby over internal network, changes target Standby boot.cfg to primary, reboots faulted slot after dump reported complete

## **NAS 5.0 & STANDBY DATAMOVERS:**

A Primary Datamover can now have more than (1) Standby Datamover to fail over to

\$server\_standby server\_2 -c mover=server\_4 -policy auto

\$server\_standby server\_2 -c mover=server\_8 -policy auto

## **Data Mover Hardware Prerequisites for Standby Configuration:**

Must have same Network configuration/setup as Primary

Must use same NIC & SCSI Hardware

## **ESTABLISHING STANDBY SERVER & FAILOVER RELATIONSHIP:**

**Rules:** Recommended 3:1 Data Mover relationship for failover [Failover Policies: auto/manual/retry]

*Failing back to original Primary Data Mover slot requires manual step by design!*

Step 1. Unexport & Unmount All File Systems from DataMover to be used as Standby

Step 2. Create Standby Server:

\$server\_standby server\_2 -create mover=server\_3 -policy auto [Standby server will reboot]

**Note:** First server in command is the “Primary”, second server is the “Standby” unit

**Verify Status:** \$nas\_server -l [Server\_3 now listed as type “4”]      \$nas\_server -i server\_2

## **Data Mover Failover Policies in /nas/server/server\_setup file:**

1=Manual failover (Default Celerra policy; all RDF setups are manual failover policy)

2=Retry (Panic will cause reboot to clear condition, if unsuccessful, failover occurs)

3=Auto (Data Mover will failover automatically after panicking)

## **DATAMOVER FAILOVER POLICIES:**

Auto →Primary Server fails over to designated Standby immediately & automatically

Manual (default) →Control Station reboots faulted Datamover to attempt recovery, but does not initiate failover to Standby

Retry →Control Station reboots primary DM once, then fails it over if still in faulted condition

**Note:** When setting up Failover Policies, keep in mind that “manual” is the default--make sure to specify “auto” instead

### **Local Celerra with (1) Primary & (1) Standby Server defined (NO RDF relationships):**

```
# nas_server -l
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 4 1000 3 0 server_3
```

**# cat /nas/server/server\_setup**

1:2:1:3:: -->Fields defined, from Left-to-Right

**Primary\_id: Backup\_id: Component: Policy: Slot#, ACL, State:**

Server\_2 : Server\_3 : constant value : Failover Policy : RDF relationship as slot\_x, ACL, State

**Note:** This file is empty if there are no Standby Server relationships, either local or RDF, defined

### **Local Celerra with (1) Primary and (1) Standby Server, but NO Standby relationships defined:**

```
# nas_server -l
```

```
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 4 1000 3 0 server_3
```

**# cat /nas/server/server\_setup** -->No entries since no Standby relationships have been defined

### **Local Celerra with (1) Primary and (1) Standby Server defined with Manual Failover Policy:**

```
# nas_server -l
```

```
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 4 1000 3 0 server_3
```

**# cat /nas/server/server\_setup**

1:2:1:1::

### **Local Celerra with both Data Movers defined as Primaries, NO Standbys or RDF Standbys:**

```
# nas_server -l
```

```
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 1 1000 3 0 server_3
```

**# cat /nas/server/server\_setup** -->File is empty because there are no local or RDF standbys defined

**Active/Active MirrorView Disaster Recovery:** No local Standby servers. Server\_2 Local Primary, with Server\_2 Remote RDF Standby. Server\_3 Remote Primary, with Server\_3 Local RDF Standby:

Local Celerra-->**# nas\_server -l**

```
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 4 2000 3 0 server_3
```

**# cat /nas/server/server\_setup**

1:0:1:1:2,0,0,:;

Remote Celerra-->**# nas\_server -l**

```
id type acl slot groupID state name
1 4 2000 2 0 server_2
2 1 1000 3 0 server_3
```

**# cat /nas/server/server\_setup**

2:0:1:1:3,0,0,:;

### **Active/Passive MirrorView Disaster Recovery:**

Local Active side with Server\_2 Primary & local Standby defined as Server\_3. Local Standby Server\_3 has RDF failover relationship on slot\_3 on the Remote Celerra & Local Primary Server\_2 has RDF Standby (failover) relationship on slot\_2 on Remote Celerra

**# nas\_server -l (Active Source side)**

```
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 4 1000 3 0 server_3
```

**# cat /nas/server/server\_setup**

2:0:1:1:3,1000,0,: -->Server\_3:no local backup:1=n/a:1=manual failover:3,1000,0=RDF Stdby slot\_3, ACL 1000, State 0

1:2:1:3:2,1000,0,: -->Server\_2:local backup server\_3:1=n/a:3=auto failover:2,1000,0=RDF Stdby slot\_2, ACL 1000 State 0

### **Fields Defined:**

Primary\_id: Backup\_id: Component n/a: Failover Policy: RDF Standby Slot#, ACL, State:

**# nas\_server -l (Passive Target side)**

```
id type acl slot groupID state name
1 4 1000 2 0 server_2
```

```
2   4  1000 3      0  server_3
# cat server_setup
1:2:1:3:: -->Server_2:local backup server_3:1=n/a:3=auto failover:no RDF relationships defined on this side
-->Server_3 not referenced since it has no local Standby or RDF relationship defined
```

## **CAUSES OF DATA MOVER FAILOVER:**

1. Failure of both internal NIC's [results in failed to ping error & failover]
2. Failure of Power Supply
3. SW, Panic or GP Exception
4. Memory Error
5. Loss of all storage connectivity
6. HW failure

**Note:** Current NAS codes [4.2.x & 5.1.x] behave as follows: If either path is lost to Symm, HBA will failover to alternate controller & port. If both cables are detached [both paths lost], then data mover will failover to Standby server.

## **TESTING DATA MOVER FAILOVER:**

Step 1: Failover Test: **\$server\_standby server\_2 -activate mover** [\$nas\_server -i]

Step 2: Failback Test: **\$server\_standby server\_2 -restore mover**

**Note:** Standby server assumes Primary's IP Address; MAC; Hostname; FS Configuration and Mounts. Can failback using CLI command or using Celerra Manager "Restore" button

## **DELETING A STANDBY SERVER & CREATING AS A NEW PRIMARY SERVER:**

Step 1. Delete Standby Status of Server\_5 for Server\_2:

**\$server\_standby server\_2 -delete mover**

Step 2. Make Server\_5 a Primary:

**\$server\_setup server\_5 -type nas**

**Note:** Data Mover should reboot automatically to build its Primary database, but reboot manually if need be.

## **EXAMPLE OF CHANGING SERVER FROM PRIMARY TO STANDBY:**

**# /nas/bin/server\_setup server\_5 -type standby**

server\_5 : is rebooting as type standby

## **SECONDARY CONTROL STATIONS:**

**\$/nas/sbin/getreason** Primary = slot\_0, status 10 Backup = slot\_1, status 11

**\$/nasmcd/getreason** [Running getreason from a Secondary Control Station]

**Note:** Each CS has its own O/S, but only one CS can mount the /nas & /nas/dos FileSystems at a time—first CS that boots will take over as Primary & is determined by the MCD daemon, which runs on both Control Stations. MCD (Master Control Daemon) runs on both CS but Box Monitor runs only on the Primary CS, as does nas\_eventlog, emcnas, etc. CS1 requires its own Modem, Phoneline, and Cable. Hourly NAS Database backups are written to /home/nasadmin.

**Scenario:** nas\_mcd listens for heartbeat of CS0. If no heartbeat registered, fails over to CS1 and initiates Call Home.

## **CONDUCTING MANUAL CONTROL STATION FAILOVER FOR LINUX:**

### **FAILING OVER FROM PRIMARY CS TO STANDY CS:**

**# /nasmcd/sbin/cs\_standby -failover**

**Note:** Issue command on whichever CS is the Primary to failover to the alternate CS—will reboot system you are on, to failover

### **FAILING OVER FROM PRIMARY CS0 to CS1:**

**# /nasmcd/sbin/cs\_standby -takeover**

**Note:** Issue this command on the Standby Control Station—unexports filesystems from Primary CS, mounts, and reboots the other Control Station as a Secondary. i.e., “takes over” from Primary to become the new Primary CS.

## **RESETTING CONTROL STATION:**

**# /nasmcd/sbin/t2reset pwron -s 1 | 0**

## **CONFIGURING CONTROL STATION TIME ZONE, DATE, & HW CLOCK NAS 5.6**

### **CHANGING CONTROL STATION TIME ZONE 5.6 (see emc214902):**

**Note:** The /usr/sbin/timeconfig utility does not exist in 5.6

**1. Verify current settings:**

**# date**

Tue May 5 08:14:20 EDT 2009

**# ls -la /etc/localtime**

lrwxrwxrwx 1 root root 36 Mar 20 09:57 /etc/localtime -> /usr/share/zoneinfo/America/New\_York

**# cat /etc/sysconfig/clock**

ZONE="America/New\_York"

UTC=false

ARC=false

**2. Use the following Perl Script to make the Time zone change, then verify:**

**# /usr/bin/perl /nas/http/webui/bin/timezone.pl -s America/Denver**

**# date**

Tue May 5 06:27:03 MDT 2009

**# ls -la /etc/localtime**

lrwxrwxrwx 1 root root 34 May 5 06:21 /etc/localtime -> /usr/share/zoneinfo/America/Denver

**# cat /etc/sysconfig/clock**

ZONE="America/Denver"

UTC=false

ARC=false

**Note:** The time zone string is based on "America/<city\_name>"--the city names can be found in the /usr/share/zoneinfo/America directory.

**3. Reboot the Celerra Control Station in order to update persistent applications, such as Apache, Tomcat, or XML API, with the new Time zone information.**

**ALTERNATIVE METHOD FOR CHANGING TIME ZONE 5.6:**

**1. Remove old time zone link file:**

**# rm -f /etc/localtime**

**2. Create new time zone link file based on city of choice from /usr/share/zoneinfo/America directory:**

**# ln -sf /usr/share/zoneinfo/America/Chicago /etc/localtime**

**3. Manually edit /etc/sysconfig/clock with new time zone string:**

ZONE="America/New\_York" --> change to --> **ZONE="America/Chicago"**

**4. Reboot Control Station and verify**

**# ls -l /etc/localtime**

lrwxrwxrwx 1 root root 35 May 5 10:09 /etc/localtime -> /usr/share/zoneinfo/America/Chicago

**# cat /etc/sysconfig/clock**

ZONE="America/Chicago"

UTC=false

ARC=false

**# date**

Tue May 5 10:10:42 CDT 2009

**VIEWING DAYLIGHT SAVINGS TIME INFORMATION 5.6:**

**# /usr/sbin/zdump -v /etc/localtime |grep 2009**

/etc/localtime Sun Mar 8 06:59:59 2009 UTC = Sun Mar 8 01:59:59 2009 EST isdst=0 gmtoff=-18000

/etc/localtime Sun Mar 8 07:00:00 2009 UTC = Sun Mar 8 03:00:00 2009 EDT isdst=1 gmtoff=-14400

/etc/localtime Sun Nov 1 05:59:59 2009 UTC = Sun Nov 1 01:59:59 2009 EDT isdst=1 gmtoff=-14400

/etc/localtime Sun Nov 1 06:00:00 2009 UTC = Sun Nov 1 01:00:00 2009 EST isdst=0 gmtoff=-18000

**CHANGING CONTROL STATION DATE & TIME 5.6:**

**# date 0504133709** →Where 05 is mnth, 04 is day, 1337 is time, 09 is year

Mon May 4 13:37:00 EDT 2009

**# date;date -u** (latter switch displays UTC time)

Mon May 4 15:47:19 EDT 2009

Mon May 4 19:47:19 UTC 2009

**CHANGING CONTROL STATION HW CLOCK TO MATCH LINUX SYSTEM CLOCK 5.6:**

**# /usr/sbin/hwclock**

Mon 04 May 2009 01:37:45 PM EDT -0.133015 seconds

**# /usr/sbin/hwclock -systohc (-w)**

**Note:** Sets hwclock based on current System Time (Linux kernel clock)

# /usr/sbin/hwclock

Mon 04 May 2009 01:37:24 PM EDT -0.072162 seconds

**HWClock Drift:**

/etc/adjtime

27.391

## ***CONFIGURING CONTROL STATION NTP CLIENT SERVICE NAS 5.6***

**GUI Method for Setting up NTP on CS:**

→Open Celerra Manager, go to Control Station properties, find NTP section, input IP address for NTP server to be used by the Control Station client service

**CLI Method:**

**1. Verify whether NTPD daemon is running:**

# ps -ef |grep ntpd

root 17682 11902 0 11:26 pts/0 00:00:00 grep ntpd

# /sbin/service ntpd status

ntpd is stopped

# /sbin/chkconfig ntpd --list

ntpd 0:off 1:off 2:off 3:off 4:off 5:off 6:off

**2. Add NTP Server IP to the bottom of the /etc/ntp.conf file per the following example:**

server 10.246.18.40

**3. Add IP Address of NTP Server (s) to /etc/ntp/step-tickers file:**

10.246.18.40

**4. If not already configured, set the NTP daemon for run-levels 3, 4, & 5, then verify:**

# /sbin/chkconfig --level 345 ntpd on | off [Enables or disables daemon for auto restart]

# /sbin/chkconfig ntpd --list

ntpd 0:off 1:off 2:off 3:on 4:on 5:on 6:off

**5. Start or restart the NTP Daemon:**

# /sbin/service ntpd start

ntpd: Synchronizing with time server: [ OK ]

Starting ntpd: [ OK ]

# /sbin/service ntpd restart

Shutting down ntpd: [ OK ]

ntpd: Synchronizing with time server: [ OK ]

Starting ntpd: [ OK ]

**Note:** If 'Synchronizing with time server' comes back as "OK", the NTP client was able to communicate with the NTP Server.

**6. Grep for the process:**

# ps -ef |grep ntp

ntp 25048 1 0 13:09 ? 00:00:00 ntpd -u ntp:ntp -p /var/run/ntp.pid

**7. Check Status of NTP:**

# /sbin/service ntpd status

ntpd (pid 25048) is running...

# /usr/sbin/ntpq -p

remote refid st t when poll reach delay offset jitter

=====

10.246.18.40 192.1.4.236 2 u 91 256 1 0.809 0.492 0.001

**8. Examine /var/log/messages file for ntpd messages. If you get errors, you may need to reboot the Control Station.**

May 4 13:09:45 fox1 ntpd[25048]: precision = 1.000 usec

May 4 13:09:45 fox1 ntpd[25048]: Listening on interface eth3, 10.241.168.30#123

May 4 13:09:45 fox1 ntpd: ntpd startup succeeded

May 4 13:09:45 fox1 ntpd[25048]: kernel time sync status 0040

May 4 13:09:45 fox1 ntpd[25048]: frequency initialized 0.000 PPM from /var/lib/ntp/drift

**9. Optionally, setup a drift value in the following file**

# vi /var/lib/ntp/drift

27.391

## ***EXAMPLE NTP SERVICE FAILING INVALID IP:***

```
# cat /etc/ntp/step-tickers  
10.241.168.172  
# /sbin/service ntpd restart  
Shutting down ntpd: [ OK ]  
ntpd: Synchronizing with time server: [FAILED]  
Starting ntpd: [ OK ]  
# /usr/sbin/ntpq -p  
remote refid st t when poll reach delay offset jitter  
=====
```

LOCAL(0) LOCAL(0) 101 8 64 1 0.000 0.000 0.001

**Note:** Above output indicates NTP not working & has an invalid NTP server IP address

### **EXAMPLE NTP SERVICE WORKING WHEN USING VALID IP:**

```
# cat /etc/ntp/step-tickers  
10.246.18.40  
# /sbin/service ntpd restart  
Shutting down ntpd: [ OK ]  
ntpd: Synchronizing with time server: [ OK ]  
Starting ntpd: [ OK ]  
# /usr/sbin/ntpq -p  
remote refid st t when poll reach delay offset jitter  
=====
```

LOCAL(0) LOCAL(0) 101 11 64 1 0.000 0.000 0.001  
10.246.18.40 192.1.4.236 2 u 10 64 1 0.682 -1.957 0.001

### **SETTING UP CS AS AN NTP SERVER:**

#### **a.) Configure NTP Service on CS0:**

```
# vi /etc/ntp.conf  
server 172.24.80.11 [Add this entry for the local Control Station External IP Address]  
server 127.127.1.0 # local clock [Leave this default entry]  
fudge 127.127.1.0 stratum 10 [Leave this default entry]
```

#### **b.) Enable NTP Daemon for NAS 5.0:**

```
# /sbin/chkconfig ntpd on
```

#### **c.) Start the Time Service on CS0:**

```
# /etc/rc.d/init.d/xntpd start | stop [NAS 4.x]  
# /sbin/service ntpd start [NAS 5.0]
```

#### **d.) Verify Time Service is Running:**

```
# ps -ef |grep xntpd "...root 16797 xntpd -A" ---or---  
# ps -ef |grep ntp  
ntp 19772 1 0 17:18 ? 00:00:00 ntpd -U ntp  
# /sbin/service ntpd status  
ntp is stopped  
# /sbin/chkconfig --list |grep ntp  
ntpda 0:off 1:off 2:off 3:off 4:off 5:off 6:off
```

#### **e.) Test by starting DataMover's NTP Service:**

```
# server_date server_2 timesvc start ntp 192.168.1.100
```

#### **f.) Synchronize DataMover to CS0 using “update” command or manually if required:**

```
# server_date server_2 timesvc update ntp  
# server_date server_2 0209201130
```

**Note:** Date is in Year, Month, Day, Time format

#### **g.) Verify by comparing Control Station Time to DataMover Time:**

```
# date # server_date server_2
```

#### **h.) Create Symbolic Link to restart Time Service upon rebooting Control Station:**

```
# /sbin/chkconfig xntpd on [Creates symbolic link /etc/rc.d/rc3.d/S55xntpd → /init.d/xntpd]
```

#### **i.) Reboot Control Station & verify**

**Notes:** Default polling to the Time Server is hourly, but this can be modified. Normal ‘fudge’ configuration is to use “stratum 10” as local ‘unreliable clock source’—but since it’s the primary Time Server here, change value to (8) to preclude client sync problems. Or,

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
if you would like to setup the Control Station to point to an external Time Server source, yet have the DataMovers point to the Control Station, and then use the CS's "local clock" as a backup if the External NTP Server is unavailable, setup ntp.conf file like this:

```
server 200.1.1.1      prefer # IP of external time server
server 127.127.1.0
```

## **SETTING UP NTP CLIENT ON LINUX 6.2/7.2 CONTROL STATIONS (pre 5.6):**

- Step 1. #vi /etc/ntp/step-tickers  
192.10.4.5 [IP Address of NTP Server]
- Step 2. Set Control Station to Autostart Time Service on Reboots:  
#/sbin/chkconfig xntpd on [RedHat 6.2]  
#/sbin/chkconfig ntpd on [RedHat 7.2]
- Step 3. Verifying Configuration & Startup Level:  
#/sbin/chkconfig --list xntpd [RedHat 6.2]  
#/sbin/chkconfig --list ntpd [RedHat 7.2]
- Step 4. Manually Starting the NTP Daemon:  
#/etc/rc.d/init.d/xntpd start [RedHat 6.2]  
#/etc/rc.d/init.d/ntpd start [RedHat 7.2]  
Synchronizing with time server: OK ]  
Starting ntpd: OK ]
- Step 5. Verify NTP Service:  
#ps -ef |grep ntp  
ntp 26728 1 0 16:38 ? 00:00:00 ntpd -U ntp

## **TROUBLESHOOTING NTP ON LINUX:**

- check to ensure that service is running  
--# /usr/sbin/ntpq -p  
--#ps -ef |grep xntpd "...root 16797 xntpd -A"  
--# ps -ef |grep ntp  
ntp 19772 1 0 17:18 ? 00:00:00 ntpd -U ntp  
--#/sbin/service ntpd status  
ntpd is stopped  
--# /sbin/chkconfig --list |grep ntp  
ntpd 0:off 1:off 2:off 3:off 4:off 5:off 6:off  
--ping the NTP Server  
--# /usr/sbin/rpcinfo -p 192.10.3.2 [Verify that Time Service port is registered]  
--#/usr/sbin/ntptrace

## **UTILITIES TO CHECK NTP:**

```
#/usr/sbin/ntptrace
#/usr/sbin/ntpdate
#/usr/sbin/ntpq
>peers
#/usr/sbin/ntpdc
>sysinfo
>listpeers
```

## **FILES USED WITH NTP ON CONTROL STATION:**

/etc/ntp.conf  
/etc/rc3.d/K74ntpd  
/sbin/chkconfig -list |grep -i ntpd [Verify if NTP daemon is running]  
/usr/sbin/clockdiff -o IPaddress [IP Address of NTP Server]  
/usr/sbin/timeconfig [Useful GUI for configuring TimeZones on CS—NAS 5.5 and lower]  
/etc/sysconfig/clock [Shows TimeZone currently configured]  
/bin/date [Current date & time—also use this to change date & time]  
/etc/ntp/drift or /var/lib/ntp/drift

## **SETTING DATE & TIME ON LINUX CONTROL STATION (NAS 5.5 and before):**

1. # date -s "4/09/03 16:15:15"
2. # /usr/sbin/setclock

### 3. # date → Wed Apr 9 16:15:30 MDT 2003

#### OBTAINING UNIX DATE ON LINUX CS:

# /bin/date '+%s'

1074016065

#### Convert to Number of Bits:

Open scientific calculator, input above number as decimal, then convert to binary:

100000000000100001011101000001

Note: Above example shows 31 bits in use to display Unix date since Jan 1, 1970

#### RESTARTING TIME SERVICE FOR LINUX 6.2 CS:

#/sbin/chkconfig xntpd on [This command creates the link → /etc/rc.d/rc3.d/S55xntp]

Note: Create symbolic link to auto-restart the service after Control Station reboots

#### CHANGING CONTROL STATION TIMEZONE ON LINUX:

The default system TimeZone for Linux generally resides in /usr/share/zoneinfo, with /etc/localtime as a symbolic link to the actual Timezone file that is desired as the reference. See man pages for tzset for more information.

#### USING CLI SYMLINK TO CHANGE FROM DEFAULT EST TO PST:

1. Create the link, or, find the proper timezone file (/usr/share/zoneinfo/PST8PDT) and copy to /etc/localtime

# cp -ip /usr/share/zoneinfo/PST8PDT /etc/localtime

Or # ln -s /usr/share/zoneinfo/PST8PDT /etc/localtime

# ls -la /etc/localtime

lrwxrwxrwx 1 root root 27 Nov 29 07:43 localtime -> /usr/share/zoneinfo/PST8PDT

2. Edit /etc/sysconfig/clock and change to reflect the correct timezone

# cat /etc/sysconfig/clock

ZONE="America/New\_York"

UTC=false

ARC=false

# cat /etc/sysconfig/clock

ZONE="PST8PDT"

UTC=false

ARC=false

#### USING TIMECONFIG TO CHANGE TIMEZONE (NAS 5.5 and below):

Step 1. # /usr/sbin/timeconfig [Select timezone of choice for Control Station]

Step 2. Manually set date and time on all Datamovers

Note: Using the GUI is probably the best way to change timezones on the Control Station, since the changes are written to /etc/sysconfig/clock and the correct timezone file is copied to /etc/localtime.

# cat /etc/sysconfig/clock

ZONE="EST5EDT"

UTC=false

ARC=false

#### VERIFYING CONTROL STATION DST TIMEZONE CHANGES:

NAS 5.4.27.2 & 5.5.24.2 contain code fixes to update the Linux glibc files so as to be able to honor the new 2007 Timezone. Run the following command to determine if the system has been updated to recognize the new start & end dates of DST, which is the 2<sup>nd</sup> Sunday in March to the first Sunday in November.

# /usr/sbin/zdump -v /etc/localtime |grep 2007

/etc/localtime Sun Mar 11 06:59:59 2007 UTC = Sun Mar 11 01:59:59 2007 EST isdst=0 gmtoff=-18000

/etc/localtime Sun Mar 11 07:00:00 2007 UTC = Sun Mar 11 03:00:00 2007 EDT isdst=1 gmtoff=-14400

/etc/localtime Sun Nov 4 05:59:59 2007 UTC = Sun Nov 4 01:59:59 2007 EDT isdst=1 gmtoff=-14400

/etc/localtime Sun Nov 4 06:00:00 2007 UTC = Sun Nov 4 01:00:00 2007 EST isdst=0 gmtoff=-18000

Note: See emc150583 for more details.

#### DATA MOVER TIME SERVICE, TIMEZONE, DATE

#### VERIFYING DATAMOVER TIME SERVICE & SETTING NTP SERVERS:

#server\_date server\_6 timesvc start ntp 162.69.63.8

#server\_date server\_6 timesvc

Timeservice State

time: Wed Apr 24 13:43:42 EDT 2002  
type: ntp  
sync delay: off  
interval: 60  
hosts: 162.69.63.8

### **DATA MOVER DISPLAY TIME:**

Data Mover display and log times are calculated from the 1970 UNIX clock in seconds, then converted to show the local timezone that the Control Station is running. In otherwords, the following command will always output the localtime as set on the CS—to make matters more confusing, the default Timezone of the Data Mover is always GMT unless specifically changed:

# server\_date server\_2

server\_2 : Wed Dec 13 12:54:27 EST 2006

# server\_date server\_2 timezone

server\_2 : Local timezone: PST

### **SETTING TIMEZONE ON DATA MOVER(old):**

# .server\_config server\_2 -v "time PST+8" (sets Timezone but without Savings time set)

**Note:** Supported 5.2.14.0 and 5.3.6.0

# server\_date server\_2 timezone CST6CDT5,M4.1.0,M10.5.0 [Stnd time +offset, Savings time + offset, then Month, Week, Day of Week—default time is /2:00 for 2:00 a.m.]

# server\_date server\_2 timezone EDT+4

# server\_date server\_2 timezone BST-1

**Note:** If desired, plug in daylight savings time information—First Sunday April, 5<sup>th</sup> Sunday October. Also, must point to an NTP server in the same timezone in order for the proper time to be returned with server\_date. See also extra examples of different timezones and syntax required.

### **VERIFYING DATA MOVER TIMEZONE DATE INFO:**

1. \$ .server\_config server\_2 -v "time"

1089329961: KERNEL: 4: Local time: Thu Jul 8 23:39:21 2004

1089329961: KERNEL: 4: GMT time: Thu Jul 8 23:39:21 2004

**Note:** Output shows default GMT time, as well as local time, which is really keyed off the local CS clock? If you specifically change DM timezone, the Local time will then change to reflect the offset from GMT time for the timezone specified.

2. Following entry will be written to boot.cfg file only when Data Mover is set to a timezone other than its default for GMT

# cat /nas/dos/slot\_2/boot.cfglhead

time timezone=PST8PDT7,M3.2.0,M11.1.0

**Note:** There is no “time timezone” entry for the default Data Mover GMT timezone

3. Following Server system file will also contain the timezone entry:

# cat /nas/server/slot\_2/system

time timezone=PST8PDT7,M3.2.0,M11.1.0

4. Use server\_date command:

# server\_date server\_2 timezone

server\_2 : Local timezone: PST

### **CHANGING DATA MOVER TIMEZONES(new):**

**Note:** Default DM timezone is GMT

# server\_date server\_2 timezone

server\_2 : Local timezone: GMT

1. To change Timezone of Data Mover to Pacific Standard Time with the new Pacific Daylight Time for 2007:

# server\_date server\_2 timezone PST8PDT7,M3.2.0/2:00,M11.1.0/2:00

**Note:** PST8 represents Pacific Stnd Time and its – 8 hour offset from GMT; PDT7 is Pacific Daylight Time with an offset of -7; M3.2.0/2:00 is the start of Savings Time; M11.1.0/2:00 is the end of Savings Time

M3 = Month (1-12), in this case March

2 = Week of the month (1-5), 2<sup>nd</sup> week of March

0 = Day of the week (0-6), with 0 always representing Sunday

/2:00 = time, where 2:00 is a.m.

### **BEFORE TIMEZONE CHANGE:**

```
# server_date server_2 timezone  
server_2 : Local timezone: GMT  
# .server_config server_2 -v "time"  
1164813455: KERNEL: 4: Local time: Wed Nov 29 15:17:35 2006  
1164813455: KERNEL: 4: GMT time: Wed Nov 29 15:17:35 2006
```

```
# server_date server_2  
server_2 : Wed Nov 29 10:17:41 EST 2006
```

#### AFTER TIMEZONE CHANGE:

```
# server_date server_2 timezone  
server_2 : Local timezone: PST  
# .server_config server_2 -v "time"  
1164813498: KERNEL: 4: Local time: Wed Nov 29 07:18:18 2006  
1164813498: KERNEL: 4: GMT time: Wed Nov 29 15:18:18 2006
```

```
# server_date server_2
```

server\_2 : Wed Nov 29 10:22:49 EST 2006 →This is actually correct since server\_date uses same time as Control Station, which is set to EST in this example—so, server\_date has nothing to do with actual DM timezone info:

```
# date
```

Wed Nov 29 10:33:02 EST 2006

```
# cat /nas/server/slot_2/system
```

time timezone=EST5EDT4,M3.2.0,M11.1.0 →File where actual timezone changes are written if anything other than default GMT

#### SETTING TIMEZONE BACK TO GMT DEFAULT:

```
# server_date server_3 timezone GMT+0
```

```
server_3 : done  
# cat /nas/server/slot_2/system  
time timezone=GMT+0
```

#### SETTING TIMEZONE INFO ON DATA MOVERS WITH NAS 5.6:

```
$ server_date server_2 timezone -name America/New_York
```

Note: Can use above format to set timezone vs. posix entry

#### DELETING TIME SERVICE ON DATAMOVER:

```
$server_date server_2 timesvc delete ntp
```

#### CELLERRA TIME SERVICES: NAS 5.1

##### Terminology:

Clock Offset—difference between local system time and Time Server time, expressed in UTC (Coordinated Universal Time), which is independent of Time Zones. Clock Offset can be negative or positive. Datamover typically slews at a rate of 10%, meaning that it would take (6) minutes to recover from an offset of (1) hour

NTP (Network Time Protocol)—Time service specifying accuracy within one millisecond over large networks

SNTP (Simple Network Time Protocol)—Subset of NTP, does not demand as much accuracy

Slewing—Gradual self-correction process to slew back to NTP Time

#### TIME SERVICE COMMANDS:

```
$server_date server_x timesvc set ntp [Polls NTP Server & syncs system time immediately—no slewing--Default]
```

```
$server_date server_x timesvc update ntp [Polls NTP Server & begins slewing to sync back up to Time Server]
```

```
$server_date server_x timesvc start ntp -synch_delay -interval 01:00 host 192.10.3.2 [This option will begin slewing system time to NTP Time after reboots or startup, per the default interval of (1) hour between polls]
```

#### SETTING UP MULTIPLE NTP SERVERS AT ONCE:

```
# server_date server_2 timesvc start ntp 10.92.5.189 10.70.154.205
```

Note: Normally, system reboots or startups will resynchronize System time to NTP Time immediately—there might be occasions where you would not want to do this.

```
$server_date server_x timesvc stats ntp [Statistics about time services]
```

```
$server_date server_x timesvc stop ntp
```

```
$server_date server_x timesvc delete ntp
```

#### USING SCRIPT TO SYNC DATA MOVER TO CONTROL STATION, RUNNING AS NTP PEER:

```
# cat time  
#!/bin/sh  
NAS_DB=/nas
```

```
export NAS_DB
now=`/bin/date '+%y%m%d%H%M%S'
sleep 40
$NAS_DB/bin/server_date server_3 $now
FOR DUAL CS ENVIRONMENT:
$ cat time
#!/bin/sh
NAS_DB=/nas
export NAS_DB
if [ ! -d /nas/sbin ]; then
exit
else
/nas/bin/server_date ALL $(/bin/date +%y%m%d%H%M%S)
fi
```

## **CELERRA SCSI SUPPORT [Wide Ultra2 SCSI--80MBps—UFWD HVD]:**

**SCSI:** Parallel interface with speed bursts. Max cable lengths 3 – 25m. Total of 16 interconnected devices. SCSI III Protocol.

**Note:** Celerra uses Wide Ultra2 SCSI, with bus speeds up to 80 MB/second. Data Mover SCSI HBA's are single-ended HVD connections, but can use an adapter to LVD

Older configurations may still exist, which use Ultra2 SCSI, 40MB/second

### **Rules:**

→Two SCSI ports must be mapped to same SYMM devices—Why?

1. For High Availability

2. For Performance reasons [507DM can overdrive a single SCSI port]

→Up to 240 SCSI id's per DM

→16 Targets per SCSI Bus Chain—one reserved for HBA

→16 LUNS typical per Target. SCSI Port A = Data & Boot Port on Bottom Port of card. Lose this and must Failover to Standby. Port B=Data Only and is Top Port on SCSI Card.

**Note:** 2.1.24.4 Code uses both ports as “Boot” and “Data” ports to eliminate this earlier failover issue!! [Still 20% occurrence?]

CTD Terminology: Controller, Target, Device{LUN}

**Example:** **/dev/rdsck/c1t1d2 c1=controller t1=target d2=LUN**

Adaptec AHA-3944UWD Ultra Fast Wide Differential Dual Port PCI SCSI Cards on 505+ using C6mini68s or c12mini68s cables

**Cables:** Usually mini-to-mini for Celerra to Symm; But, mini-to-large connector for PC to Celerra, tape unit, etc.

SCSI communicates to Symmetrix using USD4; WD4; or OSD4 electronic negotiation.

**Note:** Minichamp = 6 or 12 meter cables

**SCSI :** Small Computer System Interface—parallel interface standard for attaching peripherals to a computer

**CDB :** Command Descriptor Block

**CAM:** Common Access Method, segment of code dealing with raw I/O communications to backend storage devices

## **SCSI DISTANCE LIMITATIONS:**

Single Ended Cables = 3 meters

Differential SCSI = 25 meters

## **CELERRA/CLARIION SCSI TIMEOUT VALUES:**

**Note:** NAS codes from 4.2.8.1 - 4.2.11.x & 5.0.9.1 – 5.0.11.x required setting the io\_time parameter. NAS 4.2.12.0 & 5.1.9.4 and higher do not require the param setting as the backend type is detected automatically and the setting made.

--Timeout Values for Celerra Servers attached to SYMMETRIX must be 90 secs

--Timeout Values for Celerra Servers attached to CLARiiON must be 300 secs [5 minutes]

## **CELERRA CONFIGURATION CHANGE REQUIRED:**

**Note:** As a result of this new behavior for SCSI timeouts, Celerras attached to SYMMETRIX must have following parameter added for all NAS Codes 4.2.8.1 – 4.2.12.x. The effect of not doing this means that failover, for loss of connectivity, will not occur for 5 minutes. See Primus emc60921.

1. #vi /nas/site/slot\_param

**param storage io\_time=90**

2. Reboot all Servers

## **SCSI INTERFACE PROTOCOL:**

- SCSI is a device independent I/O bus used to connect a variety of peripheral devices to a single computer bus
- Data is addressed logically, not physically
- SCSI buses can host (8) devices on a single Bus, but only (2) devices can converse with each other at a time
- SCSI Roles are as Initiator or Target
- Initiator [SCSI Host Adapter] begins a transaction by giving another device a task
- Target [Disk Drive] carries out the task
- Typical conversation involves Initiator sending command to Target, Target carrying out Task, & then reporting outcome [Target controls Bus until released]

**Example:** Initiator instructs target to fetch a certain number of blocks starting at block number. Target calculates physical address of cylinder, head, and sector number from logical block number and sends data to Initiator.

**Note:** Computer Systems connect to SCSI bus via Host Adapter, generally built into motherboard  
Peripherals connect to SCSI bus via Controller, embedded in drive electronics

## **SCSI CONTROLLER:** Used to connect peripherals to Bus; Controller has SCSI ID and Targets have LUNs

- SCSI ID & Address are unique on the Bus
- SCSI Reset is a special bus signal that affects all devices on the Bus
- Odd Parity Bit is set to 0 if total number of 1's are odd (1 parity bit for every 8 data bits)

## **PHASES IN SCSI COMMUNICATION:**

**Bus Free Phase:** SCSI bus is free, set by Power On, SCSI reset, execution of command completion by Target, or when Target relinquishes Bus with Disconnect message

**Arbitration Phase:** Devices must arbitrate for control of Bus (BSY)

Devices with highest SCSI ID (7) wins arbitration and uses SEL signal to allow other devices to release any BSY signals from wire and to remove their ID bit from data bus

**Selection Phase:** BSY, SEL, Initiator ID

Connection established by Initiator to desired Target, except in ‘reselection’ where Target asserts I/O ATN data signal issued to Target ID; Target asserts BSY signal & Initiator releases SEL signal

**Reselection Phase:** Allows Target to reconnect to Initiator after disconnecting to complete a command

Also allows Target to Send I/O reselection signal to Initiator after successful Arbitration

**Message Phase:** Message Out always follows successful selection & is used by Target to send or receive message byte Initiator sends ATN to Target to send message bytes, and then releases

**Command Phase:** Command opcodes used by Target to receive commands from Initiator

Target reads first byte to determine number of bytes to follow

**Data Phase:** Target sends data using I/O DATA IN signal, or is ready to receive data by de-asserting I/O in DATA OUT signal. Data is transferred asynchronously or synchronously

**Status Phase:** Target sends 1 byte Success or Failure message to Initiator after command completed, or if command interrupted or refused by Target. Target releases the Bus for Bus Free Phase.

## **SCSI BUS:**

8-32 bits wide, 50-pin ribbon cable, with built-in terminating resistors

Commands, messages, Status are sent over bus as asynchronous transfers [SCSI-2 can transfer data synchronously]

Single-ended SCSI is most common, but where cable lengths need to be > than 6 meters, Differential SCSI is used

## **SCSI/FIBRE TARGET & LUN CONCEPTS:**

Scsi Bus is from 8 – 32 bits wide. The 8-bit bus uses a 50pin cable. The 16 and 32-bit buses are called “Wide SCSI”.

|                    |        |                         |                      |
|--------------------|--------|-------------------------|----------------------|
| Wide SCSI-2:       | 20MBps | 16-bit bus = 16 Devices | 3 Meter Cable Length |
| Fast Wide SCSI-2:  | 20MBps | 16-bit bus = 16 devices | 3 Meter Cable Length |
| Ultra SCSI-3:      | 40MBps | 16-bit bus = 16 devices | 1.5 Meters           |
| Ultra-2 SCSI:      | 40MBps | 8-bit bus = 8 devices   | 12 Meters            |
| Wide Ultra-2 SCSI: | 80MBps | 16-bit bus = 16 devices | 12 Meters            |

## **SCSI STATUS CODES:**

|     |                 |                                                               |
|-----|-----------------|---------------------------------------------------------------|
| 00h | GOOD            | Device server has successfully completed task                 |
| 02h | CHECK CONDITION | ACA or CA condition occurred; autosense data may be delivered |
| 04h | CONDITION MET   | Status returned after requested operation satisfied           |
| 08h | BUSY            | Logical Unit is busy—reissue command at a later time          |
| 40h | TASK ABORTED    |                                                               |

## **DEVICE CLASSES:**

00h—Disk Drives  
01h—Tape Drives  
02h—Printers  
03h—Processor devices  
04h—WORM devices  
05h—CD-ROM drives  
06h—Scanners  
07h—Optical Disks  
08h—Media Changer  
09h—Communication devices

## **TARGET & LUN SUPPORT ON CELERRA:**

SCSI=240LUNS

FIBRE=256LUNS

**Note:** This is a Symmetrix limitation. Celerra could otherwise support up to 4096 LUNs

## **TARGET & LUN LIMITATIONS ON CELERRA:**

For NAS 2.x and above, use only Target and Lun assignments for Data Volumes that start at Target 1 Lun 0 [10]

Target/LUNs 006; 007; 008; 009; 00A; 00B; 00C; 00D are reserved for Control Volumes only! Errors will be seen on Control Station if these LUNs are used for Data Volumes

**SCSI CHAINS or PORTS:** Represents the whole physical SCSI port [aka chain] to which a cable is connected to!

Chains C0, C1, C2, C3 are available for SCSI

Chains C0 -C100+ available for Fibre

Each SCSI chain is simply a SCSI connector port for a given Server.

**For Example:** A dual-scsi connector would give you Chains 0 and 1

Two Dual-SCSI cards would give you Chains 0, 1, 2, 3

**Limitations:** With our SYMMETRIX and SCSI, we are limited to a total of 240 LUNS per chain!

**Note:** In Theory, DataMover could support up to 4096 devices. Fiber supports up to 128 LUNS [256with RPQ]

**SCSI PINS or TARGETS:** There are a total of (15) pins per connector, which represent “Targets” !

8-bit SCSI bus has Targets 0-7

16-bit SCSI bus has Targets 0-15 [lose one target for termination at target 7]

Each pin is therefore equivalent to a “Target” that transmits data down a wire

Each Target or Pin can have up to 15 LUNS mapped to it as well

**Limitations:** Pin #7, or Target 7, is always reserved for SCSI termination and cannot be used!!!!!!

Therefore, maximum LUNS available are 240 for a 16-bit SCSI Target

**SCSI LUNS:** Virtual addresses—can have a total of (15) virtual addresses on each SCSI Target or Pin 16-bit buses

Listed as LUNS 0—15 [lose one LUN for termination for ‘target’ 7]

## **SCSI3 RESERVATIONS:**

SCSI3 Reservations are used in some Tape Backup implementations where Shared drives are used. Hosts can take out a persistent reservation against a drive, but CommVault does not support SCSI3 Reservations for NAS-attached drives. Celerra ends up not being able to access the drive because of a reservation conflict error. Work is being conducted by both CommVault and EMC to review this limitation.

## **HOT PLUGGING/UNPLUGGING SCSI CABLES:**

Celerra SCSI connections are not like “hot swappable” disk drives that can be removed or inserted on live systems [Hot Swappable devices have built-in circuitry & longer ground pins to allow this] without potential impact.

### **Potential Problems Due to Hot Plugging or Unplugging SCSI Connections to a Live SCSI Bus:**

1. Could cause DM to negotiate from Wide to Narrow, which may not manifest itself until a server\_devconfig probe sends an electrical pulse down the ‘unplugged/replugged’ SCSI chain, creating errors on the Bus or Data Mover panic.
2. Breaking the SCSI Bus can leave the bus in an unstable electrical state, leading to commands failing and potential data corruption, and possibility for generating double bit errors.
2. Plugging Tape Devices generates a power surge from TERMPWR on the TLU/Tape device, which could affect DM SCSI circuitry.
3. Unplugging/plugging cables creates voltage surge as devices are ungrounded or grounded. This can lead to a short circuit on the SCSI cable, blowing the Pico Fuse [which is embedded on the SCSI cables so as to be the protective point for the SCSI bus]. A danger here is that further power surges, or short circuits, could damage both the HBA and the Tape Drive device. Connections are

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
designed so that the SCSI device makes a power ground and logic ground 1ms before device connector physically contacts the Bus.  
Hot swappable devices have specially extended ground pins to help protect the SCSI bus & electrical circuitry.

## **iSCSI PROTOCOL:**

- encapsulation protocol using TCP to transport scsi commands
- iSCSI links targets and initiators and presents SCSI LUNs to iSCSI initiators
- SCSI used as the presentation interface
- GigE required for throughput, and TOE's [TCP/IP Offload Engines in NIC Cards] are being used
- Remote disks appear as local drives with iSCSI, hanging off Controller, Target, Lun
- Some drawbacks to usage of iSCSI over WANs—latency, performance—don't use over public network
- iScsi uses basic transfer length of 0x800 or 2048 bytes (2k), equivalent to (4) 512 byte blocks as in SCSI
- iSCSI uses TCP port 3260

## **IMPORTANT CONCEPTS:**

iSCSI does not know about LUNs (uses CDB via SCSI), just Targets

## **COMMUNICATION LAYERS:**

Physical Layer

TCP Header

iSCSI BHS → Basic Header Segment--only layer different than using FC with SCSI. iSCSI device driver adds PDU data and passes packet to TCP stack

CDB

Data

## **iSCSI IDENTIFIERS:**

iSCSI Nodes have globally unique names and support 'eui' and 'iqn' names

iSCSI Sessions use Session IDs (ISIDs) using TCP between iSCSI Nodes

iSCSI Connections use Connection IDs to identify logical connections

iSCSI Portals manage IP addresses and TCP Port numbers

## **iSCSI INITIALIZATION:**

iSCSI Initiator sets up TCP connection to Target, then 'Discovers' SCSI Targets and Logs into Target via Session [Discovery or Normal]

Normal SCSI commands report on LUNs

## **TWO SESSIONS USED IN iSCSI:**

Discovery: Uses SendTargets and Logout commands

Normal: Accepts all commands

## **iSCSI SECURITY:**

IPSec and IKE encryption

Kerberos v5, SRP, SPKM1/2, and CHAP authentication

## **CELLERRA iSCSI:** Introduced NAS 5.3

### **NBS:**

Network Block Service (version 2.0) is the protocol that runs on top of the TCP, hence is connection-oriented, and can run over copper or optical media. Client side applications issue requests to Block Device Driver which are in turn passed to Block Server via TCP. Client device driver keeps an exported pseudo disk list that makes storage appear to be local, just as a local disk which can be partitioned, formatted, etc. Storage Objects on Celerra are file systems and files. Current implementation for authentication is CHAP 1-way from Client to Server.

## **TYPES OF iSCSI TOPOLOGIES:**

### **NATIVE iSCSI SAN**

→ Entire topology between iSCSI Client Initiator and iSCSI Target Storage array is connected from end-to-end over Ethernet, with an IP switch in the middle, and transmitting SCSI over IP

### **HETEROGENEOUS IP SAN**

→ A topology where some parts of the SAN are using IP to transmit SCSI, while others are using FC to transmit SCSI, with perhaps a Bridge to translate between iSCSI/Fibre Channel protocols

→ An iSCSI Host can use either a NIC or HBA device, while FC Target must use an HBA

## **MICROSOFT iSCSI:**

→ Microsoft iSCSI Initiator is a software driver installed on Windows 2000, 2003, & XP systems, but comes native in the OS for Windows 2008 & Vista (using Winsock Kernel mode interface—WSK)

**Note:** An example of a compatible version would be Initiator version 2.08

- An iSCSI Client is a Host or iSCSI Initiator which attaches to an IP network and sends requests and receives responses from iSCSI targets
- Microsoft recommends a minimum GbE Ethernet for iSCSI
- Typical iSCSI involves a Windows Host running the MS iSCSI software Initiator
- Microsoft recommends using Windows 2003 or 2008 Server for Microsoft Server Cluster (MSCS) support
- Use of dynamic disk volumes for iSCSI is only supported on Vista & Windows 2008
- Microsoft iSNS Server comes native with Windows 2008 (maintains iSNS registrations, de-registrations, and queries iSNS clients)
- MS Initiator supports CHAP (username and secret) and IPSEC (IKE protocol for authentication and packet encryption) on sw and hw initiators

### **iSCSI INITIATOR DISCOVERY MECHANISMS:**

SendTargets—SendTarget ports are statically configured to discover target portals at service startup, etc

iSNS—statically configure the iSNS address, Initiator can then obtain list of targets from iSNS server

HBA Discovery—MS Initiator obtains list of targets from HBA

Manually configured targets—manually configuring iSCSI targets

### **TARGETS vs. HOST INITIATORS:**

Celerra Servers are usually configured as “Targets”, hosts the iSCSI LUNs, and runs the iSCSI service, while the Host Windows platform act as the HBA “Initiator”, and once logged into the “target”, sees the iSCSI luns as if they were locally mounted partitions on the Windows system.

### **CELERRA MANAGER:**

Can configure & manage LUN, Target, iSNS management, and CHAP

### **iSCSI TOPOLOGIES:**

Bridging—use of iSCSI and Fibre Channel in mixed environment, not supported for Celerra

Native—use of only standard Ethernet switches, routers, and media for iSCSI→NO FIBRE CHANNEL (Default for Celerra)

### **iSCSI PROTOCOL:**

iSCSI is a open network protocol and network service running over TCP/IP. Network addressing is done via Portal Groups, which associate an iSCSI Target to an assigned network service port. Protocol allows for host initiators to communicate with iSCSI targets on storage devices using scsi commands between Host & storage. iSCSI Initiator takes SCSI CDB's and encapsulates them in PDUs, then wrapped in TCP & IP for transport to iSCSI Target.

### **iSCSI:**

--Celerra uses iSCSI in a solution in which there are Ethernet switches and routers. iSCSI is a Client/Server model. The iSCSI target and host initiators receive CDB's from SCSI Layer, encapsulated within iSCSI PDU (Protocol Data Units) that are then sent via IP to host

--iSCSI provides ‘block access’ vs. file access, an attribute which is helpful for databases (Oracle/Exchange)

--An iSCSI connection is a network portal connection that binds an Initiator with a Target (TCP port & IP address socket used by iSCSI node)

--Single iSCSI name per Host

--iSCSI can be managed from CLI or Celerra Manager

--Virtual LUN module in DART to support iSCSI LUNs

--DART runs iSCSI service to maintain updates for Internet Storage Name Service and Entity Status Inquiry [ESI] messages

--Build file systems >than double the capacity of iSCSI LUNs to support snaps

--Maximum of 256 LUNs allowed per Target

--iSCSI LUNs are based on File Storage Objects (SCSI-3 standard with direct-access disk emulation)

--Client access restricted using LUN masking for each LUN within a Target [auth. process makes LUNs avail. to hosts]

--iSCSI LUNs are created by specifying File System, Target, and LUN number [fs3\_T1\_LUN17]

--Default port is 3260

--Support for Digests, CHAP, iSNS, ImmediateData, FirstBurst, and Session-level 0 error recovery

--Celerra Host creates iSCSI Targets from within file systems as the access point (Initiators) to storage, using LUN Masking to restrict access from Initiators (Mask is assigned to each LUN within the Target, all Initiators denied access until mask is assigned)

--iSCSI memory requires contiguous physical memory

### **VMWARE ISSUES:**

#### **1. Memory Corruption Issues affecting iSCSI LUNS and VMWare machines**

**Note:** See emc196974 and AR115513 for 5.5 and 5.6 memory corruption issues on iSCSI LUNs, which especially affects VMWare Virtual Machines (VMs), as they will BlueScreen and run chkdsk if the lun is corrupt]. Fixed in full NAS versions 5.5.37 and 5.6.40.

#### **2. VMWare UUID changes after upgrading from NAS 5.5 to 5.6**

**Note:** See emc189395. Problem is that the Protocol Identifier Value (PIV) in the SCSI INQ response has changed format, which then triggers the VMWare UUID to change. The only way to recover the ESX Server access to iSCSI LUNs is to resignature the LUNs. In

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
extreme cases, the volume labels may need to be re-labeled and re-registered on all VMs. There is a special VMWare procedure to recover volumes: essentially, enable LVM Resignaturing on ESX Server & rescan, then disable LVM Resignaturing, re-label volumes in Datastores to their original names, rescan storage from all ESX Servers, re-register all VMs in VirtualCenter, etc.

### **iSCSI PDU (PROTOCOL DATA UNIT):**

The basic iSCSI packet is called the Protocol Data Unit, contains Header segment, additional header segment, Header digest, SCSI cmd & data, Header data digest

### **SCSI COMMAND SET USED WITH iSCSI:**

SPC-3→Command set used with printers, scanners, other SCSI devices, using Media Sense, Inquiry, Reset, etc.

SBC-2→Provides SCSI Block Commands for interacting with SCSI disk devices

**Note:** In combination, these command sets allows Hosts to manage LUNs as ‘local devices’

### **iSCSI STACK FROM HOST TO STORAGE:**

LAN→NIC Driver on Host→IP→TCP→Stream→Connection→Session→Target→Storage LUN→Virtual LUN→File Storage Object→File System→Logical Volume→CAM/SCSI/FC→SAN

### **iSCSI COMPONENTS:**

Logical Units; iSCSI Targets; LUN Masking; iSCSI Service, iSNS Name Service; CHAP Secret; Network Portals & Portal Groups

**iSCSI LUN MASKING NAMING FORMATS:** Each name is treated as an individual iSCSI initiator

iqn: iqn.1992-05.com.emc:mytarget-1

eui:eui.5006048DC7DFB1AF (16 digits hex)

### **TARGET ACCESS POINTS FOR INITIATORS:**

--Network Portal consists of IP Address & TCP Port number

-Portal Group is similar to a SCSI port and determines iSCSI sessions (identified by tags)

### **iSCSI TARGET FUNCTION:**

→Targets receive initiator requests via TCP

→Targets extract the SCSI commands from the iSCSI PDU's

→Targets route SCSI task to LUNs for execution

→Targets send status, data, and sense data back to Host Initiator

### **CELLERRA iSCSI:**

→As an iSCSI Target, Celerra supports Windows and Linux iSCSI initiators, receiving iSCSI commands

→Windows 2000 & 2003 can install a MS iSCSI SW initiator, while this feature is native in Windows 2008 & Vista

→Initiators encapsulate SCSI cmd's, data, status info into iSCSI PDUs

→Initiators log in and establish iSCSI sessions with iSCSI Targets

→Initiators discover iSCSI LUNs from Target

→Initiators send PDU's to Target on the Storage Device

→Once Initiator logs into a Target, the LUNs associated with the Target appears as a local SCSI disk device on the Host

→Initiators log into IQN's and export physical drives for LUNs that are masked to Celerra

→All endpoints are iqns

→Source iqn is the name of the iSCSI initiator

→Target iqn is name of ‘target’ on Celerra, which acts like a SCSI device and exports LUNs

**Note:** Targets are represented by software on the Celerra, with IQN's in EUI format

### **NETWORK PORTALS:**

→Initiators & Targets use network interfaces, called network portals, to communicate

→Initiator is identified by IP address while Target is identified by both IP address & TCP listening port (iSCSI port 3260)

→Rule, must have unique IP Address for each Network Portal bound to an Initiator

### **PORTAL GROUPS:**

→Collection of one or more network portals identified by a common tag (used for session control)

### **iSCSI NODE NAMES:**

→Each iSCSI Initiator and iSCSI Target node uses a globally unique permanent name

→Identifies Initiator & Target

→Independent of hardware location

→Allows for free movement of adapters and port addresses

→Uses iSCSI iQN or Qualified Naming Authority

→Use with DNS domain name and name becomes reserved

### **iSCSI QUALIFIED NAMES & ALIASES:**

#### **iSCSI Qualified Name (IQN):**

iqn.1987-05.com.cisco.1234abcdef987601267da232.betty

[Type; Date; Naming Authority; Subgroup Naming Authority]

#### **EUI NAME EXAMPLE:**

eui.02004567a425678d

[Type; EUI Identifier, ASCII Encoded Hex]

iSCSI ALIAS:

Unicode Alias for the long IQN or EUI names referenced above, i.e., a plain name used to identify the name

### **CELERRA iSCSI LUNS:**

→ Celerra iSCSI luns are dedicated file storage objects created from within a regular file system that emulate a SCSI disk device via software emulation. On the iSCSI Host initiator, the iSCSI LUN appears as a local disk with individual files, but cannot see any other iSCSI LUNs that might be built on the same file system

→ Celerra supports virtually provisioned LUNs or regular dense LUNs, but not both on the same file system

→ Automatic file system extension feature is supported only for virtually provisioned iSCSI luns

→ iSCSI LUNs can be extended on Celerra, but the iSCSI Hosts must run utilities to discover the expanded iSCSI lun

→ Luns interpret SCSI CDBs and executes SCSI commands—Celerra uses software for processing SCSI commands

→ Celerra uses regular dense Luns, or PBR (Persistent Block Reservation) to ensure that there is always space available for the Lun—server\_df may report that the Lun is full, eventhough it has not yet been written to. PBR reserves space in a Reservation Pool, but disks are not taken from the pool until needed

### **Types of iSCSI lun objects within the Celerra file system:**

PLU, SLU, TWS

→ PLU are Production Logical Units, or iSCSI luns, normally addressed from 0-127 (try not to use lun # 128-254), visible to Host Initiator, space is persistently reserved in the file system, reported as used space by Celerra

→ SLU are Snap Logical Unit Point-in-time copies of the PLU using pointers to blocks of data, normally addressed from 128-254 as temporary luns, promoted to LUN status for access. Size reported as % of the PLU size between 0-100%.

→ TWS are Temporary Writable Snaps, or a RW version of the SLU, used during Snap promote and restore operations, is deleted when demoted

→ LUN size is restricted to 2TB

### **LUN MASKS:**

Masks are used to control access to LUNs on iSCSI Targets

### **CELERRA iSCSI DEVICE DISCOVERY:**

**iSCSI (Internet Storage Name Service):** Discovery & naming protocol for discovery of iSCSI devices on TCP/IP network

#### **Two Types of iSCSI Discovery can be achieved:**

→ Celerra operates as an iSNS Client for updates from the iSNS Name Service, where auto discovery of initiators, targets, portals, & portal groups occurs [iSNS Discovery]

→ Celerra can be manually configured using SendTargets to configure Target's network portal (Target iSCSI name, TCP port & IP address) for the Initiator [SendTargetsDiscovery] to establish a discovery session with iSCSI service on the Target.

### **CONFIGURING iSCSI LUNS FOR CELERRA (5.3-5.5):**

1. Create and mount file system on Data Mover

**Note:** File System is called virtual\_iscsifs

2. Enable iSCSI License in Celerra Manager (not required for CLI)

3. Create iSCSI Target on DM, providing qualified name of DM (Port 3260)

# server\_iscsi server\_2 -target -alias target1 -Q iqn.1992-05.com.emc:test -create 1000:np=10.241.169.44 (1000 = portal group id, port 3260 used by default from CLI)

WebUI>iSCSI>Targets>New>Choose Data Mover: server-2 >Name: target1>Network Portals: 10.241.169.44:3260 (DM IP and Port 3260)

4. Create iSCSI LUN mask for the Target, specifying DM, target, Initiator, and LUN range

# server\_iscsi server\_2 -mask -set target1 -initiator iqn.1991-05.com.microsoft:nas81.celerra1.emc.com -grant 0-100

WebUI>iSCSI>Targets>rightclick target Properties>LUN Mask>New>Initiator: iqn.1991-

05.com.microsoft:NAS81.celerra1.emc.com (Open MS iSCSI Initiator application and copy the iqn to the WebUI box)>Grant LUNs: 0-100

5. Create iSCSI LUN specifying DM, target, LUN #, File System, and Size of LUN

# server\_iscsi server\_2 -lun -number 0 -create target1 -size 100M -fs virtual\_iscsifs -virtually\_provisioned yes

**Note:** Cannot create virtually provisioned iSCSI LUN from WebUI—all other iSCSI luns can be created from WebUI. Create multiple LUNs under same Target ID. Virtually Provisioned LUNs only supported in 5.5 via RPQ.

6. Enable iSCSI service on DM and point to iSNS Server [Windows 2000 Server with iSCSI Initiator installed]

# server\_iscsi server\_2 -ns isns -server 10.241.169.100

# server\_iscsi server\_2 -service -start

WebUI>Server\_2>iSCSI>Configuration>iSCSI Enabled

**Note:** iSCSI LUN will now be visible in WebUI

7. Add CHAP authentication:

# server\_security server\_2 -add -policy chap -name iqn.1991-05.com.microsoft:nas46.celerra2.emc.com

8. Install Microsoft iSCSI Initiator driver on Win2k/Win2k3 system [free download] and configure using iSCSI Initiator Properties

9. Add Target Portal IP addresses of Data Mover Target:

a.) iSCSI Initiator Properties>Discovery>Target Portals Add>IP Address or DNS name: 10.241.169.44:3260

**Note:** If the target is already listed, proceed to next step

**Target Portals:**

10.241.169.44 3260

10. Go to Targets tab>highlight iSCSI Target>select Log On to Target: check the box for “Automatically restore this connection when the system boots”

**Note:** If the target is already listed in the Status column as “Connected”, it has already been added to the “Persistent Targets” tab, and so you cannot select the “Automatically restore this connection...” box again.

11. Create iSCSI Partitions:

a) Start>Run>Diskmgmt.msc>If wizard is presented to convert to dynamic disk, Cancel>Rightclick the Unknown/Not Initialized Disk number>Initialize Disk>disk is now seen as Basic Online volume

b) Rightclick the Unallocated partition>New Partition>select Primary Partition>Confirm partition size>Assign a drive letter>Format this partition with the following settings: NTFS, FAT, FAT32, Provide a Volume Label designation, then select checkbox for Perform a quick format [Partition is formatted and marked Healthy]

## **DELETING iSCSI LUN:**

# server\_iscsi server\_2 -lun -list

server\_2 :

target: fs2\_lun  
lun size(MB) filesystem  
1 15360 fs2\_lun ( id=26 )

# server\_iscsi server\_2 -target -list

server\_2 :

alias\_name portal\_groups iscsi\_name  
fs2\_lun 1 iqn.1992-05.com.emc:sl7e10807001210000-1

# server\_iscsi server\_2 -lun -delete 1 -target fs2\_lun

server\_2 : done

## **THINGS TO KNOW ABOUT CONFIGURED SYSTEM:**

→Cannot change target's qualified name after creation

→Network portal modifications do not affect active sessions between Target & Initiator

→Deleting an iSCSI target deletes target and associated LUN masks, and deregisters from iSNS

→Cannot delete target, however, if iSCSI Initiator logged in or LUN is configured (delete all LUNs first)

**Async Param Problem:** 5.5.29.1

Default value for AsyncEvent is 1 to enable async event logging by the target.

When set to 0, the target sends async logout messages, and during addition of new iSCSI luns, a LUN Inventory is triggered which makes all the Celerra iSCSI luns unavailable.

Corrective action is to set param iscsi AsyncEvent=1

## **CELLERRA ISCSI FILES FOUND IN /etc:**

```
-rw-r--r-- 1 root bin      535 Jun  8 22:33 iscsi.conf (most importance config file, read by iSCSI svc on startup)
-rw-r--r-- 1 root bin      116 Jun  8 20:46 iscsi_initiator.conf
-rw-r--r-- 1 root bin      172 Jun  8 22:33 iscsi_lun.conf
-rw-r--r-- 1 root bin      270 Jun  8 20:46 iscsi_lunmask.conf
-rw-r--r-- 1 root bin       7 Jun  8 17:05 iscsi_pggroups.conf
-rw-r--r-- 1 root bin      21 Jun  8 17:05 iscsi_portals.conf
-rw-r--r-- 1 root bin      49 Jun  8 17:05 iscsi_targets.conf
-rw-r--r-- 1 root bin     210 Jun 23 21:24 chapdb
```

**drwxr-xr-x 2 root bin 1024 Jun 23 21:24 nbsdb →NBS directory**

**Note:** iSCSI LUNs are listed in this directory

```
lrwxr-xr-x 1 root bin      58 Jun  8 20:46 fs213_T1_LUN0_APM00050802675_0000 fsid=213 vlu=Disk

## CELLERRA iSCSI COMMANDS:

→ Celerra is the “target” and the Windows host is the “initiator”

### # server\_iscsi server\_2

server\_2 :

Error 2100: usage: server\_iscsi { <moveovername> | ALL }

```
-target <target_options>
| -lun <lun_options>
| -mask <lun_mask_options>
| -ns <name_service_options>
| -service { -start | -stop | -status }
| -snap <snap_options>
| -help
```

To get detailed options for target, lun, lun mask and name service, please type "-help" or only type "-target", "-lun", "-mask", "-ns" and "-snap" respectively after typing in the server name.

### # server\_iscsi server\_2 -target

```
-target {
-alias <alias_name> [-Q <iscsi_name>]
-create [<pg_tag>:np=<np_list> [<pg_tag>:np=<np_list> ...]]
| -delete <alias_name>
| -rename <old_alias_name> <new_alias_name>
| -bind <alias_name> <pg_tag>:np=<np_list>
| -unbind <alias_name> { <pg_tag> | np=<np_list> }
| -info { <alias_name> | -all }
| -stat { <alias_name> | -all }
| -list
```

### # server\_iscsi server\_2 -lun

```
| -lun {
-number <lun_number> -create <target_alias_name> -size <size>[M|G|T]
-fs fs_name [ -vp {yes|no} ] [ -readonly {yes|no} ]
| -extend <lun_number> -target <target_alias_name> -size <size>[M|G|T]
| -delete <lun_number> -target <target_alias_name>
| -info { <lun_number> | -all } [-target <target_alias_name>]
| -stat { <lun_number> | -all } [-target <target_alias_name>]
| -modify <lun_number> -target <target_alias_name> -readonly {yes [-Force] | no}
| -list [-target <target_alias_name>]
```

### # server\_iscsi server\_2 -mask

```
| -mask {
-list [<target_alias_name>]
| -info <target_alias_name> {-initiator <initiator_name> | -all }
| -set <target_alias_name> -initiator <initiator_name>
{ -grant <access_list>
| -deny <access_list> }
```

| -clear <target\_alias\_name> -initiator <initiator\_name>

## # server\_iscsi server\_2 -ns

| -ns isns

{ -info

| -set { -server <IP>[:<port>] | -esiport <port> }

| -clear { -server | -esiport | -all }

## # server\_iscsi server\_2 -service -status

server\_2 :

\*\*\*\* iSCSI Service \*\*\*\*

Status: Running

iSNS is configured to listen on ports:

TCP Port: 3260 -----output abridged-----

## **SETTING iSCSI LUN AS READ-ONLY FOR A TARGET:**

# server\_iscsi server\_2 -lun -modify 10 -target cel1 -readonly yes -Force

server\_2 : done

## # server\_iscsi server\_2 -lun -info 10

server\_2 :

Logical Unit 10 on target cel1:

(Production) fsid=31 size=5120MB alloc=134MB dense read-only

path=/cel1\_10/fs31\_T1\_LUN10\_APM00071600514\_0000/fs31\_T1\_LUN10\_APM00071600514\_0000

replication=available destination

max\_extension\_size=927MB

Healthy

**Note:** Not sure how effective the RO setting is. I did get a “write-protected” popup when trying to copy new files to the iSCSI lun, but in many cases, some folders and files were shown as copied before the popup error appeared. Bottomline, further testing showed that only rebooting the Data Mover would prevent files from being copied. Furthermore, after rebooting, the iSCSI lun was actually not accessible at all from the Windows Host, meaning that RO actually means no Host access. And, once the iSCSI lun was set back to RW, none of the files that were previously thought to have been copied over, were actually there. So, some quirks about this behavior.

## **CREATING iSCSI TARGETS WITHOUT & WITH QUALIFIED NAME:**

\$ server\_iscsi server\_2 -target -alias target1 -create 1000:np=192.168.25.122,192.168.25.123

\$ server\_iscsi server\_2 -target -alias target2 -Q iqn.1992-05.com.emc:test -create

## **CREATE LUNS on iSCSI TARGET:**

\$ server\_iscsi server\_2 -lun -number 2 -create target1 -size 1000 -fs iscsi02 (creates LUN 2)

## **SET LUN MASK ON TARGET:**

\$server\_iscsi server\_2 -mask -set target1 -initiator iqn.1991-05.com.microsoft:nas46.celerra6.emc.com -grant 0-100

## **SETTING iSNS SERVICE:**

\$ server\_iscsi server\_2 -ns isns -set -server 192.168.25.46

## **STARTING & VERIFYING iSCSI/iSNS SERVICE:**

\$ server\_iscsi server\_2 -service -start | -status

\$ server\_iscsi server\_2 -ns isns -info (iSCSI Client Service Status)

\$ server\_iscsi server\_3 -ns isns -info

server\_3 :

iSNS Client Service Status

-----

service : stopped

server : UNKNOWN →This is normal if customer is NOT running the Name Service for iSCSI

entity : UNASSIGNED

source :

ESI support : TRUE

ESI port : UNASSIGNED

timeout : 3000

trace : FALSE

PG support : TRUE

# server\_iscsi server\_2 -service -status (iSCSI Service Status)

server\_2 :

\*\*\*\* iSCSI Service \*\*\*\*

Status: Running

iSCSI is configured to listen on ports:

TCP Port: 3260

Header Digests are preferred

Data Digests are not preferred

### **iSCSI SERVICE LISTED IN LOCAL NETD FILE:**

\$ cat /nas/server/slot\_2/netd

**iscsi start**

**iscsi hiwat=0x60000 →TCP High Watermark reception tweak for clients using low MTU's with iSCSI—AR73389**

### **VERIFYING TARGET LIST & QUERYING SPECIFIC TARGET:**

**\$ server\_iscsi server\_2 -target -list**

server\_2 :

alias\_name portal\_groups iscsi\_name

SQL1\_Data 1 iqn.1992-05.com.emc:apm000520060760000-2

**\$ server\_iscsi server\_2 -target -info SQL1\_Data**

server\_2 :

### **VERIFYING LUN LIST & QUERYING:**

**\$ server\_iscsi server\_2 -lun -list**

server\_2 :

target: SQL1\_Data

lun size(MB) filesystem

0 102400 SQL1\_Data ( id=24 )

**\$ server\_iscsi server\_2 -lun -info 0**

server\_2 :

Logical Unit 0 on target SQL1\_Data:

(Production) fsid=24 size=102400MB alloc=3182MB dense

path=/SQL1\_Data/fs24\_T2\_LUN0\_APM00052006076\_0000

**\$ server\_iscsi server\_2 -lun -info -all -target target1**

**\$ server\_iscsi server\_2 -lun -s -a**

server\_2 :

Logical Unit 0 on target 1850r8-iscsi:

(Production) fsid=25 size=1000MB alloc=0MB dense

path=/1850r8/fs25\_T4\_LUN0\_APM00042403638\_0000/fs25\_T4\_LUN0\_APM000

42403638\_0000 (snapped)

replication=source

max\_extension\_size=11787MB

Statistics:

Total SCSI CDBs: 136

Read: 63 Failed: 0 Blks read: 338

Write: 28 Failed: 0 Blks written: 248

## **VERIFYING LUN MASK LIST & QUERYING:**

**\$ server\_iscsi server\_2 -mask -list**

server\_2 :

target: SQL1\_Data

initiator\_name grant LUNs

iqn.2000-04.com.qlogic:qla4010.fs20520b01057 0

**\$ server\_iscsi server\_2 -mask -info SQL1\_Data -initiator iqn.2000-04.com.qlogic:qla4010.fs20520b01057**

server\_2 :

Initiator Lun Mask:

Initiator Name: iqn.2000-04.com.qlogic:qla4010.fs20520b01057

grant=0

**Note:** Where ‘SQL1\_Data’ is the alias name for the Target

**\$ server\_iscsi server\_2 -mask -list target1**

**\$ server\_iscsi server\_3 -mask -list**

server\_3 : no iscsi lun masking entry

## **ADDING CHAP SECURITY:**

**\$server\_security server\_2 -add -policy chap -name iqn.1991-**

**05.com.microsoft:auslander.csunet.csuohio.edu**

**# server\_security server\_2 -info -policy chap** (displays CHAP security info)

server\_2 :

chapdb name=iqn.1991-05.com.microsoft:auslander.csunet.csuohio.edu pass=\*\*\*\*\*

chapdb name=iqn.1991-05.com.microsoft:outlander.csunet.csuohio.edu pass=\*\*\*\*\*

**Note:** Use GUI to verify Portals, Available Targets, Active Sessions, Configure Partitions.

/slot\_2/etc

**# cat chapdb**

chapdb name=iqn.1991-05.com.microsoft:auslander.csunet.csuohio.edu pass=3539615135133561513D233719173D17

chapdb name=iqn.1991-05.com.microsoft:outlander.csunet.csuohio.edu pass=3539615135133561513D233719173D17

## **CELLERRA iSCSI HOST SOLUTIONS:**

→Exchange 2000 Integration with SnapSure module

→SnapSure Manager for Celerra iSCSI LUNs, using Client-side software to manage iSCSI LUN Snaps

→Eng. White Paper exists that describes possibility of using Celerra iSCSI luns as repository for boot images for Network diskless clients using PXE. Clients would boot using an iSCSI HBA [QLogic QLA4010—need to download specific bios separately] to boot

Windows 2003 Clients from the Celerra iSCSI LUN. Basically, the HBA bios establishes the target location of the boot image, establishes iSCSI session with Celerra target, sets the iSCSI LUN as the boot device, at which time the Windows system recognizes the boot device and goes through normal boot as if the LUN were local. Another boot method would be to use a separate PXE Server for the Client systems to download a winBoot/I bootstrap into RAM, at which point the program executes and connects to the iSCSI LUN. See “iSCSI Booting...” White Paper from Powerlink for more information.

### **EXCHANGE 2000 INTEGRATION:**

- Configure MS Exchange 2000 to use Celerra iSCSI LUNs for Exchange Logs and Databases
- Migrate Storage groups to Celerra iSCSI LUNs via wizard
- Use SnapSure to Restore & Delete storage group snaps, Delete Storage group Store, Promote Storage group snap by assigning iSCSI LUNs to make accessible to remote systems, Demote Storage group snap, Schedule a Storage group snap.
- Best Practices Guide suggests that Windows Server timeout for Exchange be set to 600 secs from 40 secs

### **EXCHANGE SNAPSURE LIMITATIONS:**

- Do not use MS Terminal Services to access SnapSure Manager
  - SnapSure temporarily mounts Exchange when creating iSCSI Snaps
  - Do not schedule Snaps during ‘At System Startup’ or ‘At Logon’
  - Each Information Store and Log Files for Exchange must be on separate iSCSI Disks
- LU 1 →Transaction Logs and System Files  
LU 2 →Priv Information Store  
LU 3 →Pub Information Store

### **QLOGIC 4010 MODEL iSCSI HBA:**

When using Qlogic 4010 iSCSI initiators, ensure min NAS 5.3.15.306. On Windows 2003 host, ensure the MS iSCSI Service is installed. Ensure initiator name is the same in both MS iSCSI GUI and in Qlogic Sansurfer. Run c:>mountvol /E to enable automount of promoted snaps on Windows in order to assign drive letters dynamically. LUN numbers cannot be >than 128 for this feature. Set the following param to 0 to disable ReportLunsOverflow:

**param iscsi ReportLunsOverflow=0**

### **INSTALLING CELERRA iSCSI APPLICATIONS:**

- SnapSure for Exchange 2000
  - SnapSure Manager for iSCSI
  - Celerra Logical Disk Service (CLD)
1. Ensure that Windows Host has Microsoft iSCSI Software Initiator installed first
  2. Install EMCCLDPack\_1\_4\_8.exe & select complete setup
  3. Configure DCOM Access permissions during InstallShieldWizard [add System and Administrator accounts to CLD service]
  4. Set Authentication Level to “Packet” in the General properties tab for CLD Service
  5. Set security access permissions in the Security properties tab
- \*Use custom access permissions and add SYSTEM & Administrator, and any other accounts required, to the service

### **USING SNAPSURE MANAGER for iSCSI:**

**Purpose:** Create Snap, Promote iSCSI Snap to SLU, on LocalHost or RemoteHost, Demote an iSCSI SLU, Restoring PLU from iSCSI Snap, Delete iSCSI Snap. Scheduling iSCSI Snaps

Programs>Celerra Tools>SnapSure Manager for iSCSI>should be able to see all Celerra PLUs (Production Logical Units)

1. Create Snap of Celerra iSCSI LU (Logical Unit) using SnapSure Manager for iSCSI
2. Rightclick iSCSI Logical Unit and choose new
3. Promote the iSCSI snap to an SLU on the local or a remote Host

**Note:** Celerra will automatically add the lun mask for the host. Use Explorer, Disk Manager, MS iSCSI Initiator programs to view SLUs

4. Verify promoted SLU from Celerra:

**# server\_iscsi server\_2 –target –info <target\_name>**

**Note:** SLU can be mounted and used as a Temporary Writeable Snap (TWS), but it's important to know that when the snap is demoted, the TWS information is lost!

5. Use EMC SnapSure Manager for iSCSI>Snap>Demote to demote the SLU

### **EXCHANGE MANAGEMENT iSCSI EXTENSIONS:**

- Migrate Exchange Stores and Logs to Celerra iSCSI Luns
- Create SnapSure Backups of Exchange Storage Groups [Create iSCSI Snap, Promote, Backup the SLU]
- Conduct Single Mailbox Restore using offline ‘Recovery Server’
- Conduct Point-in-Time or Up-to-the-Present Restores

## **GENERAL iSCSI SNAPSURE LIMITATIONS:**

- Snaps must not be in ‘Promoted’ Status
- PLU cannot be in “Restoring” status [Admins must quiesce PLU applications first]
- Snaps are created temporarily until changes are committed to PLU
- Snaps reserve space for allocated blocks on the source LUN and are called “sparse files” (Production LUNS are “dense files”)

## **iSCSI RESTRICTIONS/RULES/BEST PRACTICES:**

- Do not allow multiple initiator access to the same iSCSI Lun (but not a hard requirement)
- MS Initiators only support single connections per session
- Use IQN numbers in lowercase
- Max iSCSI LUN size NAS 5.3 is 1TB
- Max iSCSI LUN size NAS 5.4-5.6 is 2TB
- Linux iSCSI initiator’s can only work with 32 LUNS or less
- Do not use Lun #’s greater than 128-254 for PLU’s
- Do not run nas\_fsck on iSCSI luns without Eng. approval
- iSCSI Snapshots are only useful for DR purposes if saved off to tape
- Do not stop iSCSI Service if Initiators are logged in
- Multiple iSCSI luns can be configured on a single Celerra file system
- Initiators use only a single TCP connection to the Target
- iSCSI Luns are not supported for VDMs
- Checkpoints, IP Replications, Cava, MPFS Highroad, & DHSM are features not supported on Celerra iSCSI file systems
- IPsec & Dynamic Disks are not supported
- Native iSCSI supported for Celerra, not ‘bridging’ topologies
- MSCS (MS Cluster Service) is supported with limitations (no multiple connections per session)
- Both MS Exchange & SQL Server application timeout values on Host Servers should be set to 600 secs.

## **KNOWN iSCSI ISSUES:**

- NAS 5.5 Upgrade issue if iSCSI LUN doesn’t have 100MB free space, the lun will become totally corrupt and unavailable—needs enough space to write out new directory structure (see emc141515)

## **TROUBLESHOOTING iSCSI:**

→ For Windows systems, install DebugView Utility--download from [www.sysinternals.com/files/dbgvnt.zip](http://www.sysinternals.com/files/dbgvnt.zip)

**HKLM>Software>EMC>CLDSvc>Configuration**>Set Debug & Verbose values to 1 & reboot Windows System

→ Set following Debug Logging on Celerra [Log facilities are ISCSI, NBS, VLU, & IPSNS]

**# .server\_config server\_2 -v "logsys set severity ISCSI=LOG\_DEBUG" | NBS | VLU | IPSNS**

**Note:** Remember to turn off debug logging when done

**# .server\_config server\_2 -v "logsys set severity ISCSI=LOG\_PRINTF"**

→ Network Trace: Filter on Port 3260

## **USING HIDDEN iSCSI LOG:**

**# .server\_config server\_2 -v "iscsi log"**

Commands are:

pc → print current page  
pw → print page at write position  
pn → print next page  
pp → print previous page  
pw → print write position page  
pg=n → print page n  
nt → do not show time stamps  
ts → show time stamps  
cl → clear event log  
dis → disable logging  
en → enable logging

## **SET FOLLOWING PARAM TO GATHER ISCSI SESSION STATISTICS:**

**param iscsi.CollPerfStats=1**

**\$ .server\_config server\_x -v "iscsi eng showsessions"**

\*\*\* IscsiSessions \*\*\*

Sessions for Target: iqn.1992-05.com.emc:apm000433060400000-25

Outstanding Tasks:

Average number of tasks: 0.49

Normalized Std Dev (R^2): 0.01

## iSCSI ENG USAGE:

**# .server\_config server\_2 -v "iscsi eng"**

Usage: iscsi eng cmd

Where cmd is one of:

dumpdb [db=target|lun|portal|pgroup|lin|lunmask]

dumpviewfile - displays the view file

logout [name=aliasname] - logout target sessions

makeviewfile - generates a new version of the view file

setviewversion version=num - Sets the view file version

showluns [name=aliasname] - displays logical units

showmasks [name=aliasname] - displays target lun masks

showportals - displays portals

showsessions [name=aliasname] - displays target sessions

showtargets - displays a list of targets

targetinfo [aliasname] - displays target information

threads [add|kill=thrs] - add, kill, or display # of iSCSI threads

## BASIC TROUBLESHOOTING STEPS:

1. Verify IP connectivity
2. Check iSCSI service on DM and Initiator service on Host

3. Verify Initiator is logged into target
4. Verify Target & Initiator portal settings
5. Verify Target LUN mask, name, and access granted
6. Verify Initiator & Target iSCSI names for typos
7. Verify CHAP configuration
8. Verify status of Backend
9. Set debug logging on Celerra

## **REPAIRING/RECOVERING iSCSI CONFIGURATION FILES:**

1. The iSCSI configuration is located on the Control Station in /nas/server/slot\_x/iscsi file and on the Data Mover in the /etc/iscsi.conf file

**Note:** If for some reason, either of the locations is missing its complete file, then copy the file from the good location to restore, or find a valid copy in the NAS\_DB Backup

2. If the file is missing or corrupted in both locations, and the Data Mover has NOT been rebooted, then we can regenerate the iSCSI configuration by using the following command—simply copy the file to the proper location:

**# .server\_config server\_2 -v “iscsi eng makeviewfile”**

1126894703: UFS: 6: inc ino blk cache count: nInoAllocs 1: inoBlk a5076b04

1126894703: UFS: 6: inc ino blk cache count: nInoAllocs 2: inoBlk a5076a84

1126894703: ADMIN: 4: Command succeeded: iscsi eng makeviewfile

3. If various other iscsi\_\* files are corrupted, but the iscsi.conf or iscsi file is known to be good, do the following to rebuild the appropriate files:

a. Delete all iscsi\_\* files from .etc

b. Reboot data mover to clear cache

c. Replay the iscsi or iscsi.conf file to create the other files by doing the following, then associate all LUNs to Targets:

**#.server\_config server\_2 -v “iscsi target action=create name=itang iqn=iqn.1992-**

**05.com.emc:apm000517019120000-1 sn=1 1:np=10.6.3.203:3260”**

**#.server\_config server\_2 -v “iscsi target action=mask name=itang initiator=iqn.1991-**

**05.com,Microsoft:itangpc grant=1-2”**

Modify lun action=create line by removing fsid= & size= entries, and enter correct path=

Associate Lun to target itang, LUN id=2 using:

**# .server\_config server\_2 -v “iscsi lun action=create number=2 target=itang**

**path=/itangfs1/fs29\_T1\_LUN2\_APM00051701912\_0000”**

**\$ .server\_config id=1 -v “iscsi lun action=create number=0 target=dm2**

**path=/dm2\_iscsi0/fs44\_T1\_LUN0\_20051214\_165301”**

4. If more extensive recovery is required, engage EE for assistance

5. If iSCSI Luns can no longer be accessed via iSCSI protocol, but data must be obtained, use following Windows Utility to access:

a. Download Virtual Disk Driver from chitchat.at.infoseek.co.jp/vmware

b. c:\>vdk.exe install /auto

c. Start driver & verify: c:\>vdk.exe start c:\>vdk.exe driver

d. Access iSCSI file system on Server from CS0 and copy the LUN within the same file system, but as a different name

#cp fs29\_T1\_LUN2... fs\_recover

e. Map drive to Share containing the new LUN filename and read the file

c:\>vdk.exe view fs\_recover

f. Open file as a device and start copying data to safe location

c:\>vdk.exe open \* fs\_recover

## **PERSISTENT BLOCK RESERVATION:**

iSCSI LUNs use PBR to preallocate blocks for the LUNs. Use following command to verify PBR:

**\$ .server\_config server\_2 -v “file pbrcheck ufs checkonly <vol\_id\_of\_fs>”**

## **iSCSI PERFORMANCE BEST PRACTICES:**

→Use RAID 1 configurations for random I/O (SQL, Exchange)

→Use RAID 5 when access is via sequential I/O

→Configure DAE's as either all-Random I/O shelves or all-Sequential shelves

→Use AVM or MVM, depending on needs and complexity of disk & metavolume layout

→Use Dense LUNs for critical data

→Use sparse LUNs using file system auto extension and monitor

→Use snaps to restore data or to promote a Snap to PLU status

## **CELERRA DATABASE & VOLUMES CONFIGURATION:**

### **COMMAND OUTPUTS/TOOLS NAS 5.3 & HIGHER:**

**# nas\_fs -i fs03**

This procedure may be required to complete an SRDF Restore or a failing NAS Upgrade.

1. # cd /nas/opt/emc/SYMCLI/V6.0.0/shlib

2. Tar existing contents and copy to safe location:

# tar -cvf symcli600lib\_files.tar \*

3. Copy replacement symcli library files into /nas/opt/emc/SYMCLI/V6.0.0/shlib

# cp -ip symcli600lib\_files.tar /home/nasadmin

4. Untar the new files while in the /nas/opt/emc/SYMCLI/V6.0.0/shlib directory

# tar zxvf 60111.tar.gz

-r-xr-xr-x root/root 270475 2005-08-17 17:36:14 libstorpd.so

-r-xr-xr-x root/root 13264343 2005-08-17 17:36:13 libsymapi.so

-r-xr-xr-x root/root 805569 2005-08-17 17:36:13 libsymlvm.so

5. Verify Link on following file:

# cd /usr/lib

# ls -la

lrwxrwxrwx 1 root root 31 Sep 15 02:28 libstorpd.so -&gt; /usr/symcli/shlib/libstorpd.so

**Note:** If link does not exist, create link in /usr/lib directory:

#ln -s libstorpd.so /usr/symcli/shlib/libstorpd.so

6. Verify that symcli or symcfg commands work

7. Conduct # nas\_rdf –restore

**Note:** See Primus emc120887 & AR69029 for more details on Solutions Enabler Version 6.0.0 problem and Celerra SRDF operations**RECONCILING CELERRA AND SYMMETRIX DEVICE DATABASES:****VERIFYING WHAT DEVICES CELERRA SEES:****\$ nas\_diskmark -l -all** [Lists all SYMM devices, sizes, TID's, & GateKeepers for Celerra; same as devconfig]**\$ nas\_diskmark -m -all** [Use this to diskmark all disks for all servers]**\$ server\_devconfig server\_x -l -s -a** [Lists all Symm devices, Addresses, Director Number/Type, and GateKeeper]**\$ server\_devconfig server\_x -p -s -a** [Lists all Devices ‘discovered’ on each chain for a DataMover]**\$ server\_devconfig server\_x -c -s -a** [Adds new devices to Celerra Database; \$/nas/volume/volumes|disks]**# nas\_disk –delete d40 –perm** [Deletes volume and removes diskmark]**# nas\_diskmark -m -a -monitor y**

Verifying disk reachability

Verifying file system reachability

Verifying local domain

Verifying disk health

Verifying gate keepers

Verifying device group

**USING SERVER DEVCONFIG:** Equivalent to the nas\_diskmark command**\$server\_devconfig server\_2 -c -s -a** [Running this command updates the following Celerra Database files]**DOES & DON'Ts BEFORE RUNNING DEVCONFIG –CREATE ON CELERRA:**

→don't run without first verifying paths &amp; bind tables via devconfig –probe and fcp bind show

→don't run if BCV devices are mirrored on, as these devices would not be seen by Celerra—BCV's are seen only when split, or mirrored off (aka, uxf state)—while devices are established, BCV diskmark is overwritten &amp; restored only when split back off

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
 →don't run for Celerra systems attached to Clariion backends without first verifying that there are no trespassed LUNs  
 →don't run –create without first making backup copies of camdisk files (-create will update the camdisk, disks, and scsidevs files)  
 All Volumes→ /nas/volume/volumes  
 All Disks→ /nas/volume/disks  
 Server GateKeepers→ /nas/server/slot\_x/scsidevs  
 Server Devices→ /nas/server/slot\_x/camdisk. Devconfig –create will update this file with new devices  
 All GateKeepers→ /nas/dev. Gatekeepers are used with Symm, not Clariion backends

### **BYPASSING NAS 5.4 HEALTHCHECK FAILURES:**

### **USING DEVCONFIG TO ADD NON-CELERRA FBA DEVICES AFTER UPGRADE TO NAS 5.4:**

**Note:** NAS 5.4 does a database healthcheck when running the devconfig –create command. It's possible to have some Celerra devices as FBA devices rather than Celerra\_FBA for older systems that are just upgraded. See Primus emc116641. Telltale messages are shown below. Run the server\_devconfig command to force the addition of "FBA" devices to Celerra database:  
 000185701868 018A d15 emulation is FBA, should be CELERRA\_FBA

```
# server_devconfig server_x -c -s -a -discovery n -Force y [Force option ignores healthcheck]
```

```
# nas_diskmark -m -a -d n -Force y
```

SL7E1081700022 storage API db out of sync, last updated 2009/03/29-02:34:19

Forcing discovery

Discovering storage (may take several minutes)

done

### **VERIFYING CAM TABLES BY SCSI CHANNEL:**

```
# .server_config server_5 -v "camshowconfig"
```

CAM Devices on scsi-0:

TID 00: 0:d0 1:d1 2:d2 3:d3 4:d4 5:d5 15:d6

TID 01: 0:d7 1:d8 2:d9 3:d10 4:d11 5:d12 6:d13 7:d14 8:d15 9:d16 10:d17 11:d18 12:d19 13:d20 14:d21 15:d22---abridged----

### **VERIFYING CELERRA VOLUMES DATABASE CONSISTENCY:**

1. Verifying Device mappings from Backend

```
/nas/tools/dbchk -p
```

**Note:** Script by default will verify database files located in /nas/volume directory and crosscheck with server\_devconfig probes  
 2. Run following commands as a second check—any mismatched entries will cause an eiffel dump

```
# nas_fs -i -all
```

```
# nas_volume -i -all
```

```
# nas_disk -i <d_name or id=>
```

### **KEY VOLUME DATABASE FILES:** /nas/volume

disks →List of diskmarked volumes that Celerra sees. Devconfig –create adds to this file, nas\_disk –d will remove entries from file

filesys →List of filesystems created on Celerra

slices →Slices used in creating metas

symms →Storage systems that Celerra is attached to

volumes →Volumes used in creating file systems

/nas/server/slot\_x/camdisk

/nas/server/slot\_x/ufs →Entries in this file removed when perm unmounting filesystem, likewise added when mounting

/nas/server/slot\_x/volume →Entries removed when perm unmounting fs, added when mounting

### **FILESYS FILE:**

22:IPrep\_src:0:y:1:113:2:::0:**26@1**:23: →FSID '22' is a backup of FSID '26' at Host ID 1, related to IP Replication or TimeFinder (the “@1” matches up with index number in the output of nas\_cel –list)

**DESCRIPTION OF EACH COLUMN IN FILESYS FILE:****30:fs\_time1\_snap1:0:n:1:155:::1115308301:29:1:::**

1. 30 = filesystem id
2. fs\_time1\_snap1 = filesystem name
3. 0 = filesystem acl -- not used
4. n = in use, n=no, y=yes, f=frozen, c=corrupted
5. 1 = volume type, for timefinder 1=uxfs , 6=mirrored
6. 155 = meta volume id the filesystem is created on
7. blank = rw servers
8. blank = ro servers
9. 1115308301 = absolute backup time – time last backup was created or refreshed
10. = 29 = backup of , the volume id of the filesystem this is the backup of
- 11.1 = filesystem type-- 0=local, 1=bcv
- 12.blank = volume id of backup filesystems of this filesystem
- 13.blank = avm pool the filesystem is created from
- 14.blank = if this is an avm pool, the filesystems built from the pool
- 15.blank = avm pool type

**VALIDATING SERVER DEVICE DATABASE CONSISTENCY AND BINDING TABLES:****1. Use Devconfig Probe to List out Each SCSI Chain and the Devices associated with them:**

# server\_devconfig server\_5 -p -s -a

Chain 0 Devices 1-176

Chain 16 Devices 1-176

**2. Use Devconfig List to determine FA Associated with each Chain :**

Chain 0 Devices 1-176 →04B

Chain 16 Devices 1-176 →03B

**3. Use Devconfig List or Camdisk file to determine if there are extra devices listed in Camdisk that are not seen in Probe:****List:**

|     |   |      |                   |     |      |             |
|-----|---|------|-------------------|-----|------|-------------|
| 177 | n | 8631 | 000182502561-004B | STD | d177 | 5,3,1,2,4,6 |
| 178 | n | 8631 | 000182502561-004C | STD | d178 | 5,3,1,2,4,6 |
| 179 | n | 8631 | 000182502561-004D | STD | d179 | 5,3,1,2,4,6 |
| 180 | n | 8631 | 000182502561-004E | STD | d180 | 5,3,1,2,4,6 |

**Camdisk Contains Extra Devices:**

177:c32t5l10+52666104B320+,c48t5l10+52666104B010+:

178:c32t5l11+52666104C320+,c48t5l11+52666104C010+:

179:c32t5l12+52666104D320+,c48t5l12+52666104D010+:

180:c32t5l13+52666104E320+,c48t5l13+52666104E010+:

**4. Confirm whether extra devices not seen in probe are in use or not:**

#nas\_disk -l

|     |   |      |                   |     |      |             |
|-----|---|------|-------------------|-----|------|-------------|
| 177 | n | 8631 | 000182502561-004B | STD | d177 | 5,3,1,2,4,6 |
| 178 | n | 8631 | 000182502561-004C | STD | d178 | 5,3,1,2,4,6 |
| 179 | n | 8631 | 000182502561-004D | STD | d179 | 5,3,1,2,4,6 |
| 180 | n | 8631 | 000182502561-004E | STD | d180 | 5,3,1,2,4,6 |

**Note:** Determine from customer or field if devices are actually no longer assigned to Celerra and then remove using nas\_disk -delete**5. Compare persistent & dynamic binding tables to ensure that all Chains match up to correct FA port:**

# .server\_config server\_5 -v "fcp bind show"

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 50060482bfd1fb13 HBA 0 **FA-04ba**Chain 0016: WWN 50060482bfd1fb12 HBA 0 **FA-03ba**

Chain 0032: WWN 0000000000000000 HBA 1 FA-04ab

Chain 0048: WWN 0000000000000000 HBA 1 FA-03aa

\*\*\* Dynamic Binding Table \*\*\*

Chain 0000: WWN 50060482bfd1fb13 HBA 0 ID 0 Inx 00:00 Pid 0000 S\_ID 021000 Sys

Chain 0016: WWN 50060482bfd1fb12 HBA 0 ID 0 Inx 01:01 Pid 0016 S\_ID 021f00 Sys

Chain 0032: WWN 0000000000000000 HBA 1 ID 1 Inx 02:81 Pid 0032 S\_ID 000000 Non

Chain 0048: WWN 0000000000000000 HBA 1 ID 1 Inx 03:81 Pid 0048 S\_ID 000000 Non

**Note:** Persistent & Dynamic binding tables match for those FA ports that have actual disk devices assigned [FA-4b and FA-3b]

## **DETERMINING IF CELERRA & SYMAPI DATABASES ARE IN SYNC, THEN FIXING DATABASE IF CELERRA VOLUMES HAVE BEEN REASSIGNED OR DELETED:**

**Note:** This is not the procedure for a 'straight' addition of 'new' volumes to Celerra--see other sections

Step 1. \$nas\_disk -l → Verify "d3-d101" list [Example Only]

Step 2. \$server\_devconfig server\_2 -p -s -a

Step 3. Compare nas\_disk output of "d" volumes against server\_devconfig -probe:

### **WHAT DOES OUTPUT OF SERVER DEVCONFIG PROBE SHOW?**

This column equates to the listing of "d" volumes: **val= 3** thru **val= 101**,etc

If there are "d" devices listed in nas\_disk that are not "seen" by the datamover's when conducting the "probe", then the extra nas\_disk "d" devices are no longer physically attached to the Celerra, either as a result of Volume Changes, Reassignments, etc. If this is determined to be the case, then the following would be required to cleanup the Celerra Databases and re-sync the SYMAPI db:

Step 4. Create list of "d" volumes that are candidates for deletion [Ensure that they are "not in use" = n in nas\_disk -l output]

Step 5. Make a copy of the /nas/volume/disks and /nas/volume/volumes file

Step 6. Edit each of the above files and delete the appropriate "d" volumes

Step 7. Re-run \$server\_devconfig server\_x -c -s -a on all datamovers [precaution to ensure that all devices are 'discovered']

Step 8. Rebuild the SYMAPI Database by first renaming it, then running the following command:

### **LOCATION OF SYMAPI DATABASE ON CELERRA:**

# mv /nas/symapi/db/symapi\_db.bin /nas/symapi/db/symapi\_db.old

Correct permissions for symapi\_db.bin file:

-rwxrwxr-x 1 nasadmin nasadmin 2715490 Jun 14 21:05 symapi\_db.bin

# /nas/sbin/nas\_rdf -localinit [This command should run clean with following output]

Discover local storage devices ...

This operation may take up to a few minutes. Please be patient...

### **Note:**

If having trouble creating FileSystems, check Device Table and Impl Bin Flag Settings. By default, Server\_2 is the server that actually creates File Systems, therefore you would want to verify what Devices it can see.

#server\_devconfig server\_2 -l -s -a [Shows what Server\_2 sees from the NAS Database tables]

#server\_devconfig server\_2 -p -s -a [Probes live SCSI chains to read what devices are out there]

So, the two listings should match. If not, may entail rebooting DataMover and then running #setup\_slot -i 2 to rebuild the database

## **TROUBLESHOOTING SYMAPI DB PROBLEMS:**

1. Collect files from /nas/symapi/\* directory & /nas/log/symapi.log

2. Obtain Full Debug Log if requested by EE:

a.) move symapi\_db.bin and rename

b.) # export SYMAPI\_DEBUG=-1

c.) # export SYMAPI\_DEBUG\_FILENAME=/home/nasadmin/symapi\_debug.log

d.) Run Symm Discover: #/usr/symcli/bin/symcfg discover >discover.out

e.) Exit the shell to revert back from debug logging

**Note:** Don't forget to export symapi\_debug to a file. In certain situations, with debug turned on, symcfg or symcli commands may fail and output debug info to terminal.

## **USING IPCS TO CHECK FOR SEMAPHORE LOCKS ON SYMAPI:**

# /usr/bin/ipcs -s

**Note:** Might use this command to identify semaphore locks if the nas\_rdf -localinit command fails, etc.

## **NAS DISK DISPLAY OF CONTROL LUNS ON VARIOUS CELERRA CABINETS:**

### **NS SYSTEMS--CONTROL LUNS DISKMARKED FOR SYSTEMS WITH NBSNAS:**

\$ nas\_disk -l

| id | inuse | sizeMB | storageID           | devID | type       | name | servers |
|----|-------|--------|---------------------|-------|------------|------|---------|
| 1  | y     | 11263  | APM00033500569-0000 | CLSTD | root_disk  | 1,2  |         |
| 2  | y     | 11263  | APM00033500569-0001 | CLSTD | root_ldisk | 1,2  |         |
| 3  | y     | 2047   | APM00033500569-0002 | CLSTD | d3         | 1,2  |         |
| 4  | y     | 2047   | APM00033500569-0003 | CLSTD | d4         | 1,2  |         |
| 5  | y     | 2047   | APM00033500569-0004 | CLSTD | d5         | 1,2  |         |
| 6  | y     | 2047   | APM00033500569-0005 | CLSTD | d6         | 1,2  |         |

**Note:** For NS systems with NBSNAS, Data Movers must diskmark Control Luns, as the Servers actually do the querying and writing to these volumes on behalf of the Control Station.

\$ server\_devconfig server\_3 -p -s -a

server\_3 :

SCSI devices :

chain= 0, scsi-0

```
symm_id= APM00033500569 celerra_id= APM000335005690000
tid/lun= 0/0 type= disk sz= 11263 val= 1 info= DGC RAID 5 009900000000000NI
tid/lun= 0/1 type= disk sz= 11263 val= 2 info= DGC RAID 5 00990100010001NI
tid/lun= 0/2 type= disk sz= 2047 val= 3 info= DGC RAID 5 00990200020002NI
tid/lun= 0/3 type= disk sz= 2047 val= 4 info= DGC RAID 5 00990300030003NI
tid/lun= 0/4 type= disk sz= 2047 val= 5 info= DGC RAID 5 00990400040004NI
tid/lun= 0/5 type= disk sz= 2047 val= 6 info= DGC RAID 5 00990500050005NI
chain= 16, scsi-16
```

```
symm_id= APM00033500569 celerra_id= APM000335005690000
tid/lun= 0/0 type= disk sz= 0 val= -5 info= DGC RAID 5 009900000000000NI
tid/lun= 0/1 type= disk sz= 0 val= -5 info= DGC RAID 5 00990100010001NI
tid/lun= 0/2 type= disk sz= 0 val= -5 info= DGC RAID 5 00990200020002NI
tid/lun= 0/3 type= disk sz= 0 val= -5 info= DGC RAID 5 00990300030003NI
tid/lun= 0/4 type= disk sz= 0 val= -5 info= DGC RAID 5 00990400040004NI
tid/lun= 0/5 type= disk sz= 0 val= -5 info= DGC RAID 5 00990500050005NI
```

**Note:** -5 means that device can be seen but is not owned by that SP

**\$ .server\_config server\_3 -v "fcp bind show" "fcp topology"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 500601611060172f HBA 0 SP-a1 Bound

Chain 0016: WWN 500601691060172f HBA 1 SP-b1 Bound

**Note:** For systems running NBSNAS, Data Movers must see all Control Volumes, hence the diskmarks. Also note that Control Luns are supposed to be seen down SPA, hence when you probe, the values are seen on Chain 0 SPA, not SPB, as in above output. Captive systems do not use Name Servers, so bind table entries show up as ALPA connections.

### **GOLDEN EAGLE, EAGLE, ALL OTHER SYSTEMS:**

**Note:** Devices should not show up in nas\_disk output as diskmarked volumes

**\$ nas\_disk -l**

| id | inuse | sizeMB | storageID-devID     | type  | name       | servers |
|----|-------|--------|---------------------|-------|------------|---------|
| 1  | y     | 4095   | WRE00022000830-0000 | CLSTD | root_disk  | 1,2,3,4 |
| 2  | y     | 4095   | WRE00022000830-0001 | CLSTD | root_ldisk | 1,2,3,4 |

**# server\_devconfig server\_2 -p -s -a**

server\_2 :

SCSI devices :

chain= 0, scsi-0

```
symm_id= WRE00022000830 celerra_id= WRE0002200083000
tid/lun= 0/0 type= disk sz= 4095 val= 1 info= DGC RAID 5 00990000070B6CL
tid/lun= 0/1 type= disk sz= 4095 val= 2 info= DGC RAID 5 009901000070D7CL
tid/lun= 0/2 type= disk sz= 2047 val= -99 info= DGC RAID 5 009902000070F7CL diskerr= unmarked
tid/lun= 0/3 type= disk sz= 2047 val= -99 info= DGC RAID 5 00990300007117CL diskerr= unmarked
tid/lun= 0/4 type= disk sz= 2047 val= -99 info= DGC RAID 5 00990400007139CL diskerr= unmarked
tid/lun= 0/5 type= disk sz= 2047 val= -99 info= DGC RAID 5 00990500007166CL diskerr= unmarked
```

**Note:** The -99 should be seen via probe for Control Volumes for Golden Eagle, Eagle cabinets, & always indicates no diskmark.

**# tail -4 /nas/volume/disks**

```
-1000:rootd1000:0:yU:1:WRE00022000830::1000:0002:7:
-1001:rootd1001:0:yU:1:WRE00022000830::1001:0003:7:
-1002:rootd1002:0:yU:1:WRE00022000830::1002:0004:7:
-1003:rootd1003:0:yU:1:WRE00022000830::1003:0005:7:
```

**Note:** This information must be in the disks file to prevent the volumes from being diskmarked by the Servers. If these entries are missing, there is a configuration problem.

**# .server\_config server\_2 -v "fcp bind show"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 50060160006002ab HBA 0 SP-a0 Bound

Chain 0016: WWN 50060168006002ab HBA 0 SP-b0 Bound

### **CAMDISK FILE:**

**#more /nas/server/slot\_2/camdisk** [File outlines Data Mover SCSI Channels]

Example: 1:c0t0l0 + 52656001A320+: [Verify Boot Port for DM as c0t0l0]

**Note:** Camdisk file is static file that is represented by the devconfig –list command. File is not read on reboots, but does play key role in data mover failover/failback.

## **SCSIDEVS FILE:**

**# more /nas/server/slot\_2/scsidevs**

Lists Gatekeeper & Tape Devices: 1:gk01:0:c0t15l15:526560030320:002804000060:

**Note:** This file is recreated when the devconfig –create command is run. For single Symm cabinets, only 1 gatekeeper is used, and should be lun 15. Clariion backends do not use the gatekeeper device.

## **REPAIRING CELERRA GATEKEEPER DATABASE: \$nas\_diskmark -mark -all**

Step 1. Make copies of following files & delete from directory: \$/nas/dev [scsi chains] /nas/volume/disks\volume\symms

**/nas/server/slot\_\*\scsidevs**

Step 2. **\$nas\_diskmark -m -a** [rewrites the above files with current information]

Step 3. Repair dynamic tables to match up with persistent tables:

**\$.server\_config server\_x -v “fcp bind show”**

## **DISKMARK OVERVIEW PROCESS:**

1. New disks are discovered via probe
2. Celerra diskmark is written
3. Checks performed to verify paths
4. NAS\_DB updated with new devices

## **PERMANENTLY DELETING DISKMARKS FROM CELERRA VOLUMES:**

**# nas\_disk -delete d11 -perm**

## **REPLAYING DISKMARKS TO RESTORE PROPER DISKMARKS:**

**Note:** Most important files are the camdisk and disks file, which need to matchup

1. Zap any incorrect diskmarks first

**\$.server\_config server\_x -v “zapdiskmark c0t1l2 128” | 129**

2. Recover correct camdisk file & disks file from SCCS

3. Replay or Restore the Diskmarks:

**# nas\_license -l**

| key      | status | value       |
|----------|--------|-------------|
| site_key | online | 43 fc b2 05 |

**# nas\_diskmark -R -a -m or # nas\_diskmark -m -a -R** (NAS 5.4.22, NAS 5.5 syntax change)

Enter password: 43fcb205

**Note:** Password is derived from site\_key in output of nas\_license -l

4. Run devconfig –probe to verify no mismatched TID's or conflicts

**Caution:** Never run command without verifying camdisk file is 100% correct. The –R command will probe each device to read its diskmark—if it cannot, it will then diskmark the volume with whatever is in the Camdisk file. So never run this command if you have not verified the camdisk file is what you wish to present or you could cause data loss. So, you would use this procedure to restore diskmarks to volumes based on what you had in your camdisk file.

## **DIFFERENCE BETWEEN “SYMCFG” DISCOVER AND –LOCALINIT COMMANDS:**

--Symcfg discover updates SYMCLI database

--nas\_rdf -localinit updates both SYMCLI and NASDB Files as shown below

### **/nas/server/slot\_2/:**

|            |   |      |      |                   |          |
|------------|---|------|------|-------------------|----------|
| -rw-rw-r-- | 1 | root | root | 923 Jun 21 15:18  | volume   |
| -rw-rw-r-- | 1 | root | root | 44 Jun 21 15:18   | scsidevs |
| -rw-rw-r-- | 1 | root | root | 127 Jun 21 15:18  | mount    |
| -rw-rw-r-- | 1 | root | root | 2451 Jun 21 15:18 | camdisk  |

### **/nas/volume/:**

|            |   |      |      |                   |         |
|------------|---|------|------|-------------------|---------|
| -rw-rw-r-- | 1 | root | root | 5419 Jun 21 15:18 | volumes |
| -rw-rw-r-- | 1 | root | root | 29 Jun 21 15:18   | symms   |
| -rw-rw-r-- | 1 | root | root | 4490 Jun 21 15:18 | disks   |

## **HOW TO DETERMINE SYMAPI VERSION ON CELERRA:**

**# /nas/symcli/bin/symcli SYMAPI Version 4.3.2.0**

**Note :** Symapi version 5.3.1 and lower only supported 128 hypers/drive. Symapi version 5.3.2 and higher supports 256 hypers, found in NAS 5.2.11-3 and higher.

**COMPARING DEVICE DATABASES BETWEEN SERVERS:**

Step 1. Output Results of Server Devconfig 'List' for both Servers to Files:

```
$server_devconfig server_4 -l -s -a > list4
$server_devconfig server_5 -l -s -a > list5
$diff list4 list5 [compare differences for possible database inconsistencies]
```

Step 2. Output Results of Devconfig 'Probe' for both Servers to Files:

```
$server_devconfig server_4 -p -s -a > probe4
$server_devconfig server_5 -p -s -a > probe5
$diff probe4 probe5 [compare differences]
```

Step 3. Conduct Devconfig 'Create' and Output to Files:

```
$server_devconfig server_4 -c -s -a > create4
$server_devconfig server_5 -c -s -a > create5
$diff create4 create5 [compare results]
```

**COMMENT:** Use this to compare datamovers that are connected to same SA's or FA's

**UPGRADE 5.1 TO 5.2 CREATES DISKMARKS ON CONTROL VOLUMES NS SERIES:**

**# nas\_disk -l** output shows dismarked volumes

|    |   |      |                     |           |         |
|----|---|------|---------------------|-----------|---------|
| 47 | n | 2047 | APM00024700388-0002 | CLSTD d47 | 1,2,3,4 |
| 48 | n | 2047 | APM00024700388-0003 | CLSTD d48 | 1,2,3,4 |
| 49 | n | 2047 | APM00024700388-0004 | CLSTD d49 | 1,2,3,4 |
| 50 | n | 2047 | APM00024700388-0005 | CLSTD d50 | 1,2,3,4 |

**# server\_devconfig server\_2 -p -s -a** [output shows diskmarked volumes]

```
tid/lun= 0/2 type= disk sz= 2047 val= 47 info= DGC RAID 5 02060200009190CL
tid/lun= 0/3 type= disk sz= 2047 val= 48 info= DGC RAID 5 020603000091BCCL
tid/lun= 0/4 type= disk sz= 2047 val= 49 info= DGC RAID 5 020604000091E7CL
tid/lun= 0/5 type= disk sz= 2047 val= 50 info= DGC RAID 5 02060500009213CL
```

**# cat /nas/volume/disks**

```
47:d47:0:n:2047:APM00024700388:1,2,3,4:233:0002:7:
48:d48:0:n:2047:APM00024700388:1,2,3,4:234:0003:7:
49:d49:0:n:2047:APM00024700388:1,2,3,4:235:0004:7:
50:d50:0:n:2047:APM00024700388:1,2,3,4:236:0005:7:
```

**Note:** Last two columns are incorrect and need to be changed as follows

→Add two zeroes in front of 02, 03, 04, 05 and change type from “1” to “7” in last column

**CORRECTIVE ACTIONS REQUIRED TO REMOVE DISKMARKS:**

1. Remove diskmarked “d” volumes from database: #nas\_disk -d d47 [thru d50]
2. Using output from devconfig -probe, zap diskmarks for each volume to blocks 128 & 129:  
\$.server\_config server\_2 -v “zapdiskmark c0t0l2 128” & for 129 [d47→repeat for d48-d50]
3. Edit /nas/volume/disks file to pad two zeroes in 2<sup>nd</sup> to last column and in last column change type from “1” to “7”
4. Run diskmark command and verify: #/nas/sbin/nas\_diskmark -m ALL

**CORRECT OUTPUT FROM DEVCFIG:**

```
tid/lun= 0/2 type= disk sz= 2047 val= -99 info= DGC RAID 5 02060200009190CL diskerr= unmarked
tid/lun= 0/3 type= disk sz= 2047 val= -99 info= DGC RAID 5 020603000091BCCL diskerr= unmarked
tid/lun= 0/4 type= disk sz= 2047 val= -99 info= DGC RAID 5 020604000091E7CL diskerr= unmarked
tid/lun= 0/5 type= disk sz= 2047 val= -99 info= DGC RAID 5 02060500009213CL diskerr= unmarked
```

**Note:** Optionally, use following command to remove disk volumes and dismarks: #nas\_disk -d dxx -perm

**SYMMETRIX DATABASE V. CELERRA DATABASE:**

Symmetrix database consists of the following databases: **/nas/symapi/db/symapi\_db.bin** & **/nas/dev**

Any changes to Celerra Volumes requires that the Symmetrix database be updated manually

**VERIFYING GATEKEEPER DEVICES ON CELERRA:**

1. Run \$server\_devconfig server\_x -p -s -a to see if the Gatekeepers are recognized correctly:  
tid/lun= 0/2 type= disk val= -99 info= 5266470AF050 diskerr= -1 (or unmarked) [Example of properly seen GateKeeper]
2. Verify that AS400 Bit is "on" for the Gatekeeper Volume [see BIN file>Edit Volumes]
3. To update Celerra DataBase, run following on every Server: \$server\_devconfig server\_x -c -s -a

4. To update Symmetrix DataBase, run following:

```
--#mv /nas/symapi/db/symapi_db.bin /nas/symapi/db/symapi_db.old  
--#/nas/dev [move all devices listed here to an archive directory]  
--Run #/nas/sbin/nas_rdf -localinit [this will update the Symm DB to match the Celerra DB]
```

## **DUPLICATE DEVICES--CASE STUDY:**

### **Symptoms:**

- Cannot Mount or Create a file system
- Duplicate symmID-devID's Listed When Running #nas\_disk -l

```
# nas_disk -l
```

| id | inuse | sizeMB | symmID           | devID | type      | name | servers |
|----|-------|--------|------------------|-------|-----------|------|---------|
| 1  | y     | 4153   | 000184500672-000 | STD   | root_disk |      | 1,2,3,4 |
| 3  | n     | 34526  | 000184500672-008 | STD   | d3        |      | 1,2,3,4 |
| 10 | y     | 34526  | 000184500672-008 | STD   | d10       |      | 2,1,4,3 |

**Error:** 2001-10-22 17:45:23 server\_4:0: server\_mount server\_4 ufs01/gs1: filesystem is unreachable

**Cause:** Volumes were removed from the Celerra without updating SYMM & CELERRA DATABASES correctly

### **Solution:**

- Verify the running BIN File to check Volume assignments
  - Ensure that the duplicate or ghost volumes are not in Use
- a.) vi /nas/volume/disks and /nas/volume/volumes and remove the offending entries
  - b.) Run #nas\_rdf -localinit

## **REMOVING DATAMOVER FROM CELERRA:**

1. If Standby Server: \$server\_standby server\_x -d mover
2. Ensure no Volumes Mounted or Exported:  

```
$server_export server_x -a -p -u          $server_umount server_x -p -a
```
3. Umount Root File System as well:  

```
$server_umount server_x -p root_fs_x
```
4. \$server\_cpu server\_x -halt now
5. \$/nas/sbin/t2reset pwroff -s 2 [Power down the datamover]
6. #/nas/sbin/setup\_slot -d 2 [Deletes the old slot number]
7. #/nas/symapi/db/symapi\_db.bin [rename to db.old]
8. Run Symapi Update: #/nas/sbin/nas\_rdf -localinit

## **VERIFYING DATAMOVER DEVICE DATABASE CONSISTENCY:**

1. \$server\_devconfig server\_x -p -s -a [Outputs what the DataMover can physically “see” down each SCSI Chain or Port]
2. \$/nas/server/slot\_x/camdisk  
Contents of Camdisk and Server\_devconfig Probe should be consistent.

### **Some Reasons for DataBase Inconsistencies:**

1. BIN File Change not properly applied to the Celerra
2. Use of VOLUME LOGIX to reassign SYMMETRIX Volumes that the Celerra sees
3. Use of SDDR on the SYMM side
4. Faulty Hardware Components: SCSI Cable on DataMover or to SYMMETRIX; Bad HBA; Bad Director
5. Replaced, Added, or Deleted SYMM disk drives that have not been properly Mapped to Celerra and/or Database updated
6. Rezoning HBA's without adding Devices to Database using \$server\_devconfig server\_x -c -p -s -a

## **HOW TO VERIFY VOLUME DATABASE AFTER NEW DRIVES ADDED:**

1. Add New Devices to Celerra Database: \$server\_devconfig server\_2 -c -s -a

2. Compare Databases for inconsistencies:

```
$server_devconfig server_2 -p -s -a  
$server_devconfig server_2 -l -s -a  
$nas_disk -l [ensure that there are no duplicate entries]
```

## **ADDING NEW VOLUMES TO EXISTING SINGLE CELERRA:**

1. After installation of new BIN file ensure new Volumes are 'write enabled'.
2. BackUp of the Celerra Database to a known dir: \$/nas/sbin/nasdb\_backup /nas /home/nasadmin/EMC1
3. Verify current disk list & note last “d” devices on list: #nas\_disk -l
4. Run \$server\_devconfig server\_x ALL -p -s -a and verify that all new volumes are being seen down the SCSI chains correctly! If not, refer to PRIMUS "emc7974" for guidance
5. Run \$server\_devconfig server\_x ALL -c -s -a [Verify Volumes have been added--\$more /nas/server/slot\_x/camdisk]
6. Rename following file: \$/nas/symapi/db/symapi\_db.bin to /nas/symapi/db/symapi\_db.old

**Note:** Conduct this step whenever adding, reassigning new volumes or adding new DMs because the SYMAPI database must first be "moved" before the command given in Step 7 can "update" the SYMAPI database and thus make it consistent with the Celerra's Camdisk Database.

**Caution:** *This step NOT required for NAS Codes > than 4.2.13.0 or if no TimeFinder or Checkpoints are used*

- Step 7. As root, run the following command: `#/nas/sbin/nas_rdf -localinit`

## **ADDING NEW VOLUMES TO CELERRA WHEN SRDF IS INVOLVED:**

1. Run a backup of NAS database: `#/nas/sbin/nasdb_backup /nas /home/nasadmin/nasdb.bak.date`
2. After new volumes having been added via BIN file, and synchronized, verify that all new devices are seen by all DM's on both R-1 and R-2 side and then add to both sides:  
`$server_devconfig -p -s -a`  
`$server_devconfig -c -s -a`
3. Rename old Symapi database on R-1 Celerra:  
`#mv /nas/symapi/db/symapi_db.bin /nas/symapi/db/symapi_db.date`
4. Run `nas_server -l` and note which DM's are local production [acl=1000] & which are RDF standby DMs [acl=2000]
5. Run `#/nas/sbin/nas_rdf -init` on R-1 Celerra to discover remote devices and create R1/R2 pairs in `symapi_db.bin`
6. Repeat steps 3 -6 on the Target R-2 Celerra
7. Conduct queries to ensure that RDF Groups are seen correctly on both R-1 and R-2 Control Stations:  
`# /nas/symcli/bin/symcfg list`  
`# /nas/symcli/bin/symdg list`  
`# /nas/symcli/bin/symrdf -g 1R1_1 query` [R-1 Side]  
`# /nas/symcli/bin/symrdf -g 1R2_500_1 query` [R-2 Side]

## **PRESENTING NEW STORAGE DEVICES/VOLUMES/DISKS TO CELERRA FROM CLARIION:**

1. EMC Navisphere Manager (version 6.19)

RAID Groups>RAID Group 2>Bind LUN>RAID Group for New LUN:

**Note:** Select existing RAID Group with correct RAID Type and freespace, or create new RAID Group at this point  
LUN ID: 30

Number of LUNS to Bind: 10

Default Owner \*Auto

LUN Size 100 \*GB >Apply

2. Assign LUNS to Celerra Storage Group and provide HLU's:

Storage Groups>Celerra\_ns2>rightclick Select LUNS:

Available LUNS → Selected LUNS (Move luns from left to right)

Assign HLU number for each LUN>Apply (Must be valid HLU numbers >than 15)

3. Perform rescan of storage system from WebUI, or run following command:

`#nas_diskmark -mark -all`

## **DELETING & REASSIGNING CELERRA VOLUMES SYMMETRIX BACKEND:**

- Step 1. Backup all affected file systems before making LUN change

- Step 2. Make backup copy of `/nas/server/slot_x/mount` file

- Step 3. Permanently unmount affected file systems

- Step 4. Make Bin file change on symmetrix side

- Step 5. Verify paths to backend on each data mover and inspect Bind Tables for path issues

- Step 6. Discover new disks on all Servers: `$server_devconfig server_x -c -s -a` [Updates Camdisk]

- Step 7. Verify that camdisk has been updated with the intended changes and matches `server_devconfig -probe`

- Step 8. Remount each affected file system

## **UPDATING DATAMOVER'S VOLUME DATABASE:**

**Solution:** Running the following command updates the "camdisk" file and does not require a Server reboot

**`$server_devconfig server_x -c -s -a`**

**Note:** This command dynamically updates the "camdisk" file and is recorded in the `/nas/log/cmd_log` file

## **REMOVING SYMM DEVICES FROM CELERRA DATABASE FILES:**

`$nas_volume -i strv34`

- Step 1. Ensure Volumes to be deleted are no longer in use [`$nas_disk -l` look for "n" and Symm Volume or Device #]

- Step 2. If devices are in use, must identify which Servers and/or File Systems are using the Devices:

`$nas_fs -i fs01 [fs02, etc.]`

Step 3. Conduct BackUp of NAS DataBase: \$/home/nasadmin/nasdb\_backup /nas /home/nasadmin

Step 4. Make BackUp copies of /nas/volume/disks and /nas/volume/volumes files

Step 5. Use \$/nas/sbin/rootnas\_disk -d roottd189 [command to remove BCV devices from Celerra database]

**Note:** Devices are dynamically removed from Disks and Volumes files

\$nas\_volume -l is /nas/volume/volumes

\$nas\_disk -l is /nas/volume/disks

### **Locations for Celerra Configuration & Volume Information:**

\$/nas/volume/volumes

\$/nas/volume/disks

\$/nas/server/slot\_x/camdisk

[scsi chains & devices listed]

\$/nas/server/slot\_x/volume

[hyper volumes and associated Disks/TID's]

\$/nas/server/slot\_x/ufs

[file systems for this slot]

\$/nas/server/slot\_x/scsidevs

[gatekeeper devices]

\$/nas/server/slot\_x/mounttab

[lists out mountpoints and volume ID numbers for file systems]

\$/nas/server/slot\_x/SCCS

[Backup databases of volume and disks files, etc.]

### **OBTAINING LISTING OF SCCS DIRECTORIES ON ALL SERVERS:**

**\$ ls -l \$NAS\_DB/server/slot\_\*/\***

### **EXTRACTING SCCS DB FILES FROM SERVER SLOT:**

**# tar cf -./SCCS/{\*cam\*,\*vol\*} | (cd /tmp; tar xpvf -)**

#cd /tmp;ls

p.camdisk.l p.volume. s.camdisk.l s.volume.l

#view s.volume.l

**Note:** Find appropriate date and version of desired file

#sccts get -r1.38 volume.l

#view volume.l

### **SCCS DATABASE RESTORE PROCEDURE: Celerra Database BackUp Files**

The SCCS program is invoked by the NAS Database Backup program and runs just after the top of each hour. This program will back up critical /nas/server, /nas/volume, and other configuration files that have been modified during the preceding hour and place them in their respective SCCS directory, usually with a name such as “s.netd.l” and “p.netd.l”. An important thing to remember about this limitation is that only the last change prior to the NAS\_DB backup, within the past hour, will be captured—so when troubleshooting database issues, keep this in mind as the complete record of all changes are not necessarily captured. The easiest way to verify the various changes made to any specific file is to simply go to the SCCS directory and cat the desired file:

**# cat s.netd.l**

h18535

s 00000/00000/00017

d **D 1.15** 05/02/07 14:04:11 nasadmin 15 14

c -rw-rw-r-- 1 nasadmin nasadmin 389 Feb 7 13:37 netd

e

s 00001/00001/00016

d **D 1.14** 04/12/12 20:03:06 nasadmin 14 13

c -rw-rw-r-- 1 nasadmin nasadmin 389 Dec 12 20:01 netd

e

s 00001/00001/00016

d **D 1.13** 04/11/14 20:02:32 nasadmin 13 12

c -rw-rw-r-- 1 nasadmin nasadmin 390 Nov 14 19:12 netd

**Note:** The above highlighted items show the various version levels for the netd file. Change directory back one level and run **#sccts get -r1.15 netd.l** to retrieve a copy of the contents found in Version 1.15 of this file—rename the file to a desired name and repeat the process to retrieve other versions of the file.

**# sccts info**

bmparams.l: being edited: 1.2 1.3 nasadmin 04/12/17 15:01:42

buff.l: being edited: 1.4 1.5 nasadmin 04/12/17 14:01:57

camdisk.l: being edited: 1.6 1.7 nasadmin 05/01/14 14:01:47

cluster.l: being edited: 1.1 1.2 nasadmin 04/09/20 17:01:31

**Note:** Use above command to list out database files available. Also note that when we retrieve a file, we call the “camdisk.l” file from the “s.netd.l” database by using the –r1.15 syntax. We do not recover files from the “p.netd.l” database.

## **RECOVERING FILES USING SCCS:**

### **1. Go into the SCCS directory for the slot in question—run List & Grep for appropriate file:**

```
# ls -la |grep file [/nas/server/slot_9/SCCS]
-r--r--r-- 1 root root 39 Apr 30 11:31 file.l
-rw-r--r-- 1 nasadmin nasadmin 35 Apr 30 11:01 p.file.bak.l
-rw-r--r-- 1 nasadmin nasadmin 35 Apr 11 23:01 p.file.l
-r--r--r-- 1 nasadmin nasadmin 195 Apr 30 11:01 s.file.bak.l
-r--r--r-- 1 nasadmin nasadmin 511 Apr 11 23:01 s.file.l
```

### **2. Select the file with the date that you are looking for & cat the contents to obtain version information:**

```
# cat s.file.l
```

```
h31713
s 00001/00001/00000
d D 1.3 03/04/11 23:01:43 nasadmin 3 2
c -rwxrwxr-x 1 nasadmin nasadmin 39 Apr 11 21:47 file
s 00000/00000/00001
d D 1.2 02/10/06 10:03:05 nasadmin 2 1
c -rwxrwxr-x 1 nasadmin nasadmin 40 Oct 6 07:44 file
s 00001/00000/00000
d D 1.1 02/09/17 11:01:18 nasadmin 1 0
c date and time created 02/09/17 11:01:18 by nasadmin
```

**Note:** Example here shows (3) versions

3. Retrieve a version of the file contents by version number while in /nas/server/slot\_9 directory:

```
# sccs get -r1.2 file.l
```

```
get: SCCS/s.file.l: Warning: No id keywords.
1.2
1 lines
```

**Note:** Even though you see version numbers listed under “s.file.l”, you retrieve different versions by calling “file.l”

```
# cat file.l
```

```
file initialize nodes=65536 dnlc=262144
```

**Note:** In above example was able to show that the nodes and dnlc settings were different in the past than now, probably due to a NAS upgrade or patch that reset the settings to the current, lower values seen on the system

```
# cat file
```

```
file initialize nodes=22528 dnlc=65536
```

4. If you find the correct version to restore, simply rename the “file.l” as file and reboot server

**Note:** Contact Support Center for information on trimming SCCS databases and correcting permissions problems that prevent SCCS backups from working on servers—emc167945.

## **Deleting a DataMover:**

```
# /nas/sbin/rootnas_server -delete server_5
```

## **CELERRA SCSI BOOT PORT ON DATAMOVER:**

Port A=Chain0=both Boot Port and Data and is the Lower Port on SCSI Card. So, if it fails, DM must failover to its Standby unit!!  
Port B=Upper Port, Data Only

**Server setup Command:** Used to setup type and protocol for a DataMover

```
-t {nas|nms|standby} -L specify the DART image to load at next boot -P {nfs|cifs -o start|stop|delete}
```

## **USING SETUP SLOT -INIT ON DATA MOVERS:**

```
#/nas/sbin/setup_slot -init -t nas 2
```

When to Run Setup\_Slot? Adding or replacing Hardware, rediscover disks and rebuild bind tables, or when boot.cfg file is damaged.

**Note:** NAS 5.5, # export TRACE\_LEVEL=9 to get debug trace output of all the functions that setup\_slot performs—logs to /var/tmp

```
-rw-r--r-- 1 root root 11776 Mar 26 12:08 setup_slot_trace.log
```

**Probing for Newly Added SCSI Disks:** \$server\_devconfig server\_4 -p -s -d [listing: -l -s -a ]

**Probing for New Non-Disk SCSI Devices:** \$server\_devconfig server\_4 -p -s -nondisks [-l -s -n to list]

**UPDATING MAC ADDRESSES ON IFCONFIG FILES FOR DM:****# /nas/sbin/setup\_slot -upgrade 2**

**Note:** This command is very useful in properly updating MAC addresses in the ifconfig files when the MAC addresses are either not present or have been deleted, or new devices have been added, etc.

**DISKMARKING NEW VOLUMES:**

# nas\_diskmark -a -m [updates camdisk, volumes files, &amp; diskmarks for all Servers]

# server\_devconfig server\_2 -c -s -a [Updates camdisk, volumes file, &amp; diskmarks for specific data mover]

**Adding & Verfying New SCSI Drives/Devices and Camdisk File:**

1. #server\_devconfig server\_x -probe -s -all [shows all the scsi devices on the scsi chain that Celerra can see]
2. #cat /nas/server/slot\_x/camdisk [shows Camdisk File configuration of a specific slot or DataMover]

3. If the Devconfig and Camdisk are different:

**Note:** Must be run on each Data Mover!!

#server\_devconfig server\_x -c -scsi -all [Makes Celerra re-probe SCSI chain and updates Camdisk config file]

4. Redo Steps (1) and (2) to verify

**CAMDISK ENTRY DEFINED:**

1:c0t010+526562001310+:

1=Device name; c0=DM scsi boot port A chain 0; c1=port B chain 1; t0=target; l0=Lun; +5265=SymmCode; 62=Last 2digitsSSN; 001=SymmDev.ID; 31=Symm SA#; 0=SA Port#

**CAMDISK EXAMPLE:**

130:c0t8115+566901206550

|      |                                                |
|------|------------------------------------------------|
| 130  | Celerra device ID                              |
| c0   | SCSI Chain                                     |
| t8   | Target number                                  |
| 115  | Lun number                                     |
| 5669 | microcode family                               |
| 01   | Last two digits of the Symmetrix serial number |
| 206  | Symmetrix device number                        |
| 55   | Symmetrix director number (breakdown below)    |
| 0    | Port number                                    |

**Note:** Determine Symm Director from chart below

| Director number | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Processor A     | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 | 09 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| Processor B     | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | 32 |
| Processor C     | 33 | 34 | 35 | 36 | 37 | 38 | 39 | 40 | 41 | 42 | 43 | 44 | 45 | 46 | 47 | 48 |
| Processor D     | 49 | 50 | 51 | 52 | 53 | 54 | 55 | 56 | 57 | 58 | 59 | 60 | 61 | 62 | 63 | 64 |

**SERVER LOG MESSAGE: Failed to locate volume...**

1. Check Boot.cfg file to see if it contains Volume & Hyper information
2. Check /nas/server/slot\_x/volume file to see if Volume information is intact
3. Check /nas/server/slot\_x/disks file to see if Disk information is intact

**SERVER INODE STATS: \$ server\_df server\_x -i**

**Note:** This is a command that communicates directly with the DataMover, so is good for troubleshooting purposes! Server\_df calculates space of FS based on blocks in use—since we use 8k blocks, we may see more usage than a client system. Also, when doing async I/Os, Superblock is not flushed each time, meaning Free Block Count on-disk is incorrect. The On-Disk Superblock gets updated after reboots or after FSCK Phase 5, but In-Block Superblock values are accurate all the time.

**HOW TO VERIFY DISK USAGE/SIZE OF DIRECTORIES FROM CS0 ROOT:**

# cd /;du -sk \* |sort -g [Outputs Usage in kb under Root or in Current Path] 36 root

2232 boot

3628 nasmcd

5076 etc

5776 bin  
7976 sbin  
13308 home  
15680 var  
26764 lib  
286156 nas  
363684 usr

### **VERIFYING CURRENT PARENT DIRECTORY SIZE:**

# du -sk

### **VERIFYING DISK USAGE BY SPECIFIC FILE OR DIRECTORY:**

# du -sk /nas

286160 /nas

### **DISK USAGE BY PARENT DIRECTORY:**

# du -h --max-depth=1 -x

**VFSTAB File:** Virtual File System Table lists all file systems and swap devices:

# mount -p [Prints what's mounted in the /etc/vfstab directory]

### **DISK USAGE AND FILESYSTEM INFORMATION:**

#df ~ or df \$HOME [Lists out the number of free blocks in Home directory]

# df -h # df -k # du -h # du -sh /\* |grep M

# du -s # df system

#server\_df server\_2 [lists out the FileSystems and usage info]

#nas\_fs -size fs1 or nas\_fs -i fs1 [outputs info on a specific FileSystem]

#nas\_volume -i meta [outputs info on Meta Volumes]

#nas\_volume -i d3lstr1|mtv1 [details on a specific volume] \$nas\_slice -i slc1

# du -sh /\* →Best method for seeing actual sizes

### **EXAMPLE DIRECTORY USAGE:**

\$ df -h \$du -h

| Filesystem    | Size | Used | Avail | Use% | Mounted on |
|---------------|------|------|-------|------|------------|
| /dev/sdc3     | 1.5G | 1.4G | 84M   | 95%  | /          |
| /dev/sdc1     | 30M  | 2.8M | 26M   | 10%  | /boot      |
| none          | 251M | 0    | 250M  | 0%   | /dev/shm   |
| /dev/sde1     | 1.7G | 617M | 1.0G  | 37%  | /nas       |
| /dev/sda1     | 133M | 107M | 26M   | 80%  | /nas/dos   |
| /dev/sdf1     | 1.7G | 657M | 1.0G  | 39%  | /nas/var   |
| server_3:/mnt | 8.4G | 2.5G | 5.9G  | 30%  | /mnt       |
| server_3:/mnt | 8.4G | 2.5G | 5.9G  | 30%  | /mnt       |

### **Verifying Space Utilization on DataMover FileSystems:**

**Control Station:** \$df -k

**Servers:** \$server\_df ALL

**FileSystem:** #mount -F nfs server\_2:/mailstore /mnt \$cd /mnt;df -k

**Switches:** \$df . [space on current directory] \$df -a [space on all FileSystems] \$df -i [used and free inodes]

### **CELLERRA QUOTAS:**

**Intro:** File System quotas limit amount of data Users can store on a FileSystem. Tree Quotas limit amount of data Users can store in Subdirectories of a FileSystem. Quotas can be limited by Bytes of Data [Blocks], Number of Files [Inodes], or both. The limit on number of files is dependent on Inodes—inodes are used for Files, Directories, & Symbolic Links. Filesystem Quotas can be applied to individual Users or Groups of Users. Control Station manages via CLI by blocks, files, users, filesystems [NOT Groups for CIFS]. Windows 2000 Quotas are applied to the whole disk partition and cannot be applied to individual Folders. Quotas can be set using default values for all users, or set explicitly for Users/Groups, either via single fs basis or by DM basis.

### **DEFAULT FILES CREATED BY NFS QUOTAS IN SYSTEM FOLDER (Pre NAS 5.5):**

**Note:** Following files are created and stored in the “/fs20/.etc” directory when implementing Quotas. They are system files and should not be touched or edited ever. The .etc directory is created when Quotas is first configured from Unix side or after first mapping to CIFS FileSystem Share from Windows.

|                        |           |      |     |                                                 |
|------------------------|-----------|------|-----|-------------------------------------------------|
| config_file            | rw-r—r--  | root | bin |                                                 |
| config_file.InProgress | rw-r—r--  | root | bin |                                                 |
| quotas                 | rw-rw-rw- | root | bin | [User quotas file—created when first turned on] |
| quotas.config          | rw-rw-rw- | root | bin | [Other configuration information]               |
| quotas.group           | rw-rw-rw- | root | bin | [Group quotas file]                             |
| rpt_file               | rw-r—r--  | root | bin | [created after first report is run]             |
| rpt_file.InProgress    | rw-r—r--  | root | bin |                                                 |

**Note:** Verify that InProgress reports are completed or not by running octal dump against the files

```
# od -xc *InP*
```

## **CELERRA QUOTAS DATABASE:**

With NAS 5.5, the quotas, quotas.group, & quotas.config database files were moved from the hidden .etc directory of each production file system to the hidden /slashetc directory of the file system. A NAS Upgrade from 5.4 to 5.5 reflects the database change in the Server Log—Please note that the Quotas DB is now called Version 3 in NAS 5.5 because of this change:

**2007-03-27 10:38:37: UFS: 4: Quota Upgrade: Upgrading from quota version 2 to version 3 (fs /fs06)**

## **NAS 5.5 QUOTAS DB:**

**Note:** Following example shows the various files stored in the “.etc” and the “slashetc” directories on the file system

[root@nyip1 m3]# ls -la .etc

```
-rw-r--r-- 1 root bin 60 Jun 2 2006 config_file
-rw-r--r-- 1 root bin 9 Jun 2 2006 config_file.InProgress
-rw-r--r-- 1 root bin 0 Jun 2 2006 config_file.sids
-r--r--r-- 1 root bin 262144 May 10 10:28 gid_map
-rw-r--r-- 1 root bin 36 Jun 2 2006 rpt_file
-rw-r--r-- 1 root bin 9 Jun 2 2006 rpt_file.InProgress
-rw-r--r-- 1 root bin 6 Jun 2 2006 rpt_file.sids
```

/nasmcd/quota/slot\_2/m3/slashetc

[root@nyip1 slashetc]# ls -la

```
----- 2 root root 8192 May 10 15:34 ACLdata
----- 2 root root 8192 Jun 2 2006 ACLrecord
-rwxr-xr-x 2 root root 262144 May 10 10:28 gid_map
-rw-rw-r-- 2 root bin 1048832 Jun 2 2006 quotas →User Quotas database
-rw-rw-r-- 2 root bin 128 Jun 2 2006 quotas.config →Quotas configuration db
-rw-rw-r-- 2 root bin 64 Mar 28 2007 quotas.group →Group Quotas database
----- 2 root root 8192 May 10 10:28 ufsasyncDB
-rw-r--r-- 2 root bin 0 Jun 2 2006 viruschecker
```

## **PROCEDURE FOR REVEALING THE SLASHETC DIRECTORY NAS 5.5:**

**Note:** When exposing the slashetc directory to view, the link count is set to 2. Because of the link count behavior, we can then safely remove the slashetc directory, which actually only decrements the link count from 2 to 1, at which point the directory contents are invisible again.

1. Following example shows the method for revealing the hidden “slashetc” directory that contains the actual Quotas database files

**# .server\_config server\_2 -v "shadow showetc fs1"**

/nasmcd/quota/slot\_2/fs1

# ls -la

```
drwxrwxrwx 2 root bin 1024 Jan 5 2007 slashetc
```

2. Change to the slashetc directory:

# cd slashetc

# ls -la

```
----- 2 root root 8192 Nov 14 15:20 ACLdata
----- 2 root root 8192 Jan 5 14:08 ACLrecord
-rwxr-xr-x 2 root root 262144 Nov 3 12:55 gid_map
-rw-rw-r-- 2 root bin 1056000 Jan 5 13:35 quotas
-rw-rw-r-- 2 root bin 64 Jan 5 13:32 quotas.config
-rw-rw-r-- 2 root bin 64 Mar 28 2007 quotas.group
----- 2 root root 8192 Nov 3 12:55 ufsasyncDB
```

3. When done, remove the slashetc folder so as not to leave the QuotasDB exposed, as database files could be deleted:

**# rm -rf slashetc**

**Note:** Different syntax? **# .server\_config server\_x -v "shadow showetc \mnt1\danfstest"**

## **NAS QUOTAS COMMANDS:**

--Edit command is an Eiffel executable which creates (2) temp files called “mount-point-file” & “Uid-List-File” to store mountpoint information and UIDs/GIDs, respectively.

--A mac/config command is then sent to DM to create a report file (rpt\_file) [The DM removes the rpt\_file & rpt\_file.tmp in the .etc directory of the file system and creates a new “rpt\_file.tmp” in which is parses the UID list to report on all User with non-zero limits. Quota information is then compiled and the file renamed to “rpt\_file”].

--If quotas need to be edited, the edquota executable is called by Control Station, which reads the “rpt\_file” and opens vi editor—changes are then updated to DM by mac config commands to quotas for users and quotas.group for group quotas, and to in-memory copies of quota records.

## **QUOTA SUPPORT BY NAS CODE:**

1.2 Introduces User Quotas--also called Inodes Quotas

2.2 Introduces Group Quotas, with Quotas charged to a User’s primary group

4.0 Introduces Soft Quotas & Win2k Quotas, warning when threshold is reached, with grace period of 1 week by default

5.0 Introduces Tree Quotas, which can be used to limit Inodes or Blocks used, are set at the Directory level

**Note:** Using filesize quotas with DHSM migrated file systems—byte usage for tree or owner could be more or less than expected.

## **TYPES OF QUOTAS USED WITH CELERRA: USER/GROUP/DIRECTORY (Tree)**

→User quotas, applies to file system either explicitly, per User, or as default quota limits applied to all Users

→Group quotas, applies to file system explicitly, per Group, or as default limits

**Note:** Group quota applies to sum of storage for all users having the group as their default primary group

→Windows 2000 Quotas, applies to whole partition, and is based on User quotas

→Tree Quotas, applies to directory tree

→Quota db is stored in files named quotas & quotas.group in the .etc directory of each file system as binary structure dqblk form

→Quotas are managed from Control Station CLI using nas\_quotas commands or GUI

## **QUOTA FUNCTIONALITY/FACTS:**

--Quotas limit the bytes of storage used, the number of files used, or both

--Quota blocks are calculated in 8192 bytes, filesize by 1024 bytes

--Quotas are calculated for Blocks or Bytes Usages in (1k), meaning 1024 byte increments

--Default quota policy is still Block size, yet most CIFS applications should use Filesize

--User & Group quotas are based on UID/GIDs and are applied to the overall filesystem, whereas TreeQuotas apply only to a directory

--File limits count inodes for files, directories, or symbolic links

--Quota limits are tracked separately for User, Group, or TreeQuotas (aka QTrees)

--Nested tree quotas are not supported, i.e., cannot have multiple TreeQuotas within the same directory tree

--Default grace period (soft quota) is one week for both CIFS & NFS users, though only CIFS users will receive popup warning message (if configured). Once a grace period expires, the quota turns hard, and no further writes allowed.

--Quota records are indexed by UIDs

--MPD file systems allow tracking of root users for usage (countRootUsageInQuotaTree)

--Explicit quotas override global default quotas for users or groups

--Quota limits cannot be enforced for root user or root group

--Anonymous users UID=-2 can be set using “anon” with nas\_quotas

--Quotas database files are located in hidden .etc directory of the file system

--Can use both Group & User Quotas concurrently—whichever reaches limit first determines extent of write access

--Quotas support NFS & CIFS, though CIFS supports only Filesize quotas, while NFS supports both Block & File Size

--Win2k Quotas can work with either Passwd/Group file or Usrmapper access to map to Users/Groups

--Tree Quotas also have soft & hard limits, with filesize or blocksize policies

--Tree Quotas are limited to 2047 different Trees per file system

## **TWO TYPES OF QUOTA POLICIES:**

**Blocks**→default, calculates disk usage in terms of 8kb fs blocks and usage of all files (files, directories, symbolic links)

**Filesize**→disk usage calculated in terms of file sizes, as in CIFS environments, and does not include directories or symbolic links

**Note:** If a system started out with the default policy of blocks, then later set the param to filesize, the proper sequence of events should be to reboot server. User & Group quotas will recalculate properly to presently filesize. Tree Quotas, on the otherhand, would require manual intervention and use of the Quota Recalc Tool to fix 8k block to show 1k file. Please note that when looking at Quotas usage from reports and comparing to server\_df output, the two values will always be different

## **CIFS vs. NFS:**

NFS can use either block or filesize quotas

CIFS should use only filesize

## **USER QUOTAS RESTRICTS HOW LARGE FILE SYSTEM SIZE APPEARS TO CIFS USERS:**

If the file system is 1GB in size, but a User's quota is 100MB, the User will only see 100MB of total disk space from their Windows client. NFS Users, on the otherhand, will be able to see the total file system size of 1GB.

## **EFFECTS OF TURNING QUOTAS ON OR OFF:**

File system will be frozen and will affect CIFS & NFS users

Quota-checking is done when first turning quotas on (after being turned off), and after fsck when fs is mounted

## **SETTING DEFAULT USER/GROUP QUOTAS:**

#nas\_quotas -edit -config -fs fs1 (set the user and group quotas, and it will apply to the file system)

## **SETTING EXPLICIT ANONYMOUS USER QUOTAS:**

#nas\_quotas -edit -user -fs fs1 anon

## **TURNING ON/OFF BOTH USER & GROUP QUOTAS:**

#nas\_quotas -on | -off -both -fs fs1

## **REPORTING QUOTAS BY FILE SYSTEM:**

#nas\_quotas -report -user -fs fs1

## **VIEWING USER/GROUP QUOTA CONFIGURATION:**

#nas\_quotas -report -config -fs fs1

## **USER QUOTAS:**

1. Turn quotas on: \$nas\_quotas -on [-off] -fs hfs1
2. Edit User quota: \$nas\_quotas -e -u -fs hfs1 1556
3. Verify with Report: \$nas\_quotas -r -u -fs hfs1 1556

## **GROUP QUOTAS:**

Step 1. Set Param & Reboot: **param cifs useUnixGid=1**

Step 2. Setup Group quota: #nas\_quotas -g -e -fs ufs1 1001

**Note:** useUnixGid=0 (default) assigns GID to Windows User based on Primary Domain group; useUnixGid=1 assigns GID from GID field for the User in the /etc/passwd or NIS map. Quotas are charged to a User's Primary Group.

# server\_param server\_2 -facility cifs -i acl.useUnixGid -v

server\_2 :

```
name          = acl.useUnixGid
facility_name = cifs
default_value = 0
current_value = 0
configured_value =
user_action   = none
change_effective = immediate
range         = (0,1)
description   = Set the unix GID for CIFS created files (default:off)
detailed_description
```

Sets the GID mapping for files created on a Windows client. param cifs useUnixGid=0 Assigns the GID of the Primary Domain group to which the user belongs. param cifs useUnixGid=1 Assigns the Windows user's GID (as found in the GID field of the /etc/passwd file or NIS database entry).

## **QUOTAS SET FOR INDIVIDUAL USERS: Default="Blocks-Used"**

**Note:** To use Quotas on an NFS File System, you must be using (1) of the following (3) User-Based Authentication Methods:

a.) NIS Services for Unix    b.) Local Passwd & Group files on DataMover    c.) Usrmapper

1. If using local Passwd/Group files on Data Mover or Usrmapper, need to obtain UID's/GID's in order to set-up Quotas.
  - Lookup UID's, Edit Passwd file, and put file onto Datamover: \$server\_file server\_4 -p passwd passwd
  - Lookup UID's of users in /var/usrmapper/usrmap.db on Usrmapper Server
2. **Create or Edit a User 'Quota':** #nas\_quotas -e -u -fs ufs76 1005 [UID for user: todd]
  - This opens up the Quota file in the vi Editor: "Userid: 1005 FS ufs76 blocks (0) inodes (0)"
  - Enter your quota value in **blocks (0)** and leave inodes at (0), then save and exit the vi editor
3. **Turn On Quotas for the FileSystem:** #nas\_quotas -on {-off; -clear} -fs ufs76 {Using 'clear' erases all quotas & turns off}
4. **Verify Quotas by Report:** #nas\_quotas -r -u -fs ufs76 1005 [should show entries you made to the 'blocks' column]

**Note:** You can change Quotas at any time using the ‘nas\_quotas -e’ editor--changes are dynamic.

**QUOTAS SET FOR ANONYMOUS USERS:** \$nas\_quotas -e -u -fs ufs34 anon

**QUOTAS SET ON A DATAMOVER BASIS:** Quotas set for each User would apply to all FileSystems on that DataMover

1. #nas\_quotas -e -u -m server\_5 1005 [leave UID off to set for all users]
2. #nas\_quotas -on -m server\_5
3. #nas\_quotas -r -u -m server\_5 1005 [leave UID off for report on all users]

**FILESIZE QUOTAS:**

**param quota policy=filesize**

**Note:** Set quota policy and reboot data mover—quota tracking will change from “Blocks Used” to “Bytes Used”

4. Turn Quotas on using “\$nas\_quotas -on -m server\_4”

**Note:** You cannot have both *Blocks* and *FileSize* policy set for the same DataMover—only one Method or the other

**SETTING UP QUOTAS FOR PROTOTYPE USERS ON A USER BASIS:**

1. Create Quota for Prototype User: “\$nas\_quotas -e -u -fs ufs34 1000” -vi edit Blocks or Bytes (0)
2. Setup Quotas for other Users: #nas\_quotas -e -fs ufs34 -p 1000 1001 1002 1003 1004 1005 [creates quotas for others]
3. Turn quotas on: \$nas\_quotas -on -fs ufs34

**Note:** The prototype user is the first UID listed—all other UID’s inherit quota attributes of UID 1000. A benefit here is that you will not have to Edit the values separately for each of the other UID’s.

**Caution:** If you change Values for Proto User, then you must re-run Prototype -p command for other Users.

**SETTING UP QUOTAS FOR PROTOTYPE USERS ON A DATAMOVER BASIS:**

1. Create Quota for Prototype User: “\$nas\_quotas -e -u -m server\_4 1000” and edit Blocks or Bytes values.

Setup Other Users by UID: \$nas\_quotas -d -m server\_4 -p 1000 1002 1002 1003 1004 1005

Turn quotas on: \$nas\_quotas -on -m server\_4

Clearing Quotas on a Server: \$nas\_quotas -clear -m server\_4 [also turns Quotas off]

**TESTING QUOTAS FROM A UNIX CLIENT:**

1. Make sure your UID number is the same on both the UNIX client and the Celerra DataMover [passwd/group files or usrmapper]  
**Note:** Use Solaris “admintool” program to create Users—manually editing /etc/passwd file will not work on Solaris!
2. Mount Data Mover File System to Unix Client: #mount 193.1.21.183:/g3data1 /mnt
3. MakeFiles as ‘Root’ on Unix Client for Testing: #mkfile 2m one two three #chmod 777 one two three [allows everyone]
4. #cd /mnt;ls -la [to verify that you can view the mounted file system]
5. #cd / and login as the test user “todd” with UID 1005
6. #exec login login: todd password: nasadmin \$/usr/local/todd \$cd / \$whoami ‘todd’
7. Begin Copying Test to DM: \$cp one two three /mnt
8. Watch copy operation from NT Client mapped to same file system; Refresh shows status of copy operation

**Unix client:**

#quota -v tom [command to check quota information from NFS clientside]

**CLEARING QUOTAS:**

**\$nas\_quotas -clear -fs ufs1**

**Note:** Quotas cannot be cleared for single Users or Groups, only the entire fs!

**SETTING QUOTAS FOR A USER BY FILE SYSTEM:**

**\$nas\_quotas -u -e -fs ufs1 5005**

Edit either the Blocks or Files section and close vi editor session

**RUNNING QUOTAS REPORTS ON A FILE SYSTEM:**

**\$nas\_quotas -u -r -fs ufs1**

**TURNING ON/OFF QUOTAS:**

**\$nas\_quotas -u -on | -off -fs ufs1**

**TROUBLESHOOTING QUOTAS:**

**NETD File:** /nas/server/slot\_x/netd: rquotad action=start [Read into the Boot.cfg file upon shutdown]

Nested mountpoints can create problems using the "Editor" and "Report" commands [commands won't work]

**Server Log:**

2002-11-10 21:16:18: CFS: 3: write failed, startOffset = 0x0, status = 52

2002-11-10 21:16:18: CFS: 3: write failed, startOffset = 0x2000, status = 52

**Cause:** File\_QuotaExceeded, // 52 [From NAS 2.1.30.2]

**Disk Quota Exceeded Error:**

--Client receives when Hard Quota Limit reached

--Client receives when Soft Quota limit crossed and Grace Period expires

**Problem:** Quota Editing & Reporting does not work with nested mountpoints

**Solution:** Mount filesystem temporarily on 'non-nested' mountpoints

### **CANNOT APPLY QUOTA TO USER “ROOT”:**

**#nas\_quotas -u -e -fs fs20 0**

‘quotas not support for root (0)’

### **QUOTA PARAMETERS IN 5.4 CODE:**

**\$ .server\_config server\_2 -v "param quota"**

| Name | Location | Current | Default |
|------|----------|---------|---------|
|------|----------|---------|---------|

|                                 |            |            |            |
|---------------------------------|------------|------------|------------|
| quota.countRootUsageInQuotaTree | 0x0139efb8 | 0x00000001 | 0x00000001 |
|---------------------------------|------------|------------|------------|

**Note:** includes root users in tree quota usage

|              |            |            |            |
|--------------|------------|------------|------------|
| quota.maxuid | 0x013931d8 | 0x00000000 | 0x00000000 |
|--------------|------------|------------|------------|

|              |            |          |          |
|--------------|------------|----------|----------|
| quota.policy | 0x01393218 | ‘blocks’ | ‘blocks’ |
|--------------|------------|----------|----------|

**Note:** Default is ‘blocks’, based on number of 8kb fs blocks allocated. Policy using ‘filesize’ means quota usage by file usage in 1kb increments. Cannot implement this param without first having quotas turned off and rebooting data mover with new param value set

|                         |            |            |            |
|-------------------------|------------|------------|------------|
| quota.useQuotasInFsStat | 0x0139f008 | 0x00000000 | 0x00000000 |
|-------------------------|------------|------------|------------|

**Note:** When set to 1, displays free-space on a Quota basis to Unix users based on their User, Group, Tree quotas. Otherwise, returns total free-space in whole file system

**# server\_param server\_2 -f quota -l** (use –i –all for verbose output)

server\_2 :

| name | facility | default | current | configured |
|------|----------|---------|---------|------------|
|------|----------|---------|---------|------------|

|                           |       |   |   |  |
|---------------------------|-------|---|---|--|
| countRootUsageInQuotaTree | quota | 1 | 1 |  |
|---------------------------|-------|---|---|--|

|        |       |   |   |  |
|--------|-------|---|---|--|
| maxuid | quota | 0 | 0 |  |
|--------|-------|---|---|--|

|        |       |          |          |  |
|--------|-------|----------|----------|--|
| policy | quota | ‘blocks’ | ‘blocks’ |  |
|--------|-------|----------|----------|--|

|                   |       |   |   |  |
|-------------------|-------|---|---|--|
| useQuotasInFsStat | quota | 0 | 0 |  |
|-------------------|-------|---|---|--|

### **SOFT QUOTAS & “GRACE PERIOD”:**

--WIN2K Clients receive warning popup but can still write to File System and have an infinite warning state [grace period N/A]

--Unix Clients granted grace period when soft quotas reached but receive no Warning message and "grace period" expires after set amount of time—default is 1 week for Block/Bytes & Inode settings

--Win2k has infinite grace period setting whereby inode & block grace period = “-1”

--When Win2k has NoLimit set, values show up in nas\_quotas –edit as “-2”

--Warning/Event Logged whenever soft quota disk or file usage limit reached

--Use "Soft Quotas" as warning tool prior to reaching "Hard Quota" limits for Users or File Systems--default value is 100MB

### **CHANGING DEFAULT GRACE PERIOD FOR SOFT QUOTAS:**

**# nas\_quotas -c -e -fs fs16**

#### **File System Quota Parameters:**

fs fs16

**Block Grace: (-1.0 )** [By default, Grace Period for Soft Quotas is 7 days]

**Inode Grace: (-1.0 )** [By default, Grace Period for Soft Quotas is 7 days]

\* Default Quota Limits:

User: (soft = 8192, hard = 10240) inodes (soft = 0, hard= 0)

Group: (soft = 0, hard = 0) inodes (soft = 0, hard= 0)

Deny disk space to users exceeding quotas: (yes)

\* Generate Events when:

Quota check starts: (no)

Quota check ends: (no)

User's soft quota crossed: (yes)

User's block quota exceeded: (yes)

**Note:** Use the above command to Edit the Quotas Configuration file for Filesystem ‘FS16’ . Set the Block Grace: (-1.0) to change Grace period to infinity.

### **UNIX CLIENT BEHAVIOR WHEN SOFT & HARD QUOTA LIMITS REACHED:**

#### **SYSTEM CONSOLE MESSAGE:**

“/mnt/fs20/files/getreason”: Disk quota exceeded”

**Note:** Error seen on client when copying files to Celerra and Hard Quotas is reached—copy operation is aborted.

#### **QUOTA REPORT FOR FS20:**

|      | Bytes Used (1k) |      |          | Files |
|------|-----------------|------|----------|-------|
| Used | Soft            | Hard | Timeleft | Used  |

#201 6999 5000 7000 7.0days 300

### **SERVER LOG MESSAGES:**

UFS: 4: Block soft quota crossed (fs /fs20, uid 201)

UFS: 3: Block hard quota reached/exceeded (fs /fs20, uid 201)

CFS: 3: write failed, start Offset = 0x28000, status=52

**Note:** The “write failed” error is written to Server Log whenever a User that has exceeded their Hard Quota is trying to copy additional data to Celerra. This behavior is not duplicated from a Windows 2000 Client for Windows 2000 Quotas.

### **VARIOUS QUOTA ERROR MESSAGES:**

CFS: 3: write failed, startOffset = 0x2000, status = 52

**Note:** User Quota exceeded: File\_QuotaExceeded

CFS: 3: write failed, startOffset = 0x35, status = 63

**Note:** Group Quota Exceeded: File\_GroupQuotaExceeded

CFS: 3: write failed, startOffset = 0x33e99a000, status=67

**Note:** Tree Quota exceeded: File\_TreeQuotaExceeded

2006-03-15 20:26:04: CFS: 3: write failed, fsid = 224, startOffset = 0x3cb1000, status = 25

**Note:** Error when NFS client tries to write to full file system

2006-03-22 12:26:14: UFS: 3: Block hard quota reached/exceeded (fs /fs\_quota, uid 32774)

**Note:** Message showing hard limit reached for UID

## **WINDOWS REPORTS QUOTAS VALUES DIFFERENT THAN NAS QUOTAS REPORTS:**

Problem is that quota policy was not set to “filesize” [which needs to report file sizes in 1k blocks, not 8k blocks]

### **Resolution:**

1. Set param file: param quota policy=filesize
2. Turn off quotas: \$nas\_quotas -both -off -fs fs01
3. Reboot DM and turn quotas on: \$nas\_quotas -both -on -fs fs01

## **WINDOWS 2000 QUOTAS & CLIENT BEHAVIOR WHEN SOFT & HARD LIMITS REACHED:**

### **CLIENT ERROR—Soft Quota:**

No Client PopUp message seen if crossing just the “Soft Quota” threshold

### **SERVER LOG MESSAGE—Soft Quota:**

UFS: 4: 4: Block soft quota crossed (fs /fs21,uid 602)

### **WINDOWS QUOTAS TAB:**

fs21 on ‘fox’ (E): Rightclick mapped drive to Celerra>Properties>Quota>Quota Entries>

Warning [Yellow Warning Triangle appears beside User that has crossed Soft Quota limit]

### **CLIENT ERROR—Hard Quota:**

“Error Copying File or Folder

X Cannot copy celerra\_info: There is not enough free disk space. Delete one or more files to free disk space, and then try again.”

### **SERVER LOG MESSAGE—Hard Quota:**

UFS: 3: 5: Block hard quota reached/exceeded (fs /fs21, uid 602)

**Note:** Further attempts to write to disk by Client are denied but do not log any further Server Log messages

### **WINDOWS QUOTAS TAB:**

Warning Triangle message remains for User that has crossed either Soft or Hard Quota limits

### **TREE QUOTAS MESSAGES:**

UFS: 4: Block soft quota reached (fs /fs1 treeid 1)

UFS: 4: Inode hard quota exceeded (fs /fs1 treeid 1)

## **QUOTA MANAGEMENT:** Can use Unix, Win2k, or Control Station CLI

WIN2K Clients can only set quotas by "bytes" on Users using My Computer>Select Volume>Properties>Quota Tab [NOT blocks, NOT inodes, NOT Groups] and allows setting of soft quota warnings

UNIX Clients can only view Quota reports by use of "rquota" daemon that runs on datamover and UNIX client

### **COMMANDS:**

**#quota      #quota -v      #quota -v dave      #quota dave**

## **RQUOTA DAEMON ON DATA MOVER:**

**# /usr/sbin/rpcinfo -p 10.241.169.54 |grep quota**

100011 1 tcp 57687 rquotad

100011 1 udp 49166 rquotad

**\$quota -v user |<uid>**

## **USING QUOTA TO QUERY A UID FROM CONTROL STATION:**

**# quota 32769**

Disk quotas for user #32769 (uid 32769):

```
Filesystem blocks quota limit grace files quota limit grace
10.241.169.54:/fb
    41   5120  5120      16     0     0
```

**USING QUOTAS WITH WINDOWS 2000:****Caution:** To use quotas as Windows 2000 Quotas, Celerra Inode, Group, & Grace Periods for Soft Quotas should be disabled!

--Quota Policy should also be set to “filesize” for Windows 2000 Quotas

--Windows 2000 Quotas will work using Usrmapper V3 or Passwd/Group files on DMs, but not NIS!

--Unless Inodes limit Quotas, User will still be able to create files, but they will be ‘empty’ 0-byte files

--MPFS clients will not be able to mount a File System with Quotas enabled

--Windows 2000 Quotas uses “bytes” for quota calculation, while Celerra uses ‘blocks’ for amount used

--Minimum Block size used with Windows 2000 Quotas is 4k v. 8k Celerra Block size

Quotas are only applied to the upper level share or "partition", not individual folders! You can set Windows Quotas on any Share if you map a drive to it. Also note that if you set a hard quota limit for a particular user, the size that the user sees for the partition will match their 'hard limit' even though the partition itself may have far more disk space available.

**Note:** When setting up Quotas from Windows 2000, make sure DataMovers have following param set first!**param quota policy=filesize***Click on Mapped Share>Properties>General Security>Quotas Tab>Quota***Status:** Disk Quotas are disabled [default level] Enable quota management Deny diskspace to users exceeding quota limit**Important:** If set to ‘No’, will allow CIFS & NFS Users to use disk space beyond SOFT & HARD Quota limits**Select the default quota limit for new users on this volume:** \*Do not limit disk usage [default setting] Limit disk space to \_\_\_\_\_ Set warning level to \_\_\_\_\_**Select the Quota logging options for this volume:** Log event when a user exceeds their quota limit Log event when a user exceeds their warning level**Quota Entries>Quota>New Quota Entry>Add new User for Quotas:****Note:** Applying quotas from the Windows 2000 Server forces a Usrmapper call so as to map a new UID for the User to which the Quota has been established [if a new User]. The User then immediately appears in the Quotas Report on the File System.**QUOTA REPORTS: By File System, DataMover, or User****QUOTA REPORT BY UID:****# nas\_quotas -r -u -fs fs20 201****Note:** If using NIS, can run reports by Username or Groupname

Report for user quotas on filesystem fs20 mounted on /fs20

| User | Bytes Used (1K) | Files | Used  | Soft     | Hard | Timeleft | Used | Soft | Hard | Timeleft |
|------|-----------------|-------|-------|----------|------|----------|------|------|------|----------|
| #201 | 69991           | 50001 | 70001 | 6.4days1 | 3001 | 01       | 01   | 01   | 01   | 01       |

**# nas\_quotas -r -u -fs fs20**

Report for user quotas on filesystem fs20 mounted on /fs20

| User | Bytes Used (1K) | Files  | Used   | Soft     | Hard | Timeleft | Used | Soft | Hard | Timeleft |
|------|-----------------|--------|--------|----------|------|----------|------|------|------|----------|
| #201 | 69991           | 50001  | 70001  | 6.4days1 | 3001 | 01       | 01   | 01   | 01   | 01       |

### **QUOTA REPORT BY FILESYSTEM:**

**\$nas\_quotas -r -fs fs01**

### **QUOTA REPORT BY DATAMOVER:**

**\$nas\_quotas -r -m server\_2**

### **QUOTA CONFIGURATION BY FILESYSTEM:**

**\$nas\_quotas -config -report -fs fs01**

### **QUOTA CONFIGURATION BY SERVER:**

**#nas\_quotas -config -report -mover server\_7**

```
+-----+
| Quota parameters for filesystem fs16 mounted on /fs16:
+-----+
| Quota Policy: blocks
| User Quota: ON
| Group Quota: OFF
| Block grace period: (1.0 weeks)
| Inode grace period: (1.0 weeks)
| Default USER quota limits:
|   Block Soft: ( 8192), Block Hard: ( 10240)
|   Inode Soft: ( 0), Inode Hard: ( 0)
| Default GROUP quota limits:
|   Block Soft: ( 0), Block Hard: ( 0)
|   Inode Soft: ( 0), Inode Hard: ( 0)
| Deny Disk Space to users exceeding quotas: YES
| Log an event when ...
|   Block hard limit reached/exceeded: YES
|   Block soft limit (warning level) crossed: YES
|   Quota check starts: NO
|   Quota Check ends: NO
```

**Note:** Running a Quotas Configuration Report will also log an entry in the Server Log and update the respective /.etc/config\_file  
2004-11-29 17:00:26: ADMIN: 4: Command succeeded: file quota /data config report=/data/.etc/config\_file

### **ESTABLISHING OR EDITING QUOTAS:**

**\$nas\_quotas -u -e -fs fs01 602** [Brings up Vi session—Edit Soft & Hard values]

**\$nas\_quotas -u -e -fs fs01 -block 1000 -i 5000 602** [Sets up Quota directly from CLI]

**\$nas\_quotas -g -e -fs fs20 -block 10000 -i 40000 801**

**# nas\_quotas -e -g -fs m3 32780** (edit specific Group quota)

### **TURNING USER OR GROUP QUOTAS ON/OFF:**

**\$nas\_quotas -on -fs fs20** [Turns on User Quotas for FileSystem that has Users defined for Quotas]

**\$nas\_quotas -g -on -fs fs20** [Turns on Group Quotas for FileSystem that has Groups defined]

**-off** [Turns Quotas off]      **-clear** [Clears all Quota records]      **-both -on** [Turns On both User/Group Quotas]

**\$ .server\_config server\_3 -v "file quota \"/fs5\"type=user off"** [Be aware fs must be unmounted to turn on or off]

```

## **CONFIGURING USER/GROUP QUOTAS:**

1. Set Block or Inode quotas on User, Group, FileSystem, or Data Mover basis
2. For Windows 2000 Quotas, or if Quota Policy = Files, set following parameters:

/nas/site/slot\_param [These params change Quotas from 8kb Block Size to 1kb File Size quotas]

**param quota policy=filesiz**

3. Turn Quotas on [by User, Group, or Both, or Datamover] | -off | -clear

**\$ nas\_quotas -u -on -fs fs01**

**\$ nas\_quotas -g -on -fs fs01**

**\$ nas\_quotas -both -on -fs fs01**

**\$ nas\_quotas -user -on -mover server\_2**

4. Edit Quotas by File System per DataMover:

**\$ nas\_quotas -config -edit -mover server\_2**

5. Turning Off and Deleting Quotas:

**\$ nas\_quotas -u -off -fs fs01 [Turns Quotas Off]**

**\$ nas\_quotas -u -clear -fs fs01 [Clearing Quotas; -m server\_2]**

**Note:** Turning quotas "off" retains existing Quotas configuration, but "clearing" Quotas resets all values to 0 and turns quotas 'off'

6. Creating a Quota for an Anonymous User:

**\$ nas\_quotas -edit -u -fs fs01 anon**

7. Creating Group Quotas:

**\$ nas\_quotas -group -edit -fs fs01 1101**

**Note:** Quotas are applied against a User's Primary Group

8. Using Proto User to Create Quotas:

**\$ nas\_quotas -edit -u -fs fs01 -p 1000 1001 1002** [Where 1000 represents the prototype User]

9. Using Proto User to Create Group Quotas:

**\$ nas\_quotas -edit -g -fs fs01 -p 1100 1101 1102** [Where 1100 represents the prototype Group]

## **SETTING UP WINDOWS 2000 QUOTAS (aka USER QUOTAS):**

1. Since the general recommendation is to use Quota Policy Filesize when using Windows, ensure the following param is set:

**# server\_param server\_2 -facility quota -modify policy -v filesize**

server\_2 : done

Warning 17716815750: server\_2 : You must reboot server\_2 for policy changes to take effect.

**# tail nas\_log.al**

2007-01-05 13:10:48.958 server\_2:0:9857:S: server\_param server\_2 -facility quota -modify policy -v filesize

# cat /nas/server/slot\_2/param

**param quota policy=filesize** →server\_param writes entry to param file

2. Reboot Data Mover

**Server Log messages:**

2007-01-05 13:32:11: UFS: 4: Quota limits will be checked on byte usage, in units of 1024 bytes

2007-01-05 13:32:11: UFS: 4: Checking USER quotas ...

2007-01-05 13:32:11: UFS: 4: Quota Check started (fs /mensha)

2007-01-05 13:32:11: UFS: 4: Quota Check completed (fs /mensha)

2007-01-05 13:32:11: UFS: 4: USER quota is ON.

3. Map to the toplevel Share of the Celerra file system Share&gt;Properties&gt;Quota tab

4. Check the ‘Enable Quota Management’ &amp; ‘Deny disk space to users exceeding quota limit’ boxes, then set values:

\*Limit disk space to 1 GB

\*Set warning level to 800 MB.

5. Select quota logging options if desired:

--Log event when a user exceeds their quota limit

--Log event when a user exceeds their warning level

6. Click on ‘Quota Entries’&gt;Quota&gt;New Quota Entry &amp; add Users to which to apply quotas to

**Note:** Only Users object types are allowed when configuring Windows quotas—Windows does not yet use the concept of Group quotas

7. Click o.k.—Status: Disk quotas are disabled should turn from Red light and message to Green light and following message:

Status: Disk quota system is active

8. Verify User Quotas from Control Station &amp; Data Mover perspective:

**# nas\_quotas -config -report -fs mensha**

```
+
+-----+
| Quota parameters for filesystem mensha mounted on /mensha:
+-----+
| Quota Policy: filesize
| User Quota: ON
| Group Quota: OFF
| Block grace period: (1.0 weeks)
| Inode grace period: (1.0 weeks)
| Default USER quota limits:
|   Block Soft: ( 819200), Block Hard: ( 1048576)
|   Inode Soft: (    0), Inode Hard: (    0)
| Default GROUP quota limits:
|   Block Soft: (    0), Block Hard: (    0)
|   Inode Soft: (    0), Inode Hard: (    0)
| Deny Disk Space to users exceeding quotas: YES
| Log an event when ...
|   Block hard limit reached/exceeded: YES
|   Block soft limit (warning level) crossed: YES
|   Quota check starts: NO
|   Quota Check ends: NO
```

**# nas\_quotas -report -fs mensha**

Report for user quotas on filesystem mensha mounted on /mensha

```
+-----+
|User | Bytes Used (1K) | Files |
+-----+-----+-----+-----+
|     | Used | Soft | Hard |Timeleft| Used | Soft | Hard |Timeleft|
+-----+-----+-----+-----+-----+-----+

```

## **WINDOWS 2000 QUOTA DEFAULTS:**

**Quota Policy:** filesize [turned on by default]

**User Quota:** ON [User quotas turned on by default—Windows 2000 does not use Group quotas]

**QUOTAS SUPPORT FOR MPFS:** Introduced in NAS 5.0

## **CELLERRA TREE QUOTAS:**

### **CELLERRA TREE QUOTAS (NAS 5.0+):**

Support for 'QUOTAS' based on Tree Directories [Quotas based on a directory tree structure by limiting number of blocks and/or inodes that can be created in a particular directory structure—treats every directory Tree as a separate "file system"]. Usages are computed on all files in the tree, irrespective of Owner. Besides allowing Soft & Hard Quotas, can also be used to "monitor" usage by setting limits to "0". File Handles identify the Tree Quotas using a unique identifier called 'TreId'. After turning Tree Quotas on, DART tracks usage and enforces limits.

→Max of 2047 Tree Quotas per file system, with max size of Tree Quotas capped at 4TB

**Note:** Number of Tree Quotas per fs raised to 8191 with NAS 5.6.45

### **TREE QUOTAS DEFINED:**

Tree Quotas are different and separate from User or Group Quotas or Windows 2000 Quotas in that quotas are set on specific directories or "trees". Tree quotas are tracked for all files and directories in the tree regardless of owner. Tree quotas are treated separately from user/group quotas in that files created in a Tree Quota will also count against user/group quotas. Use Tree quota function to create the directory and manage Tree Quotas through CLI. Tree Quotas can be moved within the File System using Unix move command.

**Correction:** Files owned by Users that have User Quotas, even within a Tree Quota structure, does apply to User quotas.

### **PURPOSE OF TREE QUOTAS:**

--Use to limit or monitor number of files/directories [inodes], or amount of diskspace [blocks] used in a directory tree.

--Tree Quotas are tracked only within the Tree for users/groups

--Tree Quotas can contain Hard or Soft limits, and be used with Filesize or Block Quota policies

### **COUNTING ROOT USAGE IN TREE QUOTAS:**

**param quota countRootUsageInQuotaTree=0 | 1**

**Note:** With NAS 5.2 and higher, if filesystem type is MPD, then Root User usage can be tracked against TreeQuota limits, however, root user will not be restricted from going over the limit—set to 1 to enable tracking.

### **REPORTING, LISTING, & VERIFYING TREE QUOTAS CONFIGURATION:**

#### **1. Run file system list to see tree quotas in effect:**

\$ nas\_quotas -tree -list -fs fs2

```
+-----+  
| Quota trees for filesystem fs2 mounted on /fs2:  
+-----+  
| TreId| Quota tree path (Comment) |  
+-----+
```

```
| 1 | /dir3 ()
| 2 | /dir4 ()
```

**Note:** Above output shows list of tree quotas contained on file system called “fs2”. The actual tree quotas paths are /fs2/dir3, /fs2/dir4

## **2. Run Tree Quotas Reports against whole file system or specific Trees:**

**\$ nas\_quotas -tree -report -fs fs2**

Report for tree quotas on filesystem fs2 mounted on /fs2

| Tree | Bytes Used (1K)  | Files      |
|------|------------------|------------|
| #1   | 936  1000  10504 | 31  50  90 |
| #2   | 0  0  16         | 1  0  0    |

done

**\$ nas\_quotas -tree -report -fs fs2 1**

Report for tree quotas on filesystem fs2 mounted on /fs2

| Tree | Bytes Used (1K)  | Files      |
|------|------------------|------------|
| #1   | 936  1000  10504 | 31  50  90 |

Done

## **3. Review Specific Quota Configuration:**

**\$ nas\_quotas -report -config -fs fs2 1**

```
+-----+
| Quota parameters for filesystem fs2 mounted on /fs2:
+-----+
```

### **| Quota Policy: blocks**

- | User Quota: OFF
- | Group Quota: OFF
- | Block grace period: (1.0 weeks)
- | Inode grace period: (1.0 weeks)
- | Default USER quota limits:

- | Block Soft: ( 0), Block Hard: ( 0)
- | Inode Soft: ( 0), Inode Hard: ( 0)

- | Default GROUP quota limits:

- | Block Soft: ( 0), Block Hard: ( 0)
- | Inode Soft: ( 0), Inode Hard: ( 0)

### **| Deny Disk Space to users exceeding quotas: YES**

- | Log an event when ...

- | Block hard limit reached/exceeded: NO

- | Block soft limit (warning level) crossed: NO

- | Quota check starts: NO

- | Quota Check ends: NO

**Note:** The ‘Deny Disk Space...’ value must be set to ‘YES’ in order for Tree Quotas to honor the hard limit. It does mention this in the 5.4 Quotas documentation, but it could be more clearly stated.

## **QUERYING TREE QUOTA INFO USING NAS\_FS:**

**# nas\_fs -query:"\*IsRoot==False:Type==uxfs" -fields:TreeQuotas -format:"%q" -query:"\*" -fields:ID,Filesystem,Path -format:"%s,%s, %s\n"**

```
2.coreprod,
1.coreprod, /options_new
2.linux, /lx7_sadmin
1.linux, /lx386_tp
```

## **DISPLAYING TREE QUOTAS DIRECTLY FROM BROWSER TO CONTROL STATION:**

<https://10.241.169.53/action/treeQuotaDisplay>

## **TREE QUOTAS RECALC TOOL (Quota Check Tool):**

**Problem:** Tree Quota usage may not match true fs usage--why?

-->The quota policy was changed after tree quotas created

-->The quotas.tree file is missing or corrupt

-->A software bug caused the calculation to be incorrect

**Previously, not an easy fix--Unlike user & group quotas, tree quotas can't be enabled or disabled when data exists—no easy way to recalculate usage--the only procedure was:**

-->Move all the data from the tree to a temporary location

-->Delete and recreate the tree

-->Repopulate the tree with the data

### **Normal Tree Quota differences that are not real problems:**

-->Quota policy when the tree was created was set to filesize. du reports block usage so it will likely be larger than what is returned by the quota report. If there are a large number of small files in the tree the du output and the quota report could differ greatly.

-->param quota countRootUsageInQuotaTree was set to 0 when the tree was created or the tree was created before 5.2.12 when root usage wasn't counted against the limit. Changing this param has no effect on the trees created earlier even if you run the recal tool.

## **USING THE TREE QUOTA RECALC/CHECK TOOL:**

**Note:** This tool only applies to issues related to space & inode usage within a Tree—compare the du output of a specific tree quota (/tree) to the Tree Quotas report to determine if a true size discrepancy exists. Functionally, the Tree Quota Check Tool traverses the quota tree & recomputes usage, as well as usages for User & Group quotas (if turned ON)—available in NAS 5.3.23.0 & 5.4.18.0.

### **1. Navigate to the file system through the rootfs:**

**# cd /nas/rootfs/slot\_2/fs01**

### **2. Locate appropriate Tree Quota in question:**

**# nas\_quotas -l -t -fs fs01**

| Quota trees for filesystem fs01 mounted on /fs01:

|                                   |         |         |
|-----------------------------------|---------|---------|
| +-----+                           | +-----+ | +-----+ |
| TreeId  Quota tree path (Comment) | +-----+ |         |
| +-----+                           | +-----+ |         |
| 1   /tree1 ()                     |         |         |
| 2   /tree2 ()                     |         |         |

### **3. Check the size of the Tree Quota using du command(Run during offpeak time):**

**# du -s tree1**

10712064 tree1

### **4. Run Tree Quota Report to determine if discrepancy exists:**

**# nas\_quotas -r -t -fs fs01 1**

Report for tree quotas on filesystem fs01 mounted on /fs01

|                                                              |                     |                     |
|--------------------------------------------------------------|---------------------|---------------------|
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |
| Tree  Bytes Used (1K)  Files                                 | +-----+-----+-----+ |                     |
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |
| Used   Soft   Hard   Timeleft  Used   Soft   Hard   Timeleft | +-----+-----+-----+ |                     |
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |
| #1  10815144  01 01   01 01   01 01                          | +-----+-----+-----+ |                     |

### **5. If true discrepancy exists, it can be fixed by running the following recal command:**

**#.server\_config server\_2 -v "file quota /fs01 type=tree check path=/tree1"**

2005-09-27 22:16:32: UFS: 4: Performing treeQuotaCheck on directory tree

**Note:** Use following syntax for VDMs

**\$ .server\_config movername -v "file quota /vdm\_name/file\_system type=tree check path=/quota\_tree\_path"**

### **6. Verify effectiveness by rerunning Tree Quota report:**

**# nas\_quotas -report -tree -fs fs01 1**

Report for tree quotas on filesystem fs01 mounted on /fs01

|                                                              |                     |                     |
|--------------------------------------------------------------|---------------------|---------------------|
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |
| Tree  Bytes Used (1K)  Files                                 | +-----+-----+-----+ |                     |
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |
| Used   Soft   Hard   Timeleft  Used   Soft   Hard   Timeleft | +-----+-----+-----+ |                     |
| +-----+-----+-----+                                          | +-----+-----+-----+ | +-----+-----+-----+ |

**TREE QUOTA SIZE ISSUE (AR70615):**

At times, quotas.tree file can grow to be excessively large, though 2047 tree quotas limit per file system is supposed to prevent this from happening—use following procedure to truncate file:

1. Upload truncate executable to file system ./etc directory
2. Make backup copy of quotas.tree file if feasible
3. Run truncate command to truncate quotas.tree to 65536 bytes: #./truncate quotas.tree 65536
4. Verify that file was truncated to 64k
5. Unmount and then remount the file system
6. Run quota report against file system
7. Create test tree quota and view using tree report

**Hard Quota Events:** Server Log Error; QUOTA EXCEEDED (EDQUOT) Error returned

**Soft Quota Events:** Server Log Message; Grace Period Starts—once expired will act as a Hard Quota

Limiting Quota Event Notification: After a hard limit is hit, we enable the event generation only after the files are deleted below the soft limit. This is the behavior of bsd (UNIX) quotas and Celerra behaves the same.

**TABLE OF EVENT ACTIONS:**

| Action                                                         | Server_Log | Email |
|----------------------------------------------------------------|------------|-------|
| Soft quota hit                                                 | yes        | yes   |
| Soft quota hit after files deleted                             | yes        | no    |
| Hard Quota hit                                                 | yes        | yes   |
| Hard quota hit after files deleted                             | yes        | no    |
| Soft quota hit after files deleted<br>after hard quota reached | yes        | yes   |
| Hard quota hit                                                 | yes        | yes   |

**SETTING UP TREE QUOTAS:****1. Customer should decide on Policy to use: Blocks or FileSize**

Blocks-->Usage calculated in 8k blocks, the default

FileSize-->Bytes added or removed, recommended for cifs, limits & warnings based on 8k block

**param quota policy=filesize**

**2. Create directory path under mountpoint, to which TreeQuotas are going to be applied:**

**# nas\_quotas -on -tree -fs fs2 -path /proj1/user1**

done

**Note:** This creates TreeQuota called “user1” id=1 in the path /fs2/proj1/user1. The directory “user1” cannot exist prior to creating the TreeQuota and must be created by the TreeQuota command.

**# nas\_quotas -on -tree -fs fs2 -path /proj2/user2**

done

**3. Run List to verify new TreeQuotas created:**

**# nas\_quotas -list -tree -fs fs2**

```
+-----+
| Quota trees for filesystem fs2 mounted on /fs2:
+-----+
|TreeIdl Quota tree path (Comment) |
+-----+
| 1 |/proj1/user1 () |
| 2 |/proj2/user2 () |
```

**4. Edit the TreeQuotas and apply Hard & Soft Limits:**

**# nas\_quotas -edit -tree -fs fs2 1**

treeid : 1

fs fs2 blocks (soft = 1000, hard = 10000) inodes (soft = 0, hard = 0)

**Note:** Above sets soft quota at 1MB and hard quota at 10MB. Default values of 0 for inodes means that no values are set and are therefore unlimited.

**# nas\_quotas -tree -edit -block 20000:10000 -inode 20000:10000 -fs fs2 1**

done

**Note:** Above command edits Hard & soft quota, respectively, for both ‘Blocks/Bytes’ or ‘Inodes/Files’ without use of vi

**5. Export the TreeQuota directory for CIFS:**

# server\_export server\_2 -P cifs -n project1 /fs2/proj1/user1

server\_2 : done

# server\_export server\_2 -P cifs -n project2 /fs2/proj2/user2

server\_2 : done

# server\_export server\_2

share "project1" "/fs2/proj1/user1" maxusr=4294967295 umask=22

share "project2" "/fs2/proj2/user2" maxusr=4294967295 umask=22

## **6. Set NT permissions on the TreeQuota folders**

### **7. Make Quota configuration changes using the following:**

# nas\_quotas -config -edit -fs fs2

File System Quota Parameters:

fs fs2

Block Grace: (1.0 weeks)

Inode Grace: (1.0 weeks)

\* Default Quota Limits:

User: (soft = 0, hard = 0) inodes (soft = 0, hard= 0)

Group: (soft = 0, hard = 0) inodes (soft = 0, hard= 0)

Deny disk space to users exceeding quotas: (yes)

\* Generate Events when:

Quota check starts: (no)

Quota check ends: (no)

User's soft quota crossed: (no)

User's block quota exceeded: (no)

## **8. Run TreeQuota Reports or Obtain Config Information:**

# nas\_quotas -tree -list -fs fs2

# nas\_quotas -config -report -fs fs2

## **DELETING TREE QUOTAS:**

### **1. If NFS or CIFS exported, unexport first**

### **2. Obtain TreeQuotas list:**

\$ nas\_quotas -tree -list -fs fs2

```
+-----+
| Quota trees for filesystem fs2 mounted on /fs2:
+---+-----+
|TreeIdl Quota tree path (Comment)           |
+---+-----+
| 1 | /dir3 ()                           |
| 2 | /dir4 ()                           |
```

### **3. Delete data from the TreeQuotas & then delete the quota tree directory:**

\$ nas\_quotas -off -tree -fs fs2 -path /dir3

done

\$ nas\_quotas -off -tree -fs fs2 -path /dir4

done

**Note:** Deletes TreeQuotas directory called "dir3" and "dir4"--directory must be empty of all data before this command will succeed

### **4. Clear TreeQuotas for the file system:**

\$ nas\_quotas -clear -tree -fs fs2

done

## **TREE QUOTA COMMANDS:**

\$nas\_quotas -tree -on -fs fs06 -path /fs06/Tree [Turns Quotas On & creates dir. "Tree" in path /fs06/fs06/Tree]

\$nas\_quotas -tree -edit -fs fs06 -path /fs06/Tree [Edit Quotas]

\$nas\_quotas -tree -report -fs fs06 -path /fs06/Tree [Reporting]

\$nas\_quotas -tree -off -tree -fs fs06 -path /fs06/Tree [Turn quotas off first, then -clear to remove]

\$nas\_quotas -tree -clear -fs fs06 [Clears Tree Quotas from FS indicated]

**Note:** Command syntax changes slightly from NAS 5.0 to 5.1 in setting up Tree Quota path structure

\$ .server\_config server\_3 -v "file quota \"/fs5\"type=tree off"

\$ .server\_config server\_3 -v "file quota \"/fs5\"type=tree on"

### RUNNING TREE QUOTAS REPORTS:

\$nas\_quotas -tree -report -fs fs06 1 [Issues report for Tree Quotas for specified tree]

\$nas\_quotas -tree -report -fs fs06 [Generates Quota Report on all quota trees]

### LISTING TREE QUOTAS—VERIFYING:

# nas\_quotas -tree -list -fs treefs

```
+-----+
| Quota trees for filesystem treefs mounted on /treefs:
+-----+
|TreeId| Quota tree path
+-----+
| 1 | /tree1
| 2 | /tree2
| 4 | /tree4
| 5 | /tree5
```

### SETTING TREE QUOTAS LIMITS:

1. Set limits on Tree: \$nas\_quotas -tree -edit -fs fs06 1 [Opens up Tree Quota Editor for Hard & Soft limits]

  fs fs06 blocks (soft=2000, hard=5000) inodes (soft=2000, hard=5000)

2. # nas\_quotas -tree -edit -block 20000:10000 -inode 20000:10000 -fs fs2 1 [Example sets Hard & Soft Tree Quota Limits, resp.]

3. Set Grace Period: \$nas\_quotas -config -edit -fs fs06 [Opens editor to allow you to set Grace periods]

Note: Quotas limits are enabled with 0 limits by default. Use –edit command to setup block & inode hard & soft limits

# nas\_quotas -tree -edit -block 20000:10000 -inode 20000:10000 -fs fs2 1

done

# nas\_quotas -tree -report -fs fs2

Report for tree quotas on filesystem fs2 mounted on /fs2

```
+-----+
| Tree   | Bytes Used (1K) | Files
+-----+-----+-----+
|       | Used | Soft | Hard |Timeleft| Used | Soft | Hard |Timeleft|
+-----+-----+-----+
#1    | 0| 10000| 20000|      | 1| 10000| 20000|      |
#2    | 0| 0| 0|      | 1| 0| 0|      |
```

### SERVER LOG ENTRIES WHEN SOFT & HARD TREE QUOTAS ARE REACHED:

2005-07-13 16:13:22: UFS: 4: Block soft quota crossed (fs /fs2, treeid 1)

2005-07-13 16:23:11: UFS: 3: Block hard quota reached/exceeded (fs /fs2, treeid 1)

### NAS 5.3 FEATURES:

#### CREATING TREE QUOTA COMMENTS:

\$nas\_quotas -tree -on -fs fs06 -comment <comments> -path /fs06/Tree

Note: NAS 5.3 introduces Quota\_Descriptor feature, which are nothing more than comment fields

\$nas\_quotas -tree -on -fs fs06 -comment “ -path /fs06/Tree [removes comment]

#### EDITING TREE QUOTA LIMITS:

\$nas\_quotas -edit -tree -fs fs06 1

#### CHANGING OWNERSHIP AND PERMISSIONS:

#chown 6009 /quotaTrees/tree1

#chmod 755 /quotaTrees/tree1

Note: To set Quota Descriptor, must have QuotaTree itself created, though the last component of the tree (tree1) must not exist

### TYPICAL CONTENTS OF FS .ETC FOLDER FOR TREE QUOTAS:

```
# ls -l /nas/rootfs/slot_2/fs_A0/etc
-rw-r--r-- 1 root bin 60 Mar 12 09:08 config_file
```

```
-rw-r--r-- 1 root bin 9 Mar 12 09:08 config_file.InProgress  
-rw-rw-rw- 1 root bin 0 Mar 12 09:08 quotas  
-rw-rw-rw- 1 root bin 44 Mar 4 11:53 quotas.config  
-rw-rw-rw- 1 root bin 96 Mar 12 09:29 quotas.tree  
-rw-r--r-- 1 root bin 1028 Mar 12 09:32 rpt_file  
-rw-r--r-- 1 root bin 0 Mar 12 09:32 rpt_file.InProgress  
drwxr-xr-x 2 root bin 80 Mar 12 09:29 treeQuotaDB  
# ls -l /nas/rootfs/slot_2/fs_A0/.etc/treeQuotaDB  
lrwxr-xr-x 1 root bin 19 Mar 4 11:55 1 -> 10001.1a.b.40475f8a
```

## ARCHIVING, DELETING, CLEARING, RESTORING TREE QUOTAS:

**Note:** Might use the following method to delete a Tree Quota from a file system or as a way to correct a corrupted database

1. **#tar -tcvf tree1.tar.gz /fs1/tree1/\***
2. Remove Quota Tree Information: **#rm -rf /fs1/tree1/\***
3. Disable Quotas for FS1: **\$nas\_quotas -tree -off -fs fs1 -path /tree1**
4. Clearing Quotas for FS1: **\$nas\_quotas -tree -clear -fs fs1**
5. Recreate Quota Tree: **\$nas\_quotas -tree -on -fs fs1 -path /tree1** [May need to chown & chmod directory]
6. Restore Tree Database: **#tar -tzvf tree1.tar.gz /fs1/tree1/**

## HANDLING SPACES IN TREE QUOTAS PATH STATEMENTS:

**#nas\_quotas server\_2 -tree -on -fs filesystem1 -path "/department share"**  
or **#nas\_quotas server\_2 -tree -on -fs filesystem1 -path /department\share**

## TREE QUOTA LIMITATIONS:

- Max. of 2047 Quota Trees per file system
  - Tree Quotas cannot be nested
  - Tree Quotas can be moved within the same FS
  - Tree Quotas limited to 4TB due to 32bit O/S
  - Max. file size restricted to 4TB (vs. normal 16TB) when Quota policy set to ‘filesize’
  - Name of tree quota directory cannot exist on filesystem prior to setting up with Tree Quotas commands!
  - Cannot view a User’s Tree Quota Usage from Explorer Quotas Tab—Celerra returns total fs space information.
- Note:** NAS 5.1.16.0 introduces ability to return User, Group, or Tree Quotas information [to be changed with 5.1.18.2]

## ENABLING WRITES TO A 4TB TREE QUOTA AT 100%:

→Though the limitation of being able to report on a maximum of 4TB worth of Quota information still exists, the following parameter change allows customers to keep writing to a file system even when the 4TB limit has been reached. This change is effective with NAS 5.5.38 and 5.6.42:

```
# nas_quotas -tree -list -fs cifs_xp1  
+-----+  
| Quota trees for filesystem cifs_xp1 mounted on /cifs_xp1:  
+-----+  
| TreeId| Quota tree path (Comment) |  
+-----+-----+  
| 1 | /treed () |  
$ .server_config server_2 "file quota /cifs type=tree allowOverflow treeid=1"  
$ .server_config server_2 "file quota /cifs type=tree allowOverflow list"
```

## TREE QUOTAS LIMITATION FIXED FOR NFS AND CIFS CLIENTS:

Problem is that Users see only full file system quota and not the tree directory. AR29527 fixes for CIFS [5.1.16.0/5.2.1.0] and AR34993 fixes for NFS [5.1.20.0].

## CELLERRA FILE SYSTEM COMMANDS:

**FileSystem Commands:** #server\_df ALL #server\_export [NFS or CIFS] #server\_mount #server\_file [copies files from CS to DM and vice versa] #server\_archive [archiving] #nas\_fs -l #nas\_fs -n ufs1 -c vol1  
#nas\_volume -l #nas\_volume -n meta1 -c -M d4 #nas\_volume -s meta1 [verify volume size]

**# showmount -e 172.19.32.10** [shows the Exported File Systems on the indicated IP Address]

#server\_df server\_2 or #server\_df ALL #mount -F nfs server\_3:/mount1 /mnt [to mount remote filesystem]  
[NAS 4.0 introduces support for grouping of file systems for TimeFinder/FS operations]

**EXAMPLE:** \$fs\_group -n grp1 -c fs1 fs2 fs3

**Creates Group:** grp1 [Type 100 FileSystem]

## **CELERRA AUTOMATIC FILE SYSTEM USAGE NOTIFICATION HWM (File System Full):**

**Note:** By default, the Celerra will automatically log an event to /nas/log/sys\_log when any file system reaches 90% full

**Celerra Checks using dskMon and Cron Job every (3) Minutes:**

# cat /nas/site/cron.d/nas\_sys

3 \* \* \* \* root /nas/sbin/dskMon > /dev/null 2>&1

# .server\_config server\_2 -v "param file"

| Name                 | Location   | Current    | Default                                |
|----------------------|------------|------------|----------------------------------------|
| file.fsSizeThreshold | 0x01b890c0 | 0x0000005a | 0x0000005a → 5a hex = 90 decimal = 90% |

**Example /nas/log/sys log:**

Dec 11 08:40:33 2006 CFS:4:1 Slot 2: 1165855248: filesystem size threshold (90%) crossed (fs /sector)

**Note:** An event also shows up under Celerra Manager for CFS

## **CHANGING THE DEFAULT 90% FULL FS HWM USAGE NOTIFICATION:**

**Example of changing from 90% default to 80% full:**

**param file fsSizeThreshold=80**

**Using server param to modify value:**

\$ server\_param server\_2 -facility file -modify fsSizeThreshold -value 80

**Note:** Requires server reboot

**Using dskMon.cfg to set different file systems to different HWM thresholds:**

1. vi edit the /nbsnas/etc/dskMon.cfg file to specify file systems, change the default, disable the feature, etc.

# The default high-water mark for all FSeS is 90%. To change this

# default, uncomment the following line and change 90 to whatever

# you want it to be:

# DefaultHiWater 90 → Excerpt from the dskMon.cfg file

## **CREATING FILE SYSTEM HWM ALERTS FROM CELERRA MANAGER:**

Notifications>File System Usage>create new HWM notification and indicate email or SNMP trap

**Automatically creates a new JServer event file and loads on the Celerra:**

# nas\_event -L -i

3: /nas/jserver/event\_config/events.cfg

# pwd

**/nas/jserver/event\_config**

# ls -la

-rw-r--r-- 1 root root 109 Dec 11 10:41 events.cfg

# cat events.cfg

# This file has been automatically generated by JServer Facility

# JServer Facility

#

facilitypolicy 135, 4

**Events are logged /nas/log/sys log & appear on Celerra Manager status page:**

Mon Dec 11 09:50:21 PST 2006 Warning JServer Alert W0 (space); File System 'sector'; value=94.9% → Celerra Manager Status

Dec 11 09:50:21 2006 JServer:4:201 Alert W0 (space); File System 'sector'; value=94.5% → /nas/log/sys\_log

## **HOW TO CREATE FILE SYSTEMS USING A SPECIFIC DATAMOVER:**

**Note:** By default, all file systems will attempt to use "server\_2" to build the file systems

#nas\_fs -n mail5 -c mtv05 -o mover=server\_9

## **QUERYING FOR FILE SYSTEM USING XHMP:**

# nas\_fs -query:id==37 -fields:Name,type -format:"%s %s\n"

EPWxtra2\_DR uxfs

**Nas slice Command:** -l Slice Table -d delete -n name -c create -r rename -i details \$nas\_slice -n slv24 -d d24 4096

**\$nas\_slice -n slv25 -d d24 max** [to use the rest of the device for the slice volume]

**Nas volume Command:** -l Celerra Volume Table & names -d -n -r -c {-S stripe size -M meta[meta=default volume type\*]}

\***Note:** That is, if you do not specify a Volume Type, it will create a MetaVolume by default!!!!

-s total size -x extend a volume -i detailed info -acl -C to clone volume {volume\_name; disktype=; svol:dvol}

**\$nas\_volume -n str5 -c -S 8192 slv24,slv25** [Creating Stripe Volume]

**\$nas\_volume -n mtv1 -c -M str4,str5,str6** [Creating Meta Volume]

## **VERIFYING FILE SYSTEM SPACE ON DM:**

**\$server\_df server\_4 or \$server\_df server\_4 ufs201**

## **EXTENDING CELERRA FILESYSTEM:**

**CAUTION:** Recommend failing over to Standby DataMover to conduct File System Extend!

- Step 1. Locate Available Devices to Build New MetaVolume(s): \$nas\_disk -l \$nas\_volume -s d24 [specific info on volume]
- Step 2. Create new Slice or Stripe or Meta: In this case, need only a 2GB Slice from a 15GB d24 Volume:

**\$nas\_slice -n slv24 -c d24 2048**

- Step 3. Create New MetaVolume from Slice: \$nas\_volume -n mtv24 -c slv24
- Step 4. Reboot DataMover to flush RAM & thereby provide more resources for it to create “Extended” file system.
- Step 5. Have a Standby Server for the Primary system and test failover... [need to define why]
- Step 6. Extend File System: \$nas\_fs -x g3ufs7 mtv24 [yields g3mtv7]

**Note:** You can Extend File Systems using “MetaVolumes”; “Symm Device Volumes”; or “Slice Volumes”

**Example:** \$nas\_fs -xtend g1ufs13 d70                   \$nas\_fs -xtend g1ufs13 slc70

## **DATA MOVER ROOTFS EXTENSION PROCEDURE (extending rootfs):**

### **Introduction:**

With NAS 5.2, new design features were introduced [SecMap Caching, Internal Usermapper, VDMs] that did not fully take into account the space and inode requirements imposed on the rootfs of each Data Mover, in many cases leading to the disabling of SecMap Caching and inability to upgrade from External to Internal Usermapper. SecMap Caching requires (2) rootfs inodes for every UID or GID mapping made. Internal Usermapper requires (4) rootfs inodes for every UID or GID mapping made. The default size of the rootfs is 128MB, with a total of 16,000 inodes (1 inode/8k block) available for system use. With new installations of NAS 5.2.10.3 and higher, the inode density of the rootfs was increased from 16,000 to 130,000 inodes (1 inode/1k block), yet remains 128MB in overall size.

### **CAUTION!**

- If disks are not available, an emergency CCA should be submitted to add storage so that the rootfs extension can occur
- The extension of the rootfs should only be done by a qualified EMC Field Service person
- DO NOT extend the root\_fs with volumes built on ATA drives or any other drive technology than Fibre Channel RAID 5 4+1 disks (see enhancement AR145405)
- DO NOT extend the root\_fs with volumes built on anything other than the storage system where the Celerra boots from
- Use extreme care before issuing the rootfs extend command so as not to mistakenly overextend the rootfs
- With NAS versions below 5.2.19.0 and 5.3.13.0, extending the root file system to a size greater than 48G will prevent Usermapper from being able to calculate new uid and gids

### **ROOTFS FULL ISSUES:**

- Unable to create new Shares
- Unable to map new Users or Groups
- Unable to modify the localgroups database
- Unable to create new CIFS VDM container

**Note:** Keep in mind that Secmap and Internal Usermapper entries use symbolic links that are often larger than 83 bytes, resulting in allocation of extra 8kb blocks, and may result in more actual disk space being used than reported by the Linux Control Station du command. See AR81639.

## **EXTENDING DM ROOT FILE SYSTEM TO GAIN MORE SPACE & INODE CAPACITY:**

### **1) VERIFY CURRENT ROOTFS SPACE & INODE USAGE:**

**# server\_df server\_2**

```
server_2 :
Filesystem      kbytes   used   avail capacity Mounted on
root_fs_common  13624    2072   11552  15%   /.etc_common
root_fs_2       128592   119432  9160   92%   /
-->Ability to add to localgroups db may be disabled at 92% full mark
```

**# server\_df server\_2 -i**

```
server_2 :
Filesystem      kbytes   used   avail   capacity   Mounted on

-->Inode threshold of 95% has been reached
```

### **2) VERIFY AVAILABILITY OF FREE STORAGE FOR EXTENSION:**

#### **a.) Find available d volume to use:**

**# nas\_disk -l**

```
id inuse sizeMB storageID-devID type name servers
1 y 11263 APM00023801040-0000 CLSTD root_disk 1,2
2 y 11263 APM00023801040-0001 CLSTD root_ldisk 1,2
7 n 108323 APM00023801040-0010 CLSTD d7 2,1
```

**# nas\_volume -s d7**

total = 108323 avail = 108323 used = 0 ( 0% ) (sizes in MB)

Note: d7 has 108GB of space available, so performing an extension is possible

**b.) Alternatively, identify a pool with space available for the extension:**

**# nas\_pool -list**

```
id inuse acl name
3 y 421 clar_r5_performance
```

**# nas\_pool -size clar\_r5\_performance**

```
id = 3
name = clar_r5_performance
used_mb = 900848
avail_mb = 2372920
total_mb = 3273768
potential_mb = 381137
```

**3) VERIFY CURRENT STATUS & NAME OF ROOT FILE SYSTEM:**

**# /nas/sbin/rootnas\_fs -s root\_fs\_2**

```
total = 111 avail = 110 used = 1 ( 0% ) (sizes in MB) ( blockcount = 262144 )
volume: total = 128 (sizes in MB) ( blockcount = 262144 )
```

**# /nas/sbin/rootnas\_fs -i root\_fs\_2**

```
id = 2
name = root_fs_2
acl = 0
in_use = True
type = udfs
worm = off
volume = root_volume_2
```

**# /nas/sbin/rootnas\_volume -i root\_volume\_2**

```
id = 12
name = root_volume_2
acl = 0
in_use = True
type = meta
volume_set = root_slice_2,root_s70_2
disks = root_disk,root_ldisk
clnt_filesys= root_fs_2
```

**4) USE OPTION I or II BELOW WHEN EXTENDING ROOTFS ON SYMMETRIX OR CLARIION**

**I. EXTENDING ROOTFS ON SYMMETRIX OR CLARIION STORAGE USING SLICE FROM CLI:**

**1.) Create Slice using root\_nas command for rootfs (Server 2 in this example):**

**# /nas/sbin/rootnas\_slice -n root\_slice\_2a -c d7 2048** (root\_slice\_2a is just the slice name to be used for the extension)

```
id = 1170284631
name = root_slice_2a
acl = 0
in_use = False
slice_of = d7
offset(MB)=0
size (MB)= 2048
volume_name = root_slice_2a
```

**2.) Extend Root File System from Slice created in previous Step:**

**# /nas/sbin/rootnas\_fs -x root\_fs\_2 root\_slice\_2a**

```
id = 2
name = root_fs_2
acl = 0
in_use = True
```

```
type      = uxf5
worm     = off
volume   = root_volume_2
pool      =
rw_servers= server_2
ro_servers=
rw_vdms  =
ro_vdms  =
auto_ext = no,virtual_provision=no
stor_devs = APM00023801040-0000,APM00023801040-0001,APM00023801040-0010
disks    = root_disk,root_ldisk,d7
```

**Note:** A 2GB extension takes a couple of minutes and can be done with the Server online. However, EMC recommends that this procedure be done during regular maintenance windows as CIFS access can be impacted if done 'online' on a busy server.

### **3.) Verify extension results:**

```
# /nas/sbin/rootnas_fs -s root_fs_2
```

```
total = 1935 avail = 1934 used = 1 ( 0% ) (sizes in MB) ( blockcount = 4456448 )
volume: total = 2176 (sizes in MB) ( blockcount = 4456448 )
```

## **II. EXTENDING ROOTFS ON SYMM OR CLARIION STORAGE USING STORAGE POOLS--AVM:**

### **1.) Use following command syntax to extend rootfs using CLARiiON or SYMMETRIX STORAGE POOLS:**

```
# /nas/sbin/rootnas_fs -xtend root_fs_2 size=2G pool=clar_r5_performance (pool=symm_std) -option slice=y
```

```
id      = 2
name   = root_fs_2
acl     = 0
in_use  = True
type    = uxf5
worm    = off
volume  = root_volume_2
pool    = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
ro_servers=
rw_vdms  =
ro_vdms  =
auto_ext = no,virtual_provision=no
stor_devs = APM00023801040-0000,APM00023801040-0001,APM00023801040-0010,APM00023801040-002B,APM00023801040-0024,APM00023801040-0023,APM00023801040-0028
disks   = root_disk,root_ldisk,d34,d18,d30,d20
```

**CAUTION:** Use extreme care before executing command to ensure -option slice=y is correctly chosen

### **2.) Verify Extension:**

```
# server_df server_2
```

```
server_2 :
Filesystem      kbytes   used   avail capacity Mounted on
root_fs_2        1978504   1152   1977352  0%   /
# server_df server_2 -i
```

```
server_2 :
Filesystem      inodes   used   avail capacity Mounted on
root_fs_2        1985982   383   1985599  0%   /
```

## **USING ROOT LDISK RESERVE VOLUME OPTION\*:**

**root\_ldisk\_reserve (reserved volume built on Control LUN 1)**

**root\_disk\_reserve (reserved volume built on Control LUN 0)**

**Note:** root\_ldisk\_reserve begins on LUN 1 at the end of the (16) 64MB UFSLogs, offset 1024MB. The ldisk\_reserve volume is currently used during upgrades to extend rootfs file systems (to bring up to 128MB), and for increasing the size of the panic handlers

**\*CAUTION: This method is no longer sanctioned by Engineering & must not be used. If data volume cannot be used for an extension, contact TS2/EE—there are situations that may necessitate the use of the root\_ldisk\_reserve. Make sure that you are using the root\_ldisk\_reserve and NOT root\_disk\_reserve**

**1) Verify Root File System Space:****# server\_df server\_2**

```
server_2 :
Filesystem      kbytes   used   avail capacity Mounted on
root_fs_common  13624    2072   11552  15%   /.etc_common
root_fs_2       128592   119432  9160   92%   /

```

**2) Verify Root File System Inode Availability:****# server\_df server\_2 -i**

```
server_2 :
Filesystem      inodes   used   avail capacity Mounted on
root_fs_common  21822    18     21804  0%   /.etc_common
root_fs_2       15865   6875   8990   54%   /

```

**3) To use root\_ldisk\_reserve volume to extend the rootfs:****Note:** Determine if root\_ldisk\_reserve volume has capacity available to extend rootfs**# nas\_volume -l**

```
91      y 1 0  root_ldisk_reserve 0  69,70,71,72

```

**# /nas/sbin/rootnas\_volume -s id=91**

total = 10239 avail = 9999 used = 240 ( 2% ) (sizes in MB)

**Note:** Above output shows approximately 10GB of space available, which means that a 2GB extension can be done**4) Verify Naming Convention for Current Rootfs Volumes:****# /nas/sbin/rootnas\_fs -i root\_fs\_2**

```
id      = 2
name    = root_fs_2
acl     = 0
in_use  = True
type    = uxf
volume  = root_volume_2
#/nas/sbin/rootnas_volume -i root_volume_2
id      = 464
name    = root_volume_2
acl     = 0
in_use  = True
type    = meta
volume_set = root_slice_2,root_s70_2 -->Highlighted slice is the name of current slice used for original rootfs
disks   = root_disk,root_ldisk
Int_filesys= root_fs_2
```

**I. EXTENDING ROOTFS FOR SYMMETRIX STORAGE:****1) Create Slice using root\_s70 naming convention (SYMMETRIX STORAGE)--Make sure that you are using the root\_ldisk\_reserve and NOT root\_disk\_reserve as follows:****# /nas/sbin/rootnas\_slice -n root\_s70\_2a -c root\_ldisk\_reserve 2048** [2048 indicates 2GB slice]

```
id      = 84
name    = root_s70_2a
acl     = 0
in_use  = False
slice_of = root_ldisk_reserve
offset(MB)= 240
size (MB)= 2048
volume_name = root_s70_2a
```

**2) Extend Root File System from Slice (SYMMETRIX STORAGE):****# /nas/sbin/rootnas\_fs -x root\_fs\_2 root\_s70\_2a**

```
id      = 2
name    = root_fs_2
acl     = 0
in_use  = True
type    = uxf
volume  = root_volume_2
pool    = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
```

```
ro_servers=
rw_vdms =
ro_vdms =
symm_devs = APM00040303779-0000,APM00040303779-0001,APM00040303779-0010
disks = root_disk,root_ldisk,d7
```

## **II. EXTENDING ROOTFS FOR CLARIION STORAGE:**

### **1.) Use following command syntax to extend CLARiiON-Based Celerra Systems:**

```
# /nas/sbin/rootnas_fs -xtend root_fs_2 size=2G pool=clar_r5_performance -option slice=y
```

### **2.) Verify Extension:**

```
# server_df server_2
```

```
server_2 :
Filesystem      kbytes   used   avail capacity Mounted on
root_fs_2       1047920  110368  937552  11%   /
# server_df server_2 -i
```

```
server_2 :
Filesystem      inodes   used   avail capacity Mounted on
root_fs_2       1047550  73673   973877  7%   /
# server_df server_2 -i
```

**Note:** Latest guidance is to extend a ROOTFS by at least (2) GB but may need to be larger, depending on default inode density and size of User/Group database. For Clariion Backends that do not have an 11GB root\_ldisk\_reserve volume available, there may be the need to create a new RAID 0 LUN from data volumes and add to a storagegroup before extending the rootfs.

**Caution:** Please be aware that in NAS versions before 5.2.19.0 or 5.3.13.0, an extension of the rootfs >than 48Gb will prevent Usermapper from being able to calculate new uid/gids.

## **NAS 5.3 ROOTFS INODE EVENTS:**

With NAS 5.3, the default threshold for logging CallHome events for inode usage on a rootfs is 90%. Parameter can be adjusted with following param:

```
param file fsInodeThreshold=
```

## **BLOCK SIZE HASH PARAMETER:**

Occasions where Celerra might have a problem traversing the indirect block hash list. The default indirect block hash size is 2, and if there are too many hits on the same hash list, the CPU could eat up all the CPU time trying to traverse the list. Increase default to 64:

```
param ufs indBlkHashSize=64
```

**Note:** Adjust to higher value when indirect block queue is very large. Problem is generally associated with very large files, as large files require many indirect blocks and the hash queues used to locate all of a file's indirect blocks can be consumed. NAS 5.3 changes the default hash size to 64.

## **FILE SYSTEM SYNC BEHAVIOR:**

Default sync thread behavior is to flush and cleanup file system modifications from memory every 30,000 msec. [30 secs]

With pre-510 data movers, could run out of memory for intensive fs operations, resulting in panic. Can increase frequency of file system sync behavior:

```
param ufs syncInterval=30000 [hex=7530]
```

**Note:** Default ufslog flush interval is that thread wakes up to flush every log changes every 30 seconds [30,000 msec]. In some cases, lowering the flush interval to 10,000 [10 secs] may help prevent panics on busy systems.

```
# .server_config server_2 -v "param ufs logHoldListSz" [use to reduce max pending transactions]
ufs.logHoldListSz INT 0x01b95558 1000 1000 (0,4294967295) FALSE REBOOT 'NA'
```

## **VALUES FOR UFSLOG & PERFORMANCE ISSUES—FEB 2007:**

**param ufs logHoldListSz=128 | 30 → 30** is the new default for NAS 5.6

```
param ufs syncInterval=15000
```

**Note:** See emc149588 for more information. With NAS 5.6, the new standard is to set the logHoldListSz to 30, thus allowing for more frequent ufslog flushes. Waiting for the queue to build to 128 has been found to cause too many forced flushes, which can cause performance issues.

## **WHY DO WE USE THE " T2RESET" COMMAND V. THE "SERVER CPU" COMMAND?**

1. Use the “t2reset” whenever you’ve edited the “boot.cfg” file, as in preparing to run an FSCK. The Server will reboot from the /nas/dos/slot\_x/boot.cfg and NOT rebuild the “boot.cfg” from scratch as it normally does on reboot.

2. Similarly, use the “server\_cpu” reboot command when you do want to rebuild the server’s configuration files [aka, “boot.cfg”]. The Server rebuilds the “boot.cfg” from the files located in the /nas/server/slot\_x.

## **CONDUCTING FSCK'S ON CELERRA SERVERS**

### **INTRODUCTION TO CELERRA FSCK:**

#### **Intro:**

FSCK's should be carefully planned, and in most cases, conducted using the Standby Data Mover--though depending on the situation, the Primary Server itself may be required. The basic methodology for using the Standby Server (or Production Server) is to temporarily or permanently unmount the production file system from the Server and then associate the Server with the file system to be FSCK'ed. This method is used when a single file system is involved and when the file system check is being conducted in a 'scheduled' manner.

**Note:** Other methods are available for recovering Servers from Rolling Panics and situations where the data mover will not boot, and where the file system(s) requiring FSCK are unknown—see other sections.

#### **EXAMPLE:**

```
# server_umount server_2 -t fs01 /fs01 →Production Server (temp unmount)
# server_mount server_3 -v fs01      →Standby Server (virtual mount puts metavolume info into Standby DART memory)
```

### **FSCK TRIVIA:**

#### **FAST FSCK & FIX INODE FUNCTION:**

With NAS 4.2.7.0 & higher, Celerra introduced multi-threaded 'fastfsck' using 32 Threads vs. single-thread. FSCK's now run extremely fast compared to previous codes. Beginning with 2.2.54.0, 4.0.18.0, 4.2.3.0, & 4.1.5.0, "fixinode" function was built into fsck. More recently, AR's 65330 & 57764 have been built into NAS 5.5.7.0+ to make ACLCHK multi-threaded instead of single-threaded, and also to improve Phase I of FSCK to redistribute workload among threads so that the process becomes faster. Also note that with NAS 5.4.18.0+, if DART detects a corrupted ACL database, the file system will be unmounted and marked for auto-fsck.

**Server Log Symptoms indicating need for FSCK:** Vnon lookup problem bad ino; Read Block failure referencing FS;

\$ls -laR [Running this list command against a FS may reveal problems]

**Locating Bad Inode:** \$find . -inum 1222877 -print

**Panic Asserts:** Asserts are Error Traps placed into the Code when certain thresholds or illegal conditions occur

### **MINIMUM NAS CODE VERSIONS TO USE FOR ALL FSCK's:** See AR45584, 56565, 72001, 75889

**5.1.26.0**  
**5.2.22.1**  
**5.3.25.2**  
**5.4.26.4**  
**5.5.24.2**

**Note:** The fsck information here can become dated--please make sure to use the latest approved nas.exe for the code family in which the FSCK is required.

### **FSCK REQUIREMENTS:**

1. Verify BackEnd & Fabric integrity before conducting FSCKs, especially after events which precipitate the need for an FSCK
2. For CLARiiON backends, make sure that there are no Uncorrectable Sector issues with LUNs prior to performing FSCK after IO Failure despite all retries panics
3. Verify that LUNs are not trespassed for Clariion Systems
4. Verify dual-path availability to BackEnd from the Server used for the FSCK
5. Verify that Write & Read cache are enabled on Clarion Systems
6. Verify most recent 5.1 or 5.2 nas.exe is used for FSCK due to recent issues with Alternate Data Streams/Named Streams corruption
7. Verify contents of lost+found directory prior to, and after each FSCK

**Note:** When appropriate, move the contents out of the lost+found directory to a salvage directory (lost+found limited to 18 blocks). Or, more easily, simply rename the lost+found directory to salvage1, repeat fsck, rename lost+found to salvage2, etc.—the fsck process will recreate the lost+found directory automatically

#### **EXAMPLE:**

```
# mkdir salvage →Create temporary directory at root of file system being FSCK'ed
# cd lost+found
# mv \#* ..\salvage &
```

8. Preferred FSCK method is to use the Standby Server to run FSCK against production file systems, while keeping Production Server up for all other undamaged file systems (there are new exceptions to this general practice, as seen below)
9. All file systems require ACLCHK procedure after the FSCK process is completed. ACLCHKS are mutually inclusive to FSCKs and are not run as a stand-alone operation.
10. All file systems except NFS-only systems, & MPD DIR3 file systems, require CIFS Update to rebuild Shadow files at each directory level of the file system. CIFS Updates are manually initiated.

11. Set FSTOOLS debug logging on the Server running the FSCK so as to observe and capture FSCK info from the Server Log

**Note:** Do NOT set FSTOOLS debug levels on NAS Versions 5.4 or 5.5 as it will pollute Server Log with excess information!

12. FSCK Rule of Thumb is to run FSCK subsequent times until the Server Log shows a complete and clean pass through all Phases

**Note:** (3) passes are not uncommon, sometimes more are required, sometimes less

12. Verify correct File System “volume” number before running .server\_config command—it is NOT the file system name or id number

#### **EXAMPLE:**

# nas\_fs -l

| id | inuse | type | acl | volume | name   | server |
|----|-------|------|-----|--------|--------|--------|
| 31 | y     | 5    | 0   | 171    | fstest | 2      |

**Note:** Look for “volume” column and use that number for the “file fsck uufs 171” command—remember to add +1 to Server Number seen to derive correct Server where file system is mounted—see comment below regarding changes here in NAS 5.4

### **SPECIAL FSCK RULES AND CONDITIONS REGARDING STANDBY SERVER:**

1. Do not use the Standby Server method for performing FSCK’s on file systems with IP Replication sessions established

#### **Performing FSCK on File System with Replication:**

a.) Suspend the replication session

**Note:** If using .server\_config to FSCK, unmount file system first, remount using \$ server\_mount -v to Production Server

b.) Use nas\_fsck from the Production Server, or .server\_config method

c.) Restart the replication session after fsck is completed

**Note:** Starting with NAS versions 5.4.27.x & 5.5.24.0, the server\_mount -v command will not allow a file system with replication running, to be mounted to any Server except the production Server—AR78568.

2. Starting with Napa 3 [NAS 5.5.23.2], if using the Rvector Tool to repair a file system that panics with an Uncorrectable Sector issue, the FSCK must be kicked off using the # nas\_fsck command on the Production Data Mover.

#### **Celerra FSCK checks.**

It is useful to know that an FSCK can only correct File & Directory references or links [unreferenced files; incorrect link count; bad directory entry; missing bitmap blocks; truncated inodes], NOT data. FSCK’s always update the superblock information and write a value to the block if FSCK is interrupted. Also, in rare situations, such as those involving the ADS issue, FSCK’s can actually cause file damage, especially to CAD/CAM, jpegs, and bitmap files.

#### **How long should an FSCK take?**

The time required to run an FSCK on newer multi-threaded NAS codes is generally much faster than in versions prior to 4.2.7.0.

Though FSCK times are always dependent on factors, such as, file system size, file system directory layout and depth, number of files in directories, and overall damage to the metadata of the file system itself, a good rule of thumb is that a 300-400GB file system should be able to complete the first FSCK in about an hour, give or take a half-hour. However, whenever considering the total time required to conduct file system maintenance, be aware that an FSCK may need to run up to (3) times in order to completely repair the metadata, and that an ACLCHK is also required, as well as CIFS Updates on pre-MPD file systems.

#### **What does an FSCK check for and do for repairs?**

--Checks integrity of Superblock and rebuilds if necessary from alternate superblock

--Checks and fixes link count for each inode in file system [Link count is number of references to inode, checked by counting the number of times the inode was referenced in the directory blocks. A reference count of zero will cause a valid inode to be moved to lost+found]

--Checks that block numbers in direct & indirect fields are unique to each inode [if two inodes share data block, both are removed]

--Verifies that all directories are connected to root

--Verifies that each directory entry has an inode [invalid inodes are cleared from directory entries]

--Verifies that “.” entry points to itself, and “..” entries point to parent of the directory

--Checks and fixes Cylinder Group summaries

### **FSCK PHASES:** FSCK contains three basic Phases: Validate Inodes, Validate Directories, & Summary Check

#### **FSCK PHASE 1: Validate Inodes**

Superblock checked. Inode & directory bitmaps are created, as are inode link count map [consisting of inodes with link count > than 1 and directories > than two]. For each unallocated inode, checks to ensure that data blocks have zero pointers. For each allocated inode, checks direct and indirect blocks and marks them as used in the used block bitmap. If multiple streams are found, a container bitmap is created, which is then link count & reference checked in a special phase 1M.

#### **SERVER LOG EXAMPLE:**

2004-08-15 16:23:20: FSTOOLS: 4: Phase 1: Validate Inodes

2004-08-15 16:23:21: FSTOOLS: 4: 0 % complete

2004-08-15 16:24:29: FSTOOLS: 3: INCORRECT BLOCK COUNT I=4205067 (304 should be 288)1092605069: FSTOOLS: 3: (CORRECTED)

2004-08-15 16:32:57: FSTOOLS: 3: INCORRECT BLOCK COUNT I=2097192 (304 should be 288)1092605577: FSTOOLS: 3:

(CORRECTED)

2004-08-15 16:33:13: FSTOOLS: 4: 50 % complete

2004-08-15 16:34:02: FSTOOLS: 4: 60 % complete

2004-08-15 16:34:04: FSTOOLS: 3: INCORRECT BLOCK COUNT I=6237193 (304 should be 288)1092605644: FSTOOLS: 3:  
(CORRECTED)

2004-08-15 16:35:11: FSTOOLS: 4: 70 % complete

2004-08-15 16:36:10: FSTOOLS: 4: 80 % complete

2004-08-15 16:37:07: FSTOOLS: 4: 90 % complete

2004-08-15 16:38:08: FSTOOLS: 4: 100 % complete

2004-08-15 16:38:08: FSTOOLS: 5: Inode Phase: took 888361490 Usec

### **FSCK PHASE 2: Validate Directories**

Checks all directories starting from root, for traversal, link count, and connectivity. Parent map can fix incorrect “..” entries.

Creates reference map for inodes in directory blocks, which should match with inode map created in Phase 1. If there are unreferenced inodes, they are moved to lost+found. Directory entries are added to traversal list and scanned. Connectivity of all directories checked from root-if disconnected are placed in lost+found.

### **SERVER LOG EXAMPLE:**

2004-08-15 16:38:08: FSTOOLS: 4: Phase 2: Validate Directories

2004-08-15 16:38:21: FSTOOLS: 4: 0 % complete

2004-08-15 16:38:28: FSTOOLS: 4: 10 % complete

2004-08-15 16:38:52: FSTOOLS: 4: 20 % complete

2004-08-15 16:39:23: FSTOOLS: 4: 30 % complete

2004-08-15 16:39:54: FSTOOLS: 4: 40 % complete

## **USING PRODUCTION OR STANDBY SERVER TO FSCK FILE SYSTEMS:**

**Note:** Do not use Standby Server to run an FSCK on a production file system that has a replication session established, or a file system being repaired using the Rvector Uncorrectable Sector method—see comments outlined above.

### **I. RUNNING FSCK:**

#### **NEW WAY FOR DOING MOST FSCKs—NAS 5.4 & 5.5:**

Step 1. Kick off FSCK from Production Server:

```
# nas_fsck -start milla -mover server_2
id          = 75
name        = milla
volume      = v139
fsck_server = server_2
status      = In-progress
```

**Note:** FSCK automatically unmounts & remounts the file system. NAS 5.4 & 5.5 no longer requires setting FSTOOLS debug logging levels. ACLCHK is also run as part of the FSCK process.

Step 2. Monitor FSCK progress in Server Log:

```
2006-11-14 13:43:22: FSTOOLS: 4: 0: FsId: 75 Fsck Started (Manual).
2006-11-14 13:43:33: FSTOOLS: 4: 3: FsId: 75 Aclchk Started (Auto).
2006-11-14 13:43:34: FSTOOLS: 4: fsck completed.
2006-11-14 13:43:34: FSTOOLS: 4: 1: FsId: 75 Fsck Succeeded
```

Step 3. If the log shows FSCK corrections, run again until an FSCK pass runs cleanly

#### **TRADITIONAL SUPPORT METHOD AND FOR OLDER CODE VERSIONS:**

Step 1. Temporarily unmount Production FS from Server:

```
$ server_umount server_2 -temp m3 /m3
server_2 : done
```

Step 2. Virtually mount production file system to Standby Server:

```
$server_mount server_3 -v m3
```

**Caution:** Using this command does not actually 'mount' the filesystem, but does load the data structure into the memory of the Data Mover. If the site requires a large number of file system fsck's, an option would be to break the Standby relationship and convert the Standby to a Primary, and then do the FSCK as you would do normally. Since the data mover loads the file system structures into memory, these structures must be removed after performing an fsck by either rebooting the Server or running the umount command:

```
$server_umount server_3 -v m3
```

Step 3. Set FSTOOLS Logging on Standby Server:

```
$server_config server_3 "logsys set severity FSTOOLS=LOG_DBG3"
```

**Note:** This debug setting is no longer required with NAS Versions NAS 5.4 or 5.5 and may overrun the Server Log with superfluous messages.

Step 4. Identify correct File System and Volume ID:

```
# nas_fs -l
id  inuse type acl volume  name      server
30    y     1 0   133    m3           1 (fsid=30, volumeid=133)
```

Step 5. Start FSCK using Volume Number of File System—derived from #nas\_fs -l output:

```
$server_config server_3 "file fsck ufs 133=30"
```

*server\_3 : commands processed: 0*

**Error: RPC: Timed out**

**Note:** When running the FSCK command, you will see an "RPC Error" timeout message—the FSCK is running—do not issue command again or another FSCK will be queued. Please note that NAS versions 5.3.20, 5.4, and 5.5 use a newer syntax than previous versions of NAS.

#### **EXAMPLE FSCK SYNTAX FOR PRE-NAS 5.3.20 VERSIONS:**

```
$ .server_config server_3 "file fsck ufs 133"
```

Step 6. Monitor FSCK Progress:

```
$server_log server_3 -s -f |grep -i Phase [or Summary or FSTOOLS]
```

Step 7. When all FSCK passes are completed, remount File System to Production Server:

```
$server_mount server_2 m3 /m3
```

**Note:** Follow-through with ACLCHKs and CIFS Updates, as appropriate (no CIFS Update required on MPD file systems)

Step 8. Cleanup any leftover data structures on the data mover used to conduct the FSCK by running:

```
$server_umount server_3 -v m3
```

#### **NAS 5.4 ADDENDUM:**

##### **There are a number of significant changes with FSCK:**

→ You can run either the nas\_fsck or the .server\_config fsck commands when repairing file systems

→ Server may initiate an autofsck if corruption is detected—system will panic and run autofsck

→ Up to two concurrent nas\_fsck's can be run per DM

**param ufs skipFsck=1**

**Note:** Default NAS 5.4 & 5.5 value is 0, which is to perform autofsck on corrupted file system during reboots. Set this value to 1 to disable auto-fsck of corrupted file systems on reboot—instead, will leave file system unmounted to allow Data Mover to mount all other file systems during reboot, etc. Default value for NAS 5.6 was changed to 1, meaning that file systems will not be auto-fscked during bootup.

**# server\_param server\_2 -facility ufs -info skipFsck -v**

server\_2 :

```

name      = skipFsck
facility_name = ufs
default_value = 1 →NAS 5.6 default
current_value = 1
configured_value =
user_action = none
change_effective = immediate
range     = (0,1)
description = If enabled, fsck will not be run on a corrupted FS while booting up and FS will be left unmounted.

```

**Note:** User must manually run FSCK and then remount file system. Important to note that this is the default behavior if corrupted file system found on bootup.

**param ufs skipAclChk=1** [Use this option to run fsck without running the ACLCHK]

**Note:** Change can be loaded directly into memory prior to FSCK: **\$ .server\_config id=4 "param ufs skipAclChk=1"**

**SERVER\_CONFIG COMMAND LINE SYNTAX CHANGE:**

**\$ .server\_config server\_2 "file fsck ufs 203=22"** [Where 203=Vol ID and 22=FSID]

**Note:** NAS 5.4 or 5.5 will run an integrated ACLCHK during the FSCK process, whether using .server\_config or #nas\_fsck

**USING NAS FSCK TOOL:****# nas\_fsck -start id=93 -mover server\_2****# nas\_fsck -start fs30 -mover server\_5**

```

**\$ nas\_fsck -info ufs2**

name = ufs2

id = 23

volume = v134

fsck\_server = server\_5

inode\_check\_percent = 100

directory\_check\_percent = 100

used\_ACL\_check\_percent = 100

free\_ACL\_check\_status = Done

cylinder\_group\_check\_status = In Progress

**Note:** Use nas\_fsck -list and -info to keep track of fsck sessions and get specific info on fsck progress

**#nas\_fsck -aclchkonly** [Option for running aclcheck only—cannot be run with fs exported]

**#nas\_fsck -fsckonly** [Option for running fsck only]

## **II. RUN ACLCHK ON PRODUCTION SERVER—NOT STANDBY!:**

### **CRITICAL ACLCHK RULES:**

1. NAS 5.4/5.5 performs builtin aclchk and in most cases should not need to be run separately
2. Make a backup copy of the Server's mount & export/export.shares files
3. Always permanently unmount the Production file system and remount to a new, temporary mountpoint for the ACLCHK process to ensure that there is no access to the file system allowed during the ALCHK process
4. If allowed, stop CIFS as well to prevent any CIFS Admins from connecting to the C\$ share [If not an option, advise customer to not allow Admin users to connect to the Celerra Admin Shares].
5. NAS 5.1 and below will log errors during ACLCHK if users are accessing file system. NAS 5.2 and higher will lock the database during the aclchk and block user access—for any files in use, aclchk will wait for user access to be released.

### **BEGIN ACLCHK PROCESS:**

- Step 1. Permanently unmount and remount file system to temporary mountpoint:

**#server\_umount server\_2 -p fs1 /fs1**

**#server\_mount server\_2 fs1 /aclchk**

- Step 2. Start ACLCHK:

**#server\_config server\_2 "file aclchk /aclchk fix"**

**Note:** Similar to the FSCK command, it is not uncommon to see an RPC timeout error after issuing the command. Check Server Log to verify—depending on NAS version, should see an entry similar to the following:

**2003-07-16 21:16:40: ADMIN: 4: Command succeeded: file aclchk /aclchk fix**

**# server\_log server\_4 -a -s |grep CFS**

**2004-09-21 21:06:21: CFS: 4: aclchk: Done; status = 0**

**Note:** Grep for CFS when running NAS 5.1.19 and higher or ADMIN

**Caution: Do not use the -v flag when running aclchk—results will not print to the Server Log**

- Step 3. Open Server Log to Monitor Progress:

**\$server\_log server\_2 -s -f**

**Note:** The ACLCHK succeeded command and completion summary are written to the Server Log

### **EXAMPLE:**

2003-07-16 21:16:40: ADMIN: 4: Command succeeded: file aclchk /aclchk fix

2003-07-16 21:16:40: CFS: 4: aclchk: Done; status = 0

2003-07-16 21:16:40: ADMIN: 4: Command succeeded: file aclchk /aclchk fix

- Step 4. Permanently unmount File System and remount to original Mountpoint.

- Step 5. Re-export all exports:

**\$server\_export server\_2 -a**

## **III. RUNNING CIFS UPDATE:**

### **CIFS UPDATE RULES:**

1. Turn on SMB debug prior to running CIFS Update in order to see logging events: “**logsys set severity SMB=LOG\_DBG3**”
2. File System must be mounted, exported, and the CIFS service stopped in order to be effective when rebuilding the Shadow file.
- Note:** If CIFS cannot be stopped, the CIFS Update may not start, though in emergencies, this method can be tried without harm
3. Turn off group Quotas prior to running CIFS update

### **BEGIN CIFS UPDATE PROCESS:**

Step 1. Stop CIFS on Production Server:

**\$server\_setup server\_2 -P cifs -o stop**

Step 2. Run CIFS Update on mountpoint of File System:

**\$server\_config server\_2 "cifs update /export force level=0"**

**\$server\_config server\_2 "cifs update '/export/folder with spaces' force level=0"** [Syntax when folders have spaces]

**Note:** Verify progress in Server Log—CIFS updates are logged every 600 seconds until completed

**EXAMPLE:**

1003979370: SMB: 4: Update of : /mbs running since 600 s 340639 files, 42093 dirs have already been updated

1003979970: SMB: 4: Update of : /mbs running since 1200 s 780547 files, 94904 dirs have already been updated

1003980448: SMB: 4: Update of : /mbs completed after 1678 s

1003980448: SMB: 4: Update of : 1170072 files, 127689 dirs

Step 3. After Update is completed, Start CIFS:

**\$server\_setup server\_2 -P cifs -o start**

Step 4. Have customer verify CIFS access

## **STOPPING CIFS UPDATES:**

**Note:** Use the following command to stop any of the commands that use CIFS Update

**#server\_config server\_x "cifs update abort"**

## **CLEANING UP "LOST+FOUND" DIRECTORY ON FILESYSTEMS DURING FSCKs:**

**Symptom:** Server\_log shows error during FSCK: "2002-03-08 13:36:33: FSTOOLS: 3: SORRY. NO SPACE IN lost+found DIRECTORY1015612". Lost+found is a directory that is limited to 18 blocks of data.

**Cause:** During FSCK's, inodes that cannot be reconciled are removed and placed in the filesystem's "lost+found" folder. With extensive inconsistencies, this directory can rapidly be filled, preventing the FSCK from correcting any further problems.

**Fix:** Always check and cleanup the lost+found directory before and after each FSCK using following method

1. Create new directory underneath mountpoint of filesystem [#mkdir fsck]

2. Go into lost+found directory, output list of inodes to file, and move contents to temp directory:

**#cd lost+found**

**#du -h >/home/nasadmin/lostfound.fs02**

**#mv \#\* ..//fsck &**

## **LOST+FOUND:**

**# cd mt3/lost+found**

```
-rw-r--r-- 1 1000 203 1519 Mar 1 10:12 #00707548
-rw-r--r-- 1 1000 203 1110 Mar 1 10:12 #00707549
drw-r--r-- 1 1000 203 5342208 Nov 16 15:33 #01209752
```

**How to Access Lost+Found Entries:** #cd \#01209752 or #more \#00707548 to see file contents

## **OTHER FSCK METHODS:**

### **I. .Server Config FSCK Method Using either Production Server or Standby:**

**Note:** Used for Single FS FSCK while leaving DM up and running

Step 1. Verify File System Name, FSID, & Volid:

**# nas\_fs -I**

|    |       |      |     |        |      |        |
|----|-------|------|-----|--------|------|--------|
| id | inuse | type | acl | volume | name | server |
| 40 | y     | 1    | 0   | 150    | fs2  | 1      |

→Notice that FSID=40 and Volume ID=150

Step 2. Temp. unmount file system:

**# .server\_config server\_2 -v "file umount /fs2" or # server\_umount server\_2 -temp fs2 /fs2"**

Step 3. Virtually mount file system on either Production Server or Standby Server using -v:

**# server\_mount server\_3 -v fs2**

server\_3 : done

Step 4. Set debug logging and start FSCK:

**#server\_config server\_3 "logsys set severity FSTOOLS=LOG\_DBG3"**

**Note:** This debug setting is no longer required with current versions of NAS 5.4 or 5.5

**#.server\_config server\_3 "file fsck uxfs 150=40"**

**Note:** Syntax varies with NAS Version. Use above syntax for 5.3 and higher. Older NAS versions may use "file fsck uxfs 150".

Step 5. Verify completion of FSCK in Server Log and remount fs when completed:

**# server\_mount server\_2 fs2 /fs2**

Step 6. If virtually mounted to Server\_3, make sure to unmount it as well:

**# server\_umount server\_3 -v fs2**

## **II. BOOT.CFG FSCK METHOD FOR ROOTFS or PFS:**

**Note:** Used to FSCK Root or Production File Systems during t2reset. Example below shows FSCK of root and a production fs.

Step 1. Make backup copy of boot.cfg file:

**#cp /nas/dos/slot\_2/boot.cfg /nas/dos/slot\_2/boot\_ori**

Step 2. Identify FSID and Volume ID's of File Systems to be FSCK'ed:

**# nas\_fs -l**

| id | inuse | type | acl | volume | name      | server |
|----|-------|------|-----|--------|-----------|--------|
| 2  | y     | 1    | 0   | 12     | root_fs_2 | 1      |
| 38 | y     | 1    | 0   | 146    | fs1       | 1      |

Step 3. Edit boot.cfg and place following entries between the “mount begin” line and “file mount” lines:  
mount begin

**logsys set severity FSTOOLS=LOG\_DBG3**

**file fsck ufs 12=2**

**file fsck ufs 146=38**

file mount ufs rw / 12=2 rw

file mount ufs rw /fs1 146=38 rw

**Note:** Be aware of syntax change for performing fsck. Above entries are correct for NAS 5.3 and higher. NAS 5.2 or below requires use of “file fsck ufs 12” as the correct line syntax.

Step 4. Use t2reset to reboot DM without rebuilding the boot.cfg file from /nas/server/slot:

**#/nas/sbin/t2reset reboot -s 2**

**Note:** “server\_cpu” would rebuild the “boot.cfg” file from the /nas/server/slot files—we want to use the edited boot.cfg file

Step 5. Monitor FSCK progress in Server Log:

**#/nas/sbin/log\_slot -s -f 2**

2006-05-30 13:25:10: FSTOOLS: 4: 1: FsId: 38 Fsck Succeeded

2006-05-30 13:25:10: ADMIN: 4: Command succeeded: file fsck ufs 146=38

Step 6. Restore Boot File:

**#cp /nas/dos/slot\_2/boot\_ori /nas/dos/slot\_2/boot.cfg**

Step 7. Reboot DataMover:

**#/nas/bin/server\_cpu server\_2 -r -m now**

**Note:** Use this method to FSCK root filesystem of DM and to restore server to operation while selectively choosing which file systems to mount and which to keep unmounted. Use # to comment out any production file systems that you do not want mounted.

## **III. MOUNTING ALL FS EXCEPT FOR ONE BEING FSCK'ed:**

**Note:** Run FSCK on single fs while bringing all others back online—comment out mountpoint of file system in boot.cfg and run fsck just prior to eof line in boot.cfg file.

Step 1. Make backup copy of boot.cfg file:

**#cp /nas/dos/slot\_2/boot.cfg /nas/dos/slot\_2/boot\_ori**

Step 2. Identify FSID and Volume ID's of File Systems to be FSCK'ed:

**# nas\_fs -l**

| id | inuse | type | acl | volume | name      | server |
|----|-------|------|-----|--------|-----------|--------|
| 2  | y     | 1    | 0   | 12     | root_fs_2 | 1      |
| 38 | y     | 1    | 0   | 146    | fs1       | 1      |

Step 3. Comment out the file system to be fsck'ed & add fsck near end of file:

mount begin

file mount ufs rw / 12=2 rw

**#file mount ufs rw /fs1 146=38 rw**

---

logsys delete output console

**logsys set severity FSTOOLS=LOG\_DBG3**

**file fsck ufs 146=38**

**#verify\_eof**

Step 4. Use t2reset to reboot DM without rebuilding the boot.cfg file from /nas/server/slot:

**#/nas/sbin/t2reset reboot -s 2**

**# server\_mount server\_2**

server\_2 :

root\_fs\_2 on / ufs,perm,rw

fs1 on /fs1 ufs,perm,rw,<unmounted>

Step 5. Monitor FSCK progress in Server Log:

**#/nas/sbin/log\_slot -s -f 2**

2006-05-30 14:11:05: FSTOOLS: 4: fsck completed

2006-05-30 14:11:05: FSTOOLS: 4: 1: FsId: 38 Fsck Succeeded

2006-05-30 14:11:05: ADMIN: 4: Command succeeded: file fsck ufs 146=38

Step 6. Restore Boot File:

**#cp /nas/dos/slot\_2/boot\_ori /nas/dos/slot\_2/boot.cfg**

Step 7. Remount fs when ready, or reboot DataMover:

**# server\_mount server\_2 -a**

#### **IV. FSCK on Alternate Superblock:**

**#/nas/sbin/rootnas\_fsck fs2 -b 32**

**Note:** Command run recently at 5.3.21 site for following problem that was not being cleaned by regular fsck:

2005-11-02 23:51:47: FSTOOLS: 3: PERSISTENT RESERVATION BLK COUNT WRONG IN SUPERBLK

2005-11-02 23:51:47: FSTOOLS: 4: PBR count should be 14919, but it is 404 Correcting PBR count

### **CELERRA ACL SUPPORT:**

#### **Running ACLCHK Using “.server config” Command, followed by CIFS Update:**

Step 1. **#server\_umount server\_6 -p fs1 /export/htdocs** [Original production mountpoint]

**#server\_mount server\_6 fs1 /aclchk** [New mountpoint from which to run the ACL CHECK]

Permanently unmount PFS from original mountpoint. Create new mountpoint for aclchk purposes and permanently remount filesystem to this mountpoint. Conduct aclchk.

**Note:** Filesystem being aclchk'ed is NOT exported at all!

Step 2. Conduct ACL Check on Server\_6: **\$server\_config server\_6 "file aclchk /export/htdocs fix"**

Step 3. Open Server Log to Monitor: **\$server\_log server\_6 -s -f** [Will show ACL Check completion]

Step 4. Permanently unmount File System and remount to original Mountpoint.

Step 5. Re-export all exports: **\$server\_export server\_6 -a**

Step 6. Stop CIFS Service: **\$server\_setup server\_6 -P cifs -o stop**

Step 7. Run CIFS Update on FS: **\$server\_config server\_6 "cifs update /mntpoint force level=0"**

Step 8. Restart CIFS & Verify Customer Access

### **ACL DATABASE CORRUPTION AND OVERFLOW ISSUES (aclid overflow):**

#### **1. ACLEDUMP shows error:**

**\$ .server\_config server\_2 -v "acl dump=/ug\_fs\_001/sc52ld-BAK"**

1131472328: SMB: 3: Dump with no ThreadCtx

Dump of rights of /ug\_fs\_001/sc52ld-BAK

===== UNIX =====

USER 0x66c6 GROUP 0x67f7 mode=rwxrwxrwx

===== NT =====

aclId=606693

1131472328: UFS: 3: getAcl: Bad gen number 0x1, on disk gen is 0x3e for slot 0x941e5

Unable to load SD (28=InternalError)1131472328: ADMIN: 4: Command succeeded: acl dump=/ug\_fs\_001/sc52ld-BAK

#### **2. Server Log errors:**

# server\_log server\_2 -sltail

2005-11-08 11:58:06: UFS: 3: getAcl: Bad gen number 0x1, on disk gen is 0x44 for slot 0x8625

2005-11-08 11:58:06: UFS: 3: getAcl: Bad gen number 0x1, on disk gen is 0x3e for slot 0x8626

2005-10-17 10:57:42: CFS: 3: Setsd: setAcl failed 3

2005-10-17 10:57:42: CFS: 3: File\_NamingNode::synchronizeAcl Cannot store SD status : 3

2005-10-17 10:57:42: CFS: 3: File\_NamingNode::setAttr : cannot synchronize ACL status 3

2005-10-17 10:57:48: UFS: 3: Filesystem 35 ACL slotIndex goes beyond 1M

#### **3. Printstats ACLDB command shows error:**

**\$server\_config server\_2 -v "acl database=/fs23 printstats"**

"ACL Database of 131 fs locked in shared

1129660119 ACLUPD:3:parseAclDatabase: invalid database nextFree

AclDatabase of 131 fs unlocked

1129660119: ACLUPD:3: Run file aclchk <fs> to check and fix the acl database

End parse: RefCounter=20"

**Note:** For large databases, it may be better to run command without –v so as to output to Server Log.

## **EXAMPLE ACLDB CHECKANDCOMPACT COMMAND:**

**Note:** NAS 5.4 contains potential ACL database ID overflow problem when using the MIXED or MIXED\_COMPAT access policy. 5.4.17.504 & 5.4.18.300 have been released as a fix to prevent the acldb overflow issue from occurring on file systems, and also to compact the ACL database on existing file systems where it has not yet reached its maximum value of one million records. The acldb overflow issue occurs because MIXED or MIXED\_COMPAT policies do not make proper use of ACL tables, allowing them to quickly fill to their max. value of 1 million records. If a fs reaches 1 million records and becomes corrupted, then it's likely that all ACLs will be lost and a procedure to rebuild the ACLDB from scratch will need to be performed. See emc117671 & emc131087. The current "checkandcompact" tool has not been terribly successful and is being revamped. In addition to the previously mentioned MIXED & MIXED\_COMPAT issue, the ACLDB Overflow issue can also occur on file systems that are not using the aforementioned accesspolicies. Changes are in development to improve ACL Record availability by caching the on-disk ACL records into memory, as well as to retain the older ACL Cache mechanism. Tools are also being developed to assist in identifying and removing duplicate ACL Records from the ACL Database. See AR68014 & 76015.

## **ACLDDB CACHE MISS PROBLEM/ACLDDB GROWS:**

Celerra stores each file system's ACL database in the root of the file system (/slashetc/ACLdata | ACLrecord). The inode of each file or directory contains a link to an entry in the ACL database for its Windows ACLs. Ideally, each ACE, such as Everyone Full Control, is only referenced once in the ACLdb, and all files or directories that have the same ACL setting would reference the same ACLdb entry in its inode. However, due to required efficiencies, especially for new file writes, the Celerra keeps an LRU cache of the most recently accessed acls for files/directories in memory. When files are being written, the data mover searches cache for a match to the ACL—if a match is not made, then a new ACLdb entry is created. If a match is made, then the file is written with the inode link referencing the entry for the ACL in the ACLdb. For file reads, ACLs are read into cache so that if changes are made and a write is made, the ACL is properly linked to its original ACLdb entries. However, the cache is finite and if files are recycled very quickly, the ACL Cache will become 'flushed' and not contain the necessary record, thereby causing a new ACL record to be created. Over time this can cause the ACLdb to grow and eventually reach the 1 million record mark, at which point the file system ACLs are corrupted and need to be rebuilt, resulting in loss of all customer ACLs.

## **REASONS FOR ACL CACHE MISSES:**

--Heavy load on file systems where vnodes are quickly recycled, could lead to cache miss

--file system freeze and thaws can result in cache flush, then when write occurs (rely on the Read to put ACL record into cache), cache miss

--certain applications that Write without doing Reads first, can also cause cache miss

## **NAPA MAINTENANCE RELEASE STRATEGY FOR FIXING ACLDB ISSUES:**

The original ACL cache mechanism was built upon the VFS\_FileSystem object, tied to the Vnode/NamingNode cache in the VFS layer. A new ACL cache is being designed at the UFS layer that will be initialized upon file system mount and the ACL db cached. When a file write is being done, the setAcl() call will search the cache and only allocate a new aclid (ACL Record) if there is a cache miss. A built-in tool will compress the acl database to eliminate any existing duplicate entries. If the new ACL cache cannot be initialized (pre-510 Hardware, param disables the cache), then the VFS layer cache will be used.

**param ufs skipAclCache=0** →Default value 0 means that new UFS cache is enabled, and caches ACLs per maxAclCached  
**param ufs maxAclCached=** →Max cached entries per Blade (value between 2-8Million, with 4M the default)  
**param ufs defAclHashSz=256** →Cache table size for new aclCache—hidden param

## **NEW ACL CACHE, PARAMETERS, & CLEANUP TOOL WITH NAPA I (5.5.21.4):**

**Note:** See emc117671 for more details about ACL db overflow issues. It is possible in some cases to receive the following ACL db error, yet upgrade the code to the latest NAS 5.5 version, and run the nas\_fsck –aclchkonly option to clean up the ACL db without resorting to a complete rebuild of the ACL database.

**2007-03-16 13:33:01: UFS: 3: Filesystem 143 ACL slotIndex goes beyond 1M**

**# /nas/bin/nas\_fsck -start fs06 -aclchkonly**

ACLCHK: in progress for file system fs06

### **Server Log Entries:**

**MODIFYING ACL CACHE SIZE:**

**# .server\_config server\_2 -v "aclModCacheSz aclCacheSize=2000000"**

**NEW ACL CACHING PARAMETERS:** Home Depot Fix AR68014 5.3.23.3040

**\$server\_config server\_2 -v "param ufs skipAclCache=1"**

**Note:** Default value = 0, new cache is initialized. Set to 1 to disable the new cache, remount file system to put into effect.

**# .server\_config server\_2 -v "param ufs skipAclCache"**

ufs.skipAclCache INT 0x01067e94 0 0 (0,1) TRUE NONE 'NA'

**\$server\_config server\_2 -v "param ufs maxAclCached=2097152"**

**Note:** Where size of cache is a value from 2—8 hash records, with default being 4 million unique acl hashes [4194304]—AR76015.

**CLEANING UP ACL DUPLICATES USING -ACLCHKONLY:**

**# nas\_fsck -start fs1 -aclchkonly -mover server\_2**

Error 4423: fs fs1 is exported

**Note:** -aclchkonly can only be run against unexported file systems. Unexport file system or permanently unmount from original mountpoint and remount to temporary mountpoint in order to conduct -aclchkonly.

1. Permanently unmount fs:

**# server\_umount server\_2 -p fs1 /fs1**

server\_2 : done

2. Mount to temporary mountpoint:

**# server\_mount server\_2 fs1 /aclchkonly**

server\_2 : done

3. Run -aclchkonly to remove duplicates:

**# nas\_fsck -start fs1 -aclchkonly -mover server\_2**

ACLCHK: in progress for file system fs1

4. Verify progress in Server Log:

2006-05-30 15:23:32: FSTOOLS: 4: 3: FsId: 38 Aclchk Started (Manual).

## **ACL DATABASE DELETE AND RECREATE PROCEDURE:**

**Note:** In certain cases, the ACL database may become corrupt and require deletion and re-initialization. Do not run this procedure without Eng. approval!

1. Typical indicators of ACL damage:

2002-07-12 16:23:38: UFS: 4: Cleaners ino 62d2f80, cg 62d3050, dirty 62d36d0

2002-07-12 16:23:38: UFS: 3: incorrect ACL magic number : 1275068417, possibly corrupted

2002-07-12 16:23:38: UFS: 3: error reading the ACL header

2005-08-22 21:59:13: UFS: 3: getAcl: Bad gen number 0x1, on disk gen is 0x37 for slot 0x1d

2005-08-22 21:59:57: UFS: 3: Invalid free acl: real gen: 55, aclid: 1048605, rent: 424

2005-08-22 21:59:57: UFS: 3: inative:releaseAcl failed with status 28

2. Create hardlink to hidden etc directory on affected file system:

**\$ .server\_config server\_4 "shadow showetc \fs1"**

1088518964: CFS: 3: Made link for name 'ACLrecord', fileId 8

1088518964: CFS: 3: Made link for name 'aCLdata', fileId 9

**Note:** Command creates a hardlink for above two files to a directory called "slashetc" at the root of the file system in question.

3. Mount DM root from CS and cd to newly created directory:

**#cd /mnt/fs1/slashetc**

4. Save copy of ACL database records before zeroing out:

**#server\_file server\_2 -get /fs1/\etc/ACLrecord ACLrecord | ...ACLdata ACLdata**

5. Zero out ACL database by touching new file called "foo", then copying that null file over the following files:

ACLdata | ACLrecord

# touch foo

# cp foo ACLrecord

# cp foo ACLdata

# ls -l

----- 2 root root 0 Jul 12 17:32 ACLdata

----- 2 root root 0 Jul 12 17:32 ACLrecord

----- 2 root bin 1071931392 Jul 12 10:48 NameInfo0

-rw-rw-r-- 1 root root 0 Jul 12 17:32 foo

6. Remove all files from slashetc, the slashetc directory, umount from CS0, reboot DM:

# rm \*

rm: remove `ACLdata'? y

rm: remove `ACLrecord'? y

rm: remove `NameInfo0'? y

rm: remove `foo'? y

# cd ..

# rmdir slashetc

# umount /mnt

# server\_cpu server\_2 -r -m now

7. Run .server\_config server\_2 "file aclchk /fs1 fix" to rebuild ACL database

1026510218: UFS: 4: Bad Acl for inode 66034, status 7, id 4996 →These entries are normal when the ACL db is being rebuilt

1026510218: UFS: 3: getAcl: error from readACLBLOCK: 0x7

8. Perform CIFS Update of affected file system:

**\$ .server\_config server\_2 "cifs update /fs1 resetacl"**

**Note:** This step is not an absolute. Some situations may not require the use of resetacl—if customer is using Roaming profiles, citrix, Terminal Services, etc.

9. Verify access to file system

### **Additional Tool to Consider:**

**# .server\_config server\_2 -v "inodeScan"**

1235617833: UFS: 3: inodeScan action={report|reset|truncate} fsid=xxx inum=xxx

### **VIEWING ACL DATABASE INFORMATION:**

## **NAS ACCESS CONTROL LEVELS(ACLs)**

Used to define 'Access Control Levels' for DataMovers, Users, FileSystems, or Volumes.

### **Creating a new User or Group for ACL Tables on Celerra:**

**# nas\_acl -name acme -create -user 202 level=2**

done

**# nas\_acl -l**

| index | type | level | num_id | name     |
|-------|------|-------|--------|----------|
| 1     | user | admin | 201    | nasadmin |
| 2     | user | admin | 202    | acme     |

**Note:** Example created a new user called “Acme” with UID of 202 and “admin” level rights

### **NAS ACL LEVELS AVAILABLE: 2-9 [Default levels are 2, 3, 4]**

2=Admin      Read—Write—Delete [Highest privilege level, has access to all ‘objects’]

3=Operator    Read--Write

4=Observer    Read Only [lowest access rights]

**Note:** Setting an ACL of 432 to an ‘object’ grants Observer=RO; Operator=RW; Admin=RWD, but no Ownership since the leftmost 4<sup>th</sup> digit has been omitted. ACL 444=All users RWD access; ACL 333=Level 2&3 RWD but no access for Level 4; ACL 222=Level 2 RWD only, no access. For Levels 3 & 4; ACL 5111=Ownership given but no others have access; ACL 7432

### **NAS ACL CHART:** Examples: Admin RWD=222

| Owner | Read | Write | Delete                        |
|-------|------|-------|-------------------------------|
| 0     | 0    | 0     | [Universal access, RWD]       |
| 2     | 1    | 1     | [Admin R, no access everyone] |
| 2     | 2    | 2     | [Admin RWD, no others]        |
| 3     | 3    | 3     | [Admin/Oper RWD]              |
| 4     | 3    | 2     | [Adm RWD, Oper RW, Obs Read]  |
| 4     | 4    | 4     | [Adm/Oper/Obs RWD]            |
| #     | 0    | 0     | [Only owner access]           |

All Users RWD=444

| Owner | Read | Write | Delete                   |
|-------|------|-------|--------------------------|
| 1     | 1    | 1     | [No access except owner] |
| 2     | 2    | 1     | [Admin RW, no access]    |
| 3     | 1    | 1     | [Admin/Oper Read]        |
| 4     | 1    | 1     | [Adm/Oper/Obs Read]      |
| 4     | 4    | 1     | [Adm/Oper/Obs RW]        |
| #     | 1    | 1     | [Only Owner access]      |
| 7     | 4    | 3     | O/A RWD, Op.RW, Obs Read |

**Note:** Leftmost number would indicate “Owner”, and is particularly important when setting ACLs for Data Movers. Owner value 1 indicates nasadmin. So, all of the above examples show 3-digit ACLs. Use 4-digit values when assigning ACLs to Servers.

### **NAS ACL RULES:**

→Root User has universal access

→When no 'Owner' is specified, then a 0 in R-W-D column gives universal access to all users

→If 'Owner' defined, then a 0 or 1 in R-W-D column means 'no-access' for anyone except 'Owner'

## **CELLERRA ACL's (Not Windows ACLs):**

### **CREATING ACL's ON FILE SYSTEM:**

**# nas\_fs -acl 444 fs01**

**# nas\_fs -i fs01**

|      |        |
|------|--------|
| id   | = 23   |
| name | = fs01 |
| acl  | = 444  |

### **CREATING ACL WITH OWNER, DEFAULT OWNER NASADMIN:**

**# nas\_fs -acl 1432 fs01**

|      |        |
|------|--------|
| id   | = 23   |
| name | = fs01 |

acl = 1432, owner=nasadmin, ID=201

### **REMOVING ACL ON FILE SYSTEM:**

**# nas\_fs -acl 000 FS1**

### **CREATING ACL's FOR DATAMOVERS:**

**# nas\_server -acl 1432 server\_4**

**# nas\_server -l** [Lists ACL's for Servers]

**Note:** Notice that ACLs for Data Movers require a 4<sup>th</sup> leftmost digit that signifies Server Ownership, in this case “1” = nasadmin

**DEFAULT ACL FOR DATAMOVERS:** Set at 1000 for User “nasadmin” at installation [nasadmin=owner (1)]

### **Allowing Other Users to Run Server Commands on DataMover:**

Step 1. Create New ACL User: \$nas\_acl -name tony -create -user 500 level=2

Step 2. Change ACL on DM: \$nas\_server -acl 432 server\_2

### **DELETING ACL's FOR DATAMOVERS:**

**# nas\_server -acl 000 server\_4** [Changes ACL back to 000, the default, which = Universal Access for Everyone]

### **CREATING ACL's FOR VOLUMES:**

**# nas\_volume -acl 432 vol65**

### **CREATING ACL's FOR USERS:**

**# nas\_acl -name test1 -create -user 1001 level=3**

**# nas\_acl -n <user> -c -user 1005 level=2**

### **VERIFYING ACL's FOR USERS:**

**# nas\_acl -l** [Lists ACL's for Users & Groups only]

**# nas\_acl -i -user 1005**

### **DISPLAYING ACLs FOR USERS:**

**# nas\_acl -info -user 201**

id = 1

name = nasadmin

level = admin

user\_id = 201

**# nas\_acl -info -user 501**

id = 2

name = mvadmin

level = 9

user\_id = 501

**Note:** If nas\_server or nas\_acl produces the following error (as logged to screen & in /nas/log/nas\_log.al.err), then check the /nas/site/acl\_param file—most likely it is corrupted—repair file from SCCS backup.

2006-09-26 15:26:54.982 db:0:16555:E: nas\_acl -info -user 201: Execution failed: not\_off: Precondition violated.

[EXTRACTOR.next]

**# cat acl\_param**

1:nasadmin:1:201:2:

2:mvadmin:1:501:9:

## ***CELLERRA MULTIPROTOCOL***

### **ACCESS & AUTHENTICATION IN MULTI-PROTOCOL ENVIRONMENT: CIFS v. NFS**

**USER AUTH:** \$server\_cifs server\_x -add security=NT | UNIX | SHARE [NFS & CIFS AUTH]

**NETWORK SECURITY:** \$server\_export server\_x -o access=, root=, anon=, rw=, ro=, /mntpoint [NFS Export & SHARE access]

**FILE/DIRECTORY:** \$server\_mount server\_x -o accesspolicy=NATIVE | NT | UNIX | SECURE fs01 /fs01 [NFS UGO & CIFS ACLs]

**LOCKING:** \$server\_mount server\_x -o noblock | rlock | rwlock fs01 /fs01 [NFS Locks & CIFS Deny Modes]

**I/O:** \$server\_mount server\_x -o rw | ro fs01 /fs01 [File System Mount]

### **NFS USER AUTHENTICATION:**

--Users authenticated as part of logon process to local system, but only as a lookup to a passwd file or NIS database

--NFSv2 & 3 Clients provide UID & GID credentials when accessing remote mounts

### **CIFS USER AUTHENTICATION:**

--Users logon to workstation with Username/Password/Domain & workstation passes to DC using RPC for the 'netlogon' process. DC passes to SAM (Security Account Manager), which compares Username & Hash against database. Access Token generated that includes SID of User & SIDs of Groups that are a member of. Netlogon process then hands back SAT to workstation's LSA (Local Security Authentication), a User Profile is selected or created and Explorer Interface is built for the User.

### **CIFS FILE OWNERSHIP/PERMISSIONS:**

--All Users assigned UID & default GID

--All files also have UID & GID assigned

**Note:** Default behavior is to assign the User with the GID of the Primary Windows Group (usually Domain Users). When setting useUnixGid=1, DART will assign the User's GID (Primary Group) based on the GID field in the local ./etc/passwd file or the NIS map for the User:

**param cifs useUnixGid=1**

## **MULTIPROTOCOL MODEL:**

### **Layer                      Security Entity**

|                |                                |                 |
|----------------|--------------------------------|-----------------|
| User Auth      | NFS Auth                       | CIFS Auth       |
| Network        | NFS Export                     | Share ACL       |
| File/Directory | NFS ugo-rwx                    | CIFS ACL        |
| Locking        | NFS Locks                      | CIFS Deny Modes |
| Structure      | File System Namespace for both |                 |

**Note:** NFS users present UID/GIDs to Server when authenticating, and are trusted by the server. CIFS users are authenticated by Domain Controllers or localgroups database for Local Users Support, SIDs mapped to UID/GIDs, and access-checking based on SIDs. In general, Celerra mappings between both protocols must use same User name identity, and SIDs are translated to UID/GIDs on the file system. Celerra uses default umask values for CIFS shares so that files and directories will have a default UNIX permission set. NFS Exports can provide some security levels. Translating ACLs to UNIX mode bits and back are not 100% reliable. Current recommended solution is to use MIXED accesspolicy, which will always use the ACL for access-checking, and allows the best translation of ACLs to UNIX, and NT Credentials for Unix if you need to be able to translate more than 16 UNIX groups into the ACL. Files will receive permissions based on directory permissions or inheritance. Celerra uses a single Lock Manager for both CIFS and NFS.

## **MAKING CIFS PERMISSIONS OBEY UNIX PERMISSIONS IN MIXED ENVIRONMENTS:** NAS

4.1.7.2 +

### **RULE ONE:**

***Do not use Usrmapper in mixed environments where the same User, whether from Unix or NT, needs to access the same files!***

**Comment:** Unix perms can be used to manage file systems when Unix-based administration & usage is more common than CIFS

### **General Eng. Guidance:**

- Ensure that all UNIX groups map cleanly into corresponding NT Groups
- Use accesspolicy=UNIX for mounting file systems
- Ensure that umask on all NT CIFS Shares matches those used by NFS Clients

### **Set the following parameters on Datamovers:**

/nas/site/slot\_param

**param cifs useUnixGid=1**

**Purpose:** Default DART behavior is to apply primary group membership as ‘Domain Users’. When changed to a value of 1, files created by a Windows user will apply a GID matched from either a local passwd file or the NIS database.

**param cifs useUnixGid=0**

**Note:** Windows User default GID of Domain Users is assigned to newly created files, directories—only applies to CIFS Users.

**param cifs acl.extendExtraGid=1**

**Note:** When set to 1, this parameter will map up to 15 additional Unix Secondary groups to NT Users, as found in the NIS or local Group files for that User. Data Mover will parse the NIS or ./etc/passwd file to match Username, then locate any Secondary Groups that a User is a member of from the NIS map or /etc/group file.

## **VIEWING UNIX PERMISSIONS FROM WINDOWS:**

**param cifs acl.extacl=2**

[Unix access rights are visible on Windows ACLs for files & directories—Windows Users can view Unix perms and change]

**param cifs acl.takegroupship=0**

**Note:** =1 Sets the new Primary group on files changed by NT user when useUnixGid=1 is in effect (0=default)

**param cifs acl.restrictedTakeOwnership=1**

**Note:** Enables assignment of GID based on source specified by acl.useUnixGid parameter. Purpose of param is to help determine source of GID for copied files from Windows User.

**param cifs acl.restrictedTakeOwnership=1**

**Note:** When set to 1 for UNIX or SECURE accesspolicy, only Root User (uid=0x0) can take Ownership of unix-permissioned files (except for Backup/Restore privilege)

**param cifs resolver=1**

**Note:** Using the “cifs resolver=1” enables DART to matchup a User’s Name from local passwd file or a NIS database. The first

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
preference will be to matchup the username without the domain extension applied. However, if a mapping cannot be made, a 2nd attempt to resolve UIDs is made by applying the ‘.domain’ extension to a User’s name.

### **param cifs resolver=0**

**Note:** Username.domain extension is always used when mapping UID/GIDs from passwd or NIS rather than just ‘username’.

#### **Example:**

murphys:x:35012:1000:Law, Murphys=murphys:/home/murphys:/bin/ksh [ordinary Unix-style & Celerra's new method with parameter "cifs resolver=1" enabled]

murphys.compucom:x:35012:1000:Law, Murphys=murphys:: [NT Domain style--old method]

**Comment:** User's name would be 'parsed' from Password file or NIS Database from the first line of the example if the "cifs resolver=1" option is selected. Otherwise, a 2nd line item would be required to define the "user.domain".

### **param cifs acl.checkacl=0**

**Note:** In this mode, only Unix permissions are checked—NT ACL’s or SIDs are not checked. This bit is set to 0 by default whenever CIFS is stopped.

### **param cifs acl.checkacl=1**

**Note:** Both Unix and Windows ACLs are checked. Default value for Celerra. Bit is set to 1 whenever CIFS is started.

## **SETTING ACL BEHAVIOR:**

**Note:** extacl parameter is used to manage special capabilities built around ACL management for two basic functions:

- 1.) Backup/Restore of UNIX attributes, symbolic links, access rights, UNIX modes using CIFS-based backup tools--NTBackup
- 2.) To view/change UNIX access rights from ACL management tools, like Windows Explorer

**param cifs acl.extacl=0** →(Default)Bit 0 param=0, DM presents UNIX meta-data for files/dirs for CIFS backups--EMC ACE Type →Bit 0 param=1, Celerra uses Standard ACE Type and encodes info in SID for the ACE

**param cifs acl.extacl=2** →Bit 1 set, param=2, CIFS users can view and change Unix perms; Unix perms show as (3) ACEs in ACL

**param cifs acl.extacl=4** →Bit 2 set, param=4, Unix perms presented in ACL so that CIFS backup applications can backup/restore

**param cifs acl.extacl=8** →Bit 3 set, param=8, CIFS apps. backup Unix symb. links with special ACL as 0-byte files

**Note:** When param is not set, CIFS Backups would follow the symbolic link to backup actual files

**param cifs acl.extacl=16** →Bit 4 set, param=16, CIFS apps. Backup UNIX names (all (3) names, M256, DOS 8.3, UNIX)

**Note:** UNIX names are encoded in special ACE in the file so that CIFS applications can backup/restore

**param cifs acl.extacl=32** →Bit 5 set, param=32, allows UNIX clients to View and Modify ACLs on Celerra using emcsetsd

**param cifs acl.extacl=64** →Bit6 set, param=64, UNIX rights are applied by granted rights and denied rights by DACL.

Normal behavior is for UNIX rights to files to be granted rights + rights not denied in DACL. Additionally, when this bit is set, requests to change files or directories are denied if they involve any of the (3) specil inheritance ACEs. In practice, this means that ACLs must be set using the Advanced options in Security>Properties from Explorer (i.e., uncheck Inheritance)

## **BINARY BIT SETTINGS TABLE:**

**2^6=64    2^5=32    2^4=16    2^3=8 (Bit3, etc)    2^2=4 (Bit2)    2^1=2 (Bit1)    2^0=1 (Bit0)**

Each of the above represents Bit0 through Bit6, as read from right-to-left. For example, if you wanted to set the Bit5 value for supporting the emcsetsd tool, the decimal value for the param would be 32 (or a range from 32-63). If you wanted to set the Backup/Restore symbolic link value, Bit3, the decimal value would be 15 (Base2 binary values for Bits 0, 1, 2, & 3 are combined). By having a decimal param value of 0 set means that none of the above Bits 0-6 are set, but a param value of 1 means that Bit0 is set.

#### **Shorthand Table:**

Bit0 = mask value 1 is set

Bit1 = mask value 2 is set

Bit2 = mask value 4 is set

Bit3 = mask value 8 is set

Bit4 = mask value 16 is set

Bit5 = mask value 32 is set

## **MOCKUP OF BIT TABLES AND BINARY VALUES:**

| Bit 6<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 5<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 4<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 3<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 2<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 1<br>Binary<br>Values | Dec.<br>Valu<br>es | Bit 0<br>Binary<br>Values | Dec.<br>Valu<br>es |
|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|---------------------------|--------------------|
| 1000000                   | 64                 | 0100000                   | 32                 | 0010000                   | 16                 | 0001000                   | 8                  | 0000100                   | 4                  | 0000010                   | 2                  | 0000000                   | 0                  |
|                           |                    | 0100001                   | 33                 | 0010001                   | 17                 | 0001001                   | 9                  | 0000101                   | 5                  | 0000011                   | 3                  | 0000001                   | 1                  |
|                           |                    | 0100010                   | 34                 | 0010010                   | 18                 | 0001010                   | 10                 | 0000110                   | 6                  |                           |                    |                           |                    |
|                           |                    | 0100011                   | 35                 | 0010011                   | 19                 | 0001011                   | 11                 | 0000111                   | 7                  |                           |                    |                           |                    |
|                           |                    | 0100100                   | 36                 | 0010100                   | 20                 | 0001100                   | 12                 |                           |                    |                           |                    |                           |                    |
|                           |                    | 0100101                   | 37                 | 0010101                   | 21                 | 0001101                   | 13                 |                           |                    |                           |                    |                           |                    |
|                           |                    | 0100110                   | 38                 | 0010110                   | 22                 | 0001110                   | 14                 |                           |                    |                           |                    |                           |                    |

|         |    |         |    |         |    |
|---------|----|---------|----|---------|----|
| 0100111 | 39 | 0010111 | 23 | 0001111 | 15 |
| 0101000 | 40 | 0011000 | 24 |         |    |
| 0101001 | 41 | 0011001 | 25 |         |    |
| 0101010 | 42 | 0011010 | 26 |         |    |
| 0101011 | 43 | 0011011 | 27 |         |    |
| 0101100 | 44 | 0011100 | 28 |         |    |
| 0101101 | 45 | 0011101 | 29 |         |    |
| 0101110 | 46 | 0011110 | 30 |         |    |
| 0101111 | 47 | 0011111 | 31 |         |    |
| 0110000 | 48 |         |    |         |    |
| 0110001 | 49 |         |    |         |    |
| 0110010 | 50 |         |    |         |    |
| 0110011 | 51 |         |    |         |    |
| 0110100 | 52 |         |    |         |    |
| 0110101 | 53 |         |    |         |    |
| 0110110 | 54 |         |    |         |    |
| 0110111 | 55 |         |    |         |    |

## **CONFIGURING DART TO APPLY PERMS TO USERS WITH SECONDARY UNIX GROUPS:**

Introduced with 4.2.13.100:

**param cifs acl.extendExtraGid=1**

**param cifs resolver=1**

**Note:** When using the new “extendExtraGid=1” parameter, must also use “cifs resolver=1” param.

Explanation:

Param allows Windows User to be able to add up to (15) Secondary Unix Groups to their NT Credential when logging in from CIFS, using either NIS or local /etc/passwd and group files. Customer was using NIS Service to map Unix Users and Groups, “accesspolicy=SECURE”, a umask of “027” on all Shares, & “param cifs resolver=1”. Whole point is that customer did not wish to manually create Windows 2000 Groups for every Unix Secondary Groups.

**Note:** There is a general NFS limitation, when using AUTH\_SYS RPC Security Calls, of (16) Groups that a Unix User can be a member of. Solaris 8 can be tuned to allow for a total of 32 Groups per User (Future NAS may allow 32 Groups).

## **USING EMCSETSD & EMCGETSD UTILITIES FOR VIEWING/SETTING ACLS FROM UNIX HOST (Introduced NAS 5.2):**

**Note:** These tools are unix-based and are designed to View and/or Modify NT ACLs when remote mounting a Celerra CIFS File System from either a Solaris, HPUX, or Linux Host. The emcgetsd and emcsetsd tools are found on the Celerra Applications & Tools CD>CifsTools>unixactools>hpxu | linux | solaris directories. You can also run the tool from the Control Station by simply copying the Linux binary files to /home/nasadmin.

1. Add the following param to the Data Mover and reboot (only required for emcsetsd tool, not emcgetsd):

**# server\_param server\_2 -facility cifs -modify acl.extacl -value 32**

**Note:** Using server\_param to change the acl.extacl value does not require reboot

**param cifs acl.extacl=32**

2. Create CIFS Share for file system to be setup/tested

share "emc" "/fs1" maxusr=4294967295 umask=22

3. Copy the "emcsetsd" and "emcgetsd" utilities from the Applications & Tools CD to a directory on the Control Station

4. Make the binary utilities executable:

**# chmod 755 emesetsd emcgetsd**

5. Mount the Data Mover from the CS (may need to export file system to CS IP address for RW access):

## # mount server\_2://fs1 /dm

6. Add a User to a Folder Path with permissions and flags desired:

# ./emcsetsd -D win2kemc -g tommie,RWXPDO,0x3 /dm/fs1/SD

Server=server\_2, Path in the server=//fs1/SD

1 ACE added

7. Verify by using "emcgetsd":

# ./emcgetsd /dm/fs1/SD

Server=server\_2, Path in the server=//fs1/SD

Dump of //fs1/SD Security Descriptor

#### **PROBLEM OF UNRESOLVED SIDs: MIGRATIONS OR TAPE RESTORES**

Scenario is that in complex multi-domain environments, there is often the possibility that data will be copied to the Celerra containing SIDs that cannot be resolved. Default behavior is to either fail when copying data or to assign Everyone Full Control. Because of this, Engineering has developed the concept of the ‘delayed SID’—the concept of setting a SID to an ACL without completing authentication. This condition will occur if the SID is unknown on the DC or if there is no Unix mapping in the passwd file, NIS database, or Usrmapper server.

#### **BASIC PARAMETERS TO TRY WHEN MIGRATING UNRESOLVABLE/BROKEN SIDS:**

**Note:** First used for Emcopy issue

```
param cifs acl.mappingErrorAction=3
```

```
param cifs acl.retryAuthSid=600
```

**param cifs acl.FailOnSDRestoreError=0** [Consider setting to 1 if msg desired in Server Log]

acl.mappingErrorAction=3 → Store ACE & SID, but don't try again if resolution to DC fails

acl.mappingErrorAction=1 → Save ACE & SID, keep SID in pending state if resolution to DC fails

acl.mappingErrorAction=0 → Do not save SID & ACE if resolution to DC fails

#### **DEFINITIONS:**

**param cifs acl.mappingErrorAction=3** (means that Bits 0 & 1 are set)

**Note:** This parameter defines rules for unknown mappings between SID, UID, GID on ACL setting, either because DC does not know SID or User Name is not yet mapped to UID/GID. Max value is decimal 15 for this param in NAS 5.4

Bit 0 = stores unknown SIDs (decimal value=1)

Bit 1 = stores SIDs without Unix GID/UID mappings (decimal value=3)

Bit 2 = enable debug traces (decimal value=7, the max. value that can be set for this parameter)

Bit 3 = Only do lookup in cache (secmap or globalSidcache or per connection SID cache—decimal value=15)

**param cifs acl.retryAuthSid=600**

**Note:** This parameter sets the timeout value of 600sec. between authentication retries for unknown SIDs

**param cifs acl.FailOnSDRestoreError=0**

**Note:** This parameter suppresses any errors resulting from unresolved ACLs during migration of files to Celerra, migrating all resolvable SIDs properly and placing unresolved SIDs in the delayed SID state. Without this setting, errors will be returned when copying files with unresolvable SIDs, resulting in copying of files with default Everyone Full Control applied. Use these parameters when conducting an EMCopy/CDMS migration or any type of migration involving unresolvable SIDs.

#### **CHANGING DEFAULT CIFS TIMEOUT MAY HELP IN CASES OF UNRESOLVABLE SIDS:**

In certain situations, such as for orphaned SIDs, or SIDs that cannot be resolved in other domains because of Trusts or firewall issues, Clients may experience long “pauses” as directories are traversed—this is because of the 20sec CIFS timeout value. In extreme cases, setting this value to 1388=5000=5 secs may help speed things up.

cifs.NTsec.DCTimeout 0x015d6b54 0x00004e20 0x00004e20 [default value 4e20=20,000=20secs

#### **CELERRA AND NEGATIVE CACHING OF UNKNOWN SIDS:**

Prior to NAS 5.3.2, 5.2.11, and 5.1.23, Celerra did not cache unknown Sids. What would happen is that each time the unknown Sid was presented, we went off to DC's trying to lookup SID, eventually causing performance problems with large networks. Fix would be to ensure that Global Sid Caching is enabled on the DM. We should now cache negative lookups so that we don't continually try to resolve the same unknown SID. Besides Server Log messages, a key indicator of the health of authentication sessions are SessionSetups, as seen from server\_cifsstat. See AR41213.

**Server Log Example of Successful Negative Caching:** 2004-03-26 09:32:26: SMB: 3:

Usr='AUdoggetsm':Grp27=:SidTypeUnknown error=SUCCESS SID=S-1-5-15-8b33b8-7481765b-250e54d6-24b3

**Note:** This feature applies only to Group SIDs

#### **USING SETACL TO CLEANUP ORPHANED SIDS FROM CELERRA FILE SYSTEMS:**

Set the following data mover params, reboot, and then run Setacl command to flush unresolvable or unknown or orphaned SIDs from the Celerra File Systems—reboot after Setacl is completed. Always verify that UID/GID mapping database is correct, that correct Interface is specified for the respective Comname, and that CIFS is up and running during the Setacl process:

1. Set following params on Data Mover:

**param cifs acl.FailOnSDRestoreError=0**

**param cifs acl.mappingErrorAction=3**

2. Reboot Data Mover

3. Set SMB Debug Logging:

**\$server\_config server\_x -v "logsys set severity SMB=LOG\_DBG3"**

4. Run Setacl Against File System using Correct Interface Name to flush unresolvable, unknown, or orphaned SIDs:

**\$server\_config server\_x "cifs update /mntpoint force setacl if=fsn0"**

**# .server\_config pal1 "cifs update /pal\_fs2 force setacl if=pal2"** [Setacl using VDM Container name ‘pal1’]

**Caution:** When running setacl, do so from top-level share of each Comname, making sure to specify the correct interface name for the comname. Failure to do this could replace built-in localgroup information with the wrong comname. Also, you may need to set **SMB=LOG\_DBG3** in order to see cifs update entries in Server Log.

2005-07-01 08:47:17: ADMIN: 4:[pal1] Command succeeded: :1 cifs update /pal\_fs1 force setacl if=pal1

2005-07-01 08:53:00: SMB: 4:[pal1] Update of : /root\_vdm\_1/pal\_fs1 completed after 343 s

2005-07-01 08:53:00: SMB: 4:[pal1] Update of : 1452338 files, 119766 dirs, 1572093 Acl

5. Reboot Server after setacl is completed on all file systems

#### **ACL RECORDS:**

ACL records and database are stored in /etc directory of each file system, recording checksum, reference count, size of data.

ACL record has header with ACLID magic number, revision, and next free acl record slot.

ACL records and acl data are compared—acl record entries are deleted if there is a mismatch

## **RESETTING ACL's: \$server\_config server\_2 "cifs update /mountpoint/path resetacl"**

An important tool for "access denied" issues on specific CIFS files/folders is the "resetacl" command, which restores "Everyone Full Control" to the folder that it is run against. Use this as a quick way to restore administrative access to a subfolder or CIFS Share.

**Caution:** Administrator will have to reset NT Perms on the affected folder for the Users and Groups that were previously assigned.

**\$server\_config server\_2 "acl reset=/etc/PIPE/netlogon"**

**\$server\_config server\_2 "acl reset=/etc/PIPE/srvsvc" [or \$PIPE?]**

**Note:** Resetacl CIFS Update rebuilds the Shadow file and resets all CIFS attributes back to their default [Archive On, Read-Only, Hidden, and System Off], meaning that tape backups would run the equivalent of a full backup. Use resetacl only as a last resort and only if the customer agrees, as this command will open up all directories and files to Everyone Full Control access and would require extensive customer work in reapplying NTFS permissions. If required, the resetacl can be run on a Server that is not running a CIFS configuration as there is no need to consult with the Domain Controllers while running this command.

## **RUN “CIFS UPDATE” TO RE-LINK NFS FILE NAMES & CIFS 8.3 FILE NAMES:**

Step 1. Check CPU of Server prior to kicking off cifs update

Step 2. If there are Users connect to the Share that you are updating, stop and restart CIFS

**Note:** The cifs update will not start if Users are connected to the Share (SMB: 3: Error: Update cannot be done on share in use)

Step 3. Set SMB debug logging in order to see entries in Server Log:

**# .server\_config server\_2 "logsys set severity SMB=LOG\_DBG3"**

Step 4. Run CIFS Update Command:

**# .server\_config server\_2 "cifs update /sf02\_fs1 force level=0"**

command(s) succeeded

**Note:** Must see the “command(s) succeeded” message or the process is not running

Step 5. Verify progress of CIFS Update by checking command log—should see an entry for command succeeding, then an update every 600 seconds, and finally, an update completion message. Use server\_sysstat to check CPU usage during the update—a cifs update should use 5-15% CPU load.

2005-07-01 10:48:06: ADMIN: 4:[sf02] Command succeeded: :1 cifs update /sf02\_fs1 force setacl if=sf02

2005-07-01 10:58:06 :SMB: 4: Update of :/sf02\_fs1 running since 600 s 340639 files, 42093 dirs have already been updated

2005-07-01 10:60:50: SMB: 4:[sf02] Update of :/sf02\_fs1 completed after 164 s

2005-07-01 10:60:50: SMB: 4:[sf02] Update of : 418206 files, 55090 dirs, 473292 Acl

Step 6. Make sure to turn off SMB debug logging when completed:

**# .server\_config server\_2 "logsys set severity SMB=LOG\_PRINTF"**

## **USING SETACL TO UPDATE UID/GID VALUES ON-DISK:**

**Intro:** The “setacl” command forces the Datamover to read the ACL List from each Folder/File on the directory tree to obtain SID information. DM requests DC validation of each User & Group SID. Upon authentication by DC, DM searches queries Usrmapper for SID match, and reapplies UID/GID information associated with that SID to each User or Group’s ACE. If Usrmapper is not used, then the mappings change from SID match to Username/Groupname match, using 1.) Local DM “passwd” or “group” file 2.) NIS Database files 3.) Usrmapper Database

### **IMPORTANT CAVEATS PRIOR TO RUNNING SETACL:**

1. Please understand what the correct “source” of User and Group Mappings are before running “Setacl”. For instance, if local passwd and group files are populated on the data mover, but Usrmapper and SID History are in use, then you would want to rename the local passwd/group files prior to running setacl so as to get the correct UID-to-SID mapping from Usrmapper--this becomes an issue mainly when multiple SIDs are mapped for a User that may have the same name.

2. Please advise customer that a reboot may be necessary prior to starting setacl (and is actually preferred), as well as stopping & restarting CIFS, and that a reboot is always required after completing setacl on a given Server.

3. Please note that the CIFS process must be running during the setacl process, but that if many Users are actively connected, you may need to stop and restart CIFS in order to make setacl run.

4. Always verify that the correct Interface is matched up with the correct Compname before running setacl—failure to do this could adversely affect permissions on the entire file system. Use server\_export, server\_cifs, etc., to match-up compnames to interfaces to file systems.

5. Be aware that if local group permissioning is in use and the Domain Users or Domain Admins GID has changed, that you may need to run an “lg update force” before running the setacl.

6. Set SMB Debug logging prior to running setacl:

**# .server\_config sf02 "logsys set severity SMB=LOG\_DBG3"**

7. Start setacl and monitor Server Log. If the process seems to run slow, the DC that we are connected to may not be the best DC to use for the setacl process. Reboot the Data Mover to stop setacl & prepare for invalidate/validate. Alternatively, have customer reboot Domain Controller. Use sysstat to monitor cpu levels--normal CPU usage for a setacl should be between 10-20%:

```
$ .server_config server_2 -v "pdc invalidate=168.247.33.200"  
$ .server_config server_2 -v "pdc validate=168.247.34.250"  
$ .server_config server_2 "cifs update /mntpoint force setacl if=fsn0"
```

**Note:** Make sure “Command(s) succeeded” prompt returns. If prompt returns and complains about “share is in use”, then you will need to stop and restart CIFS and try the command again. Monitor server log for status of the update.

8. Make sure to turn off debug logging when completed:

2005-07-01 10:48:06: ADMIN: 4:[sf02] Command succeeded: :1 cifs update /sf02\_fs1 force setacl if=sf02

2005-07-01 10:50:50: SMB: 4:[sf02] Update of : /root\_vdm\_1/sf02\_fs1 completed after 164 s

2005-07-01 10:50:50: SMB: 4:[sf02] Update of : 418206 files, 55090 dirs, 473292 Acl

```
# .server_config server_2 "logsys set severity SMB=LOG_PRINTF"
```

## **HOW USERS/GROUPS AUTHENTICATE TO DATA MOVER FOR ACCESS:**

1. User conducts SessionSetup connection to Data Mover, presenting NT/Win2k Access Token [Access Tokens are built by Domain Controller every time a User successfully logs into the Domain]
2. If SecMap Cache is not enabled (NAS 5.2+) and SIDs are not stored locally, DM must validate SIDs of User and Groups
3. DM receives confirmation of User/Group SIDs, combines with Security Access Token & localgroups db information, & caches User credentials for that logon session
4. Dart checks User Credential against file system objects before allowing access to folders and file
5. Objects created by User combines UID/GID information with SID in the ACL, which gets written to the file or directory object as an ACE

## **EXAMPLE OF SETACL PROCEDURE AFTER REBUILDING USRMAPPER DATABASE:**

### **RUNNING SETACL COMMAND TO UPDATE FILE SYSTEM ACLs WITH NEW UID/GIDs:**

**EXAMPLE:** Duplicate UID/GIDs have been assigned due to Usrmapper issue. New Usrmapper database constructed and converted into Usrmapper Version 3.1.2 or higher

1. Remove old passwd/group files from all data movers
2. Replace Usrmapper database with newly converted or repaired database
3. Start Usrmapper and CIFS
4. Always run ACL DUMP against known directory to validate BEFORE SETACL & AFTER SETACL changes to UID/GIDs:

```
$ .server_config server_6 -v "acl if=fsn0 dump=/mnt4/its"
```

5. Update localgroups database on each Data Mover by running:

```
$ .server_config server_5 -v "lg update force"
```

**Note:** This will read each localgroups entry and update GIDs based on Usrmapper, or other mapping source

6. Reboot Server to refresh memory and disconnect all CIFS users

7. Set SMB Debug logging:

```
# .server_config sf02 "logsys set severity SMB=LOG_DBG3"
```

8. Leave CIFS running and immediately issue setacl command

```
$ .server_config server_5 "cifs update /fs01 force setacl if=interface0"
```

**Note:** If setacl fails because ‘shares are in use’, stop & restart cifs and issue command again

9. Track progress of setacl in the Server Log:

**2003-08-23 17:11:36: SMB: 4: Update of : /fs01 running since 9000 s 39854 files, 2554 dirs have already been updated**

2005-07-01 10:50:50: SMB: 4:[sf02] Update of : /root\_vdm\_1/sf02\_fs1 completed after 164 s

2005-07-01 10:50:50: SMB: 4:[sf02] Update of : 418206 files, 55090 dirs, 473292 Acl

10. After Setacls have completed, reboot data mover (will also turn off debug logging)

## **MONITORING SETACL PROGRESS:**

Setacl will update the Server Log every 600 secs. If you encounter the following errors in the log, it doesn’t mean that setacl has completely failed, but it could be indicating a problem with a Domain Controller or unresolvable SIDs. Setacl should rip through a 300GB file system in a half hour or less. To monitor progress, run server\_df and record the number of inodes used in the file system. Also, run server\_sysstat to see if CPU is being utilized—DM should use 10-20% CPU for a setacl. Then, at any of the update points, see how fast the setacl check is progressing. In the above example, a 69GB file system was taking an extremely long time to run and indicated a problem with a DC and Invalid SIDs that could not be resolved. The following corrective steps were taken:

## **SETACL FAILURE--DOES NOT COMPLETE--SERVER LOGS ERRORS:**

2003-08-23 14:41:40: SMB: 4: Update /fs01 cannot fix ACL for  
/fs01/fs01/usmt/nttoxp/userdata/SPlatts/USMT2I.UNC/C/DATA/NOTES/Lotusme1.dic c0000078

2003-08-23 14:41:41: SMB: 4: Update /fs01 cannot fix ACL for  
/fs01/fs01/usmt/nttoxp/userdata/SPlatts/USMT2I.UNC/C/DATA/NOTES/mail.box c0000078

**ERROR TRANSLATION:**

C:>err c0000078  
# for hex 0xc0000078 / decimal -1073741704 :

**STATUS\_INVALID\_SID ntstatus.h**

**CORRECTIVE STEPS FOR RUNNING SUCCESSFUL SETACL:**

1. Set following params to ignore Unknown SID mapping issues:

```
param cifs acl.mappingErrorAction=3
param cifs acl.retryAuthSid=600
param cifs acl.FailOnSDRestoreError=0
```

2. Reboot Data Mover to stop setacl and to set params

3. Force connection to another Domain Controller by issuing:

**\$ .server\_config server\_5 -v "pdc invalidate=168.247.33.200"**

**\$ .server\_config server\_5 -v "pdc validate=168.247.34.250"**

**RESULTS:**

**DC=PLANTDFS01(168.247.33.200) ref=2 time=3 ms INVALID [Invalidate this DC by using “pdc invalidate=” command]**

DC=\*SMBSERVER(168.247.33.73) ref=2 INVALID

DC=\*SMBSERVER(168.247.33.74) ref=2 INVALID

**>DC=PLANTDFS06(168.247.34.250) ref=13 time=0 ms [Connected to this DC using “pdc validate” command]**

**Note:** Stop and restart CIFS if needed to force DC switch

4. Alternatively, have customer reboot the Domain Controller

**Note:** Above steps were used at Kemper. After switching to new DC, setacls ran quickly and successfully:

**2<sup>nd</sup> SETACL ATTEMPT ON FS01:** Completed in just under 6 minutes

2003-08-23 18:42:46: SMB: 4: Update of : /fs01 completed after 359 s

2003-08-23 18:42:46: SMB: 4: Update of : 178322 files, 15214 dirs, 193533 Acl

**SETACL LIMITATIONS & PRECAUTIONS:**

--Always run ACL DUMP on a known directory where you expect GIDs or UIDs to be updated BEFORE & then AFTER “setacl”

**\$ .server\_config server\_6 -v “acl if=fsn0 dump=/mnt4/its”**

--Run setacl with Force flag:

**\$ .server\_config server\_6 “cifs update /mntpoint force setacl if=fsn0”**

--“Setacl” will not run against ATM interfaces and will panic the data mover—only known workaround is to have a fast Ethernet interface and add to cifs configuration using –Enable command and use this for the setacl

--If using “SIDHistory”, whereby Users may have multiple SIDs, this command may not function as expected

--Always run with CIFS started

**EXAMPLE OF ACLDUMP OUTPUT:** [with SIDHistory SID involved]

**# .server\_config server\_2 -v "acl if=fsn0 dump=/personal/its/dbarker"**

===== UNIX =====

## **CELLERRA ACL FLAGS & ACCESS RIGHTS:**

**Note:** Use ACLDump to output Unix, NT, and ACL information

-->UNIX section describes user and group content (name:number), plus Unix access right

-->NT section describes Owner and Primary group of file

    Owner of file (Unix name: uid Nt name:Sid)

    Primary group (Unix name: gid Nt group name:Sid)

-->ACL section contain the following values for each ACE:

    Owner type (USER/GROUP) Unix name:uid/gid NT name:Sid DENIED/GRANT Flags Mask and Rights

### **Flag Values:**

|                                  |                                                                    |
|----------------------------------|--------------------------------------------------------------------|
| #define EFFECTIVE_ACE            | (0x0) // effective only                                            |
| #define OBJECT_INHERIT_ACE       | (0x1) // ACE used on File creation                                 |
| #define CONTAINER_INHERIT_ACE    | (0x2) // ACE used on Dir creation                                  |
| #define NO_PROPAGATE_INHERIT_ACE | (0x4) // ACE not propagated                                        |
| #define INHERIT_ONLY_ACE         | (0x8) // ACE used only for inheritance                             |
| #define INHERITED_ACE            | (0x10) // ACE inherited cannot be overwritten without spec. action |

### **Mask Values:**

|                                   |                                  |
|-----------------------------------|----------------------------------|
| #define FILE_READ_DATA            | 0x00000001                       |
| #define FILE_LIST_DIRECTORY       | 0x00000001                       |
| #define FILE_WRITE_DATA           | 0x00000002                       |
| #define FILE_ADD_FILE             | 0x00000002                       |
| #define FILE_APPEND_DATA          | 0x00000004                       |
| #define FILE_ADD_SUBDIRECTORY     | 0x00000004                       |
| #define FILE_CREATE_PIPE_INSTANCE | 0x00000004                       |
| #define FILE_READ_EA              | 0x00000008                       |
| #define FILE_WRITE_EA             | 0x00000010                       |
| #define FILE_EXECUTE              | 0x00000020                       |
| #define FILE_TRAVERSE             | 0x00000020                       |
| #define FILE_DELETE_CHILD         | 0x00000040                       |
| #define FILE_READ_ATTRIBUTES      | 0x00000080                       |
| #define FILE_WRITE_ATTRIBUTES     | 0x00000100                       |
| #define DELETE                    | 0x00010000L                      |
| #define READ_CONTROL              | 0x00020000L                      |
| #define WRITE_DAC                 | 0x00040000L // write/modify ACEs |
| #define WRITE_OWNER               | 0x00080000L                      |
| #define SYNCHRONIZE               | 0x00100000L // not used          |
| #define SECURITY_SYSTEM           | 0x01000000L // Only in Audit ACE |
| #define GENERIC_READ              | 0x80000000L                      |
| #define GENERIC_WRITE             | 0x40000000L                      |
| #define GENERIC_EXECUTE           | 0x20000000L                      |
| #define GENERIC_ALL               | 0x10000000L                      |

### **Generic Masks:**

Generic masks are stored in an ACE only if they are in an INHERIT\_ONLY ACE

### **Generic Masks Mapped On:**

```
#define GENERIC_ALL_MAP (FILE_READ_DATA | FILE_WRITE_DATA | FILE_APPEND_DATA | FILE_READ_EA |
FILE_WRITE_EA | FILE_EXECUTE | FILE_DELETE_CHILD | FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES
| DELETE | READ_CONTROL | WRITE_DAC | WRITE_OWNER | SYNCHRONIZE)
#define GENERIC_READ_MAP (FILE_READ_DATA | FILE_READ_EA | FILE_READ_ATTRIBUTES | READ_CONTROL |
SYNCHRONIZE)
#define GENERIC_WRITE_MAP (FILE_WRITE_DATA | FILE_APPEND_DATA | FILE_WRITE_EA |
FILE_WRITE_ATTRIBUTES | READ_CONTROL | SYNCHRONIZE)
#define GENERIC_EXECUTE_MAP (FILE_EXECUTE | FILE_READ_ATTRIBUTES | READ_CONTROL | SYNCHRONIZE)
```

### **Associated rights:**

R -> read access

W -> write access

X -> execute or traverse dir

P -> change permission

D -> delete

O -> take ownership

## **RESETSACL COMMAND:**

**\$server\_config server\_2 "cifs update /fs1/homedir resetsacl"**

**Note:** ACLs have two fundamental components: DACL & SACL [Directory & System Access Control Lists]

Certain situations where SACL may become corrupt if filesystems are being shared across multiple netbios names and ownership is taken by a User from a different netbios name. Well-known SIDs are replaced with larger User SID and ACL offsets can become distorted, leading to SACL corruption. Also, due to large offsets, datamover may run out of memory and panic. This condition is fixed in NAS 4.2.14.402/403 and 4.2.16.0, 5.0.16.0, 5.1.13.0 and higher. Resetsacl strips out auditing information, if set, and is harmless to run.

## **HOW TO VERIFY UNIX FILE NAMES & WINDOWS 8.3 NAMES:**

**Note:** The following command will allow you to inspect UNIX names v. Windows 8.3 names—may be useful when determining if a 0 byte file should actually be a folder—confirms whether there has been shadow file corruption

**\$server\_config server\_9 -v "shadow readdir \volta\f3u2\Victor"**

```
1041202451: CFS: 4: name: ADMIN ADMIN <DIR>
1041202451: CFS: 4: name: backup_error_ojv.txt BACKUP~1.TXT
1041202451: CFS: 4: name: tseprofile_ojv.txt TSEPRO~1.TXT
1041202451: CFS: 4: name: USERS USERS <DIR>
1041202451: CFS: 4: name: OJVTSEPROFILES OJVTSE~1 <DIR>
1041202451: CFS: 4: name: filesystem_ojv.txt FILESY~1.TXT
1041202451: CFS: 4: name: profile_ojv.txt PROFIL~1.TXT
```

**Note:** In some cases, the command will not run because of spaces or other peculiarities in the path—when all else fails, try to determine DOS 8.3 name for the next directory in the path and substitute that name:

**# .server\_config server\_7 -v "shadow readdir \data\userdata\SFISHE3\Sandy's files\Action Plans"**

```
1131570657: CFS: 3: shadow fix: getAlternateName failed: NotFound
```

**# .server\_config server\_7 -v "shadow readdir \data\userdata\SFISHE3\SANDY'~1\ACTION~1"**

## **HOW TO FIX SHADOW FILE FOR SPECIFIC FOLDERS:** [Use instead of CIFS UPDATE]

**\$server\_config server\_9 -v "shadow fix \volta\f3u2\Victor"**

**\$server\_config server\_9 -v "shadow update \ora\ImageArchives"** [Yet another version of update]

**Note:** NAS 5.1.20.401 no longer seems to log ordinary SHADOW messages. Turn on Shadow debug prior to running Cifs Update in order to see logging events: “**logsys set severity SHADOW=LOG\_DBG3**”

## **SHADOW FILE PROBLEM ON ROOTFS OF CIFS SERVER:**

### **RUNNING READDIR ON ROOTFS REQUIRES \\:**

**# .server\_config server\_3 -v "shadow readdir \\"** [Note the double slash required to run command]

```
1063307557: CFS: 4: modifyCount: 0x25
1063307557: CFS: 4: name: application.evt APPLIC~1.EVT
1063307557: CFS: 4: Found 1 entries
1063307557: ADMIN: 4: Command succeeded: shadow readdir \
```

### **RUNNING SHADOW FIX ON ROOTFS:**

**# .server\_config server\_3 -v "shadow fix \\"**

```
1063307726: ADMIN: 4: Command succeeded: shadow fix \ [zeroes out Shadow file & is rebuilt on next CIFS client access]
```

### **RESULTS:**

**# .server\_config server\_3 -v "shadow readdir \\"**

```
1063307750: CFS: 4: modifyCount: 0x27
1063307750: CFS: 4: name: . . <DIR>
1063307750: CFS: 4: name: .. .. <DIR>
1063307750: CFS: 4: name: Data DATA <DIR>
1063307750: CFS: 4: name: .etc .ETC <DIR>
1063307750: CFS: 4: name: BusDev BUSDEV <DIR>
1063307750: CFS: 4: name: HR HR <DIR>
1063307750: CFS: 4: name: temp3mc TEMP3MC
1063307750: CFS: 4: name: Scratch SCRATCH <DIR>
1063307750: CFS: 4: name: application.evt APPLIC~1.EVT
```

1063307750: CFS: 4: name: lost+found LOST\_F~1 <DIR>  
1063307750: CFS: 4: name: system.evt SYSTEM.EVT  
1063307750: CFS: 4: name: tempemc TEMPEMC <DIR>  
1063307750: CFS: 4: name: SpaceProg SPACEP~1 <DIR>  
1063307750: CFS: 4: name: security.evt SECURITY.EVT  
1063307750: CFS: 4: name: .etc\_common ~1.ETC <DIR>  
1063307750: CFS: 4: name: Operations OPERAT~1 <DIR>  
1063307750: ADMIN: 4: Command succeeded: shadow readdir \  
**CAUSE:** Rootfs was previously filled up, damaging the Shadow file!

### **SHADOW SHOW COMMAND:**

**# .server\_config server\_2 -v "shadow show \acl"**

**Note:** Creates a data file called ‘shadow’ in the path specified—only used by developers

### **GETTING CIFS FILE ATTRIBUTES:**

**\$ .server\_config server\_2 -v "shadow getattr \test\john.xls"**

1076189006: CFS: 4: j: archive

1076189006: ADMIN: 4: Command succeeded: shadow getattr \test\john.xls

**Note:** Command can show if files are RO, hidden, or archive files.

### **MISCELLANEOUS ACL RESET OF DM ROOT DIRECTORIES, FILES, PROCESSES:**

.server\_config server\_x "acl reset=/.etc/PIPE"  
.server\_config server\_x "acl reset=/.etc/PIPE/samr"  
.server\_config server\_x "acl reset=/.etc/PIPE/lsarpc"  
.server\_config server\_x "acl reset=/.etc/PIPE/srvsvc"  
.server\_config server\_x "acl reset=/.etc/PIPE/svcctl"  
.server\_config server\_x "acl reset=/.etc/PIPE/eventlog"  
.server\_config server\_x "acl reset=/.etc/PIPE/winreg"  
.server\_config server\_x "acl reset=/.etc/PIPE/wkssvc"  
.server\_config server\_x "acl reset=/.etc/PIPE/netlogon"  
.server\_config server\_x "acl reset=/.etc/PIPE/celerra"

### **ACL DUMP OF DM HIDDEN C\$ SHARE:**

1066684472: CFS: 4: name: .etc_common ~1.ETC <DIR>
```

## **MOUNTING/UNMOUNTING FILE SYSTEMS--CD-ROM's, Floppies, etc:**

**Server\_mount Command:** Filesystems, Mountpoints, type, Status, access rights, multiprotocols, accesspolicy

-perm for Permanent: remounts at bootup [Listed in DataMover's /etc/dfs/dfstab or /etc/dfs/sharetab files]

-a -o {rolrw; primary=; nonotify} disable CIFS notify option, which is on by default; nooplock—disable cifs opportunistic locks, which are on by default; accesspolicy=nolocklwlocklrwlock } -F forces RO to be RW for Timefinder/FS BCV's

**Note:** NFS & CIFS File Systems will unmount “temporarily” by default unless you use the –p option

## **CELLERRA FILE SYSTEM MOUNT/UMOUNT RULES:**

1. You can “Unmount” a File System by specifying either the ‘File System Name’ or its ‘Mountpoint.’
2. But, when you “Mount” a File System, must specify ***both*** ‘FS name’ and ‘Mountpoint.’
3. By default, File Systems are *soft* ‘unmounted’ <unmounted> if you do not specify –p for permanent!!
4. By default, File Systems are *hard* or permanently ‘mounted’, even if you do not specify the –p switch!
5. Most known mount options, such as nolock, accesspolicies, etc., are effective immediately upon issuing the command and do not require umount and remount of file system.
6. You cannot mount a file system to another data mover if it’s already mounted “RW”. You can only mount a file system to multiple data movers if the file system is mounted “RO” for all file systems.

**HARD MOUNTS DEFINED:** Permanent mounts that look like a ‘local’ file system or directory from User’s perspective

Hard mount becomes unavailable, Client will retry, eventually locking up Client machine processes

Hard mounting is the default method

**SOFT MOUNTS DEFINED:** Non-permanent mounts

Client will retry then fail, preventing local machine from locking up

Since this type of mount has “data loss” potential, recommended usage is only for READ-ONLY applications

### **Mounting All File Systems in Table:**

**\$server\_mount server\_4 -all**

### **Mounting Individual File Systems:**

**\$server\_mount server\_4 fs1 /fs1** [Default=permanent, RW]

### **Mounting FS with AccessPolicies:**

**\$server\_mount server\_4 -p -o accesspolicy=secure,rwlock ufs1 /ufs1**

**\$server\_mount server\_4 -p -o accesspolicy=NT,wlock fs\_01 /fs\_01**

**Note:** Accesspolicies are now Uppercase sensitive with NAS 5.5

### **Mounting FS with Virus Checking Scanning Disabled:**

**\$server\_mount server\_4 -o noscan fs34 /fs34**

### **Mounting SNAPSURE File System:**

**\$server\_mount server\_4 -p -o ro snaps /mntpoint**

### **Unmounting All File Systems:**

**\$server\_umount server\_4 -a -perm** [without –perm results in temporary unmount]

**\$server\_umount server\_3 -p /fs01** [Mountpoint for fs01]

**\$server\_umount server\_3 fs01** [Soft or Temp unmount; \$server\_mount server\_3 show this FS as <unmounted> but original Accesspolicies and other attributes are retained, such as Locking, etc.]

## **VERIFYING MOUNTED FILE SYSTEMS:**

**# .server\_config server\_2 -v "file mountdisplay"**

server\_2 : commands processed: 1

Current Mounted File Systems are:

ckpt ro /mnt10\_ckpt10 151=45 ro

ckpt ro /mnt10\_ckpt9 151=44 ro

ckpt ro /mnt10\_ckpt8 151=43 ro

```
ckpt ro /mnt10_ckpt7 151=42 ro
ckpt ro /mnt10_ckpt6 151=41 ro
ckpt ro /mnt10_ckpt5 151=34 ro
ckpt ro /mnt10_ckpt4 151=33 ro
ckpt ro /mnt10_ckpt3 151=32 ro
ckpt ro /mnt10_ckpt2 151=31 ro
(NULL)
ckpt ro /mnt10_ckpt1 151=29 ro
uxfs rw /mnt10 143=25 rw,accesspolicy=NATIVE
uxfs rw /gary 127=18 rw
uxfs ro /.etc_common 67=16 ro
uxfs rw / 39=2 rw
Total number of file systems is: 15
```

### **VOLUME INFO CACHING:**

NAS 5.3 caches volume structure to speed mount operations. An issue can occur when deleting file systems, however, in that the cache is not deleted, and can create problems when creating new file systems that reuse a volume id number previously ‘deleted’. NAS 5.4 deletes cached information for deleted file systems.

### **MOUNTING BCV “RO” FILESYSTEM “RW”:**

```
$server_mountpoint server_5 -c /fs2_snap1
$server_mount server_5 -F -p -o rw fs2_snap1 /fs2_snap1
```

### **LOCATING USERS/PROCESSES LINUX RED HAT 7.2:**

#### **/usr/sbin/safe\_finger**

| Login    | Name | Tty   | Idle | Login Time                  | Office | Office Phone |
|----------|------|-------|------|-----------------------------|--------|--------------|
| nasadmin |      | pts/1 |      | Mar 3 10:57 (10.240.16.84)  |        |              |
| nasadmin |      | pts/2 |      | Mar 3 11:19 (10.240.16.128) |        |              |
| nasadmin |      | pts/0 | 3d   | Feb 27 15:29 (172.24.80.35) |        |              |

**\$ /sbin/fuser -m /mnt/fs50**

/mnt/fs50: 6899c

**\$ /sbin/fuser -u** //:5975r(nasadmin) 6899r(nasadmin) 9521r(nasadmin) 16336r(nasadmin)

-v verbose -u uids -m mounted fs -k kill processes

accessing file -a display unused files

**#/sbin/fuser -k** [Kills processes from Users on a filesystem]

#### **Using the Fuser Command:**

**# fuser -u /tmp** [Lists out User processes by Username and Process ID for the Directory or File System specified]

**# fuser -f filename** [Lists out users of a particular file]

### **UNMOUNTING /NAS FILE SYSTEM IF IN USE:** ‘Resource Busy’ error when trying to unmount fs

1. Identify processes that are locking file system in use: **#/sbin/fuser -m /nas**

/nas: 1568 1575 1576 1577 1578 1579 1580 1581 1582 2220

c 2299c 2300c 2362 2362c 7719 7719c 7719e 7916c

2. Kill processes: #kill -9 1568 (.etc)

3. Unmount /nas: #umount /nas

### **MOUNTING CS1 FROM CS0 FOR COPYING FILES BACK & FORTH:**

**Note:** Only prerequisite is that you know what the path is for the root “/” partition of the control station that you want to mount. sdd3 & sdc3 are normal partition names for CS1 & CS0, respectively for Red Hat 7.2

#mount /dev/sdd3 /mnt [Mounts root partition of CS1]

#mount /dev/sdc3 /mnt [Mounts root partition of CS0]

### **The Unix Automounter Service:**

Linux uses “autofs”; Solaris uses “automounter” [/etc/auto\_master]; others use “amd”

#### **Purpose of Automounter?**

--Makes exported FileSystems available to Remote Hosts

- Use Wild-cards to mount remote directories to like-named mountpoints on local hosts
- Increases network reliability through use of multiple servers exporting large numbers of FS and Directories to Users
- Example: Common Home Directory server for Users to Login
- Defined by use of “map” files [Convert Sun automounter ‘map’ to “amd” map file using perlscript; automount2amd.pl script]
- Must have ‘portmapper’ service running

**Linux Automounter:** “autofs” is recommended and uses the “commandline” to configure

**\$ ps -ef |grep auto**

```
root 955 1 0 Nov17 ? 00:00:00 /usr/sbin/automount --timeout 1  
root 973 1 0 Nov17 ? 00:00:00 /usr/sbin/automount --timeout 1
```

**#/etc/rc.d/init.d/autofs start | stop**

**#/sbin/service autofs stop | start**

### **AUTOMOUNTER ISSUE NAS 5.3:**

**# ls -al /etc/auto.\***

```
-rwxrwxr-x 1 root root 117 Oct 14 17:45 /etc/auto.master → Problem is that access rights are set incorrectly  
-rwxrwxr-x 1 root root 575 Jul 14 14:17 /etc/auto.misc  
-rwxrwxr-x 1 root root 438 Oct 14 17:45 /etc/auto.nas  
# ps axlww | egrep auto  
040 0 31804 1 9 0 1500 644 pipe_w S pts/2 0:00 /usr/sbin/automount --timeout 1 /nasmcd/rootfs program /etc/auto.nas  
ro,,soft,intr,nosuid,noac  
040 0 31822 1 8 0 1496 640 pipe_w S pts/2 0:00 /usr/sbin/automount --timeout 1 /nasmcd/quota program /etc/auto.nas  
rw,,soft,intr,nosuid,noac
```

#### **SOLUTION:**

1. Stop automounter

**# /sbin/service autofs stop**

2. Change access rights to 644

**# chmod 644 /etc/auto.\***

**# ls -al /etc/auto.\***

```
-rw-r--r-- 1 root root 117 Oct 14 17:45 /etc/auto.master  
-rw-r--r-- 1 root root 575 Jul 14 14:17 /etc/auto.misc  
-rw-r--r-- 1 root root 438 Oct 14 17:45 /etc/auto.nas
```

3. Restart the automounter—process should be have “file” mode set, not “program” mode

**# /sbin/service autofs start**

**# ps axlww | egrep auto**

```
040 0 3466 1 8 0 1496 636 pipe_w S pts/2 0:00 /usr/sbin/automount --timeout 1 /nasmcd/rootfs file /etc/auto.nas  
ro,,soft,intr,nosuid,noac  
040 0 3495 1 9 0 1500 640 pipe_w S pts/2 0:00 /usr/sbin/automount --timeout 1 /nasmcd/quota file /etc/auto.nas  
rw,,soft,intr,nosuid,noac
```

4. Test automounter

**Note:** One symptom of this condition is that server\_export file becomes 0 bytes because it needs automounter to pull the exportdb from the Data Movers. Run #server\_export to verify fix.

### **CREATING AN AUTOMOUNT MAP FILE ON CELERRA:**

- Step 1. Create File: \$nas\_automountmap -create -out newmap

**Note:** This creates a map file of all exports on the Celerra & outputs lines similar to following:

**NFS8 -rw,intr,nosuid 192.10.2.25,192.10.2.24:/NFS8**

**legato -rw,intr,suid 192.10.2.23,192.10.2.22:/legato**

- Step 2. Use Text Editor to modify file

- Step 3. Merging an old mount and new mount map file: \$nas\_automountmap -create -in oldmap -out -newmap

- Step 4. Verifying automountmap list: \$nas\_automountmap -list\_conflict -in oldmap -out newmap

### **CELERRA AUTOMOUNTER:**

**AutoMounter Files:** /etc/auto.misc | auto.master & /nas/sys directories

**\$/etc/ls auto\*,file auto\***

auto.master auto.misc auto.nas

auto.master: ASCII text

auto.misc: ASCII English text

auto.nas: ASCII text

**Configuring Celerra With Auto-Mounter Entries:**

```
$ vi auto.misc
# $Id: auto.misc,v 1.2 1997/10/06 21:52:04 hpa Exp $
# This is an automounter map and it has the following format
# key [ -mount-options-separated-by-comma ] location
# Details may be found in the autofs(5) manpage
cd -fstype=iso9660,ro,nosuid,nodev :/dev/cdrom
# the following entries are samples to pique your imagination
#linux -ro,soft,intr ftp.example.org:/pub/linux
#boot -fstype=ext2 :/dev/hda1
#floppy -fstype=auto :/dev/fd0
#floppy -fstype=ext2 :/dev/fd0
#e2floppy -fstype=ext2 :/dev/fd0
#jaz -fstype=ext2 :/dev/sdc1
#removable -fstype=ext2 :/dev/hdd
```

**CELERRA SOFT MOUNTS:**

```
$ more auto.master
# timeout set to 2/10 of a second.
/nasmd /rootfs /etc/auto.nas ro,-t 1,soft,intr,nosuid,timeo=2,retrans=2,actimeo=1,nfsvers=3,noac,sync
/nasmd /quota /etc/auto.nas rw,soft,intr,nosuid,timeo=2,retrans=2
```

**Mount Options:**

-ro [Read Only] -blocksize=1024 -wsize=4096 [write buffer size] -intr [allow keybd interrupts to kill process]  
 -soft [Server fails to respond, return error after timeout period **-timeo=value** expires & do not retry]  
 -hard [Default Option: Client retries until Server responds—This can hang your network if not careful!!!]  
 -nouser [only root can mount FS] -noexec [do not execute files from this FS]  
 -sync [Use synchronous FS I/O] -timeout=60 [timeout after 60 seconds, for “softmounts”]

**NFS Mount Options:**

nosuid → Use this option for NFS file systems to prevent a user from running programs based on credentials of owner of file  
 noexec → forbids execution of any files from remote users

**Note:** #mount -timeo is used to change default RPC timeout values--may need to increase for RPC timeouts

**Sample Mount Problem:** Sometimes, df, sync, ls commands hang

**Cause:** Server using Hard Mounts and is down

**Solution:** Use soft mounts, timeout values, or restart NFS and Automount daemon

**Mounting All FS in Linux:** #mount -a

**Viewing All FS:** #showmount -e or #df

**Map File Built Using Syntax of “fstab” file:** /etc/fstab /etc/auto.master

| File System | Mountpoint | Options             |
|-------------|------------|---------------------|
| /dev/sdc1   | /cdrom     | iso9660,defaults,ro |

**MOUNTING DM FROM CONTROL STATION WITH PERSISTENT MOUNT:**

#mount -r server\_5:/ /dm

**Following Entry is Created in Dynamic Mount Table--/etc/mtab:**

server\_5:/dm nfs ro,addr=192.168.1.5 0 0

**Copy Above Entry into /etc/fstab:**

server\_5:/dm nfs ro,addr=192.168.1.5 0 0

**SYMPTOMS THAT AUTOMOUNTER IS NOT WORKING CORRECTLY:**

1. cannot cd to rootfs of Server
2. running server\_export lists only NFS exports, not shares
3. # nas\_quotas -r -fs stores report file not ready yet, retrying...done

4. Automounter errors seen in /var/log/messages or osmlog

Jun 11 07:48:37 go001cfs000 automount[880]: attempting to mount entry /nasmd/rootfs/slot\_4

Jun 11 07:48:37 go001cfs000 automount[6849]: >> nfs bindresvport: Address already in use

Jun 11 07:48:37 go001cfs000 automount[6849]: mount(nfs): nfs: mount failure on/nasmd/rootfs/slot\_4]

5. Output of netstat shows large number of ports in use by usrmount\_svc:

# **netstat -alp |grep -i usrmapper\_svc lwc -l** → Usrmapper Service was consuming 1010 ports

6. Automounter service still running:

```
$ ps -ef |grep auto
root    923    1 0 Jun06 ?    00:00:00 /usr/sbin/automount --timeout 1
root    941    1 0 Jun06 ?    00:00:00 /usr/sbin/automount /nasmcd/quot
```

### **SHOWING NFS EXPORT LIST ON DM:**

# **/usr/sbin/showmount -e server\_3 | 192.10.0.103**

Export list for server\_3:

```
/ 192.1.2.101,192.1.1.101,192.1.2.100,192.1.1.100
/root_ojv 192.1.1.100,192.1.1.100,192.1.1.100,192.1.1.100,192.1.1.100,192.1.1.100
/root_emc 192.1.1.100,192.1.1.100,192.1.1.100,192.1.1.100
/ojv_sa 192.1.1.100,192.1.1.100
```

**EXAMPLE:**

# **/usr/sbin/showmount -e 138.1.164.129**

Export list for 138.1.164.129:

```
/ 192.1.2.101,192.1.1.101,192.1.2.100,192.1.1.100
/nas019 rgmdebkp3-b,rgmdbs1-b
/nas022 rgmdebkp3-b,rgmdbs1-b
/nas021 rgmdebkp3-b,rgmdbs3-b
/nas056 rgmlnx03-b,rgmlnx02-b,rgmlnx01-b
```

### **SHOWING NFS HOSTS MOUNTED ON DM:**

\$ **/usr/sbin/showmount -a server\_3 | 192.10.0.103**

All mount points on server\_3:

```
192.1.1.100:/ojv_sa
192.1.1.100:/root_emc
192.1.1.100:/root_ojv
```

**EXAMPLE:**

# **/usr/sbin/showmount -a 138.1.164.129**

All mount points on 138.1.164.129:

```
rgmdbs1-b:/nas019
rgmdbs1-b:/nas022
rgmdbs3-b:/nas021
rgmlnx01-b:/nas056
rgmlnx02-b:/nas056
rgmlnx03-b:/nas056
```

**Other Files:** /etc/mtab [Shows active partitions mounted]

/etc/exports [Exported partitions]

#### **Indirect v. Direct Map Files:**

Indirect Map used for multiple Users with Relative Mountpoints, as in /home directories: user\_1 mach\_1:/export/home/user\_1

Direct Map used for direct mount statement: /home/research -rw filbert:/home/research

**Note:** Linux “autofs” does not support Direct Maps!

### **USE OF HARD vs. SOFT MOUNTS FOR NFS:**

Standard practice dictates that NFS filesystems be hard-mounted whenever conducting writes—otherwise, there is great potential for lost data if the Server crashes.

**HARD MOUNTS:** “NFS Server Not Responding” errors on screen or /var/messages file are indicators that Hard-mounts are used

**SOFT MOUNTS:** Soft-mounts are typically used for Read-Only mounts—a key indicator of a soft-mounted filesystem would be an NFS “RPC Timeout”—client retries a number of times before giving up.

**TroubleShooting Automounter:** /var/log/messages #df [will hang on client that is no longer active]

### **Mounting File Systems:**

**Quick Way to Remount or Temporarily Unmount all File Systems on a Server** [Provided that FS are in Mount Table]:

```
$server_mount server_3 -a          $server_umount server_3 -a
```

**Mounting the DataMover Root FileSystem to the Control Station:** #mount -F nfs server\_3:/ /mntptn

Or #mount -F nfs 172.16.21.183:/root\_fs\_3 /mnt

#cd /nas/rootfs/slot\_2 [another way to access root filesystem]

**Accessing DM Root From Windows:** \dm43\_ana0c\$

**MOUNTING DATAMOVER “RW” FROM CONTROL STATION:** “*Shortcut Method*”

#cd /nasmcd/quota/slot\_2/etc

**Permissions Problem When Trying to Mount to DataMover:**

If FileSystem is exported as “anon=0”, means that you are granted “user” Root access, but only “group” Other.

So, if the “mountpoint” was created by “root”, it has “user & group” as root and the “group” Other will be denied access.

Therefore, may need to “CHMOD” the mountpoint to which you want to remotely connect to:

#chmod 777 /mnt1

#mount -F nfs 172.19.32.233:/ /mnt1

**MOUNTING LINUX CONTROL STATION TO CD-ROM:**

#mount -ro /dev/cdrom /mnt/cdrom

**MOUNTING FLOPPY DRIVE WITH LINUX:**

#mount /dev/fd0 /mnt/floppy

**Mounting A Floppy Device to Sun:**

**Note:** If Sun has Volume Management installed, insert diskette and type \$volcheck at command line

Step 1. Insert floppy and from root, create mountpoint: #mkdir /floppy

Step 2. #mount -F pcfs /dev/diskette /pcfs [pcfs=PC DOS filesystem type]

**Note:** Purpose of “-F” switch is to signify a different File System format

**Mounting All FS for Linux:** #mount -a

**Mounting All FS for Solaris:** #mountall

**ARGUMENTS FOR MOUNTING NFS FILE SYSTEMS USING TCP vs. UDP:**

--Use NFS v3 over TCP, not UDP: If network is susceptible to dropped packets, UDP requires retransmission of all fragments in a datagram, whereas TCP would require retransmission of only a single packet. NFS v2 can only transfer in 8k datagrams.

Asynchronous writes using unstable flag and commit calls, and GETATTR calls are improvements over NFS v2.

--NFS/RPC timeouts for retransmissions take time, then requires complete retransmission

--NFS Streaming supported by V3 not V2

--TCP protocol allows for Congestion Window flow control, Receiver flow control based on Receive Window Size, and Congestion Avoidance and Slow Start Algorithms for recovery after packet loss.

--NFS requires retransmission at layer 5 RPC via timeout mechanism whereas layer 4 TCP uses Fast Retransmit and ACK

--In addition, NFS v3 over TCP allows for better handling of large data transfer sizes, say 32k, where UDP may overflow switches with large packet transfers

--TCP helps prevent buffer overflows in switches and pause frame flow control can be implemented

**EXPORTING/UNEXPORTING FILE SYSTEMS:**

**CELLERRA EXPORT COMMAND:**

\$ server\_export ALL [Displays exported and shared File Systems]

**Note:** Celerra shares can be created from the CLI or from the MMC console from a Windows system

→Computer Management>rightclick name>Connect to another computer>Celerra\_computername>System Tools>Shared

Folders>Shares>rightclick>New Share>Next>Folder Path: c:\m1 (enter upper mountpoint name or path for the share)>Share name: enter a name for the new Share>Select permission setting>Finish

**SCRIPT TO CREATE CIFS SHARES:**

#!/bin/bash

# script to create exports

#

NAS\_DB=/nas

for i in \$(seq 1 100); do server\_export server\_2 -P cifs -name fs3\_\$i -o netbios=dbms /fs3; sleep 1; done

for i in \$(seq 1 100); do server\_export server\_2 -P cifs -name fs4\_\$i -o netbios=dbms /fs4; sleep 1; done

for i in \$(seq 1 100); do server\_export server\_2 -P cifs -name fs5\_\$i -o netbios=dbms /fs5; sleep 1; done

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
for i in \$(seq 1 100); do server\_export server\_2 -P cifs -name fs6\_\$i -o netbios=dbms /fs6; sleep 1; done

### **SCRIPT TO CREATE DOMAIN USER ENTRIES ON CELERRA:**

```
#!/bin/bash
# script to create Internal Usermapper and Secmap Domain User entries
#
NAS_DB=/nas
for i in $(seq 30008 30999); do server_cifssupport server_2 -secmap -create -name w2ku$i -domain w2k; sleep 1; done
```

### **NFS EXPORT OPTIONS/RULES:**

--Root Users (UID=0) are considered unknown by NFS Servers unless specifically listed in export options  
--anon=uid--means that requests from unknown Users should receive ‘effective’ uid of ‘nobody’ or 65534 by default  
--User uids are checked first on data mover’s local ./etc/hosts file, then ./etc/netgroup, then NIS, and finally DNS  
--access=client--provides mount access to specified clients. Clients can be Hostname, Netgroup, Subnet, IP Address  
--root=client--provides root privilege to client in form of hostname, netgroup, subnet, IP Address. Default NFS behavior is that no Hosts have Root access  
--rw=client--exports pathname as read-mostly for specified clients, and read-only to everyone else [hostname, netgroup, subnet, IP]  
--ro option--exports pathname for NFS clients as Read-Only  
--sec=sys—SecureNFS sys security mode ro, rw=, ro=, root=, access=, wlan=, anon=, webroot, public  
--sec=krb5—SecureNFS security mode ro, rw=, ro=, root=, access=

### **EXAMPLES:**

```
export “/fs1” access=192.168.10.2 rw=192.168.10.1 root=192.168.10.1
ro rw=hostname; anon=uid root=hostname access=client {./etc/hosts or ./etc/netgroup—NIS}
access=hostname /mntpoint access=IP address /mntpoint access=Netgroup /mntpoint
access by Subnet→$server_export server_2 -o access=193.1.21.0/255.255.255.0 /mntpoint
```

**Note:** All hosts that need to connect as RW should be in “rw=” list; all hosts that should be RO should be in “access=” list;  
Using the “ro=” option forces all hosts to be Read Only, despite use of “root=”, “rw=”, for other hosts in export line. RO exports the whole export path as RO. Pathnames must be enclosed with quotations if extra spaces are in the path.

**NFS Export Note: Options [-o]:** ro,rw [default=rw]; anon=uid; root=client; access=client; rw=client ['client' means hostname', 'netgroup', 'subnetIP/mask', 'IPaddress/mask'; separate listings with colon :] Default Export for NFS if no switches used is “No Hosts Root Access”. Also, if using any of the methods listed, should ensure that there are entries in one of the following locations, in order of resolution:

1. Data Mover ./etc/hosts database
2. Data Mover ./etc/netgroup db
3. NIS Server
4. DNS Server

### **LINUX CLIENT ISSUE WITH CELERRA:**

Celerra responds to a Client NFS Write request with ERR\_STALE [Stale Filehandle] but inserts extra data into the error message, causing Linux client to hang. See AR49124,49188, 47569 DNLC entries.

### **VIEWING NFS EXPORTS FROM GIVEN IP ADDRESS:**

**# showmount -e 172.19.32.9**

### **COMMON NFS EXPORT ERRORS:**

--2002-06-12 21:23:59: NFS: 4: mount\_lookup: No match in export list, fs not exported: host 5785040a, ruid 320519936, handle 12.1017776002  
--/mnt Stale NFS file handle

**Comment:** Errors are harmless, indicating that an NFS FileSystem has been unexported but clients still have mounted

**Exporting NFS File Systems when having Client-side Write Issues:** There are certain rare occurrences whereby a network latency issue, or dropped packets [as in a failing switch] that can change the ability of a File System to be written to by remote hosts, say in the instance that the remote hosts were defined for RW access and permissions.

**Exporting the File System by Hostname and Giving Root Access also:** [As opposed to anonymous nobody access, which is RO]

**\$ server\_export server\_2 -i -o rw=acomp7:acomp8:acomp9,root=acomp7:acomp8:acomp9 /bvfs2**

### **Exporting File System by IP Address:**

**\$ server\_export server\_2 -i -o rw=192.25.88.20:192.25.88.21 /bvfs2**

Important point is that the user 'nobody' [anonymous] is given RO access to File Systems, so that if not properly defined, a user may come across thinking he has RW access, when in reality, he is assigned the “nobody” UID for RO access.

### **Common Error:**

Export error: Neither parent nor self conflict

**Note:** Error occurs when path still exists but is not currently exported.

## **EXPORTING ROOT “/” READ-ONLY ON LINUX CONTROL STATION FOR SPECIFIC HOST:**

**Caution:** Use this procedure with extreme caution—usually done for backing up Control Station partitions.

Step 1. Verify that “nfs” services are running on Control Station:

```
#/etc/rc.d/init.d/nfs status
rpc.mountd (pid 7328) is running...
nfsd (pid 7340 7339 7338 7337 7336 7335 7334 7333) is running...
rpc.rquotad (pid 7323) is running...
```

Step 2. If NFS services are not running, use following command:

```
#/etc/rc.d/init.d/nfs start | stop
```

Step 3. Verify current exports on Control Station:

```
#/usr/sbin/exportfs
```

Step 4. Add export entry to export Control Station “root” / :

```
#vi /etc(exports
/ 192.10.2.3 (IP Address of Remote Client to be allowed access to CS0 root)
```

Step 5. Refresh Exports on Control Station:

```
#/usr/sbin/exportfs -av
```

Step 6. Create mountpoint on Remote Unix Host:

```
#mkdir /cs0_romount
```

Step 7. From Remote Host, mount Control Station “/” root export:

```
#mount 192.24.80.11:/ /cs0_romount [CS0's IP Address, “/” root filesystem, and local mountpoint]
```

## **EXPORTING NFS UDP/TCP:**

Servers generally export both protocols and clients choose a default or indicate ‘proto=tcp’ from remote mounting

**NFS EXPORT TABLE LIMITATIONS:** Only 256 export entries can be displayed, though more actual exports can be applied

## **NFS EXPORT BY IP ADDRESS FOR ROOT ACCESS:**

```
$server_export server_3 -p -o root=193.1.21.210/255.255.255.0 /g1ufs1
```

## **EXPORTING ROOT FILE SYSTEM OF DATAMOVER FOR EXTERNAL CS ACCESS:**

**Note:** Procedure is listed for reference purposes only and is not condoned or supported for customer environments! Be aware that exporting the data mover over the internal interfaces from the Control Station may not show all directories. Exporting over external IP addresses and then mounting from CS will be a true NFS mount.

**Scenario:** Exporting Root File System of Server\_2 to external IP Address of CS0

1. #vi /nas/server/slot\_5/export [Add following line to DM root file system to external IP address of CS0]

```
export "/" anon=0 access=192.10.0.17:192.168.1.100:192.168.2.100:192.168.1.101:192.168.2.101
```

**Note:** “/” represents root mountpoint exported from DM. Access=IP is External IP address of CS0.

2. Reboot Server to rebuild exports

3. Mount root filesystem Read-Only from CS0:

```
# mount -r server_5:/ /dm
```

4. Following entry is made to /etc/mtab file:

```
server_5:/ /dm nfs ro,addr=192.168.1.5 0 0
```

5. Copy entry from /etc/mtab to /etc/fstab file

```
server_5:/ /dm nfs ro,addr=192.168.1.5 0 0
```

**Note:** This ensures that CS remounts the file system after a reboot, whereas just having the entry in mtab will not. Be advised that Tech Support does not condone or support exporting the DM root filesystem to any external IP address. A full package NAS Upgrade will also replace any ‘modified’ or added IP addresses in the Export file of all Servers for the “/” file system export with the default Internal IP addresses of the Control Station only.

## **MOUNTING FILE SYSTEMS OF DATA MOVERS FROM CS0:**

1. Create mountpoints for file systems to mount on CS0 [e.g., #mkdir /s2/fs1, #mkdir /s3/fs3, etc.]

2. Mount over external network so as to keep NFS functionality intact: #mount 10.64.25.14:/fs1 /s2/fs1

**Comment:** Mounts “fs1” on Server\_2 over external IP Address from CS0

## **MOUNTING DM OVER INTERNALS USING NFS V2:**

```
# mount -o vers=2 server_4:/ /mnt
```

**Note:** Use this to see all directories on datamover whereas NFS v3 may not properly display all directories.

## **DUMPING EXPORTS ON DATAMOVER:**

**\$ .server\_config server\_2 -v "export"**

1058207628: NFS: 4: /pol anon=0

1058207628: NFS: 4: / anon=0 access=10.64.25.10:192.168.1.100:192.168.2.100:192.168.1.101:192.168.2.101

## **CIFS SHARE OPTIONS:**

**Note:** Default is to export CIFS Shares as Read-Write to all Clients

ro—exports Share as Read-Only for CIFS clients

rw=client—exported read-mostly for those clients specified, but Read-Only for all others

umask=mask—allows setting Unix permissions to Share; CIFS default umask=022 or 755

**Note:** Directory permissions in octal expressed from 777; File permissions in octal expressed from 666

002=775, which is complete access to Owner & Group, and Read access to Other [includes directory search]

022=755, which is complete access to Owner & Read/Execute access to Group & Other [includes directory search]

### **Example File or Directory set to 755, or umask=022:**

-rwxr-xr-x 1 root root 0 Mar 21 10:57 file3

drwxr-xr-x 2 root root 4096 Mar 21 10:58 subfolder

### **Example File or Directory set to 775, or umask=002:**

-rwxrwxr-x 1 root root 0 Mar 21 10:52 file2

drwxrwxr-x 2 root root 4096 Mar 21 10:58 subfolder

**# server\_export server\_2 -P cifs -n home4 -o umask=002 /fs1**

Octal 777 gives rwx to User, Group, Other

Octal 666 gives rw to User, Group, Other

user==default\_user group=default\_group [Used to define User & Group access for Share-level Security]

ropasswd=share\_passwd rwpasswd=share\_passwd [Used to define RO & RW passwords for Share-level Security]

maxusr=maxusr—Sets number of simultaneous user connections to a Share [default is 4 billion]

netbios=compname—if a specific netbios name is not specified, Share is visible to all NetBIOS names on Server by default

**Other Options:** -l -P {cifs/nfs} -n {cifs sharename} -a -a-u -i -p [exports permanent for reboots] -t -u -o

## **SPECIAL CHARACTERS ALLOWED IN SHARENAMES:**

The following may be used in share names \*^%\$#@!()\_-+=?.,[]{}|

The following characters should not be used: \ and /

## **CIFS SHARES AND ACL CREATION BEHAVIOR:**

→new filesystem contains no ACLs until first exported for CIFS, then gets Everyone FC by default

→If not exported, the filesystem can only be accessed from CIFS by an Admin mapped to UID of 0

## **COMPNAMES AND NETBIOS NAMES:**

Default NetBIOS name of computer is assigned from first 15 characters of comp\_name. Use the netbios= option when creating a compname to specify a netbios name that needs to be different from the comp\_name.

## **CIFS SHARENAMES:**

Limited to 256 characters with Unicode UTF-8, or 12 if using ASCII mode

Sharenames are case-sensitive and may contain spaces

netbios=compname—CIFS share created specifically for a single netbios name

**Note:** Windows 9x Clients enumerate Shares using MSRAP Share Enumerate Calls to the Server. NT/Windows 2000 Clients use SRVSVC Share Enumerate Calls to obtain Shares listing.

### **Common Win9x Client Error in Server Log:**

“Max buffer size of the client to small (2850) 135 shares of 169 returned to the client”

## **LISTING DATA MOVER SHARES:**

**\$ .server\_config server\_2 -v “share” “sharedb info” “sharedb asc”**

1047060338: SMB: 4: HOME /

1047060338: SMB: 4: comment="Home Service"

1047060338: SMB: 4: umask=022

1047060338: SMB: 4: maxusr=4294967295 inUse=2

1047060338: SMB: 4: C\$ /

1047060338: SMB: 4: comment="Root Service"

1047060338: SMB: 4: umask=022

1047060338: SMB: 4: maxusr=4294967295 inUse=2

1047060338: SMB: 4: CHECK\$ /

```
1047060338: SMB: 4: comment="Virus Checking Service"  
1047060338: SMB: 4: umask=022  
1047060338: SMB: 4: maxusr=4294967295 inUse=2  
-----abridged-----
```

## **DUMPING ACLS ON CIFS SHARES:**

```
# .server_config server_2 -v "acl if=eand-fsn0 share=shared1"
```

Share Shared1 (EAND-FS001)

===== UNIX =====

USER ftpuser-emc:0 GROUP 1 mode=rw-----

===== NT =====

Owner=USER ftpuser-emc:0 UNIX UID=0x0 'ftpuser-emc':S-1-5-12-1-0

Group=GROUP 1 UNIX GID=0x1 ".:S-1-5-12-2-1

Owner=ALL Everyone.:S-1-1-0

ALLOWED Flags=0 Mask=1f01ff Rights=RWXPD0

No SACL

```
$ .server_config server_2 -v "acl share=home" (alternative syntax without interface)
```

## **CHANGING UMASK VALUES ON CIFS SHARES WITH ‘SERVER\_EXPORT’:**

```
$server_export server_6 -P cifs -n umask27 -o umask=027 /dawn
```

\$server\_export server\_6

```
share "umask27" "/dawn" maxusr=4294967295 umask=27
```

Comment: Our default umask value for NT Shares is “umask=022”

## **UMASK CALCULATION INTO PERMISSIONS:**

|                             |     |
|-----------------------------|-----|
| 777 UGO value               | 777 |
| 022 = umask                 | 002 |
| 755 = resultant permissions | 775 |

## **CHANGING UMASK VALUES USING .SERVER COMMANDS:**

DEFAULT UMASK: cifs.share.default.umask 0x0134eb30 0x00000012 0x00000012

Note: 0x12 is Octal value 022, which is the default value used for shares when no other specific Umask is defined. A Umask of 022 means rw-r—r—for file creation and rwx-r-xr-x for directories.

Change Umask: \$ .server\_config server\_2 -v "param cifs share.default.umask=0x2"

Note: This does not change the ‘umask=22’ listed in the output of server\_export, but changes the effective umask to the 0x2 value.

## **DAMAGED EXPORT TABLE:** [/nas/server/slot\_x/export] can have the following effects:

- Inability to mount the DataMover's rootfs either Permanently or Temporarily
- Inability of the DataMover to Failover
- Can produce error message when running Server\_Export command

## **DUMPING DATA MOVER EXPORTS FROM MEMORY:**

```
# .server_config server_6 -v "dumpexportdb"
```

## **EXPORTING/UNEXPORTING CIFS & HIDDEN SHARES:**

```
$server_export server_2 -P cifs -o user=todd,group=administrators,rwpasswd=write,ropasswd=read -n share6 /mnt1
```

```
$server_export server_2 -P cifs -u -n content$ -p [unexporting—do not need to specify mountpoint path!!]
```

```
$server_export server_2 -P cifs -n content$ -p /content/content [exporting to subdirectory level]
```

## **UNEXPORTING FILESYSTEMS:**

NAS codes >than 4.2 no longer support temporary unexporting of either NFS or CIFS—despite switch, exports will be permanent

### **Permanently Unexporting ALL Exports:**

```
$server_export server_4 -u -a
```

Un-exporting NFS File Systems: \$server\_export server\_4 -p nfs -u -all [or /path for a single FS]

Un-exporting CIFS File Systems Permanently: \$server\_export server\_4 -P cifs -a -p -u

Un-exporting Single CIFS File System Permanently: \$server\_export server\_4 -P cifs -n cifsfs -p -u

Ignore Export Table: \$server\_export server\_4 -p -ignore

Note: The –ignore option will re-export all exports or the specific export and replace all previous export options used

## **VERIFYING PATH OR SHARE EXPORTS ON DATAMOVER:**

**\$server\_export server\_2 -l -P cifs -n share**

### **RECOVERING CIFS SHARES:**

**Note:** Starting with NAS 4.x and higher, the export.shares file was created on the Control Station. Under ordinary circumstances, this file is kept up-to-date with the shares database, which is now hosted on the data mover. In some situations, there may be a need to resync the CS database to the Server db, located in [/etc/shares/@import](#) | @Global | @system

→ Make backup copy of export.shares file and run the recovery command:

**\$server\_export server\_2 -r**

### **DNS AND SHARES ISSUE:**

**Situation:** Under certain circumstances, if deleting a sharename for a specific share on a DM, then re-exporting the same sharename to a different mountpoint and DM with a different IP address, Clients will connect and see wrong information underneath the “Share” that they are accustomed to working on.

#### **Resolution:**

→ Verify problem using \$.server\_config server\_2 -v “dns dump” and compare to \$server\_cifs and \$server\_export output

→ Unexport and re-export the “Share” to the correct mountpoint and NetBIOS Server

→ Flush Client System dns cache

→ Flush DM cache using \$server\_dns server\_2 flush

### **CASE EXAMPLE:**

\$ server\_export server\_2

server\_2 :

share "shares" "/shares" netbios=DIANAS01 maxusr=4294967295 umask=22

share "edocs" "/gissshare" netbios=DIAGIS03 maxusr=4294967295 umask=22

**Note:** “shares” was mistakenly re-exported for /gissshare –o netbios=DIAGIS03 before correcting, but left following problem and client access problems to ‘shares’

**\$ server\_cifs server\_2**

```

**Note:** DM DNS Cache is now normal, along with flush of Client DNS, normal share access restored

## **ROAMING PROFILES & CLIENT/SERVER BEHAVIOR--TIMESTAMP ISSUE:**

The Celerra does not yet calculate time in nanoseconds, as do MS Clients. Therefore, when Windows 2000 & XP Clients use Roaming Profiles that are stored on the Celerra, they compare timestamps of the locally stored profile with those on the Data Mover, and because the Data Mover rounds off all timestamps to the next lowest second by default behavior, the timestamps are always different. This does not usually present a problem during Client logon because timestamps are usually newer on the client (because of the default behavior of the Celerra just mentioned). However, on Client logoff there is a substantial performance exposure because the Client then compares the timestamps of all files and considers its local copy as newer than those on the Server and so initiates a write of all files back to the Celerra. Under ordinary circumstances this does not cause a problem--however, when User profiles grow to hundreds of megabytes in size, or there are many User profiles stored on a single data mover, the potential is for a perceptible performance hit on the Data Mover during logoff periods, and Clients may see that files take several minutes or longer to open. Network traces can usually confirm this by showing the names of the files being processed during the affected timeperiod--they may show up predominantly as User Profile files.

AR39503 (primus emc77448) documents this issue, and with NAS codes 5.3.1.0, 5.2.10.0, and 5.1.21.0 and higher, a parameter and mount option was introduced to force the data mover to round up files to the next whole second. Once the param or mount option is implemented, the Client behavior requires two logon and logoff sessions to get to a point where the Client begins to recognize that the files stored on the Server are newer than the Client, that is, except for files that are genuinely changed and updated by the Client on any given day.

Specifically, after the change is implemented (param & reboot), when a Client logs in, all files are downloaded, just as always. Then, when Client logs off, Client will force rewrite of all files to the Server because the two timestamps will still be different (Client's time will be newer), but this time the Celerra will round up all files to next nearest whole second. Client will log in for the 2nd time, this time downloading all files containing the rounded up Celerra timestamps, because the times have all changed. During the 2nd logoff, things will be different--the Client will now compare timestamps and see that for the most part, the timestamps are the same as those on the datamover, and will only rewrite those files that have been worked on during the day to the Celerra, thereby decreasing the size and length of the write operations.

## **OPTIONS WHEN IMPLEMENTING NANOSECOND ROUNDUP:**

**param cifs nanoroundoff=1** [Rounds-up date of files to next second on Data Mover or globally via slot-param file]

**# server\_mount server\_2 -o cifsnanoroundup -n davefs /davefs** [use option to change timestamp on a single fs]  
davefs on /davefs uxf5,perm,rw,cifsnanoroundup

**Note:** One final comment, if a User's profile is very large, and the data is always being changed, then changes will still be rewritten constantly to the Celerra--if this is the case, then the size and validity of the data in the User's profile should be verified. In one example, a User's profile was close to 1GB in size!

**# du -sh /\* |grep M**

4.6M ./Personal

**766M ./Settings**

2.9M ./Templates

## **CREATING FILE SYSTEMS--Configuring, Mounting, Exporting:**

**Note:** 2048=2GB; 4096=4GB

- I. **Create (4) 2GB Slice Volumes:** #nas\_slice -n slv01 -c d34 2048 #nas\_slice -n slv02 -c d34 2048 2048  
#nas\_slice -n slv03 -c d34 2048 4096 #nas\_slice -n slv04 -c d34 2048 6144
- II. **Create (4) Stripe Volumes:** #nas\_volume -n stv01 -c -S 8192 d3, d4, d5 #nas\_volume -n stv02 -c -S 8192 d6, d7, d8  
#nas\_volume -n stv03 -c -S 8192 d9, d10, d11 #nas\_volume -n stv04 -c -S 8192 d12, d13, d14
- III. **Create (7) MetaVolumes (comprised of Slice, Stripe, and Disk Volumes):**  
#nas\_volume -n mtv01 -c -M slv01 #nas\_volume -n mtv02 -c -M stv01  
#nas\_volume -n mtv03 -c -M slv02, stv02 #nas\_volume -n mtv04 -c -M d15  
#nas\_volume -n mtv05 -c -M d16, slv03 #nas\_volume -n mtv06 -c -M d17, stv03  
#nas\_volume -n mtv07 -c -M d18, stv04, slv04
- IV. **Create Unix File Systems:** \$nas\_fs -i -all  
#nas\_fs -n ufs01 -c mtv01 #nas\_fs -n ufs02 -c mtv02 #nas\_fs -n ufs03 -c mtv03  
#nas\_fs -n ufs04 -c mtv04 #nas\_fs -n ufs05 -c mtv05 #nas\_fs -n ufs06 -c mtv06  
#nas\_fs -n ufs07 -c mtv07
- V. **Create Files System Mount Points for DataMover:**  
#server\_mountpoint server\_2 -c /s2-mp01 #server\_mountpoint server\_2 -c /s2-mp02  
#server\_mountpoint server\_3 -c /s3-mp01 #server\_mountpoint server\_3 -c /s3-mp02
- VI. **Mount the File Systems:**  
#server\_mount server\_2 -p ufs01 /s2-mp01 #server\_mount server\_2 -p ufs02 /s2-mp02  
#server\_mount server\_3 -p ufs03 /s3-mp01 #server\_mount server\_3 -p ufs04 /s3-mp02
- VII. **Exporting File Systems:**  
#server\_export server\_2 -p -o anon=0 /s2-mp01 #server\_export server\_2 -p -o anon=0 /s2-mp02  
#server\_export server\_3 -p -o anon=0 /s3-mp01 #server\_export server\_3 -p -o anon=0 /s3-mp02
- VIII. **Mounting a FileSystem from a Remote Client System:**  
1. Create local mount\_point first or use /mnt for Solaris  
2. Mount remote FileSystem by IP: #mount -F nfs 193.1.21.173:/remotemntpt /mnt  
3. Mount remote FileSystem by Hostname: #mount -F nfs server\_2:/mountnew /mnt [requires /etc/hosts file on Server]

## **CREATING FILE SYSTEM FROM WEBUI USING AVM PROFILE:**

**nas\_fs -name cdms -type ufs -create size=50000M pool=clar\_r5\_performance storage=SINGLE worm=off -option slice=y,mover=server\_2** (NAS 5.4)

**Note:** Above output is from cmd\_log and shows how NAS 5.4 AVM creates file system using Storage Pools

## **CREATING FILE SYSTEM FROM CLI USING AVM PROFILE:**

**# nas\_fs -name migrate -create size=1000M pool=clar\_r5\_performance -o slice=y**

## **CREATING MULTIPLE FILE SYSTEMS VIA CLI:**

**# for i in \$(seq 1 20); do nas\_fs -name fs\$i -create size=10G pool=clar\_r5\_performance; done**

## **INTRODUCTION TO CIFS [Common Internet File System]:**

CIFS is a file sharing and network access protocol based on the Server Message Block (SMB) protocol, adopted by Microsoft to run on top of NetBIOS (Network Basic Input/Output System)--the building blocks upon which traditional Windows-based Microsoft Networks are built. NetBIOS served as a 'Session Layer API' that provided (3) basic functions for a Microsoft Network: 1) Name Service host resolution 2) Datagram Delivery Service using UDP 3) Session Service that established & maintained point-to-point connection-oriented NetBIOS sessions over TCP/IP between 'networked' computer systems.

Most recently, Microsoft has redesigned CIFS to be the native file sharing protocol for Windows 2000 and implements SMB directly over TCP/IP using Port 445 (traditional networks used SMB over NBT over TCP/IP using Port 139) and makes CIFS 'transport independent.'

## **CIFS/SMB SUPPORT:**

CIFS is implemented as a Client/Server request & response protocol that supports File Sharing Services, Messaging, File Locking, Security, Authentication, & Short/Long File Naming conventions using communication mechanisms related to File Sharing, API's, Named Pipes, & Mail Slot communications. Client systems issue SMB commands that are handled by the local 'redirector' to connect to 'remote systems' or resources using connection establishment messages. After authentication & security considerations, clients receive access to Shares for opening, reading, writing, and executing files. Other forms of messages between Client & Server are Mail Slots and Named Pipes [Mail Slots is a connectionless broadcast delivery service often used in Browsing services, while Named Pipes is a form of connection-oriented messaging via a virtual circuit or 'pipe', established between client & server, so that two applications or processes can communicate with each other. Data is passed as output from (1) host process to input on the other host].

Remote Procedure Calls (RPC) are the basic mechanism by which a Client computer can make a network request to use the processing capabilities of a Server--both Client/Servers use an End Point Mapper service to listen on Port 135 for TCP/IP connection

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
requests. Clients must then conduct an RPC-bind to an interface before it can begin making SMB or other types of procedure calls.

Celerra implements the CIFS file sharing protocol to allow network access for Windows-based Users--CIFS is implemented inside the Operating System kernel for better performance and is layered on top of DART (Data Access in Real Time).

**Comment:** Celerra supports “SMB Signing”, which is a form of host-based authentication [See Q161372], with NAS 5.2 +.

## **CELERRA CIFS SERVICE:**

The Celerra CIFS Service runs as an agent on DART. The ‘service’ uses the CIFS Protocol to provide for access to ‘network resources’ or ‘application processing’ in a Windows environment [other Protocols are NFS, FTP].

## **DOMAIN CONTROLLER DISCOVERY & SELECTION:**

1. Every 15 minutes, DM broadcasts on each enabled interface requesting a list of DCs for each Domain configured
2. Every 15 minutes, DM also sends request for list of DCs from each interface to WINS server, if configured.
3. Answer to above two actions is a list of IP Addresses
4. DM builds this list as \*SMBSERVER for each IP
5. DM then queries for name of each DC on list using NBTSTAT -A 192.10.3.2 or LDAP ping for Windows 2000 systems
6. For each answer, \*SMBSERVER is replaced by name and response time

### **Notes:**

--If all DC's on list become marked as unavailable, then Steps 1 & 2 are initiated

### **What Marks a DC as Unavailable?**

1. TCP connection cannot be established, or transmission fails
2. NETLOGON request cannot be established [IPC\$ pipe broken]

**Note:** DCs marked unavailable are not used until list is refreshed

## **WINDOWS 2000 DC DISCOVERY & SELECTION:**

1. DART queries DNS for list of all DC's in the domain using \_ldap.\_tcp.dc.\_msdcs.DOMAINNAME as the DNS Service Locator
2. DART then conducts CLDAP netlogon RPC Ping call to each DC, reviewing bit 0x80 in ADS\_CLOSEST field, choosing the DC with the best response time.
3. MS clients differ at this point and checks both the response time and the site name, then queries for \_ldap.\_tcp.SITENAME.\_sites.DOMAINNAME to select DC's, choosing best priority/weight.
4. DNS is queried again for list of Kerberos Servers to use, \_kerberos.\_tcp.SITENAME.\_sites.DOMAINNAME

**Note:** CLDAP is only used in AD to discover which Site a client belongs to, then using DNS to find the right DC to use. CLDAP uses LDAP over udp on Port 389. Used to query AD domain controllers. C:>nlttest /dsgetdc:domainname

## **CLIENT USER CONNECTS TO DATA MOVER:**

1. Upon client connection, DM uses first available DC in list to authenticate
2. DM uses quick UDP NETBIOS request for name of DC
3. If successful, then establishes IPC\$ named pipes connection to DC using NETLOGON Secure Channel service
4. Client is authenticated through this Secure Channel pipe [Failure to establish IPC\$ results in DC unavailable status]

## **NFS V. CIFS ENVIRONMENTS:**

NFS is to Unix what CIFS is to Windows. Celerra bridges the two worlds by providing for a multi-protocol interface to access a filesystem via either Network OS protocol.

## **PRIMARY DIFFERENCES BETWEEN NFS & CIFS:**

### **STATEFUL V. STATELESS:**

NFS is stateless-Error recovery is the responsibility of the Server--clients continue to query until a Server

CIFS is stateful-Error recovery is responsibility of applications and generally require restarting from Client

### **HOST V. USER-BASED AUTHENTICATION:**

NFS uses Host-based authentication-machine Hostname + UID/GID of User + NIS Netgroup or Password files

CIFS uses User-based authentication-User logs on providing valid Username/Password to PDC [Challenge & Response Authent.]

### **NFS V. CIFS PERMS FOR AUTHORIZATION TO NETWORK RESOURCES:**

NFS uses Unix file permissions [RWX-UGO] to determine file access or authorization

CIFS uses Extended file permissions [RWXPDO] & ACL's to determine level of file access or authorization

### **ADVISORY V. OPPORTUNISTIC LOCKS:**

NFS uses advisory locking mechanisms to handle file integrity

CIFS locks are mandatory & employ Opportunistic & Client caching mechanisms to support enhanced file access & performance

### **UNIX FILE NAMES V. CIFS:**

NFS supports use of Unix long names only

## **CIFS FILESYSTEM FEATURES:**

File access; File & Record locking; Safe caching read ahead & write behind; file change notification; Extended attributes; Server name resolution independence; Batched requests; Unicode file names

**File Access:** Open, close, read, write, seek

**File & Record Locking:** File & record locking, as well as unlocked access to files. Applications that lock cannot interfere with applications that do not lock.

**Safe caching, Read-Ahead/Write-Behind:** Caching & Read Ahead can be done by multiple clients to files while Write Operations have to be handled by the Server.

**File Change Notification:** Applications register with Server to be notified when File or Directory contents changed

**Extended Attributes:** Such as author's name, content description, etc

**Server Name Resolution:** Use of DNS, WINS, etc allowed

**Batch Operations:** Allows for multiple requests to be served in one message, improves efficiencies

## **CIFS/NFS AUTHORIZATION OR ACCESS:**

### **UNIX ACCESS PERMISSIONS:**

Access Classes [User, Group, Other] + Access Modes [read, write, execute] = Unix Authorization

Unix uses (3) bits each to define USER, GROUP, and OTHER “rwx” permissions [RWX→UGO]

Unix file permission sets contains Unix UIDs and GIDs

**User=Owner**

**Group=Groups**

**Other=all other users except root**

Read Permissions--list files only, in directories

Execute Permissions--utilize files that you can name

Read/Execute Permissions--list and utilize files

Read/Write/Execute Permissions--list files in directories, utilize files, create/delete files

### **CIFS ACCESS PERMISSIONS:**

CIFS access is based on ACLs

NT Access mask is more verbose than Unix [contains 32 bits v. 3 bits for Unix]--many bits are used to describe Directory SDs, etc  
User-Level ACL's [RWXPDO] + Share-Level ACL's = Authorization

SD's [Security Descriptors] describe Access Rights for Users on Files, Folders, or other Objects

SD's contain Access Control Lists [ACL's] which are constructed from Access Control Entries [ACE's] and typically contain SID's [Security Identifier Descriptors] for Users and Groups & their associated rights.

**Authorization** is granted or denied after comparing the Security Access Token [SAT] to an Object's SD [security descriptor] to determine permissions overall permissions to the object. A SD is made up of an ACL containing User and Group ACE entries.

**Authentication or User Access** is determined by a Security Access Token constructed for each User based on the User SID, Group SID, and Username/Password.

### **THREE TYPES OF PERMISSION SETS USED BY NT:**

**Share-level:** Permissions set on network shares → No Access; Read; Change; Full Control

**Directory-level:** NTFS permissions set on directories → No Access; List; Read; Add & Read; Change; Full Control; Special Directory and Special File Access [RWXDPO]

**File-level:** NTFS permissions set on files → No Access; Read; Change; Full Control; Special Access [RWXDPO]

## **CIFS/NFS AUTHENTICATION:**

### **UNIX AUTHENTICATION:**

**Host-based:** Trusted Hosts or machines authenticate to each other over the network

UID/GID is the basis for User authentication for NIS Netgroup and Password/Group files

### **NFS SECURITY:**

→For every NFS request by default (including mount requests), Unix operating systems traditionally deployed the RPC security mechanism called AUTH\_SYS, which contains a set of User credentials containing UID & a list of relevant GIDs. The Server in turn uses the presented credentials for permission/access-checking for Unix file access.

→Special use cases are Root User; Anonymous User; and Users with too many Groups

### **AUTH\_SYS sends 3 important things:**

→A 32 bit numeric user identifier (/etc/passwd file)

→A 32 bit primary numeric group identifier (/etc/passwd file associated with the UID)

→A variable length list of up to (16) 32-bit numeric supplemental group identifiers (/etc/group file)

## **CIFS AUTHENTICATION:**

### **User-based:**

CIFS Server → NETLOGON process to log into NT Domain as a member server using Secure Channel IPC\$ connection.

CIFS User → Attempts access to CIFS Share

CIFS Server → Obtains UID/GID Mapping of User from Password File or Usrmapper Service

CIFS Server → Interrogates DC for security permissions [SAT] of User

CIFS User → Granted access to filesystem

**Authentication** occurs when a User connects to a DataMover and the Datamover obtains the User's NT credentials from the Domain Controller—this consists of the Security Access Token—User's SID, Group ID & SIDs, and Access Rights.

**→ Authentication is the process of establishing one's identity whereas Authorization is the process of limiting actions taken to a managed object through use of permissions and Access Tokens.**

## **CIFS AUTHENTICATION V. CIFS ACCESS:**

**Authentication** is the process of successfully logging into the datamover and obtaining a Security Access Token, which has the User's SID, Group ID & SIDs, and Access Rights.

**Access** is when the Security Access Token [SAT] is compared to an Object's SD [security descriptor] to determine a User's access.

## **MICROSOFT AUTHENTICATION METHODS:**

**LM→LAN Manager** Challenge/Response—uses weak security and sends hash of user password for WinLogon (Win95 era).

Passwords are case insensitive, restricting number of characters for use, with long passwords divided into 7-char. chunks

**NTLM→NT LAN Manager or NTLMv1** Introduced with NT, uses LanMan hash of password—adds case sensitivity and removes password division problem that LM had, no signing or encryption available

**NTLMv2→NT LAN Manager version 2** Introduced with NT SP4, native to Win2k, added via DS Client to Win9x.

Increases password space key to 128bits; Establishes secure channel Signing and/or Encryption between Client & Server to conduct Challenge/Response; Uses encryption of messages. NTLMv2 is used for Session security and also for Authentication.

**Note:** Celerra only supports the password length used with NTLMv2 in that if a client uses such a password, Server can forward to DC for authentication. See AR44353 & 41591. Native NTLMv2 support provided in 5.3.18.0/5.4.16.0—see AR56266 and primus emc108209.

**MS-KRB→Microsoft Kerberos 5** Windows 2000/XP/2003

## **SMB SIGNING:**

NAS 5.1.18.8 can co-exist in Win2k3 environments (that use SMB Signing) with modifications outlined in emc77391—versions prior to this cannot. NAS 5.2+ provides native SMB Signing support. Win2k3 uses SMB Signing by default. See AR75020 to enable SMB signing in registry by default for when SMB Signing is not governed by GPO policy. See AR85147 for SMB Signing issue related to TCP reset on connections where Client was using SMB Signing, then failed to use, at which point Celerra conducted reset to TCP connection. AR85147 will disable SMB Signing as the default in the registry of the DM.

### **SMB SIGNING ISSUE NAS 5.5:**

AR75020 made Data Mover capable of using SMB Signing with 5.5.23.0 & 5.4.25.0 when GPO Policies are left undefined—this capability was extended in the DM registry. This AR introduced a regression whereby the Data Mover will disconnect a TCP session with the Client, if the client had been using SMB Signing, and then inexplicably began not using it. AR85147 disables the registry setting on the Data Mover so that in situations where GPO Policies for SMB Signing are not defined, clients will not be forced to use SMB Signing.

## **CHANGING SPECIFIC CIFS SERVER SYSTEM REGISTRY:**

**# .server\_config server\_2 -v "ntreg**

**find=system\currentcontrolset\services\lanmanserver\parameters\enablesecuritysignature set=0"**

**Note:** SMB Signing for Data Movers that rely on registry settings (for example where GPO Settings for SMB Signing are undefined) will now be disabled by default in the registry with NAS Versions 5.4.28.0 & 5.5.25.2. The Data Mover will still support and enforce SMB Signing whenever GPO Policies are defined.

## **VERIFYING CURRENT SMB SIGNING SETTING ON DM REGISTRY:**

**# .server\_config server\_2 -v "ntreg**

**find=SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters\enableSecuritySignature"**

1173795874: SMB: 3: FOUND:\System\CurrentControlSet\Services\LanmanServer\Parameters\EnableSecuritySignature=1 (**0x1**)

## **VIEWING GLOBAL DATA MOVER SMB SIGNING SETTINGS:**

**# server\_param server\_2 -facility cifs -info smbsigning**

server\_2 :

name = smbsigning

```

facility_name      = cifs
default_value     = 1
current_value     = 1
configured_value  =
user_action       = restart Service
change_effective  = restart Service
range             = (0,1)
description       = Controls SMB signing on the data mover

```

Used to enable or disable SMB signing "globally" on the Data Mover. param cifs smbsigning=1 enables SMB signing, and is the default setting param cifs smbsigning=0 disables SMB signing. Disabling this parameter will not work unless it is also disabled on the Windows 2003 clients.

#### **Symptoms of SMB Signing When Not Supported:**

Problems could be seen with Join issues that require SMB-signing of Kerberos tickets, Client connection failures, timeouts, hangs, or Password Challenge box.

#### **SMB SIGNING GPO:**

**To configure SMB message signing Windows Server 2003, Windows XP, and Windows 2000, use the following GPO options:**

#### **DEFAULT POLICIES WIN2K:**

|                                                     | <b>Local</b> | <b>Effective</b> |
|-----------------------------------------------------|--------------|------------------|
| Digitally sign server communication (when possible) | Disabled     | Enabled          |
| Digitally sign server communication (always)        | Disabled     | Disabled         |
| Digitally sign client communication (when possible) | Enabled      | Enabled          |
| Digitally sign client communication (always)        | Disabled     | Disabled         |

#### **Domain Security Policy**

|                                                     |             |
|-----------------------------------------------------|-------------|
| Digitally sign server communication (when possible) | Not defined |
| Digitally sign server communication (always)        | Not defined |
| Digitally sign client communication (when possible) | Not defined |
| Digitally sign client communication (always)        | Not defined |

#### **Domain Controller Security Policy**

|                                                     |             |
|-----------------------------------------------------|-------------|
| Digitally sign server communication (when possible) | Enabled     |
| Digitally sign server communication (always)        | Not defined |
| Digitally sign client communication (when possible) | Not defined |
| Digitally sign client communication (always)        | Not defined |

#### **DEFAULT POLICIES NATIVE WIN2K3:**

#### **Local Computer Policy**

|                                                                           |          |
|---------------------------------------------------------------------------|----------|
| Microsoft Network server: Digitally sign communication (if client agrees) | Enabled  |
| Microsoft Network server: Digitally sign communication (always)           | Enabled  |
| Microsoft Network client: Digitally sign communication (if server agrees) | Enabled  |
| Microsoft Network client: Digitally sign communication (always)           | Disabled |

#### **Domain Security Policy**

|                                                                           |             |
|---------------------------------------------------------------------------|-------------|
| Microsoft Network server: Digitally sign communication (if client agrees) | Not defined |
| Microsoft Network server: Digitally sign communication (always)           | Not defined |
| Microsoft Network client: Digitally sign communication (if server agrees) | Not defined |
| Microsoft Network client: Digitally sign communication (always)           | Not defined |

#### **Domain Controller Security Policy**

|                                                                           |                                     |
|---------------------------------------------------------------------------|-------------------------------------|
| Microsoft Network server: Digitally sign communication (if client agrees) | Enabled                             |
| Microsoft Network server: Digitally sign communication (always)           | Enabled [Not defined in mixed mode] |
| Microsoft Network client: Digitally sign communication (if server agrees) | Not defined                         |
| Microsoft Network client: Digitally sign communication (always)           | Not defined                         |

#### **SMB SIGNING TABLE FOR WINDOWS & DART:**

#### **WINDOWS O/S**

#### **W2kPro SP4**

```

LanmanWorkstation enableSecuritySignature=1
LanmanWorkstation requireSecuritySignature=0
LanmanServer enableSecuritySignature=0
LanmanServer requireSecuritySignature=0

```

#### **W2kServer SP4**

```

LanmanWorkstation enableSecuritySignature=1
LanmanWorkstation requireSecuritySignature=0

```

LanmanServer enableSecuritySignature=1

LanmanServer requireSecuritySignature=0

### **XPPro**

LanmanWorkstation enableSecuritySignature=1

LanmanWorkstation requireSecuritySignature=0

LanmanServer enableSecuritySignature=0

LanmanServer requireSecuritySignature=0

### **W2k3 Server**

LanmanWorkstation enableSecuritySignature=1

LanmanWorkstation requireSecuritySignature=0

LanmanServer enableSecuritySignature=1

LanmanServer requireSecuritySignature=1

### **Vista**

LanmanWorkstation enableSecuritySignature=1

LanmanWorkstation requireSecuritySignature=0

LanmanServer enableSecuritySignature=0

LanmanServer requireSecuritySignature=0

### **DART O/S**

#### **DART 5.5.23/5.4.25.1 Prior to AR85147**

LanmanWorkstation enableSecuritySignature=1

LanmanWorkstation requireSecuritySignature=0

LanmanServer enableSecuritySignature=1

LanmanServer requireSecuritySignature=0

#### **DART 5.5.27.5 after AR85147 Fix**

LanmanWorkstation enableSecuritySignature=1

LanmanWorkstation requireSecuritySignature=0

LanmanServer enableSecuritySignature=0

LanmanServer requireSecuritySignature=0

### **NTLMv2 AUTHENTICATION:**

MS04-011 Hot Fix changes default to use NTLMv2. Celerra Versions 5.1.24.0, 5.2.12.0, & 5.3.4.0 can provide NTLMv2 password response to DC's. Native NTLMv2 support provided in NAS 5.3.18.0 & NAS 5.4.16.0

#### **Symptoms of Enforced NTLMv2 (settings 3, 4, or 5):**

Session Setups to Data Mover will fail

#### **NTLMV2 REGISTRY SETTINGS:**

**HKLM>System>CurrentControlSet>Control>Lsa>LMCompatibilityLevel:** REG\_DWORD

0 – Default→Send LM & NTLM responses, do not use NTLMv2 Session Security

1 – Send LM & NTLM responses, use NTLMv2 if negotiated

2 – Send NTLM responses only

3 – Send NTLMv2 responses only

4 – Refuse LM responses, Send NTLMv2 response only

5 – Refuse LM & NTLM responses, Send NTLMv2 response only

### **STRONG LDAP SIGNING:**

Native support tentatively scheduled for NAS 5.5. In an effort to further bolster network security for Windows domains, Microsoft has introduced the ability to require LDAP Signing when performing LDAP Bind queries to AD Servers.

#### **Symptoms of Strong LDAP Signing:**

With LdapServerSecurity=2 set in the registry of each Domain Controller, LDAP Bind requests to AD will fail for any authentication mode that does not use SASL or TLS/SSL, which is what occurs when trying to conduct a Join.

#### **LDAPSERVERINTEGRITY REGISTRY SETTINGS:**

**HKLM>System>CurrentControlSet>Services>NTDS>Parameters** LDAPServerIntegrity=2 [Strong LDAP Signing or SASL required]

**LDAP BIND SETTINGS:** Values are as follows for LDAP server (ldapagnt.lib) handling of LDAP bind command requests

**LdapServerIntegrity=1** Default or not defined—LDAP Server supports client request for LDAP traffic signing when handling a LDAP bind command request which specifies a SASL authentication mechanism.

**LdapServerIntegrity=2** LDAP Server requires LDAP traffic signing, unless LDAP bind request is already protected with TLS/SSL. It rejects the LDAP bind command request if other types of authentication are used.

### **DATAMOVER NETLOGON PROCESS—NT 4.0:**

## **NT AUTHENTICATION & CELERRA:**

Through the NETLOGON SERVICE, whenever the Celerra CIFS Server is started, it logs into the NT Domain as a member server and communicates to the Domain Controller using an encrypted Secure Channel for account password authentication upon startup, and then thereafter for User Authentication. During the initial session setup by the Client User, as a request for resources located on the CIFS server, the CIFS Server processes the Challenge & Reply request from the Domain Controller to the User using NTLM 0.12 Challenge & Response. If successfully authenticated by Username & Password, the User obtains a Security Access Token [SAT] which contains their SID, UID/GID, and Access Rights. This SAT is then compared to each CIFS object's Security Descriptor [SD] to determine level of access.

**Note:** See emc108209 for Celerra NTLMv2 Session Security (Signing and Sealing) or Authentication, introduced in NT 4.0 SP4  
**Two-Part Process:**

Step 1. User's username & password are authenticated by Celerra against a Domain Controller via the Netlogon Service.

Step 2. User is mapped to a valid UID/GID from a Password/Group file, NIS, or Usermapper database.

## **USER AUTHENTICATION PROCESS & THE DATA MOVER:**

--User authentication is mostly a single threaded operation on the DM, meaning that if there is a queue of 100 requests, each one is serviced in a linear fashion

--Invalid Users should normally be rejected immediately so as to not delay other requests

--However, in the case of Trusted Domains, if a User is trying to authenticate but the trusted DC is not available, originating DC will continue to probe until the 15 second Windows timeout value.

--Data Mover's timeout value is 20 seconds

## **PARAMETER TO SWITCH DC WITH ‘NO LOGON SERVER’ ERROR:**

**param cifs Ntsec.SwitchDC\_OnNoLogonServer=1**

**Note:** 5.1.18.5, 4.2.21.0 disables DC switching with default value of 1. Set 0 to enable switching of DC's with NoLogon Error. This param is no longer in 5.5 code.

## **WINDOWS NT TERMINOLOGY:**

### **SIDs**

SIDs are unique values that are used to identify a “trustee”. A ‘trustee’ is a User, Group, or Logon Session to which an ACE applies. Each ACE in an ACL has one SID associated with a ‘trustee’. Well-known SIDs identify generic Groups and Users.

### **Well-Known Sid Types:**

SID: S-1-1-0

Name: Everyone

Description: A group that includes all users, even anonymous users and guests. Membership is controlled by the operating system.

SID: S-1-5-domain-512

Name: Domain Admins

Description: A global group whose members are authorized to administer the domain. By default, the Domain Admins group is a member of the Administrators group on all computers that have joined a domain, including the domain controllers. Domain Admins is the default owner of any object that is created by any member of the group.

SID: S-1-5-domain-513

Name: Domain Users

Description: A global group that, by default, includes all user accounts in a domain. When you create a user account in a domain, it is added to this group by default.

SID: S-1-5-domain-514

Name: Domain Guests

Description: A global group that, by default, has only one member, the domain's built-in Guest account.

SID: S-1-5-11

Name: Authenticated Users

Description: A group that includes all users whose identities were authenticated when they logged on. Membership is controlled by the operating system.

**Note:** Above listing are examples only, list is very long. Current Celerra code [5.2.11.301 and lower] does not support the ability to add Well-Known Sid types to the LocalGroups database.

### **SUMMARY OF ISSUE FROM CELERRA PERSPECTIVE:**

In the process of obtaining SID information from the DC when a User connects to the Celerra, we also parse the localgroups file to see if the user belongs to any localgroups. Unfortunately, the current mechanism for retrieving SID information from the DC does not return the Everyone and other 'Well-known Sid' types such as 'Authenticated User'.

### **Access Control List (ACLs)**

An Access Control List is a table of entries (ACEs) for Objects that contain a Security Descriptor, such as files or directories, that further defines access rights for Users or Groups. Collectively, each User or Groups' Access Control Entry creates the ACL Table.

### Access Control Entries (ACEs)

Access Control Entries contain a set of access rights & SID (Security Identifier) for a User or Group to whom the rights are allowed, denied, or audited. An ACE is an entry in the ACL Table for each “trustee” (User, Group, SID, domain\trustee). Windows 2000 adds object-specified ACE’s and Automatic Inheritance. ACEs contain trustees, 32-bit access masks, ACE type (deny, audit), inheritance flag. Three types of ACEs are: Deny, Grant, and Audit

#### ACE Directory Inherit Flag (0x2)

Directory and all inherited sub-directories

#### ACE Files Inherit Flag (0x9)

Only inherited files

#### ACE Taking Ownership of Directory (0x3)

Inherit on files and directories

#### ACE FIELDS WITHIN SD:

ace\_type;ace\_flags;rights;object\_guid;inherit\_object\_guid;account\_sid

#### Security Descriptor (SDs)

Security Descriptors are the basic security information and structure for a “securable object”. The SD further identifies an Object’s Owner and Primary Group. An Object can also have a DACL (Discretionary Access Control List) and SACL (System Access Control List) associated with it to control access to the Object and control security auditing, respectively. The structure of an SD includes: SIDs of Owner & Primary Group; DACL that specifies Access Rights allowed or denied to Users or Groups; SACL that specifies access events that generate audit records; set of control bits that qualify the meaning of SD. The SDDL (Security Descriptor Description Language) uses ACE strings in the DACL or SACL components of a Security Descriptor string.

#### FOUR MAIN COMPONENTS OF THE SECURITY DESCRIPTOR:

O:owner\_sid → SID string identifying Object owner

G:group\_sid → SID string identifying Object’s Primary Group

D:dACL\_flags(string\_ace1)(string\_ace2)... (string\_acen) → Control flags for DACL and ACE strings

S:SACL\_flags(string\_ace1)(string\_ace2)... (string\_acen) → Control flags for SACL and ACE strings

#### SID STRINGS USED IN THE SD:

Owner

Primary group

The trustee in an ACE

#### SD BUFFER SIZE ISSUE: fixed NAS 4.2.13.3

**getMaxSmbSize:** Param to increase buffer size when reading SD’s from files created on other NetBIOS servers

#### DACL

Discretionary Access Control List controls access to an Object and is determined by the Object’s Owner

#### SACL

System Access Control List controls auditing for security of an Object and is determined by the Administrator

#### SECURITY ACCESS TOKENS (SATs)

Security Access Tokens are created & updated for a User each time they log onto an NT Domain. This Token identifies the User, their Groups, and privileges to resources and processes on the domain. The Operating System uses this Token to allow or deny access to resources or processes.

#### Access Rights

Access Rights are bit flags for operations that a thread can perform on a securable object (i.e., an object with an SD)

#### Access Masks Encoding

ACCESS\_MASKs are 32-bit values containing 'standard', 'specific', & 'generic' rights used to build ACE’s [Access Control Entries] on objects. This is the primary means for granting access to objects in Windows NT. Access Masks specify allowed or denied Access Rights controlled by ACEs. In addition, access masks are grouped into a number of categories:

#### Generic Access Rights

GENERIC\_ALL is used to indicate Read, Write, & Execute access

GENERIC\_EXECUTE is used to indicate Execute access

GENERIC\_READ indicates read access

GENERIC\_WRITE indicates Write Access

#### Standard Access Rights

DELETE is used to delete an object

READ\_CONTROL is the right to read an object’s SD information

SYNCHRONIZE allows the object to use synchronization and allows threads to wait for the correct state

WRITE\_DAC is the right to modify DACL in the SD of the object

WRITE\_OWNER is the right to change the owner in the SD of the object

#### SACL Access Rights

Used to get or set the SACL in an object’s SD

#### Directory Services Access Rights

Various AD object SD’s, as follows: ACTRL\_DS\_OPEN, ACTRL\_DS\_CREATE\_CHILD, ACTRL\_DS\_DELETE\_CHILD,

#### Access Mask Table:

Access Masks represent Windows permissions built with one or more bits as 32-bit values. Processes that request access to objects also present an Access Mask for the access that is requested. The O/S compares the access mask to the masks contained in the ACE entries, looking for bits that match.

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

#### Notes:

Bits 0-15 are considered low-order bits used for object specific access rights

Bits 16-22 are the bits used to define Standard Access Rights

Bit 23 is for the right to access an objects' SACL—Audit Access privilege

Bits 24-27 are reserved

Bits 28-31 are used to define Generic\_All, Generic\_Execute, Generic\_Write,& Generic\_Read, respectively, and are considered the high-order bits.

## **CIFS FILE NAME TYPES:**

**M83 → DOS 8.3 format consists of two parts:** Basename of up to (8) characters; Extension of up to (3) characters

Basename & Extension are separated by a 'period'.

All characters are legal in 8.3 format except for the following: space character "0x20" " . / \ [ ]: + | < > = ; , \* ?

**M256 → Long File Names:** Supports up to 255 Characters; indicated by setting bit2 in Flags2 field of SMB Header

Wildcards: SMB allows use of wildcards for both 8.3 Naming and Long File Naming

#### DOS 8.3 Wildcards: \* ? .

\* matches 0 or more characters until reaching the . in the name

? matches any single character, or until encounters a . in the name string. Can use multiple ??z for searches.

. matches a . or an empty extension string

#### Long File Name Wildcards:

Files may now have none, one, or more than one . within the name. 'Spaces' within file names are also allowed.

? matches single characters; can use multiple ??

\* matches entire name

## **ENFORCING STRICT/LOOSE WILDCARD MATCHING:**

**param cifs ntWildcardMode=0** e:\celshare>dir ?????? [Strict wildcard matching, only filenames with six characters are returned; Win9x style]

**param cifs ntWildcardMode=1** [Loose Wildcard matching; all filenames with six characters or less would be returned; NT]

## **CELLERRA FILE LOCKING POLICIES:**

Most Operating Systems prevent "concurrent" writes to a single file from more than one process at a time. This is called the DOS & NT "deny-mode".

**CIFS Clients:** CIFS Locks--'nolock' is the default; 'wlock', 'rwlock' [multi-protocol modes]

Lock requests are made, locks respected. I/O request made, ONLY CIFS locks respected.

CIFS Mandatory Locks--byte-

**UNIX Clients:** NFS Locks--Read, Exclusive Write Locks, & Advisory Locks

Lock requests are made, locks respected. I/O request made, (3) possible options:

Server allows client lock until another lock request is served, then updates changes before allowing other client lock.

NFS Locks considered 'cooperative', as they allow other clients to access locked files, as long as 2<sup>nd</sup> client does not try to lock file

Advisory Locks inform other Clients that a file is in use, and does not affect Read or Write access

Exclusive Locks can still be Read, but no other client can lock the file again

Read Locks can be taken out by multiple clients or processes

## **HOW CELERRA USES CIFS LOCKING MECHANISMS:**

**Note:** Byte Range and Sharing Locks are usually handled by "applications", whereas "Oplocks" in general are handled by the Client's Operating System, though they are still generally initiated as a result of Client Applications. For interoperability between NFS & CIFS File Locking, the basic rule is that: NFS Locks are Advisory & CIFS locks are mandatory.

Locking policies are Implemented during the "Mounting" of a CIFS File System using "server\_mount".

**File Locking Defaults:** "nolock", "oplocks"on, "notify" on.

**File Locking Options:** "wlock", cifs "rwlock", "nooplocks", "nonotify"

#### NFS Locks:

CIFS clients respect only CIFS locks—ignores NFS locks

Nolock→default where NFS locks are advisory & NFS client can Read & Write to a file

Wlock→NFS reads allowed, but no writes

Rwlock→NFS writes denied, read denied for read locks

“Deny Read-Write” mode request is translated into an NFS exclusive RW lock

### **Celerra Opportunistic Locks (Level I):**

Clients request oplocks in the NT\_CREATE\_ANDX or NT\_TRANSACT\_CREATE when opening a file. If the Server grants as OplockLevel or 1, Client holds a Level II Oplock and caches portion of file locally, with changes flushed to Server only after work completed or if Oplock is revoked. "Oplocks" allows Server to revoke a lock at any time, while allowing Client the opportunity to cache file data safely, and to acknowledge the oplock break request.

**Note:** Celerra does not support Level II Oplocks in NAS 5.x or below. Level I Oplocks supported NAS 4.2.14 +

### **CIFS OPPORTUNISTIC FILE LOCKING:** Client always requests, but Server always controls & grants or doesn't **EXCLUSIVE OPLOCKS:**

Client that requests an 'oplock' will receive either an Exclusive, Level II, or No Oplock grant from Server. The Client process that holds an 'exclusive oplock' is only process that has file open--this allows for safe data read & write caching, metadata caching, and record lock caching. Clients specify a lock by Length and Offset values within a file. Server will revoke this type of lock if other clients request access to same file. Client writes cached data back to Server prior to other Clients accessing file.

→Server informs client of exclusive oplock until client file is closed, at which time server is updated

### **BATCH OPLOCKS:**

Client requesting a 'batch' oplock will receive a Batch, Level II, or No Oplock from Server. Purpose of this type of oplock is to allow Clients to keep a file open that otherwise is opened and closed repeatedly by an Application. Revoked by server as above.

→Same function as Exclusive Oplock except that it will allow the Client to repeatedly Open & Close the file

### **LEVEL II OPLOCKS:**

Clients never request this, but Server may grant in response to an 'Exclusive' or 'Batch' Oplock request. This type of Oplock allows Client to cache 'read' data while files are opened on other Clients. Server revokes without waiting for response.

→Server informs client that multiple clients are accessing a file, but no modifications have been made. Client can perform Read-ahead or cached read or file attribute operations without server updates.

**Note:** Celerra supports Level II Oplocks at NAS 5.1.15.3 and higher. Default Oplocks timeout value is 10 seconds. CIFS Oplocks are always on by default, and configured on a per-filesystem basis. Oplock file changes remain local to Client system cache.

**No Oplock:** Client will always receive a "nooplock" if requested. “No Oplock” turns off Oplocks. For example, you might turn off OPLOCKS for CIFS File Systems using IIS or Database Applications such as SQL, Oracle, ClearCase, Access & MPFS file systems

**Note:** Oplocks only support "files", not "directories" or "named pipes"

### **ENSURING SYNCHRONOUS WRITES FOR DATABASES:**

**Note:** Set mountpoint option per following example—option is actually relevant for both CIFS and NFS file systems. Option was introduced to guarantee synchronous writes to critical databases.

**\$server\_mount server\_5 -o cifssyncwrite fs1 /fs1**

### **CHANGING MAX TIMEOUT VALUE FOR CIFS LOCKX REQUESTS:**

Default time that CIFS will process an incoming lockX request—idea here is to avoid locking all CIFS threads in infinite lockX requests: **param cifs maxLockXTimeout=30000** (30 seconds default)

### **HOW OPLOCKS ARE HANDLED BY AN NT SERVER:**

--Client (1) holds oplock on file

--Client (2) requests 'open' to same file

--Server revokes oplock of Client (1)

--Client (1) flushes data to Server & acknowledges revocation of oplock

--Server then responds to the open request for the file for Client (2)

**Note:** **Oplocks are a function of Client's O/S & clients always initiate request**

**OplockLevel 0:** Client has no oplocks on file

**Oplock Level 1:** Client has Level II oplock [Not supported by Celerra 5.x or below]

### **NFS LOCKING--NLM MANAGER:**

→NFS uses Network Lock Manager [NLM] for file locking by running a Lock Daemon [lockd] on each DataMover

→CIFS also uses a Lock Manager daemon

→File Locks are configured on a FileSystem basis

NLMv1: Unix style file locking

NLMv3: MS-DOS style file locking for NFS v2

NLMv4: Support for large files greater than 4GB [NFS v3]

### **NFS LOCKING\RECOVERY:**

Server reboots, clients reclaim locks via statd/NLM after Server checks against its /var/statmon/sm directory

Server keeps track of client locks using statd daemon

Celerra DataMover writes locking info its root FS; ./etc/registry/Dmhostname

If DataMover has multiple host names, add following to **/nas/server/slot\_x/param** file; “param statd” “hostname=”name1, name2”

Locking is done from Server using Datamover Host name, NOT IP address!!

### **NLM ADVISORY & COOPERATIVE NFS LOCKING:**

→ NFSv2 and NFSv3 use cooperative locking rules (aka, advisory locks), which means that multiple clients can access the same files for Reads and Writes, with clients being notified that file is in use

→ NFSv4 incorporates functionality of NLM within the protocol, and provides mandatory locking, which means client applications can be blocked if another client has the file locked

### **NLM SHARE RESERVATIONS WITH NFS:**

→ Share reservations grant a process Read and/or Write access to a file and ability to deny other processes access to the same file, hence ‘reserving’ the use of the file

→ NLM provides ‘Advisory Share Reservations’ for NFSv2 & v3 and does not prevent access

→ NFSv4 provides ‘Mandatory Share Reservations’ with OPEN operation, and reservations are enforced for file access

### **NLM RANGE LOCKING:**

→ A range lock is a range of bytes in a file, or entire file, that can have “Shared” read locks or “Exclusive” write locks—if an exclusive range lock is taken, no other process can access any range in the file until the exclusive lock is removed. Read and Exclusive locks can be changed back and forth.

### **NFSv4 LEASE LOCKING:**

→ NFSv2 & v3 grants locks by the Server until the Client releases, even if the Client crashes or goes away

→ NFSv4 implements locks for a duration period that need to be renewed by the client. If the Client fails, after the lease expires and a grace period expires, then the file is available for other clients.

### **NFSv4 DELEGATION:**

→ NFSv4 Servers can delegate actions on the client to buffer file data and metadata locally to do work before sending updates to the Server, which improves network performance

→ Delegation is configured on a file system basis with RW delegation as the default

**Note:** Turn off delegation if data is frequently shared between clients, or in the cases of databases or mission-critical data where a client failure could impact data integrity

→ Celerra supports No Delegation; Read Delegation only; Read & Write Delegation

## **SETTING UP FILE LOCKING ON CELERRA FILE SYSTEMS:**

**# server\_mount server\_2 -o noblock [nolock|wlock|rwlock]**

**Note:** Disabling noblock disables CIFS locks

### **I. NoLock-Default Mode**

NFS clients ignore CIFS locks-i.e., NFS Reads-Writes can occur unhindered

- a. When accessing via NFS or FTP, clients can Read and Write to files ‘locked’ by CIFS!
- b. When accessing via CIFS, only CIFS locks are honored.
- c. NFS or CIFS client can request to “lock” a file.
- d. Neither NFS or CIFS client can “lock” a file already locked...

### **II. Wlock-NFS Reads allowed, Writes Denied**

- a. When accessing via NFS or FTP, Client can READ but not WRITE to a file locked by CIFS.
- b. When accessing via CIFS, only CIFS locks are honored.
- c. NFS or CIFS client can request to “lock” a file.
- d. Neither NFS or CIFS client can “lock” a file already locked...

### **III. RWLock-NFS Reads & Writes denied if file locked by CIFS [safest method]**

- a. NFS or CIFS client can request to “lock” a file.
- b. Neither NFS or CIFS client can “lock” a file already locked...
- c. When accessing via CIFS, only CIFS locks are honored.
- d. When accessing via NFS or FTP, if locked, will deny all access to the file.

## **INVESTIGATING LOSS OF NFS ACCESS:**

**Symptom:** Server Log error ‘LOCK:3: lockd\_Monitor: unable to contact local Statd daemon...’

Checking Lockd Stats on Advisory, Mandatory Range, Oblocks, Break Oblocks:

**# .server\_config server\_2 -v "lockd"**

lockd stat [reset]

lockd list

```
lockd info fldp=<address>
lockd info delegp={<address>} 10
lockd remove fldp=<address>
  {type=NFS ip=<addr> pid=<pid>}
  | {type=PCNFS ip=<addr>}
  | {type=CIFS cnxp=<ptr> fid=<fid>}
```

### \$server\_config server\_2 -v 16384 "lockd stat"

```
Lockd statistics since 00:45:08 12/12/2005:
Advisory range locks Granted Blocked Denied
Shared:      22929    0    0
Exclusive:   127737614  97190   517
-----output abridged-----
```

### \$server\_config server\_2 -v 16384 "lockd list"

```
FileSystem: ufs rw /cel9dm2fs1 142=33 rw
  inum=2 NtName(utf8)=cel9dm2fs1
  fldp=0x13de80dc Opens_cnt=1 RangeLocks: Mandatory_cnt=0 Advisory_cnt=0
  inum=9428 NtName(utf8)=COLMAN
```

```
$ .server_config server_2 -v "logsys set severity LOCK=LOG_DEBUG"
```

### DISABLING OPLOCKS AND FILE CACHING ON WINDOWS CLIENTS:

HKLM>System>CurrentControlSet>Services>MRXSmb>Parameters

OplocksDisabled=1 (REG\_DWORD)

NoDeleteOnClose=1 (REG\_DWORD)

### TRADITIONAL NFS LOCKING MECHANISMS:

```
Client 1 → NLM_LOCK_MSG request → NFS Server
Client 1 ← NLM_LOCK_RES granted ← NFS Server
Client 2 → NLM_LOCK_MSG request → NFS Server
Client 2 ← NLM_LOCK_RES blocked ← NFS Server [because Client 1 already has file locked]
Client 1 → NLM_UNLOCK_MSG → NFS Server
Client 1 ← NLM_UNLOCK_RES granted ← NFS Server
Client 2 ← NLM_GRANTED_MSG ← NFS Server
Client 2 → NLM_GRANT_RES accepted → NFS Server
```

### TRANSLATING CIFS TO NFS AND NFS TO CIFS LOCKS:

--CIFS deny RW lock translates into an NFS exclusive RW lock

--NFS shared Read lock translates into a CIFS deny Write lock

### CIFS FILE SYSTEM ACCESSPOLICIES: [Policies apply only if NT Security is set]

Purpose: Accesspolicies are used in ‘multi-protocol’ environments to control Unix access permission bits and Microsoft ACL rights access for files and folders. When referring to accesspolicies, we are referring to “access-checking” based on UNIX or CIFS credentials, or both. Actual access is controlled by “user authorization” on the Server.

UGO—UNIX mode bits, rwxrwxrwx

ACL—Access Control List, contains list of ACEs for file system object

ACE—Access Control Entry

### ACCESSPOLICY OPTIONS:

→**Accesspolicy=NT|UNIX|SECURE|NATIVE|MIXED|MIXED\_COMPAT**

→Implemented on File System basis using server\_mount command

Note: Accesspolicy syntax is case-sensitive with NAS 5.2 and below—use all caps for these earlier NAS versions and also for all versions after 5.5. Accesspolicies can be changed on-the-fly by running the server\_mount command with the revised accesspolicy.

### Server Log:

```
2009-07-08 15:35:22: ADMIN: 6: Command succeeded: serverMount ufs rw /cifs1 122=32 rw accesspolicy=MIXED_COMPAT hwm=90 maxsize=0 (modifyMount)
```

```
2009-07-08 15:35:47: ADMIN: 6: Command succeeded: serverMount ufs rw /cifs1 122=32 rw accesspolicy=NATIVE hwm=90 maxsize=0 (modifyMount)
```

### EXAMPLE:

```
# server_mount server_2 -p -o accesspolicy=MIXED_COMPAT cifs1 /cifs1
```

### **ACCESSPOLICY=NATIVE (Default Policy for Celerra):**

- Access to files or directories via NFS/FTP is granted if UNIX permissions allow access
- Access to files or directories via CIFS is granted if Windows permissions on the object allows access
- ACLs and UNIX permissions are maintained on all files & folders
- File object permission changes from NFS do not affect CIFS permissions or access, and permission changes from CIFS does not affect UNIX permissions or access (each protocol is completely independent of the other)
- Users are only checked for access against the protocol being used to access the Celerra

### **ACCESSPOLICY=NT:**

**Note:** Windows access rights are controlled for each network object by Security Descriptors, which contain information about the object's owner & primary group, and also the Access Control List DACL (Discretionary ACL) & SACL. Each Access Control Entry (ACE) defines an access right for a User or Group specified in the ACL list.

- Access to files or directories via NFS/FTP is granted if both UNIX & CIFS permissions allow access
- Access to files or directories via CIFS is granted if Windows permissions on the object allows access (Unix perms are not checked)
- ACLs and UNIX permissions are maintained on all files & folders
- File object permission changes from NFS do not affect CIFS permissions or access, and permission changes from CIFS does not affect UNIX permissions or access (each protocol is completely independent of the other)
- Only UNIX users are checked against both NFS & CIFS protocols when accessing file system objects on the Celerra

### **ACCESSPOLICY=UNIX:**

**Note:** UNIX access rights are referred to as mode bits that define access for every file system object. These 'mode bits' are represented by bit strings that represent access mode/privilege granted to each User-owner, Group, Other users (rwx triplet)

- Access to files or directories via NFS/FTP is granted if UNIX permissions allow access (CIFS perms are not checked)
- Access to files or directories via CIFS is granted only if both NFS & Windows permissions on the object allows access
- ACLs and UNIX permissions are maintained on all files & folders
- File object permission changes from NFS do not affect CIFS permissions or access, and permission changes from CIFS does not affect UNIX permissions or access (each protocol is completely independent of the other)
- Only CIFS users are checked against both NFS & CIFS protocols when accessing file system objects on the Celerra

### **ACCESSPOLICY=SECURE:**

- Access to files or directories via NFS/FTP or CIFS is granted only if UNIX & CIFS permissions allow access
- ACLs and UNIX permissions are maintained on all files & folders
- File object permission changes from NFS do not affect CIFS permissions or access, and permission changes from CIFS does not affect UNIX permissions or access (each protocol is completely independent of the other)
- Both CIFS & NFS users are checked against CIFS & NFS protocols before access to files is granted
- Highest level of access security

### **CIFS & UNIX INHERITANCE RULES FOR NT, UNIX, NATIVE, SECURE:**

- When CIFS client creates file, the ACL is inherited from the directory (if there is one)
- When CIFS client creates file, Unix permissions are determined by umask of Share from server\_export
- When NFS client creates file, ACL is inherited from the directory (if there is one)
- When NFS client creates file, UNIX permissions are determined by User's umask

**Note:** Umask octal value 644 for files, 755 for directories. Celerra default umask 022 (full access to User/Owner, Read & directory search to Group & Others)

### **ACCESSPOLICY =MIXED (NAS 5.4):**

- \* Access to a file or directory through either NFS/FTP or CIFS is always determined by the ACL.
- \* Both Windows ACLs and UNIX mode bit permissions are maintained for every file and directory.
- \* ACLs for files or directories are created based on the NFS or CIFS protocol that last changed or set the permissions (i.e., if NFS client changes or sets perms on file/folder, the ACL is rebuilt based on UNIX mode bits. If CIFS client changes or sets perms on file/folder, the ACL is built based on normal Windows perms).
- \* In all cases, the ACL is used to control file or directory access regardless of whether the Client is using the NFS or CIFS protocols.
- \* ACL permissions are more granular than UNIX mode bits, consequently not all permissions set in an ACL can be translated to UNIX mode bits. In some cases the mode bits may show more permissions than a user actually has.
- \* Celerra uses default CIFS User's Windows Group as the Unix primary group when assigning group attributes to created objects

### **MIXED ACCESSPOLICY TRANSLATION OF UNIX MODE BITS INTO ACLS:**

- (3) ACL entries are created based on the UNIX mode bits of Owner, Group, Other: File Owner, Group, Everyone
- Delete/Change permissions & Take Ownership are set for the Owner but not for Everyone or other Groups

### **MIXED ACCESSPOLICY TRANSLATION OF ACLS INTO UNIX MODE BITS:**

- Windows ACL Deny option is not translated, but the Allow ACL option is (same for both MIXED & MIXED\_COMPAT)
- UNIX Owner mode bits are built from Owner entry, the ACE of the file/directory Owner, and the Everyone Group ACE
- UNIX Group mode bits are built from Group entry, the ACE of the primary group Owner, and the Everyone Group ACE
- UNIX Other mode bits are built from Other ACE, all ACE's different from User/Group, and the Owner/Group ACE

## **CIFS & UNIX INHERITANCE RULES FOR MIXED & MIXED COMPAT ACCESSPOLICY:**

- When CIFS client creates file, if inheritance flag is set, and object's parent has an ACL, the file object will inherit the ACL, and UNIX Mode bit permissions will be created based on the ACL translation.
- When CIFS client creates file, and the parent directory does not have an ACL, then Unix permissions are set according to umask values—644 Octal for Files and 755 Octal for directories
- When NFS client creates file, Unix mode bits are based on umask value and ACLs are created based on the Unix mode bit translation

## **ACCESSPOLICY =MIXED COMPAT (NAS 5.4):**

- \* Access to a file or directory through NFS/FTP/CIFS is determined by which protocol (NFS or CIFS) last set the permissions
- \* Both Windows ACLs and UNIX mode bit permissions are maintained for every file and directory.
- \* If a file or directory object had its permissions set from a CIFS client then access is determined by the ACL (aka, EXPLICIT ACL).
- \* If a file or directory object had its permissions set from a Unix client then UNIX mode bits dictate access (An ACL is still created but is not used for access checking).

**Note:** In otherwords, the last protocol that has changed or set permissions on a file or folder is the protocol that is used to govern access-checking of the object

\* ACL permissions are more granular than UNIX mode bits, consequently not all permissions set in an ACL can be translated to UNIX mode bits. In some cases the mode bits may show more permissions than a user actually has.

## **NFS ACCESS RIGHTS FOR MIXED COMPAT DEPENDS ON WHETHER DIRECTORY PERMS WERE SET BY UNIX OR CIFS:**

If Directory Set with UNIX Mode bits

If File Set with EXPLICIT Windows ACL

Then NFS User will ignore file ACL and exercise access rights based on UNIX directory Mode bits

---

If Directory Set with EXPLICIT Windows ACLs

If File Set with UNIX Mode bits

Then NFS User would be checked for access rights based on Windows directory ACL

## **MIXED COMPAT ACCESSPOLICY TRANSLATION OF ACLS INTO UNIX MODE BITS:**

- Windows ACL Deny option is not translated, but the Allow ACL option is (same for both MIXED & MIXED\_COMPAT)
- Builds None, Owner, and granted ACEs into Group and Other UNIX mode bits (different than MIXED policy)

## **MIXED COMPAT ACCESSPOLICY TRANSLATION OF UNIX MODE BITS INTO ACLS:**

→ Only two entries are created in the ACL: Owner & Everyone (MIXED policy builds (3) entries in ACL)

→ An Everyone Group ACE is created from Group mode bits, since other groups are not translated with this policy

→ The Other mode bits are ignored and not used when building the ACL

→ Delete/Change permissions and Take Ownership are set for the File Owner but not for the Everyone group

**Note:** Accesspolicies can be changed on-the-fly by issuing the server\_mount command. For example, if accesspolicy was unix, issue command to change to native and the effects are immediate—no further action required.

## **CELLERRA ACL/PERMISSION CHECKING BEHAVIOR:**

### **USING CHECKACL PARAM TO ENFORCE UNIX PERMISSIONS:**

#### **param cifs acl.checkacl=0**

**Note:** In this mode, only Unix permissions are checked—NT ACL's or SIDs are not checked. This bit is set to 0 by default whenever CIFS is stopped.

#### **param cifs acl.checkacl=1**

**Note:** Both Unix and Windows ACLs are checked. Default value for Celerra. Bit is set to 1 whenever CIFS is started.

### **FILE CREATION:**

→ When NFS client creates file or folder, ACLs are inherited from directory (if there are ACLs), UNIX permissions are determined by User's UMASK

→ When CIFS client creates file or folder, ACLs are inherited from directory and UNI permissions are determined by UMASK value on CIFS share

## **CELLERRA SECURITY MODES:**

Change Security mode on DM using “server\_cifs -a security=”. Default is “**security=nt**” when the CIFS service is started.

### **(3) CELERRA SECURITY MODES:**

**security=nt:** Default mode supports ACL's & Domain Controller Authentication. Requires /etc/passwd, NIS service, or Usrmapper/NTMigrate service to map Unix UID's & GID's to DataMover CIFS “Shares”

**security=unix:** Requires clear-text passwords. CIFS usernames checked against Datamover's “/etc/passwd” file or by NIS service AccessPolicies and NT Domain Controller Authentication do not apply to this mode!!

**security=share:** Read-Write or Read-Only access passwords on shares

**Changing CIFS Security Mode:** Changing from NT Security to Unix Security

1. Stop CIFS Service: \$server\_setup server\_3 -P cifs -o stop
2. Change Security Mode: \$server\_cifs server\_3 -a security=unix
3. Start CIFS Service: \$server\_setup server\_3 -P cifs -o start
4. Verify CIFS: \$server\_cifs server\_3 [Should see “Security Mode = UNIX” listed in output]

**Note:** If CIFS is stopped when you reboot a DataMover, it does not restart automatically. Must restart manually!

## **TYPICAL CIFS CLIENT--SERVER SMB TRAFFIC:**

### **SMB COM NEGOTIATE:**

Client sends message to Server with Dialects it supports

### **SMB COM SESSION SETUP ANDX:**

Client sends Username & credentials to server for verification

### **SMB COM TREE CONNECT ANDX:**

Sends name of disk export share to access.

### **SMB COM OPEN ANDX:**

Name of file to open

### **SMB COM READ:**

Client supplies TID, FID, file offset, and number of bytes to read to the Server—Server responds with the data

### **SMB COM CLOSE:**

Client closes file

### **SMB COM TREE DISCONNECT:** Client disconnects from network resource TID.

**TRANS2 DFS GET REFERRAL:** For DFS Shares, Server will send a referral list of Server & Shares to try for access

**Note:** ANDX client commands can chain multiple I/O commands together in a single request. TRANSACTION & TRANSACTION2 commands support large data transfers (>than 64kb).

### **TRANSACTION/TRANSACTION2:**

**Transaction:** Used as transport for older protocols such as Netlogon, Browsers, etc.

**Transaction2:** Used as transport for DCERPC interfaces such as LSA, SAMR, etc.

**NT Transaction:** Handles Audit info, Quotas, etc. [Not used for large calls]

These functions are used for large CIFS requests, capable of supplying more than 64kb data. Sub-functions of these commands are: Create directory; Find first2; Find next2; Get DFS referral; Query FS infor; Query Path info; Report DFS inconsistency; Set file info; Set path info

**Note:** Find subfunctions do folder searches; Set file info sets ACLs. Broken or orphaned ACLs make these functions take longer

**SMB TRAFFIC:** Clients exchange messages with servers in CIFS environments using Server Message Blocks (SMB)

Tid Field: Represents an authenticated connection to a server for a client 'instance'

Pid Field: Unique identifier for the Client's process id with the Server for the current session

Uid Field: Server assigned number for the Client during the session

**Note:** After authenticating a User, Server provides a Uid identifier that is all for all subsequent requests during the session.

### **INCREASING ENTRIES FOR Fid/Tid/Uid Blocks:**

#### **param cifs.listBlocks=128**

**Note:** Default=64. On certain occasions, clients may generate and not release ID's quick enough so that Celerra runs out of the 64k memory bucket caching for these Identifier Handles. Param allows for 16k FID/TID/UIDs at same time. Typical Server Log entries:  
SMB: 4: No more search handle available  
SMB: 4:increase param cifs.listBlocks (64 now)

**SMB DATA:** Typically contains data to be read or written, directory paths, etc.

**Note:** Prior to NTLM 0.12, all strings encoded using ASCII; With NTLM 0.12 & later, can include UNICODE strings that include file, resource, and user names.

## **CIFS COMMUNICATIONS:**

Traditional legacy Clients used NetBIOS Session Requests to Port 139 [SMB over NetBIOS over TCP]

Windows 2000 Clients use ‘direct hosted’ SMB over TCP

### **SMB & ACCESS MASK ENCODING:**

ACCESS\_MASK is a 32-bit value that contains 'standard', 'specific', & 'generic' rights used to build ACE's [Access Control Entries] on objects. **This is the primary means for granting access to objects in Windows NT.**

Bits 0-15 contain access mask for a specific object type.

Bits 16-23 contain the object's 'standard' access rights.

Bits 24-31 contain an object's generic access rights.

### **STANDARD SMB FILE ATTRIBUTE ENCODING:** Encoded as 16-bit value for message exchanges regarding files.

Read Only File: 0x01  
Hidden File: 0x02  
System File: 0x04  
Volume: 0x08  
Directory: 0x10  
Archive File: 0x20

### **EXTENDED SMB FILE ATTRIBUTE ENCODING:**

ATTR\_ARCHIVE: 0x020 {used to mark files for backup or removal}  
ATTR\_COMPRESSED: 0x800 {file or directory compressed. Files inherit from directory}  
ATTR\_NORMAL: 0x080 {File has no other attributes set}  
ATTR\_HIDDEN: 0x002 {File is hidden}  
ATTR\_READONLY: 0x001 {File is Read Only}  
ATTR\_TEMPORARY: 0x100 {File is temporary}  
ATTR\_DIRECTORY: 0x010 {File is a directory}  
ATTR\_SYSTEM: 0x004 {File part of or used by Operating System}  
WRITE\_THROUGH: 0x80000000 [O/S should write through intermediate cache to access file]  
NO\_BUFFERING: 0x20000000 {Server requested to open file with no intermediate buffering or caching}  
RANDOM\_ACCESS: 0x10000000 {application intends to access the file randomly}  
SEQUENTIAL\_SCAN: 0x08000000 {file to be accessed sequentially--used to optimize caching}  
DELETE\_ON\_CLOSE: 0x04000000 {server should delete file upon close}  
BACKUP\_SEMANTICS: 0x02000000 {File being opened or created for a Backup or Restore operation & should be allowed}

### **I. SMB NEGOTIATION REQUESTS:** Client -- Server interaction

SMB Negotiate dialect request is sent by Client to Server. Server responds with authentication 'dialect' to use.

**USHORT SecurityMode:** This field indicates User or Share security (1 or 0 respectively)

**USHORT MaxBufferSize:** Size of largest message which Client can send to Server

**Challenge/Response Protocol:** Challenge sent to client, response is encrypted with 168-bit session key computer from User's password--Server validates response by performing same computation and matches to cached User's Password.

**MAC (Message Authentication Code):** Messages can be authenticated using MD5 encryption similar to IPSec.

**DES** is a block encryption mode using 7-byte Key and 8-byte Data block [E (K, D) or Extended DES Ex(K,D)]

### **ASCII VALUES:**

First 128 characters are 0x00 -- 0x7F

Remaining 128 characters (0x80 -- 0xFF) map to OEM Character sets, or Code Pages as used in I18N UNICODE

### **II. SMB SESSION SETUP:** Between Client & Server

Primary purpose here is to "logon" the Client, which presents a ***Userid*** for AccountName & ***Password*** for AccountPassword

#### **Typical Client Information Sent:**

USHORT MaxBufferSize (to let Server know what its maximum receive buffer size is)

USHORT PasswordLength (account password size)

STRING AccountName (Account Name used)

STRING PrimaryDomain (Domain)

STRING NativeOS (O/S of Client)

STRING NativeLanMan (Native LAN Manager type)

#### **Typical Server Responses:**

STRING NativeOS (Server's O/S)

STRING NativeLanMan (Server's LAN Manager type)

STRING PrimaryDomain (Server's primary Domain)

If Challenge/Response Authentication used, Client supplies AccountName and AccountPassword

#### **Typical Errors:**

ERRSRV/ERRerror (no NEG\_PROT issued)

ERRSRV/ERRbadpw (password incorrect)

ERRSRV/ERRtoomanyuids (max. number of users per session exceeded)

#### **Typical Services the Client Seeks to Use:**

A: (Disk shares)  
LPT1: (Printer)  
IPC (Named pipe)  
COMM (communications device)  
????? (any type of device)

**User LogOff:**

Uid in SMB header is logged off. Server closes all files opened by this User & invalidates any further requests from that "uid"

**Tree Connects:**

Typically involve the Client's "*Tid*" and syntax to a resource such as `\server\share`

**Tree Disconnects:**

Client's resource connection, Tid, is disconnected from Server & then invalidated for further use. Open files, locks, etc., are released.

File System Information Requests:

TRANS2\_QUERY\_FS\_INFORMATION (FileSystem identified by Tid in SMB header)

SMB\_INFO\_ALLOCATION

SMB\_INFO\_VOLUME

SMB\_QUERY\_FS\_VOLUME\_INFO

SMB\_QUERY\_FS\_SIZE\_INFO

SMB\_QUERY\_FS\_DEVICE\_INFO

SMB\_QUERY\_FS\_ATTRIBUTE\_INFO

**File or Directory Creation/Open Request:**

SMB\_COM\_NT\_CREATE\_ANDX

FILE\_OPEN (open an existing file)

FILE\_CREATE (create file)

FILE\_OPEN\_IF (open if exists, or create if not)

**When Using Security Descriptors (SD's):**

NT\_TRANSACT\_CREATE

ACCESS\_MASK (access desired)

ULONG SecurityDescriptorLength (Length of SD in bytes)

ULONG NameLength (length of file in characters)

STRING Name (Name of the file)

**Client Read Requests:**

USHORT Fid (File Handle)

ULONG Offset (Offset in file to begin the Read operation)

USHORT MaxCount (Max number of bytes to return)

**Client Write Requests:**

USHORT Fid (File Handle)

USHORT WriteMode (Write mode bits)

UCHAR Data (data to write)

**Other Client Operations:**

SMB\_COM\_LOCKING\_ANDX (client file locking requests)

SMB\_CLOSE & TREE\_DISCONNECT (Closing a File & Tree Disconnect)

SMB\_COM\_DELETE (Delete a File)

USHORT Flags [Flags for Copy Operations: bit 0=file; bit1=directory; bit2=copy target as binary (0) or ASCII (1); bit3=copy source; bit4=verify writes; bit5=tree copy operation]

**Checking Directory:**

SMB is used to verify that path exists and is a directory--if not, following error returned to Client

STATUS\_NOT\_A\_DIRECTORY or SMB\_ERR\_BAD\_PATH

**File Attributes expressed by AccessFlags:**

FILE\_READ\_DATA 0x00000001 (data can be read from file)

FILE\_WRITE\_DATA 0x00000002 (data can be written to file)

FILE\_APPEND\_DATA 0x00000004 (data can be appended to file)

DELETE 0x00010000 (file can be deleted)

READ\_CONTROL 0x00020000 (Access Control List & Ownership of file can be read)

WRITE\_DAC 0x00040000 (ACL's & Ownership can be written to file)

**Checking or Setting Security on Files:**

NT\_TRANSACT\_QUERY\_SECURITY\_DESC

NT\_TRANSACT\_SET\_SECURITY\_DESC

**COMMON SMB ERRORS:**

SUCCESS 0 (request was successful)

|        |      |                                                                                             |
|--------|------|---------------------------------------------------------------------------------------------|
| ERRDOS | 0x01 | (Error is from core DOS O/S)                                                                |
| ERRSRV | 0x02 | (Error is from Server Network Manager) {ERRbadpw; ERRinvnetname; ERRbadClient;ERRnosupport} |
| ERRHRD | 0x03 | (Error is from hardware) {ERRdata; ERRbadcmd; ERRnotready--drive not ready; ERRread, etc}   |
| ERRCMD | 0xFF | (Command not in 'SMB' format)                                                               |

## **SPECIFIC SMB ERRORS:**

ERRseek (seek error); ERRbadmedia (unknown media type); ERRread (read fault); ERRgeneral (general failure); ERRsharebufexc (sharing buffer exceeded); ERRbadcmd (unknown command); ERRbadreq (Bad request structure length); ERRbadshare (An Open conflicts with an existing file); ERRlock (lock request conflict); ERRtimeout (operation timed out); ERRbadLogonTime (cannot access server at this time); ERRaccess (Client does not have necessary access rights to perform function)

## **NT 4.0 DIRECTORY LISTING BEHAVIOR:**

NT “DIR” command retrieves 16,384 bytes or 170 files for each SMB “transact2 findnextfile” transaction. Known issue where ‘DIR’ requests can cause 200 ms delays for SMB responses. ACKs are normally sent for every other TCP segment received, or unless the delayed ack time of 200ms is reached.

## **SUPERUSER ACCOUNT [aka root]:**

When accessing remote file systems over NFS, the "root" user's UID is normally mapped to the anonymous user account called "nobody", which has a UID of -2 and a "nogroup" GID of -2 [For non-negative unix systems, these values translate into a 16-bit unsigned representation of 65534].

**Note:** NFS handles requests for Users without valid credentials by mapping them also to the "anonymous" user account

## **USING ANON EXPORT FOR NFS: /etc/exports**

Set NFS access mappings to specific UID's using the "anon=100" syntax when "exporting" file systems for NFS

Set NFS access mappings to specific HOSTS using "access=taco,root=taco"

Further, if you export NFS to a specific HOST as ReadWrite [rw=taco:mountpoint,access=100] then all others will mount RO

## **CIFS FILE SYSTEM SECURITY:**

SD's describe Access Rights on NT Objects—files, directories, etc. SD's contain ACL's. ACL's are constructed from ACE's, which also describe umask permissions. Celerra uses the Domain Controller to compare a User's SAT against local SD information for CIFS objects, such as Files and Directories. Users obtain access based on their SAT v. SD of an object. All Directories and Files have Security Descriptors, which define ownership and Discretionary Access Control List information.

**EXAMPLE:** NT Folder “Shared” contains two ACE's. (1) for Everyone [SID S-1-1] READ-ONLY and (1) for Administrators [SID S-1-5-32-544] FULL CONTROL. These ACE's makeup the ACL list and resultant Security Descriptor Information [SD]

## **SEQUENCE OF EVENTS WHEN STARTING CIFS SERVICE & READING CIFS OUTPUT:**

1. When starting CIFS, server Queries WINS using combination of Broadcasts and directed IP communication
2. Receives Listing of IP's for Domain Controllers from WINS Server or Broadcasts & writes them initially as \*SMBSERVER [DMs query WINS & broadcasts every 15 minutes thereafter to produce a 'refreshed' DC list]
3. Server tries to connect to each IP address using “NBTSTAT -A 192.10.2.2”
4. Receives DC reply, and \*SMBSERVER becomes ‘DC=BIWMST-DC3 (167.150.37.3) R=1 T=437382ms S=-1,c0000001/-1’
5. When clients attempt to connect to a “SHARED” CIFS File System, a client negotiate message is sent to DC and an 8-byte Challenge key is returned. Client then uses Session Setup to authenticate to DC using Netlogon IPC\$

Usermapper[2]=[139.21.204.245] --Brackets indicate the 'Master Usermapper'

>DC indicates an active TCP connection and in new code most likely indicates the DC to which DM is logged onto

ref=163 indicates the number of internal references to an object, with ref=2 being a minimum for a valid DC

RC=3 is also an internal reference count & is fairly meaningless at a practical level

## **NETBIOS ALIASES—NT & WIN2K STYLES:**

**Purpose:** Allow the Data Mover to have more than one name [besides the Default NetBIOS name] for the same IP Address, similar to Windows O/S. Clients connect to Aliases via SMB by name. Aliases are registered with Browse Service and WINS but not AD or DNS.

--Max. (10) Netbios names or Aliases per CIFS Service Interface, with max. (29) CIFS Services per DataMover, 15 characters length  
--alias name cannot begin with @ or – characters or include white space or tab characters, or any of the following characters:

/ \ : ; , = \* + | [ ] ? < > “

--Aliases share Localgroups & Shares of Netbios Primary, but do not need NT Machine accounts

--Primary 'default' NetBIOS name still used for Domain Controller registration

--Aliases are registered in WINS and BROWSE Services, therefore must be unique on the Network [Not registered with DNS/AD]

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
--Default Netbios name is the primary machinename used for DC Registration, and maintains ownership of “Shares”, “Localgroups”, and “Configuration Settings” [i.e., Domain Controllers communicate only with primary NetBIOS names]

### **COMPNAME ALIAS EXAMPLE:**

```
# server_cifs server_2 -a compname=mary, domain=mouse.com, interface=ana0, alias=twodoors
server_2 : done
# server_cifs server_2 -Join compname=mary, domain=mouse.com, admin=backdoor
server_2 : Enter Password:*****
# server_cifs server_2
CIFS Server MARY[MOUSE] RC=2
Alias(es): TWODOORS
Full computer name=mary.mouse.com realm=MOUSE.COM
# cat netd
cifs add compname=MARY domain=MOUSE.COM interface=ana0,alias=twodoors
```

## **CIFS Configuration & Troubleshooting:**

### **Fundamental Concepts for Mixed Unix and NT Environments:**

**I. Mounting File Systems:** Mounting determines File Locking [Nolock/Wlock/RWlock] and File System Access Policies [accesspolicy=NATIVE;=UNIX; =NT; =SECURE] for CIFS. Unix locking is ‘advisory’ and transparent for NFS.

#### **Mounting File Systems for NFS or CIFS:**

a.) **Mount Command for NFS File System:** \$server\_mount server\_5 -perm -o rw fs1 /fs1 [Default=perm, RW]

b.) **Mount Command for CIFS File System:** \$server\_mount server\_5 -p -o accesspolicy=nt,rwlock fs1 /mount1  
[Default: accesspolicy=NATIVE]

**II. Exporting File Systems:** Exporting determines accesspolicies for NFS--with options like “anon=0; anon=uid; access=; rw=; root=” specified for “hosts” or “netgroups” during the \$server\_export command.

**Note:** NFS accesspolicies are based on “hosts”

#### **Exporting File Systems for NFS or CIFS:**

a.) **Export Command for NFS:** \$server\_export server\_5 -p -o anon=0 /fs1

b.) **Export Command for CIFS:** \$server\_export server\_5 -P cifs -n sharename /mount1

c.) **Unexporting:** \$server\_export server\_5 -u -p /fs1 [path]

**Note:** NFS Exporting defines Unix access policies, such as “anon=0”, “anon=uid”; “root=”; “access=”; “rw=”{=hostname, netgroup, subnetIP/mask, or IPAddr/mask}. If options are not specified, then the Default is “**No Hosts Root Access**”. CIFS Exporting is the Windows equivalent of creating “Shares”--done after setting up the CIFS service on the DM.

**III. CIFS-Server Security Modes:** When setting up CIFS, unless otherwise specified, the default security mode is “security=nt,dialect=nt1”. To change modes, use the \$server\_cifs -a security=unix [share] command.

**Note:** “security=nt” is the only mode that supports CIFS “accesspolicies” that were defined during the server\_mount command for a File System! Therefore, setting either ‘**Unix**’ or ‘**Share Security**’ renders “accesspolicies” useless.

**IV. NIS Server:** The data mover can be a NIS client, and can retrieve user and group name mappings using ‘yp match’ calls. Be aware of “cifs resolver” param and when you would use default value of 0 and value of 1. Also note that Celerra requires that all NIS entries be in lowercase.

**V. Usrmapper Service:** The “Usermapper Service” runs on Solaris, SCO, or Linux. Primary purpose is to provide mappings for NT Users/Groups with Unix UIDs/GIDs in order to access Celerra CIFS Shares over the network. Data Movers ‘point’ to the Usrmapper Server so that requests for access can be dynamically mapped to the Usrmapper Server’s usrmapper.db and usrmapper.grp.db databases. Usrmapper does not automatically synchronize either NT/PDC or Unix/NIS user-accounts databases!

#### **Usrmapper Provides NT-to-Unix User Mapping [access] to resources, and “authentication” control from an NT PDC!**

**VI. NT Users:** For Windows-based access to Celerra, the CIFS Service must be running, and (1) of the following NT Usernames to UID Mapping Services must be implemented: Password/Group files, NIS Service, Usrmapper Service

## **CIFS SERVICE CONFIGURATION RULES:**

### **CIFS SERVICE RULES:** NetBIOS Name, NT Domain Name, NIC Interface Name, and WINS Service [optional]

#### **\$server\_cifs server\_6 -a netbios=celerradm1, domain=t2dom1, interface=ana0, wins=192.10.2.2**

--CIFS Service consists of a NetBIOS and Domain Name assigned to an Interface Port

--Can Configure Multiple “CIFS Services” on a single DataMover--however, first “Cifs Service Netbios” name assigned becomes the “Default” name, which Windows Networking lists in Server Manager, User Manager, Network Neighborhood, or Explorer [i.e., when connecting to ‘Shares’ using UNC naming or Explorer: <\\celerradm1\ntshare1>]. It also becomes the “Default” security mode.

## **CIFS NETBIOS NAMING RULES:**

--You can have a very large number of IP Configurations and Interface Names given to a DataMover for both Single or Multiple NIC Ports. You assign Netbios Names to physical “ports” [ana0,ana3,etc], not to Interface names [dmzana1,dmzana2,etc]

--The same NETBIOS name can be used on ‘multiple’ NIC ports using different IP configurations

--Only one NETBIOS name can be the “default” name for a given NIC Interface [i.e., \$server\_cifs server\_6 output]

**Note:** Additional IP Configurations and different Interface Names can be created using the \$server\_ifconfig server\_6 -c -D.

Additional CIFS Services [i.e., netbios names] can then be created for each different Interface name. Therefore, a DataMover can be configured to belong to multiple NT Domains via the use and assignment of the ‘CIFS Service’ to different Interface Ports.

--Multiple netbios names can also be assigned to a Single Interface port, but only if additional IP configurations have been created using the \$server\_ifconfig server\_6 -c -D command

## **CELERRA WINS SERVICE:**

**Intro:** Required only for Data Movers that are member servers of NT 4.0 Domains. As long as the DM Wins service is defined, a CIFS Server can operate on a network that is different from Domain Controllers. The DM can also function without a WINS Server if the Domain Controller is on the same local network as the DataMover—it does this through the use of “Broadcasts” to locate Wins and also to request a list of 1C records from the Wins Server. Otherwise, if Wins servers are located on separate networks, an entry for Wins should be added to the DM so that direct IP registration and queries can be made to the Wins Server. Disable unused interfaces to prevent registration with WINS servers.

## **PORTS USED BY WINDOWS FOR WINS SERVICES:**

|                                       | UDP | TCP |
|---------------------------------------|-----|-----|
| WINS Manager                          | --- | 135 |
| WINS NetBios over TCP/IP name service | 137 | --- |
| WINS Proxy                            | 137 | --- |
| WINS Registration                     | --- | 137 |
| WINS Replication                      | --- | 42  |

### **Example One:**

#### **CIFS LOGON USING WINS/BROADCAST:**

##### **DOMAIN SMSTEST**

**DC=PLNT025(173.55.21.10) ref=1 time=96933 ms**

CIFS Server (Default) NAS2[SMSTEST]

Comment='EMC-SNAS:T2.2.35.4'

if=ana2 l=173.55.25.200 b=173.55.25.255 mac=0:0:d1:20:1:e3

**Note:** The pointer “>” & SID won’t show up until ‘touched’ by a User account, such as Administrator, from Server Manager, Explorer, or Network Neighborhood if this is the first time that CIFS has been setup on this Server

### **Example Two:**

This Output Also Shows that CIFS has Logged Into the Domain [via WINS or Broadcasts]—Only change is that if this is the first CIFS Service set up on the Celerra, you may see a slightly different output:

##### **DOMAIN SMSTEST**

**DC=\*SMBSERVER(173.55.21.20)ref=1 time=0 ms**

### **Example Three:**

This Output Shows CIFS Logged Into the Domain & also “accessed” by a User Account:

##### **DOMAIN SMSTEST**

**SID=S-1-5-6f2a2ed4-7dd53e1-24fe7268-ffffffffff** [SID of DOMAIN “SMSTEST”]

**>DC=PLNT025(173.55.21.10) ref=2 time=0 ms**

CIFS Server (Default) NAS2[SMSTEST]

Comment='EMC-SNAS:T2.2.35.4'

if=ana3 l=173.55.21.200 b=173.55.21.255 mac=0:0:d1:20:1:e4

**Note:** The SID is obtained once a valid User on the NT Domain is successfully authenticated to the Celerra—as indicated above, this could be when accessed from either Network Neighborhood, Explorer, or Server Manager. The authentication mechanism is usually provided automatically by the Usrmapper Service or from some form of Unix Passwd/Group file checking.

## **TROUBLESHOOTING CELERRA WINS:**

**Intro:** If Celerra CIFS servers are located on different logical networks than the Domain Controllers, then manual configuration of WINS addresses for CIFS is required. By design, Celerra does not work the same as a native Windows Server in the registration and renewal of its WINS netbios name. Celerra Servers register their netbios name with WINS upon each startup of CIFS, and then every 15 minutes thereafter, using broadcast and direct IP [if configured with an IP address of the WINS server]. Also at startup and every 15 minutes, Celerra queries and updates its DC list. Stopping the CIFS service will de-register the Netbios names, and starting the CIFS service will also initiate a Wins Registration and Query for 1C list.

**param cifs wins.Refresh=384**

**Note:** Default behavior is to register our Workstation and Server services with the WINS server every 15 minutes via direct IP [when configured] and broadcasts. Celerra also sends query to WINS servers by direct IP and broadcast to obtain new list of <1c> records

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
[Domain Controllers]. 384 is hex for 900 seconds or 15 minutes. Also note that for multiple Wins Server entries [in CIFS], the Data Mover registers and queries only the first WINS Server on its list [it will failover to the next Server if it does not receive a reply]

**Example from Server Log with ‘Traces=2’ enabled:**

```
2003-11-13 17:15:48: SMB: 4: Id:0x298 Send C-Registration for WINS<00> to 192.10.20.10 [direct IP for workstation service]
2003-11-13 17:15:48: SMB: 4: Id:0x299 Send C-Registration for WINS<20> to 192.10.20.10 [direct IP for server service]
2003-11-13 17:15:48: SMB: 4: Id:0x29a Send C-Registration for WINS<00> to 192.10.255.254 [broadcast....]
2003-11-13 17:15:48: SMB: 4: Id:0x29b Send C-Registration for WINS<20> to 192.10.255.254 [broadcast....]
2003-11-13 17:15:48: SMB: 4: Id:0x29c Send C-Query for SEINFELD<1c> to 192.10.20.10
2003-11-13 17:15:48: SMB: 4: Id:0x29d Send C-Query for SEINFELD<1c> to 192.10.255.254
2003-11-13 17:15:48: SMB: 4: Id:0x298 WINS<00> Registration by 192.10.20.10
2003-11-13 17:15:48: SMB: 4: Id:0x299 WINS<20> Registration by 192.10.20.10
2003-11-13 17:15:48: SMB: 4: Domain=SEINFELD<1c>, RR Flags=0x8000, Host=192.10.20.10
```

**DISABLING DNS & USING WINS WHEN BUILDING DC LIST FOR 2K3 SERVERS:**

# server\_param server\_2 -f cifs -info NTsec.getDCfromADServices -v

```
server_2 :
name      = NTsec.getDCfromADServices
facility_name = cifs
default_value = 1
current_value = 1
configured_value =
user_action = restart Service
change_effective = restart Service
range      = (0,1)
description = Use DNS to get list of Domain Controllers
detailed_description
```

When the param is set to False (0), WINS are used to build the list which is sorted using response time (SamLogon) and subnet info.

**TROUBLE GETTING RID OF INVALID DC’s FROM CIFS LIST:**

→AR87585, emc218088, NAS 5.6 and above

**Typical Message:**

Discovered from: WINS

DCd660a80c 10.110.255.228[WRO] INVALID DC=0xd660a804 shd=0x00000000 name=\*SMBSERVER

**Workaround→Set following parameter to 60 seconds to remove non-advertised DCs from Server DC Listing:**

# server\_param server\_2 -facility cifs -info DC.autoRemovalSeconds -verbose

```
server_2 :
name      = DC.autoRemovalSeconds
facility_name = cifs
default_value = 604800
current_value = 604800
configured_value =
user_action = none
change_effective = immediate
range      = (0,4294967295)
description = Time to remove obsolete Domain Controllers (no longer announced) from domain's DC list
detailed_description
```

All DCs no longer announced by WINS/DNS are automatically removed from domain's DC list after this time specified in seconds. 0 value disable to removal process.

**WINS INFORMATION & DEFINITIONS:**

Windows Internet Naming Service (WINS) is used to resolve a Netbios name on a network to its respective IP Address, and also to Register and release Netbios names with the WINS Servers. Windows Explorer, or DOS prompt "net" commands will invoke the NBT interface, using NetBIOS over TCP using Port 137. The idea behind WINS is that each Client will be configured with the WINS Server IP Addresses so that direct communication can occur, as opposed to network broadcasts.

**WINS NAME RESOLUTION MECHANISMS:**

**B-node:** Uses UDP broadcast datagrams to Register and perform WINS resolution activities

**P-node:** Called Peer-to-Peer because it uses direct IP to a defined WINS Server IP address

**M-node:** Mixed mode—Broadcasts used first, then P-node directed IP

**Note:** This is the default mode of registration by Data Mover for its Workstation and Server Services

**H-node:** Hybrid mode—P-node used first, then Broadcasts

**NETBIOS SERVICE NAMES:**

00 Redirector or Workstation Service for a netbios name

20 Server Service for a netbios name

1B PDC of a Domain (Primary Domain Controller)

1C Domain Controller records

1D Domain Master Browser service

1E Browser service on other systems than Domain Master

**WINS DATABASE PROPERTIES FOR REGISTERED NETBIOS RECORDS:**

**Renewal Interval:** Timeframe in which a client must re-register its name before being "released" by WINS server

**Extinction Interval:** A period of time after the Renewal Interval has expired in which WINS server will wait for a "released" record before it tombstones that record

**Extinction Timeout:** A period of time after Extinction Interval in which WINS will remove the tombstoned entry from its database

**Verification Interval:** Time period that an active record exists before being verified

**TROUBLESHOOTING WINS:**

**1.) Increase Server Logging for WINS**

**`$server_config server_5 "param cifs wins.Traces=2"`** → Starts debug logging

**Note:** With 5.6, you may need to use `$server_log server_x -i` option to see trace output in the server log

**`$server_config server_5 "param cifs wins.Traces=0"`** → Stops debug logging

**Note:** Sets debug logging for Wins, check Server Log for logging information. Set 'Traces=0' to stop WINS debug logging.

**2.) Query each defined WINS Server to see if records are registered for CIFS Servers:**

**`#server_config server_5 -v "wins addr=192.10.20.10 name=server"`**

1068755669: SMB: 4: SERVER <00> 4000 (Unique NetBios Name, M Node) Addr=192.10.0.109

**`# .server_config server_5 -v "wins addr=192.10.20.10 name=**"`** → Dumps records from WINS server

**Note:** Command can cause panics prior to 5.2.16.x—AR44550

**3.) Examine Server Log for Registrations, Queries, and Replies from Wins:**

**DEBUG LOG MESSAGES:**

2003-11-20 23:24:03: SMB: 4: Id:0x5b17 Send C-Registration for AP3CDM3<00> to 3.130.163.255  
2003-11-20 23:24:03: SMB: 4: Id:0x5b18 Send C-Registration for AP3CDM3<20> to 3.130.163.255  
2005-01-07 23:41:05: SMB: 4: Id:0xc03 Send C-Registration for CELPFS52<00> to 160.5.56.41  
2005-01-07 23:41:05: SMB: 4: Id:0xc04 Send C-Registration for CELPFS52<20> to 160.5.56.41  
2005-01-07 23:41:05: SMB: 4: Id:0xc05 Send C-Registration for MMBINTD1<00> to 160.5.56.41  
2005-01-07 23:41:05: SMB: 4: Id:0xc06 Send C-Query for MMBINTD1<1c> to 160.5.56.41  
2005-01-07 23:41:05: SMB: 4: Id:0xc03 CELPFS52<00> Registration by 160.5.56.41  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.5.56.18  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.3.4.16  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.21.32.21  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.5.56.18  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.128.67.246  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=161.2.56.237  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.3.4.142  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.129.14.56  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.129.14.33  
2005-01-07 23:41:05: SMB: 4: Domain=MMBINTD1<1c>, RR Flags=0x8000, Host=160.5.56.17  
2005-01-07 23:41:05: SMB: 4: Id:0xc04 CELPFS52<20> Registration by 160.5.56.41

**WINS BUG—AR55681:**

If multiple WINS servers are assigned & written to netd file as a separate line, instead of to each individual CIFS Server, when communications are lost to the first WINS server on the list, DART will not cycle to the next Wins Server. Workaround would be to add WINS to each separate Netbios Server: [server\_cifs server\_2 -add

netbios=XXX, domain=YYY, interface=ZZZ, wins=x.x.x.y.y.y]—DART will then cycle to the next server on the list. Issue resolved with NAS 5.5.1.0, 5.4.10.4, & 5.3.16.0.

**4.) WINS configuration for VDM CIFS Servers:**

Our documentation does not clearly discuss how Wins should be configured with VDM's. The recommended approach would be to add WINS to the VDM and verify in the vdm.cfg file:

**`$ server_cifs vdm1 -add wins=10.241.168.92`**

**Common WINS Suffixes:**

1Ch = Group Entry for list of Domain Controllers

1B = Address of PDC or in Windows 2000, address of PDC Emulator

## **HOW TO IDENTIFY & RESOLVE WINS ISSUES WITH CELERRA CIFS SERVER:**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Situation:</b>  | WINS & CIFS Servers on different Networks, with Celerra using direct IP communication with WINS                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Problem(s):</b> | CIFS Server cannot authenticate to NT Domain when using WINS on different Network than CIFS Server<br>Missing Entries on WINS Server for NT PDC/BDC leads to loss of connectivity with CIFS Server service<br>Incorrect IP configuration on WINS Server could lead to loss of connectivity with CIFS server service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Causes:</b>     | PDC/WINS Server missing WINS IP address in the IP Configuration Tab--CIFS server will not be able to communicate, or authenticate CIFS Users, with the NT Domain Controller.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Actions:</b>    | Missing entries in the WINS database service that defines the PDC/BDC & NT DOMAIN<br>Ensure the WINS Server has its own IP information in the following location: Rightclick "Network Neighborhood">>PROPERTIES>PROTOCOLS>TCP/IP>PROPERTIES>WINS ADDRESS<br>[verify IP address entries are present and reboot WINS server if entries are added or changed]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Actions:</b>    | Verify WINS Database Entries by opening WINS MANAGER>"Mappings">Show Database<br>You should see entries "similar" to the following:<br><b>NT DOMAIN NAME REGISTRATIONS:</b> NT Domain Name in this Example is "SMSTEST"<br>SMSTEST 1Ch [DC list for Domain with IP of PDC]<br>SMSTEST 1Eh [Browser Service registration with IP of PDC]<br>SMSTEST 1Bh [Domain Master Browser with IP of PDC]<br>SMSTEST 00h [Workstation Service with IP of PDC]<br><b>NT COMPUTER NAME REGISTRATIONS</b> for DC: NT DC in this Example is "PLNT025"<br>PLNT025 00h [Workstation Service]<br>PLNT025 03h [Messenger Service]<br>PLNT025 20h [Critical entry--defines the Server Service of the DC, to which the Celerra communicates]<br><b>Actions:</b> CORRECTING WINS DATABASE ENTRIES: You may need to add "STATIC" MAPPINGS for the NT DOMAIN CONTROLLER and NT DOMAIN to the WINS Server Database by opening WINS MANAGER>MAPPINGS>STATIC MAPPINGS>Add DOMAIN "SMSTEST" & IP Address of PDC<br>WINS MANAGER>MAPPINGS>STATIC MAPPINGS>Add NT PDC "PLNT025" & IP Address |

**Cautionary:** These fixes are not all-inclusive--there are Network Switch/Router configurations that may also prevent the CIFS Service from communicating properly with the Domain Controller across Subnets.

## **TROUBLESHOOTING WINS ENTRIES FROM DM:**

**#.server\_config server\_3 -v "wins addr=131.99.75.60 name=compucom type=0x1c"** [Wins Records for DCs]

**Note:** Plug in different WINS records for more info; 0x1b; 0x1d, etc.

## **EXAMPLE OF WINS RECORDS FOR DC's:**

**# .server\_config server\_2 -v "wins addr=172.19.3.254 name=network type=0x1c"**

1050334973: SMB: 4: NETWORK <1c> 8000 (Group NetBios Name, B Node) Addr=172.19.3.252

1050334973: SMB: 4: NETWORK <1c> 8000 (Group NetBios Name, B Node) Addr=172.19.3.253

## **TOMBSTONED ENTRIES FOR WINS:**

Server Log error SMB: 3: WINS ERROR \*<00>: No answer from 10.8.1.137

**Note:** Server recognizes that a Netbios name is tombstoned by the specified Wins server IP address. This message may also occur if a DC is not running the messenger service.

## **TROUBLESHOOTING TOMBSTONED ENTRIES:**

--Verify that Wins Servers are replicating their databases correctly

**Note:** In the case of multiple Wins entries for CIFS, the Server only registers and queries the Wins server at the first IP address on its list and relies on Wins to replicate its entries to other Wins Servers.

--Use Static Wins entries, if necessary, in order to keep Data Mover names registered in Wins [Adding the IP Address and name of the DM will create a Workstation <00>and Server Service <20>record

--Use nbtstat –a command from DC to register DM netbios name on a temporary basis—valid only for the current logon session

**c:>nbtstat -a 192.168.0.103** [Data Mover IP]

## **SET FOLLOWING ENTRY IN NETD FILE AND REBOOT SERVER:**

**1. #vi /nas/server/slot\_2/netd**

pdc trace=1

cifs start

## **2. Reboot Data Mover and Observe Server Log:**

### **CREATING ‘NON-GLOBAL’ SHARES—i.e., for specific Netbios or Compcodes only:**

**\$ server\_export server\_3 -P cifs -o netbios=homely -n HomeComingQueen /mnt13**

### **DELETING SPECIFIC NETBIOS SERVER SHARE:**

**\$ server\_export server\_3 -P cifs -u -p -o netbios=biwusrmap -n Projects /fs13**

**Note:** This immediately removes entry from export.shares file & /.etc/shares/BIWUSRMAP folder

### **LOSS OF ACCESS WHEN USERS HAVE RESTRICTED MACHINE LOGONS:**

**Note:** In situations where DM is not Joined to same Domain as Users, and where User accounts have Restricted Logon rights, users may not be able to map to the Share

“Mapped drive could not be created...An extended error has occurred”

SMB: 4: authenticate NA\useaorap S=19 SamLogonInvalidReply

Fixed in NAS 4.2.12.0 & 5.0.12.0 by querying Client name from SMB thread

### **SHAREDB:**

Shares are managed via the ShareDB, a relatively new part of code since 4.0 [in support of Windows 2000]

ShareDB relative to Share permissions are stored in the hidden .etc folder in NAS 4.2 and has been moved to the roots in NAS 5.1

With Nas 5.x, ShareDB directly manages and handles share Security descriptors

### **HOW IT IS POSSIBLE TO LOSE/CHANGE SHARE PERMS ON CELERRA:**

#### **Background:**

By default, if Shares are created on a file system, the hidden .etc directory in NAS 4.2 will contain the name of the share. If there are no share names in 4.2, then it's likely that the default Everyone FC perm has been applied, or it could mean that inheritance for the .etc directory has been set.

#### **When Share Perms Can be Lost or Changed:**

1. If the hidden .etc directory is exposed, that is, if the upper mountpoint of a file system is ‘Shared’, it is possible for someone to inadvertently deleted this folder. If anything other than the default Share perm of ‘Everyone FC’ was applied, the perms would be lost and after a data mover reboot, the .etc folder would be recreated with Everyone FC for all Shares on that file system.

2. If the inheritance bit is set on the .etc folder, it is possible that an Administrator could change or apply Share/NTFS permissions on the Upper Mountpoint, which could also then change the Share permissions to those of the underlying NTFS permissions of the upper mountpoint. In the latter case, the application of a new ACL may actually remove the existing ACL—acts as a replace vs. an edit.

#### **Resolution:**

There is no engineering solution for this problem as the system is operating as designed.

--Always create nested Shares after creating the initial mountpoint Share so as not to expose the .etc folder

--Never apply permissions on the Upper Mountpoint of the file system

### **LOCATION OF CIFS SHARES ON CELERRA—NAS 4.2:**

#### **CIFS Shares are now stored in the following locations:**

1. /nas/server/slot\_x/export.shares
2. /nas/rootfs/slot\_3/.etc/shares/@global [If Shares are not created specifically for one netbios name, all show up here]
3. /nas/rootfs/slot\_3/.etc/shares/netbios\_name [Each compname will have a default folder created in the “shares” directory, which in turn will contain “Shares” if exported to the specific compname only]

#### **Folders Stored in /.etc/shares:**

/nas/rootfs/slot\_3/.etc/shares:

@global: Folder contains HOMEDIR & all global Shares for the DataMover

@import: No entries unless \$.server\_config server\_x -v “sharedb backup” has been run, then stores shares.bak file in this folder

@system: Contains default System Shares for each Server→C\$, CHECK\$, HOME, IPC\$

/HOMELY: Each “compname” will have its own folder created & populated with Shares if specific to the Compname

### **HOW CIFS SHARES BEHAVE WITH NAS 4.x/5.0:**

#### **CIFS SHARE CREATION WITH GLOBALSHARES=0 SET:**

**param cifs srvmgr.globalShares=0**

## I. Exporting new “share” from CommandLine:

**\$server\_export server\_2 -P cifs -n CLI /mnt**

### Results:

- Since not specified in the export command, Share will be created as a “Global” Share and is written to /.etc/shares/@GLOBAL
- Share is immediately written to the “/nas/server/slot\_2/export.shares” file

## II. Exporting new “share” from Windows 2000 “Computer Management” Console:

### Results:

- Becomes a new “Share” for only the compname connected to using ‘Computer Management’ [i.e., will not become a “Global” share for all compnames & is written to [/.etc/shares/BRUCE](#)
- Share is not written to “/nas/server/slot\_2/export.shares” file

**Comment:** Neither Stopping, Starting CIFS, nor Rebooting DataMover will write new “sharename” to “export.shares” file. Though the ‘Share’ is seen in the “server\_export” output, the only way to get this new share into the “export.shares” file is to run the following command:

**\$server\_export server\_2 -r**

**Explanation:** AR28311 states that this behavior is by design in NAS 4.x and above as the CS no longer runs a “server\_mgr” daemon. In the pre-NAS 4.x model, the MMC Console created shares through CS daemon by request to Data Mover, therefore the “shares” were always kept in sync. With NAS 4.x and above, CS only maintains cache information and DART saves new Shares created from MMC Console in its Share Database in the /.etc/shares directory. Also, Shares were removed from Boot.cfg file at the 4.x and above families. Only present workaround is to use \$server\_export server\_x -r to retrieve ShareDB information from Data Mover and update the CS Cache file, “export.shares”.

## III. Exporting new “share” from CommandLine and Specifying Netbios Name:

**\$ server\_export server\_2 -P cifs -o netbios=bruce -n newcli /mnt**

### Results:

- Becomes a new “Share” for only the compname called “Bruce”
- New Share is written immediately to “export.shares” file
- New Share is also written to /.etc/shares/BRUCE [Does not populate the @GLOBAL directory]

## IV. Deleting Share from Commandline and Specific Netbios Server Name:

**\$ server\_export server\_3 -P cifs -u -p -o netbios=biwusrmap -n Projects /fs13**

## V. Exporting new “share” from Celerra WebUI Web Manager Interface:

- Becomes new share for compname to which it was created
- New Share is written immediately to the “export.shares” file
- New Share is written to /.etc/shares/REX [Does not populate the @GLOBAL directory]

## **RECOVERING SHARedb ON SERVERS RUNNING NAS 4.2 OR HIGHER:**

**Problem:** Database corruption occurred, resulting in complete loss of all shares in the /.etc/shares directory, including @system hidden administrative shares.

**Solution:** As long as there is a recoverable SCCS export.shares file, or if the export.shares file in the /nas/server/slot\_x directory is intact, recovery is fairly straightforward:

- 1.) Reboot datamover [This will rebuild the Hidden Administrative shares “C\$, CHECK\$, & IPC\$”]
- 2.) Do #server\_export server\_5 -a [This repopulates the “sharedb” into the proper folders in the /.etc/shares directory]

## **BACKING UP AND RESTORING SHARES FROM ONE DATA MOVER TO ANOTHER:**

### 1. Backup Sharedb on Server:

**# .server\_config server\_5 -v "sharedb backup"**

**Note:** Creates “shares.bak” file in [/.etc/shares/@import](#)

### 2. Copy Sharedb from Slot 5 to Destination Slot:

#cp /nasmcd/quota/slot\_5/.etc/shares/@import/shares.bak /nasmcd/quota/slot\_4/.etc/shares/@import/shares.bak

### 3. Import Sharedb into Slot 4:

**# .server\_config server\_4 -v "sharedb restore=shares.bak"**

### 4. Verify:

**# .server\_config server\_4 -v "share"**

**# .server\_config server\_4 -v "sharedb info"**

## **CIFS SHARE CREATION WITH GLOBALSHARES=1 SET:**

- I. By default, when exporting from Command Line, the CIFS Share will be created as a “Global” Share unless you specify the “Netbios” name in the export options [/.etc/shares/@GLOBAL]

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
II. However, when using the Windows 2000 Computer Management to ‘manage’ the Celerra, all Shares created will become “Global” shares because the param=1.  
III. Finally, if specified in the export command, will create the Share as a specific Share for the Netbios name [/.etc/shares/BRUCE]

## **COMMON CIFS ERROR/INFORMATION MESSAGES IN SERVER LOG:**

**Server Log:** 2002-04-25 14:59:44: SECURITY:3: /etc/group does not exists and NIS not started

**Reason:** Actual message is harmless & means that there is no "group" file located on the /etc directory of the datamover. An entry is made each time a User touches a CIFS Share.

**Resolution:** #touch group #server\_file server\_x -put group group [Error message will no longer be logged]

**Server Log:** NT\_Access\_Credential::RequestFromSID:primary nt group not mapped, use unix primary

**Note:** User is accessing DM but Windows Primary group cannot be mapped.

### **HIDDEN SHARE NOTE:**

If exporting CIFS Shares at the root FS level, the system admin shares are exposed to view [/.etc, c\$, Lost + Found, etc]. There are situations where this may not be desirable. As an alternative, export the File System with a subdirectory, such as “fs04\bruno”—then, when accessing the File System from NT, the “admin” shares will remain “hidden”.

## **DELETING CIFS SERVICE FROM DATAMOVER:**

- Step 1. Stop the CIFS service
- Step 2. Delete CIFS Service: **\$server\_cifs server\_x -d netbios=dm2** [Deletes all three: Netbios, Domain, & Interface Name]
- Step 3. Verify that the netd file has been updated correctly: /nas/server/slot\_x/netd
- Step 4. If permitted, reboot DataMover

## **DELETING CIFS SERVICE USING SINGLE COMMAND:**

**\$server\_setup server\_x -P cifs -o delete** [Removes all entries from "netd" file--much easier way to remove CIFS Service]

## **MIGRATING FROM ONE CELERRA TO ANOTHER--RETAINING ORIGINAL**

**NETBIOS NAMES:** [Within the same NT Domain]

### **PART I. MIGRATION SETUP:**

**ALPHA CELERRA CS0:** 172.24.80.10

**SERVER 4:**

**NETBIOS NAME:** SOURCE [old]

ana0 192.10.2.24

**FILESYSTEM:** origserv /origserv

**CIFS SHARE:** "sourceshare" /origserv [SOURCE]

**USRMAPPER:** Linux CS0 172.24.80.10

**WINS SERVICE:** 192.10.2.2

**NT DOMAIN:** T2DOM1

**MIGRATION NT ACCOUNT:** "T2DOM1\newby"

**Migration Servers:** SOURCE [old] → TARGET using NT 4.0 WORKSTATION [NTWK1DOM1]

**Important Note:** NT User "newby" was added to the LOCAL GROUP called "Administrators" on both Celerra Servers and the NT Workstation using User Manager interface. User "newby" was also given the following (4) specific USER RIGHTS on both Celerra Servers and the NT Workstation: **Backup Files & Directories; Generate Security Audits; Manage Auditing & Security Logs;**

**Restore Files & Directories**

**SOURCE PATH:** \SOURCE\sourceshare\migration

**TARGET PATH:** \TARGET\targetshare\destination

**METHODOLOGY:**

**\SOURCE\sourceshare\Migration\Folder1, 2, 3, 4:**

--Permissions on folder "Migration" set for Administrators & Domain Admins Full Control, and Everyone Group as Read Only.

--Created (4) LOCALGROUPS on CIFS Server "SOURCE", each with (2) Users from NT DOMAIN "T2DOM1".

--Created (4) subfolders on CIFS Server "SOURCE" underneath the Directory called "Migration".

--Assigned localgroup "LOCAL1" [T2DOM1\amato | betty] to "\FOLDER1" giving Ownership to "SOURCE\Administrators" and Full Control Permissions to Administrators | LOCAL1 [localgroup,etc.]

--Assigned localgroup "LOCAL2" [T2DOM1\nasadmin | newby] to "\FOLDER2" giving Ownership to "SOURCE\Administrators" and Full Control Permissions to Administrators | LOCAL2

--Assigned localgroup "LOCAL3" [T2DOM1\bing | bob] to "\FOLDER3" giving Ownership to "SOURCE\Administrators" and Full Control Permissions to Administrators | LOCAL3 & Read Permissions to T2DOM1\Todd1

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
--Assigned localgroup "LOCAL4" [T2DOM1\david\elf] to "\FOLDER4" giving Ownership to "T2DOM1\Administrators" and Full Control Permissions to Administrators | LOCAL4 & Read Permissions to T2DOM1\thm

#### **TARGET\targetshare\Destination:**

--Granted Ownership to Administrators and Full Control Permissions to Administrators & Everyone

#### **MIGRATION PLAN:**

Plan is to "migrate" the "localgroups" information, then all FileSystem data, from the CIFS Server called "SOURCE" on Original Celerra, to the destination Celerra CIFS Server called "TARGET" using the "external IP Address" of the Usrmapper Service on original Celerra. After the "migration", the original Usrmapper Service needs to be stopped, the database files copied over to the new Celerra Control Station, destination CIFS servers pointed to the New Usrmapper IP Address, and the new Usrmapper Primary Service started. The Plan is then to remove the original "SOURCE" server share, then its CIFS Service, and its entry in the WINS Servers database, while leaving the Netbios name "SOURCE" in the NT Domain, and finally to create the CIFS Service for "SOURCE" on the new Celerra Server\_4 on a different IP Address.

#### **PART II. CONDUCTING MIGRATION USING EMCOPY TOOLS:**

a.) Run LGDUP.EXE from NT 4.0 Workstation called "NTWK1DOM1" while logged in as the Migration User Account called "Newby" who has DOMAIN ADMINS membership in addition to the Steps outlined in Part I:

**C:\emcopy>lgdup.exe -v \source \target > lgdumpmigration.txt**

**Note:** Examine output file called "lgdumigration.txt" to see if migration of LOCALGROUPS information was successful. If not, re-verify the setup of "newby's" User Rights on all (3) Servers involved in the migration, as well as its membership as Administrator.

b.) Run EMCOPY.EXE from "NTWK1DOM1":

**C:\emcopy>emcopy.exe \source\sourceshare\migration \target\targetshare\destination /o /a /lg /s /secfix /d > emcopymigrat.txt**

**Note: Use EMCOPY Version 2.04b to conduct the EMCOPY Migration of Data, and User Ownership/Permissions!**

#### **PART III. POST MIGRATION TESTING:**

- a.) Tested access to the "destination" folder on Server "TARGET" as a Domain Administrator User. Verified that all Ownership, Permissions, and LOCALGROUP entries were migrated over identically and successfully from the "SOURCE" Server.
- b.) After migration was verified as successful and complete, saved a copy of the original Localgroups.db file from each Celerra Server involved in the migration [#/home/nasadmin/server\_file server\_4 -get localgroups.db localsource.db, etc.]
- c.) Unmapped all drive shares to "SOURCE" CIFS Server
- d.) Unexported and unmounted Shares/FileSystem from "SOURCE" [\$server\_export server\_4 -P cifs -n sourceshare -p -u]
- e.) Stopped CIFS Service on "SOURCE"
- f.) Stopped Linux Usrmapper Service on 172.24.80.10 and FTP'ed "usrmap.db"; "usrmapgrp.db", and "usrmap.cfg" database files to FTP Server and then pulled down to Linux Usrmapper Server 172.24.80.11 on the new Celerra [Tarred the whole original /var/usrmapper directory, FTP'ed, then untarred on destination Celerra Usrmapper]
- g.) Deleted CIFS Service for "SOURCE" on original Celerra called "ALPHA" [\$server\_cifs server\_4 -d netbios=source]

#### **PART IV. COMPLETING SETUP & IDENTITY CHANGE FOR NEW "SOURCE" SERVER ON CELERRA "BETA":**

- a.) Stopped CIFS Service on Server\_4 on new Celerra called BETA
- b.) Deleted entry for old Usrmapper Server: \$server\_cifs server\_4 -d usermapper=172.24.80.10
- c.) Added entry for new Usrmapper Server: \$server\_cifs server\_4 -a usermapper=172.24.80.11
- d.) Created new IP on ana1, 192.10.3.25, for new "SOURCE" server on Beta Server\_4
- e.) Created new CIFS Service for "SOURCE": \$server\_cifs server\_4 -a netbios=source, domain=t2dom1, interface=ana1
- f.) Started Usrmapper Service on BETA Control Station [Usrmapper on ALPHA must not be running!!]
- g.) Started CIFS Service on Server\_4 and verified CIFS access
- h.) Unshared the destination folder from Server\_4 "TARGET" called "targetshare" on "/temperv"
- i.) Created a new share on "SOURCE" called "sourceshare" on "/temperv"
- j.) From NT Client, mapped drive to \source\sourceshare, verified access to folders, and permissions once again
- k.) Retrieved copy of Localgroups.db database from Server\_4: \$server\_file server\_4 -get localgroups.db newlocalsource.db
- l.) Stopped CIFS Service on Server\_4 and the Usrmapper Service on BETA Control Station
- m.) Made BackUp copy of "newlocalsource.db" as "newlocalsource.bak"
- n.) Using Vi Editor: #vi newlocalsource.db

**Note:** During vi session, change all entries that have word "TARGET" to word "SOURCE" in the first part of the LocalGroups File. Then, in the bottom half of the file, change all entries that were "SOURCE" to "TARGET". Once vi session is completed, place the revised file back onto Server\_4: \$server\_file server\_4 -put newlocalsource.db localgroups.db

o.) Restart Usrmapper Service, then the CIFS Service, and verify access.

#### **PART V. OPTIONAL: MAKING "SOURCE" SERVER THE DEFAULT CIFS SERVICE ON SERVER 4:**

**Intro:** Because the "Target" Server existed first, on the new Celerra, it became the default CIFS Service for Server\_4. After the Migration Steps I-IV. are completed, do the following to make "Source" the default CIFS Service configuration on Server\_4. Delete the CIFS Services on Server\_4 and readd back the "Source" CIFS Service:

1. Stop CIFS on Server\_4

2. Stop Usrmapper Service on BETA CS0 172.24.80.11
3. Delete WINS entries from WINS Database for both "TARGET" & "SOURCE" CIFS Servers
4. Stop & Restart the WINS Service on NT
5. Delete the CIFS Configuration for SOURCE & TARGET: \$server\_cifs server\_4 -d netbios=source | target
6. Readd the CIFS Configuration for SOURCE: \$server\_cifs server\_4 -a netbios=source,t2dom1,interface=ana0 [or keep ana1]

### **RENAMING CELERRA COMPNAMES [Compname rename Netbios Rename, etc] (-rename):**

**Note:** There is no direct way to simply "rename" a Celerra compname from one name to another, but must use the following procedure, which allows a Compname to be removed from the Domain, creates a new CIFS Netbios name, undergoes a Netbios rename operation that re-indexes the Server database so as to preserve the Data Mover's Shares, LocalGroups security context, & Folder/File permissions on file systems, deletes the Netbios name, then reads and Joins the new Compname back to Active Directory. This procedure can be safely applied to regular CIFS Servers and CIFS Servers that are members of VDM containers. When using the following procedure, please note that Netbios names cannot be longer than 15 characters.

#### **1. Unjoin the original Compname from the Domain:**

→Localgroups file not touched

# server\_cifs server\_2 -Unjoin compname=W2k3, domain=abc.com, admin=Administrator

#### **2. Delete the Compname from the Data Mover's CIFS configuration:** →Localgroups file not touched

# server\_cifs server\_2 -delete compname=W2k3

#### **3. Add the name back to the Data Mover's CIFS configuration as a Netbios name:** →Localgroups file not touched

# server\_cifs server\_2 -add netbios=W2k3, domain=abc, interface=fsn01

#### **4. Rename the Netbios Server to the new name:** →Localgroups file updated with new name

# server\_cifs server\_2 -rename -netbios W2k3 W2k3prod

#### **5. Delete the old Netbios name from the Data Mover's CIFS configuration:**

# server\_cifs server\_2 -delete netbios=W2k3prod

#### **6. Add & Join the new Compname to the CIFS Configuration & AD Domain:**

# server\_cifs server\_2 -add compname=W2k3prod, domain=abc.com, interface=fsn01

# server\_cifs server\_2 -Join compname=W2k3prod, domain=abc.com, admin=Administrator

**Note:** CIFS Shares that are shared to a specific "netbios" name are updated with the new name and all Windows permissions remain intact. The Localgroups database retains its internal SID and ordinal position in the file, with only the name changed and updated. Please note that all persistent Client drive mappings will need to be deleted and readded to handle the new Compname.

### **CELERRA LOCALGROUPS.DB FILE:** NAS 2.2.x

When creating the "CIFS Service" on a DataMover, the "localgroups.db" file is automatically produced. There are several different ways to access this database file directly, or indirectly:

#### **I. NT Server Administrator:** Map directly to the root hidden C\$ share of the CIFS Server:

Start>Run box: \\polk\c\$ [cd to /etc directory and open the localgroups.db with wordpad]

#### **II. Control Station:** #mount -F nfs server\_2:/ /mnt #cd /mnt #cd .etc #ls -la #more localgroups.db

#### **III. Control Station:** \$cd /nas/rootfs/slot\_2/.etc \$ls [localgroups.db; .db.bak]

#### **IV. User Manager>User>Select Domain>\polk** [Indirectly accesses the Server's "localgroups.db" file]

Changes made while using this Interface will change and update the Server's localgroups.db

**Note:** Since all changes to the localgroups database are first stored in "/.etc/.db.cache", you may need to stop and restart the CIFS service in order to initially 'populate' or to update an existing localgroups database file. Additionally, the "/.etc/.db.bak" is an automatic backup of the "localgroups.db" file, first created whenever any changes are made and the CIFS service is shutdown.

#### **V. Control Station Screen Output :**

\$server\_config server\_x -v 16384 "lg list"

### **EXPLANATION OF LOCALGROUPS FILE SIDS:**

**Intro:** The SIDs listed at the beginning of the "localgroups.db" file refer to the various "netbios" or "comnames" [i.e., CIFS Services] created on the DM and are local machine SIDs only. These do not represent Domain SIDs. Each "machine account" contains its own SAM database [Security Accounts Manager] just as any native NT 4.0 or Windows 2000 System. Celerra is unique, however, in that each "Server" can contain multiple SAM databases, one for each "CIFS Service" created on the DM.

### **EXAMPLE OF BEGINNING OF LOCALGROUPS FILE FOR SERVER 4:**

# Localgroups database

\$RELEASE:02\$ →Indicates ASCII mode

@FILE008:1:1000:S-1-5-15-32434d45-2385-9c64f114-ffffffffff

@FSDATA:2:1560:S-1-5-15-32434d45-4103427e-479af894-ffffffffff

@FSR5T:3:1000:S-1-5-15-32434d45-310332f2-a20d8e2a-ffffffffff

@OSG96ST:4:6181:S-1-5-15-32434d45-2a033da3-abcd4245-ffffffffff

@OSG96S:6:1000:S-1-5-15-32434d45-2a033662-d0f26db9-ffffffffff

# Localgroups of server FILE008

### **I18N MODE LOCALGROUPS ENTRY:**

```
# head .db.localgroups
#
# Localgroups database
#
$RELEASE:4$ →4$ indicates Unicode mode localgroups database
```

### **MULTIPLE LOCALGROUPS DATABASE FILES:**

localgroups.db →Normal localgroups file contained on DataMover

.db.localgroups →New localgroups file created after turning on I18N and subsequently in use by DataMover

.db.cache → Some versions of NAS used this file to cache “changes” to the Localgroups file until they are flushed to file

.db.5.localgroups →Indicates that Local Users Support feature has been enabled

### **HOW TO OUTPUT SPECIFIC DM LOCALGROUPS TO SCREEN:**

**# .server\_config server\_6 -v 16384 "lg list vs=osgdata"**

### **HOW TO OUTPUT COMPLETE SERVER LOCALGROUPS TO SCREEN:**

**# .server\_config server\_6 -v 16384 "lg list"**

**Note:** Use “server\_file server\_6 –get localgroups.db localgroups.db.s6” to obtain working copy of db file

### **REMOVING LOCAL GROUPS ENTRY FROM VDM CIFS CONTAINER:**

**\$server\_config server\_2 "lg remove vs=TEST3 forever"**

### **FORCING AN UPDATE OF THE LOCALGROUPS FILE ON DM:**

**\$server\_config server\_6 -v "lg update force"**

**Caution:** Do not run this command without Engineering or TS2 approval

**Purpose:** Forces Datamover to query Domain Controllers and Usrmapper for updates to all Groups that match the “localgroups.db” file. An example of when you would use this command would be if you have rebuilt Usrmapper and now have different GIDs assigned to all Groups. This command will take the new GID from Usrmapper and update the entry in the Local Groups file. Be aware that in the case of multiple Compnames, the update does not always work and some manual editing may be required to update GIDs, but this is a rare occurrence.

### **LOCALGROUPS FILE CREATED WHEN USING LOCAL USERS SUPPORT:**

-rw-r--r-- 1 root bin 4156 Oct 18 12:24 **.db.5.localgroups**

**Note:** Introduced with NAS 5.4

### **WELL-KNOWN SID'S:**

SID: S-1-0 Null Authority S-1-5-domain-512 Domain Admins

SID: S-1-0-0 Nobody S-1-5-domain-513 Domain Users

SID: S-1-1-0 Everyone S-1-5-domain-519 Enterprise Admins

SID: S-1-3-0 Creator/Owner SID: S-1-5-domain-500 Administrator

### **NESTED GROUPS & USRMAPPER MAPPINGS:**

**Note:** You must be using Native Mode Active Directory to get this to work:

1. Create user called "nestee" -->By default, a member of Domain Users group
2. Create a Global Group called "nest1" and a Global Group called "nest2"
3. Add the user "nestee" to Group "nest2"
4. Add Global Group "nest2" to "nest1"
5. Log off computer and back on to obtain new Security Token and map new drive letter to Celerra.

**Results:** Both Global Groups "Nest1" and "Nest2" were mapped as groups by Usrmapper because the user "nestee" is a member of "nest2", while "nest2" is a member of "nest1". The user "nestee" was not a direct member of "nest1".

### **WINDOWS MIXED MODE vs. NATIVE MODE DOMAINS:**

Mixed Mode is an interim mode when preparing to move from NT 4.0 Domains to Windows 2000 domains. Win2k domains default to mixed mode when created. The basic premise is that at least one NT 4.0 BDC (Backup Domain Controller) still exists, requiring that NTLM authentication be allowed. W2k uses the RID Operations Master & PDC Emulator service to provide security descriptor services for NT, as well as a master browser. Once you switch to Native Mode operation, there is no reversing the step.

Some of the major advantages to running W2k (or higher) in Native Mode is the ability to use Universal Groups, have Nested Groups, and to provide automatic transitive 2-way trusts between domains within the forest.

#### **Windows 2003 supports (4) different domain levels:**

Windows 2000 Mixed Mode—default, supports DC's running W2k3, W2k, or NT 4.0

Windows 2000 Native—supports DC's running W2k3 & W2k

Windows 2003 Interim—supports DC's running W2k3 and NT 4.0—can upgrade directly from 4.0 to 2k3

Windows 2003—Supports only W2k3 DC's (aka, Native Mode)

**Note:** MS has replaced the terminology for W2kK3 domains from “mixed” mode to “Raise Functional Level”. If you change the functional level of a W2K3 domain in “Active Directory Domains and Trusts>Raise Domain Functional Level”, you would be setting the domain to native W2K3 mode and no DC's other than W2k3 will be able to function.

#### **QuarantinedDomains: SID Filtering**

This is a Microsoft concept to allow the ability to isolate certain trusted domains so as to avoid potential exploits. If SID filtering is enabled in the registry, or via the use of the netdom tool, all SIDs will be discarded from the named Trusted domain except for those related to the Trusted Domain SID itself.

HKLM>System>CurrentControlSet>Services>Netlogon>Parameters

1. Create new Key “QuarantinedDomains” with value of 0 or use c:\netdom /filtersids no <Trusted\_domain\_example>
2. Add Netbios name of the Domain to filter or ‘quarantine’
3. Stop and start the Netlogon service

**Note:** Side effects will affect migrations that use SIDHistory, and Universal Group SIDs will be discarded.

#### **CELERRA HOMEDIRS—Celerra Home Directory Service:**

**Introduction:** Creates Home directories on a Celerra file system, preferably underneath a nested mountpoint so as to hide folders from other Users. Homedirs requires the use of a ‘homedir’ map file, a valid network share to the file system, and the Homedir service running on the DM. User folders must be created & permissioned manually with older NAS versions, and can be set to AutoCreate if using MMC Homedir snapin. Home Directories functions the same for both NT 4.0 and Win2k Domains. Map file is parsed from the top down.

**Note:** NAS 5.2 now supports the use of multiple wildcard entries per domain. Dart will parse each line from the top down until it finds a Home Directory mapping for a User. You can have multiple trusted domains listed in the Homedir file. Older code had restrictions in that multiple wildcard entries could not be used for the same domain.

#### **HOMEDIR FILE PARSING:**

Home Directories are read and evaluated from top to bottom in the config file, with the last applicable entry applied. Because of this, use Wildcard matching at the top of the file and more specific matching at the bottom. The more specific matches would take precedence over the wildcard matches.

```
*.*:/fs1/guest  
galaxy:user1:/fs1/users  
galaxy:user2:/fs1/users
```

#### **STOPPING & STARTING HOME DIRECTORY SERVICE:**

**\$server\_cifs server\_x -o homedir            \$server\_cifs server\_x -o homedir=NO**

#### **CONFIGURING HOMEDIRS USING CELERRA MANAGEMENT SNAPIN:**

→NAS 5.5.31.6, CelerraCIFSManagement v4.2.00

1. Configure and start CIFS
2. Export path to the Home Directory Share
3. Set permissions on Home Directory path
4. Install CelerraCIFSManagement snapin on Windows Server
5. Open Celerra Management>Homedir (disabled)>Rightclick to Enable: “You are attempting to start the home directory service with an empty database. Before the service can be started the database must have at least one entry. Do you want to create new entry and now start the service?” yes

#### **Home Directory properties**

New home directory entry on da30

#### **Domain**

Dwarfs

User

\*

Path

/fs30/da30

Options

--Autocreate Directory [Only creates directory in the Homedir file, not on the share?]

Umask>modify (use default umask or set umask override for User Group Other

Resulting Homedir File is Automatically pushed to ./etc directory:

**dwarfs:\*:/fs30/da30:create**

## **NAS 5.4 HOME DIRECTORY IMPROVEMENTS:**

DART does dynamic mapping of User and Domain to homedir map db [consisting of domain, username, path]

DART uses last entry in its database to map user—therefore, last entry in the file would be used rather than first entry

→Automatic directory creation can be configured from MMC snapin for Home Directories, but still requires use of Profile path in ADUC for \cifs\home to be able to create the User directory

**dwarfs:\*:/fs30/da30:create** (the ‘create’ entry on the line indicates that automatic directory creation was enabled from the MMC)

→Regular expression parsing now used, based on Extended Regular Expression Characters (ERE), tools such as grep, awk, sed

Example:

**stunet\*:\*/homedir\_stu/users/<u>:regex:create**

**Note:** For any domain name beginning with string "stunet", map all Users to the path indicated and then automatically create a directory for the user by name, using regular expression <u> for the user. Note that in testing 5.5.31, the actual directory on the file system is not automatically created.

### **VALID EXTENDED REGULAR EXPRESSIONS (ERE):**

**^ . [ \$ () | \* + ? { \**

**Note:** Valid if found outside of bracket expressions

### **SUPPORT FOR REGULAR EXPRESSIONS IN HOMEDIR CONFIG FILE:**

**DENVERNT:^[a-k]:/Home-root1/Home1:regex**

**Note:** must add the word ‘regex’ at the end of each line in the Homedir file to recognize use of Regular Expressions

Single Character ERE Mapping:

. Matches any one character “user.”

... Matches any one of characters listed between brackets “[2ez]”

\* Matches preceding element zero or more times “\*” matches any string

+ Matches preceding element one or more times “(00)+” or “a+”

{num} Matches preceding element by the num times indicated between the brackets

^ Matches beginning of the line

\$ Matches end of the line

“^high\$” Matches single line containing nothing but text “high” in this example

| Separates two EREs and accepts a match to either the left ERE or the right ERE, or both

<d> <u> When used in path, represents Domain and User, respectively

**Highest to Lowest Precedence:** Regular expressions are evaluated with the following precedence

**[ ] Bracket Expression () Group \* + {m} Single-char. Quantifier ^ \$ Anchor | Alternator** (either or match)

→Management done via MMC Snapin on 5.4 Applications & Tools CD—Does NOT extend AD Schema

→Requires use of IE 6.0 SP1 or later

→RO option for Homedir access

## **EXAMPLE OF CREATING HOMEDIR ENTRY USING MMC SNAPIN:**

### **I. Programs>Administrative Tools>Celerra Management>Homedir (enabled)>rightclick, New>Home directory entry:**

Domain

w2k\* [Enter regular expression--asterisk matches any domain beginning with w2k]

User

\* [Asterisk matches any user name]

Path

\fs3\students

Options

Enable \_\_Auto Create Directory and \_\_Regular Expression

### **II. Open Active Directory Users and Computers><select a user>Properties>Profile**

Home folder

Select \* Connect Z: and enter UNC path to the built-in “home” directory share: \\dbms\home

### **III. When user logs into the Celerra, a directory is automatically created for the User**

## **I. CONFIGURING CELERRA HOME DIRECTORIES (HOMEDIRS):**

### **Step 1. Create Homedir Map File and push to Root File System of DM (/etc):**

#vi homedir

```
mouse:*:/webui/Users  
mouse:*:/webui/Users/2004  
mouse:*:/webui/Users/2005
```

**#server\_file server\_2 -p homedir homedir**

**Note:** Where ‘MOUSE’ = Domain Name; \* = any User—standard wildcard; /webui = upper level share or “mountpoint” of filesystem that hosts the Home Directories; /users = subfolder that contains a collection of user Folders by name

### **Step 2. Create a file system share via CLI or Computer Management/Server Manager for “/webui”:**

#### **Step 3. Create Home Directory Folders and apply permissions to each Users’ Folder**

#### **Step 4. Create User Logon Profiles via Win2k ADUC or NT 4.0 User Manager Interface:**

**NT 4.0 DOMAINS:** → USER MANAGER FOR DOMAINS

**User>nas1>profile>”Connect” Z: \\mouse\home**

**Note:** You may see an error, ‘...Could not create the HOME directory...for this user’—Ignore this message!

**WINDOWS 2000 DOMAINS:** → Active Directory Users and Computers (ADUC)

**User>nas1>profile>”Connect” Z: \\mouse\home**

**Note:** Ignore following message: “The \\mouse\home home directory was not created because it already exists...”

### **Step 5. Start Home Directory Service on DM & Verify:**

**\$server\_cifs server\_2 -o homedir | homedir=NO** [to stop service]

**\$server\_cifs server\_2**

**Home Directory Shares ENABLED, map=/.etc/homedir**

**Note:** The default CIFS share called “Home” is created automatically when you start the HomeDir service:

/etc/shares/@system/HOME --> HOME. Please ensure that the Customer does not create any other Celerra Shares with the name “Home”—reserved only for Homedirs!

### **Step 6. Log on as a User—the User’s Home Directory should be mapped in Explorer automatically**

**Note:** With Windows 2000 environments, replication may need to occur before a User’s Home Directory is automatically mapped

### **Step 7. Alternatively, log on as a User and manually map to Home Folder: START>Run: \\mouse\home**

**Note:** This method does not require that the User’s Logon Profile be enabled in User Mgr or ADUC

## **Wildcard \* Limitations for Home Directory Configurations [HOMEDIRS]:**

**Note:** Home Directories will not work when using multiple Wildcard Lines in the HOMEDIR Map File

**HOMEDIR Map Files Using Wildcard \*:** [\* symbol means any valid NT user from that Domain]

**VALID HOMEDIR MAP FILE EXAMPLE (1):** Use of Single Wildcard Line to Map all Users to a Common Home Directory

sycamore:\*/fs2/Students

**Comment:** Where "sycamore" = NT Domain; where \* = Wildcard Mapping for any valid User in the "sycamore" domain; where /fs2 = Celerra Mountpoint for Home Directory File System; where /fs2/Students = Unix Path for Home Directories

**Note:** In this example, Users would be mapped automatically to their Individual Home Directories if using the \\sycamore\home UNC path at the START>Run prompt as follows: \\sycamore\home [where "sycamore" in this case is the Netbios name of the CIFS Server] Individual User Folders must be physically created, and permissions assigned, under the "Students" Directory, as follows:

/fs2/Students/2001usr1

/fs2/Students/2002usr1

**VALID HOMEDIR MAP FILE EXAMPLE (2):** [Placing Wildcard \* Entry on Top Line only!]

sycamore:\*/fs2/Students/2001

sycamore:2002usr1:/fs2/Students/2002/2002usr1

sycamore:2002usr2:/fs2/Students/2002/2002usr2

**Note:** This configuration will only work for the Wildcard Line with the asterisk \* --all other lines above will NOT be "parsed" Wildcard entries must be on the top line of the HomeDir Map File! As per the example, you can use a wildcard entry once on the top line, but then must map all other paths explicitly by user name if the path is different than the wildcard line. This applies only to NAS codes 2.2 and lower.

## **MORE HOMEDIR SETUP EXAMPLES:**

Homedit File: t2dom1:\*/mnt30/cifs1  
Server Mgr Share: c:\mnt30 [File System ufs30 is “shared” for NT as “CIFS”]  
Server\_export: share “cifs” “/mnt30”  
**Note:** Mountpoint ‘/mnt30’ is ‘shared’ for NT as ‘cifs’  
User Mgr Profile: Z \* <\\monitor\\home>  
Explorer Folders: Subfolder “cifs1” is created under the ‘share’ called “cifs”  
User folders are created under “cifs1” [e.g., user1; user2; user3]

## **TROUBLESHOOTING HOME DIRECTORIES:**

1. Verify Service is started using server\_cifs
2. Verify that “homedit” map file contains correct mapping

## **EXAMPLE OF INCOMPLETE OR INCORRECT HOME DIR MAP FILE:**

<\\brighton\\home>

The network name cannot be found.” [Incorrect path or other configuration issue with Home Dir config file]

3. Try manually mapping to the Home Directory from START>Run: \\brighton\home

**Note:** A failure to map manually indicates that the Home Directory Service or Path are not setup correctly!

4. If automatic drive mapping letter does not appear when a User logs on, verify that NT or Windows 2000 replication has occurred
5. Set Debug Logging on Server:

**param cifs homedirTraces=1**

**Note:** With 5.6, you may need to use \$ server\_log server\_x -i option to see trace output in the server log

## **CELLERRA SECURITY MODES: NT, UNIX, SHARE**

### **UNIX SECURITY MODE:**

#### **Key Concepts:**

--NT Domain Controller not used

--UID/GID MAPPING FOR UNIX USERS PERFORMED BY NIS, OR BY LOCAL DATAMOVER PASSWD FILE

--Cannot implement UNIX Security if I18N has already been enabled

**Note 1:** Password File should include valid encrypted “password” but not the NT Domain name as part of the username

**Note 2:** Requires enabling of PlainText Passwords on the NT or WIN2K Clients that are accessing the Celerra because users are *NOT* authenticated to an NT Domain Controller [i.e., NT ACL’s are *NOT* used]

--Accesspolicies” do not apply and are not effective while using Unix Security Mode

--Consequently, must use either a local DataMover “encrypted” Passwd File or a NIS Server DataBase for File Access/Authentication

--You still need to run the CIFS service

--You export NT “shares” via the server\_export command

--Unix Users would use the NIS or local PASSWD/GROUP files for access [Client sends username and plain-text password to CIFS server and is authenticated against the local ./etc/passwd file or NIS Server Database]

--Still considered a method of “user-level authentication”, similar to NT Security [as opposed to Share-Level Security], yet no File or Directory-level ACL checking occurs.

**Implementing Unix Security in an NT Workgroup environment:** NT Registry entry to allow clear-text passwords

**Note:** Normally, you would employ Unix Security in an NFS environment if you had an NT workgroup that needed to access Unix FileSystems but did not have a Domain Controller. Typically, you would have a NIS server that would authenticate the NT User against the NIS database using Username & clear-text Passwords.

#### **Setting Up Unix Security:**

Configure DataMover Interface>Create MetaVolumes>Create FileSystems>Create mountpoints>Mount file System without accesspolicies>Export File Systems for NFS>Setup CIFS Service>Create passwd/group file & place locally on DM or use NIS Database>Set Unix Security: \$server\_cifs server\_2 -a security=unix>Start CIFS service>Export FileSystems as “shares” for CIFS

**Note:** Only need the Server’s “Netbios” name if you intend to use NT Browsing to list Celerra shares: \$server\_cifs server\_2 -a netbios=server\_2, domain=comics, interface=ana0

### **NT SECURITY MODE:**

Unix UID/GID Conversion for NT Users mandatory!

**Note:** UID/GID MAPPING FOR NT USERS DONE WITH PASSWD & GROUP FILES

[Local Passwd/Group files on DM; Using NIS Service to map to NIS db; Using Usermapper Service; or NTMigrate Utility]

--NT Security is the Default Mode. If the CIFS Service is configured and started, NT Security is the default mode.

--Default Accesspolicy is NATIVE, and is configured using the Mount command

--Eventhough you can assign more than one “NT Netbios” name for a Server for multiple NIC Interfaces, the first name used will become the default Netbios Name used for NT Security on the DataMover.

--NT Security Supports Three Types of ACL's [Access Control Lists]: NTFS File, Directory, and Share Level ACL's

**NTFS ACL Permissions**—set at the File or Directory level

**NT Share ACL Permissions**—set at the NT “share” when exported as a share

**Note:** NT will employ the most restrictive of the above permissions collectively when checking access!

--NT Clients will use NT Domain Controller for authentication

--Additionally, use of a WINS Server is mandatory when the Domain Controller is on a separate network from the DataMover

**Note:** WINS registration cannot occur across a router using Netbios Broadcasts alone—must use directed IP address of WINS Server to route across a Router

--Must use a Passwd/Group file locally on the DM or a NIS Server passwd database service

## **SHARE SECURITY MODE:**

**Note:** When exporting Share, assign password of DEFAULT\_USER

→Requires enabling of Clear-Text Passwords on the NT or WIN2K Clients that are accessing the Celerra because users are *NOT* authenticated from Domain Controllers

→Accesspolicies do not apply and are not in effect when using Share Security Mode

→Use a local Passwd & Group file on the DataMover Access by using a “default” user—INDIVIDUAL UID/GID accounts are not used. Only a single “default” user account can be assigned and must be in the local DM password file. Usernames must be limited to 20 characters and Groupnames limited to 256 characters.

**Note:** You can Export the NT “Shares” so that a User and Password are required, or you can Export “Shares” so that no User and Password box appears [i.e., would allow direct UNC connection: <\\server\share>].

→CIFS service is required

→Setup Netbios name for NT Browser service if required

### **Create mountpoints/directories on DataMover from Control Station:**

**Example:** #mkdir newshare #chmod 777 newshare

**PASSWD FILE:** admin:\*:100:300::: [where admin=user; \*=passwd field, not checked in this case; 100=UID; 300=GID]

**GROUP FILE:** share:\*:300: [where share=Group Name; \*=any user; 300=GID]

**Note:** CHMOD the file system mountpoint to allow “share” users access to the Sharepoint [**#chmod 777 newshare**]. Ordinarily, should not need to run “chown” on Sharepoints “unless” you are having trouble writing or deleting the Share.

If so, use this syntax to change ownership of the Sharepoint to the UID of the “Default User” and the GID of the Group:

**#chown 100:300 newshare** [where 100=UID of the Default User “admin” and 300=GID of Group “share”]

### **User-Level v. Share-Level Authentication: chmod 755 the ‘shared directory’**

NFS can use either User-level [server\_export; server\_cifs UNIX] or Share-level Authentication [server\_export command]

CIFS uses either User-level [server\_export; server\_cifs NT] or Share-level authentication [server\_cifs SHARE command]

Unix authenticates using Passwd or Group file or NIS Server—No ACL checking!!

DataMover [for Unix] can implement Share-level security via the “server\_export” command, defining the default UID/GID for the share. File locking or Access Checking policies do not need to be specified.

NT authenticates using NT Domain Controller supporting User, Group, Rights, File, Directory, and Share ACL's

Share Authentication: A default user is assigned to a share and can be assigned a Password or No Password.

## **NULL SESSION SUPPORT**

### **USING NULL LOGON SESSIONS (Anonymous Logons) FOR CELERRA SHARES:**

A Null Session is a NetBIOS connection made to a Server by an anonymous Client without the use of authentication—client's id field is null. Windows 2000 allows null sessions to enumerate local SAM accounts and Shares on Servers by Clients, while XP and Win2k3 allow only enumeration of Shares via null session.

#### **WINDOWS 2000:**

HKLM>System>CurrentControlSet>Control>Lsa>RestrictAnonymous: DWORD

RestrictAnonymous=0 →Default Win2k setting, no restrictions—enumerate Shares and local SAM accounts

RestrictAnonymous=1 →No enumeration of Shares or SAM accounts allowed

RestrictAnonymous=2 →Enumeration allowed only for explicit anonymous permissions

**Comment:** An example of Null Sessions support would be using the AT Scheduler to open a command prompt session and connect to remote network share using “net use”, etc. Commands run via the AT Scheduler typically use the local System Account context, not the locally logged in User account context.

**Symptom:** Logon Failure: the user has not been granted the requested logon type at this computer

#### **CONFIGURING NULL SESSION SUPPORT:**

1. Enable Null Session Support by setting the following params:

**# server\_param server\_2 -facility cifs -modify nullSession -value 1**

**# server\_param server\_2 -facility cifs -modify nullSessionNotOnFS -value 1**

2. Use Celerra Management snapin GUI from Windows Server to set following privilege on the Data Mover:

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Programs>Administrative Tools>Celerra Management>Action>Connect to Compname>Data Mover Security Settings>User Rights Assignment>double-click ‘Access this computer from the network’>Add ‘Everyone’ group

## **PARAMETERS INVOLVED:**

**param cifs nullSession=1**

**param cifs nullSessionNotOnFS=0**

**Note:** nullSession=1 allows clients to connect to IPC\$ on the DM without credentials. nullSessionNotOnFS=0 opens up access to Shares for all unauthenticated Users. Control actual file & directory access using NTFS permissions, which are still effective.

## **SETTING GUEST ACCESS TO SHARES WITHOUT AUTHENTICATION:**

1. Enable Guest account in AD
2. Set following param to allow write access to file system

**# server\_param server\_2 -facility cifs -modify nullSessionNotOnFS -value 0**

3. Use ntrights.exe utility to enable login access for Everyone group on Compname

**C:\>ntrights.exe +r SeNetworkLogonRight -u Everyone -m \\datamover\_netbios\_name**

## **CELERRA UID/GID MAPPING METHODS FOR CIFS USERS/GROUPS:**

In pre-Windows 2000 support CIFS configurations, Celerra supported UID/GID mappings by names—the search order for mappings included the local DM passwd/group file, then NIS if the NIS client was configured, and Usermapper last. In more recent NAS code, say approximately from 4.2 and higher, we use additional mapping mechanisms and with Usermapper, map by SIDs as opposed to names, though if NIS and local passwd/group files are used, we revert to name lookups.

## **DART MAPPING RESOLUTION ORDER FOR USER/GROUP AUTHENTICATION:**

### **MAPPING RESOLUTION ORDER NAS 5.1 & BELOW:**

1. Global Data Mover Sid Cache (DART resolves Group SIDs and maps to GIDs)
2. Local Password & Group files (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
3. NIS Client Service (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
4. Active Directory Mapping Utility (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively)
5. UserMapper Service (External-only) (DART resolves by User/Group names to UIDs/GIDs, respectively)

### **MAPPING RESOLUTION ORDER NAS 5.2 & ABOVE:**

1. SecMap Persistent Cache [/etc/secmap] (DART resolves by Group/User SIDs and maps to GIDs/UIDs, respectively)
2. Global Data Mover Sid Cache (DART resolves Group SIDs and maps to GIDs)
3. Local Password & Group files (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
4. NIS Client Service (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
5. LDAP iPLANET\*—optional configuration using NSSWITCH.CONF file on DM, ordering UID/GID mapping searches between LDAP Service, Files (local passwd/group), or NIS
6. Active Directory Mapping Utility (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively)
7. UserMapper Service (External or Internal) (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively for Internal Usermapper, and by Name-to-UID/GID prior to NAS 5.2)

**Note:** Do not use uppercase characters in passwd files or NIS database—use lowercase ASCII for Celerra. Also note that param cifs resolver=1 should be set when using NIS or local passwd/group files. With param set to 0, DART will request a mapping based on name.domain, and NIS will not return a mapping unless its an exact match. Keep in mind that the Global Group SID cache is kept in cache permanently, only being removed by mappings that are new and/or re-used at some frequency (LRU mechanism). When configured & populated, SecMap Cache will be the very first cache interrogated by DART for User & Group mappings.

### **\*MAPPING RESOLUTION ORDER NAS 5.4 & ABOVE:**

**Note:** LDAP iPlanet Directory Services support was introduced with NAS 5.4, via configuration of nsswitch.conf file, order of mapping Users/Groups can be specified as any combination of LDAP, Local Files, or NIS lookups

**\$ cat /nasmcd/quota/slot\_2/etc/nsswitch.conf**

passwd: files ldap nis (can be in any order that customer wishes)

group: files ldap nis

## **DEFAULT HOSTNAME SEARCH ORDER FOR DART:**

“files nis dns”

Use /etc/nsswitch.conf file to modify the default search order behavior for DART

## **I. LOCAL SID CACHE ON DM:**

From 5.2 versions and higher, DART now caches group SIDs from sources such as local group files or from other mapping mechanisms. This cache is kept in memory for as long as the Data Mover is up and running. However the number of cache entries are finite and can be increased with a parameter setting. Once the cache is filled, the next new entry is added on an LRU basis, that is, the oldest unused entry will be replaced by the newer entry. This cache is used as an efficiency mechanism to help prevent

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
authentication logjams by speeding up the mapping validation—in otherwords, if an entry is already in cache, DART does not have to go back out to the Domain Controller to conduct lookup SIDs for each Group in the domain.

**param cifs sidcache.globalSidCacheSize=1901** [Should be a prime number]

## **II. SECMAP CACHING:**

DART 5.2 introduced a persistent UID/GID-to-SID cache that is stored in the ./etc/secmap folder of the data mover. SecMap will cache the first mapping for a particular SID and note where the mapping originated: i.e., local passwd file, NIS, Usermapper, etc. Subsequent data mover access by an owner of the SID will be immediately mapped & authenticated from this cache, meaning that DART does not have to query the DC's to validate the SID again. This mechanism was introduced as an efficiency mechanism to cut down on the single-threaded authentication calls made to the DC that often translated into authentication backlogs and slow DM performance during heavy logon periods, etc.

## **III. LOCAL DATA MOVER PASSWD/GROUP FILES:**

The use of local passwd & group files on the data mover has long been the most recommended way to cut down on data mover traffic to the DC's and provide a redundant mapping database in the event that another mapping method, such as Usermapper, were ever unavailable to serve mapping requests. With the introduction of Internal Usermapper and SecMap caching, local passwd/group files are not now normally used and should only be done so as a last resort and with knowledge of the various mapping components and interactions. In addition, Version 3 style (SID in first field) passwd/group files should never be used on the data mover.

### **TRADITIONAL UNIX PASSWD FILE:**

**user.emc : \* : 501 : 100 : User Bob : :**

**Note:** User & Domain Name appended in first column; passwd field; UID; Domain GID; Comment Field]. Use of the \* asterisk means that NT Security is in use and Unix passwd field is ignored. If using UNIX Security, you would use a valid password and NOT append domain name to user entry.

### **TRADITIONAL UNIX GROUP FILE:**

**emc: \* :100**

**domain=20admins.emc: \* : 101**

**domain=20users.emc: \* : 102**

**Note:** First entry is for the NT Domain—default GID for domain is 100. Additional entries are for Groups. \*Asterisk indicates to map and domain User or Group. Please note that UTF8 characters are not supported in either the passwd or group files, only ASCII values. However, you can use and =20 to represent a space between words in a name, or ==hexahexa characters to translate UTF8 characters into ASCII readable characters. Use a tool like uni2ascii.

**# uni2ascii -Z ==%04x < group**

clearcase:x:554:

==65e5==672c==8a9e:x:555:

==5e83==544a==63b2==8f09:x:556:

## **CUSTOMER SAMPLE GROUP/PASSWD FILES:**

**\$ head -5 group**

```
001a=20dept=20accounts.corp:*:93066:S-1-5-15-8f5db4-14de7199-375b3a1a-9bc6:

aa04.corp:/*:94463:90000:S-1-5-15-8f5db4-14de7199-375b3a1a-27065:/usr/S-1-5-15-8f5db4-14de7199-375b3a1a-27065:/bin/sh
```

## **IV. DATA MOVER AS NIS CLIENT:**

See NIS section for more details. Essentially, after configuring proper data mover params, DART can map Users/Groups from NIS maps if the proper entries have been made to the databases. This method is specifically recommended for ‘mixed’ Unix/CIFS environments.

## **V. DATA MOVER AS LDAP CLIENT:**

With NAS 5.4 and above, can use LDAP client to query an iPlanet directory server to resolve users from a passwd database, or groups from the group database. Need to setup the ldap connection to the LDAP Directory Server, and have Users and Groups mapped in the LDAP database.

**# cat nsswitch.conf**

**#**

**# /etc/nsswitch.conf**

**passwd: ldap files nis**

group: ldap files nis  
hosts: dns files nis  
netgroup: ldap files nis  
**# server\_ldap server\_2 -info**

    user=b275(fde8)  
    Name=2K3\W2kU45685

## **VI. CELERRA USRMAPPER SERVICE:**

Celerra introduced an automatic User and Group UID/GID mapping mechanism that was traditionally a service run on a Unix-based system. From NAS 5.2 and higher, the Usermapper Service became integrated into the DART code and its functionality is augmented with a SecMap Caching mechanism—be aware that SecMap caching and Usermapper are not mutually inclusive. SecMap caching will add User and Group mappings based on the first mapping mechanism used on the Celerra. Usermapper is designed to be used only for pure Windows environments and should NOT be used in mixed Unix/CIFS situations.

## **CELERRA USRMAPPER 3.x:**

→Prior to 3.x, Usermapper mappings were made based on NT Usernames/Groupsnames when mapping to UID/GIDs  
→With 3.x, Usermapper mappings are based on NT SIDs for Users and Groups  
→3.x was designed to support Windows 2000, last version of Usermapper was called 3.1 for External & Internal Usermapper  
Note: Internal Usermapper is no longer ‘versioned’ per se and is an integral part of DART

## **SAMPLE “USRMAP.CFG” FILE WITH SID HISTORY LINE:**

suncor:12345:2001:9999:301:9999 [NT 4.0 Domain]  
sgho:23456:10000:10999:10000:10999  
sun\_ref\_net:34567:11000:11999:11000:11999  
network,network.lan:45678:12000:19999:12000:14999 [Windows 2000 Domain, using shortened Netbios name of domain]  
**\_history\_sid\_range\_:600:20000:24999:15000:21000**

Note: With all External Usermapper implementations, the use of the \_history\_sid\_range is mandatory, but often left out.

## **USING SORT,etc, TO VERIFY USRMAPPER DATABASE INTEGRITY:**

### **Dumping Usrmapper Database & Sorting:**

**#!/usrmap\_control dump |cut -d : -f 3,4,5 |sort**

**Sorting the Usrmap.passwd or Usrmap.group Files:** [from ‘usrmap\_control dumpfiles 1’ command]

#sort -t: -k 3 usrmap.passwd > usrmap.db

### SORTING VERSION 2.0 USRMAPPER DATABASES PRIOR TO 3.0 CONVERSION:

#sort -t: -n -k 3 usrmap.db >usrmap.passwd.sorted

#sort -t: -n -k 3 usrmapper.grp.db >usrmap.group.sorted

Comment: Use this if having problem with “preconvert.ksh” script

#sort -t: -k 3,3n usrmap.db >passwd.sorted

#sort -t: -k 3,3n usrmapper.grp.db >group.sorted

### SORTING UNIX-STYLE USRMAPPER DATABASES TO REMOVE MULTIPLE UIDS/GIDS:

#sort -k1,1 -t: -u -o check\_pass usrmap.passwd

#sort -k1,1 -t: -u -o check\_group usrmap.group

### PUTTING SPACES INTO COMMENT FIELD:

Note: Adding characters to fill spaces in comment field of “usrmap.db” file so that “correct\_dups.ksh” does not remove comments

#vi usrmap.db esc :., \$/ /xxx/g

Removing the characters from comment field:

#vi usrmap.db.new esc :., \$s/xxx/ /g

### VERIFYING USRMAPPER DATABASE RECORDS:

1. Dump Users and Groups from Usrmapper database:

#./usrmap\_control dump |grep “:user “>users [Outputs complete User database records to file called ‘users’]

#./usrmap\_control dump |grep -v “:user “>groups

[Outputs all records except ‘users’—note that two additional lines are also in the output—“UID” and “GID”, so take that into consideration when doing a word count list of the files].

2. Verify that UID and GIDs are in consecutive and numerical order:

#cat users lawk -F: '{print \$3;}' >users.sorted

Note: This should output only the column of UID numbers for review of numerical order,etc. Not sure this will work for multiple domains and ranges.

3. #view users.sorted esc : set list :set nu [Observe beginning line & ID number, then go to end of file ‘shift’ + G & compare]

4. #cat users | wc -l [compare with any previous known dumps of the ‘users’ or passwd files]

5. #cat users lawk -F: '{print \$3;}' >userlist

6. #cat groups lawk -F: -v '{print \$3;}' >grouplist

### REMOVING DUPLICATE ENTRIES FROM USER OR GROUP FILE:

# cat groups\_final | awk -F: '{print \$1":"\$2":"\$3":"\$4":";}' >groups\_sorted

Note: When running this for the passwd file, the number of \$columns will be different

# cat users\_oct lawk -F: '{print \$1":"\$2":"\$3":"\$4":"\$5":"\$6":"\$7;}' >users\_awk

### SORTING OUT DUPLICATE NAMES FROM USRMAPPER OUTPUT FILES:

Purpose: If the customer has deleted and readded user or group accounts from NT, we end up with multiple records in the usrmapper database for the same name, eventhough the SIDs are unique—if placed onto the DM, the DM will only parse down to the first name that it is looking for—and based on the way that records are added, the first of two duplicate “names” will not be the correct one.

**Step 1.** #cat usrmap.passwd lsrt -k 3,3 -g -t: -r -o passwd.rsorted

**Step 2.** #cat passwd.rsorted lsrt -k 1,1 -t: -u -o passwd.unique

**Step 3.** #cat passwd.unique lsrt -k 3,3 -g -t: -o passwd.final

Comment: Repeat steps with Group file. Purpose of these steps are to take a passwd database and reverse sort by UID from Highest to Lowest Value. Reason for doing this is that if you have multiple entries that share the same name [different SID, i.e., the User or Group was deleted and then readded on the NT Side with the same name], the duplicate name that we want to keep will be parsed first in the file. Then, the second sort goes through the file and preserves the first record in column one as the “unique” item and deletes any other ‘duplicate’ names. Finally, the last sort simply restores the file to its original sorted state, in ascending UID/GID value.

### SORTING OUT COLUMN (3) FROM UNIX PASSWD OR GROUP FILE IN ASCENDING ORDER:

#cat usrmap.db |cut -d: -f3 | sort > /tmp/aaa

## **TROUBLESHOOTING EXTERNAL USERMAPPER:**

1. Check Server Logs for entries related to Usermapper Primary or Secondaries
2. Check “usrmapper.log” for errors
3. On Windows Systems, check Event Viewer Application Logs
4. Test functionality of Usrmapper by outputting database files
5. Delete temporary \_\_db\* files if having trouble restarting Usrmapper on Linux
6. Debug Usrmapper entries using “usrmapper” commands:

## **EXTENDING UID/GID RANGES:**

**Note:** This procedure is required for changing the usrmap.cfg file for any External Usermapper configuration. It is also required for an Internal Usermapper running in CONFIG mode. Using the comma, you should be able to add multiple separate UID or GID ranges, as in the following example:

### **ORIGINAL RANGE :**

t2dom3,t2dom3.local:100:200:300:400:500

**EDITED RANGE :** Creates two additional UID ranges and one additional GID range

t2dom3,t2dom3.local:100:200:300,600:615,75000:76999:400:500, 80000 :81000

**Note :** The proper way to implement a range change would be to stop Usrmapper, edit the ranges, start Usrmapper, then verify that the ranges have been “read” into the Usrmapper database properly by running the following command:

# strings usrmappc.db

100:200:300,600:615,75000:76999:400:500,80000:81000:202:401

t2dom3

**Note:** The above entry shows that the new ranges have been recognized properly, and the last two columns show the next available UID & GID that will be used by Usrmapper, respectively.

**Warning!:** The UID/GID Ranges of a Usrmapper 3.0.6 – 3.0.10 can only be extended once from that of the original range. A third extension attempt will fail.

**RANGE EXTENSION issue is resolved by Usrmapper 3.1.1**

## **SERVER CIFS OUTPUT--LAST ACCESS=0/1 FOR USERMAPPER:**

# server\_cifs ALL |grep -i usrmapper

**Usermapper[0] = [10.10.28.46] last access 1**

**Usermapper[0] = [10.10.28.46] last access 0**

**Note:** Last access 1 means that last mapping request to the DM was a failure. A new connection request should change this status. Last access 0 means that last mapping request to DM was a success.

## **CONTROL STATION ALIASING FOR USERMAPPER REDUNDANCY:**

### **ASSIGNING AN “IP ALIAS” TO CS0:**

**Purpose:** When using dual control stations in a High Availability CS0-to-CS1 failover environment, you would assign a separate IP Address to CS0’s “eth2” interface as an “alias”, and then point all CIFS Servers to this “alias” IP Address. Once an IP Alias is in place, upon Control Station failover, the IP Alias will failover to CS1. As long as all Data Movers point to the alias IP, then CIFS communication with the Usrmapper Service will not be interrupted.

**Note:** The IP Alias is only assigned to the external interface “eth2” on CS0.

## **CONFIGURING CS0 WITH AN ‘IP ALIAS’ FOR USRMAPPER:**

### **1. Create the Alias on CS0 for External Interface ‘eth2’:**

a.) #/nas/sbin/nas\_config -IPalias -c -n eth2 0

**Note:** IPalias should be a ‘user defined number’ from 0 through 255—can have up to 255 aliases

b.) Do you want slot\_0 IP Address <172.24.80.11> as your alias [Yes or No]: No

c.) Please enter an IP address to use as an alias: 172.24.80.9

done

**Note:** Creates the following file called /nas/site/cs\_aliases/

# cat /nas/site/cs\_aliases/ifcfg-eth2:alias

DEVICE=eth2:alias

IPADDR=10.19.20.167

NETMASK=255.255.252.0

BROADCAST=10.19.23.255

### **2. Verify Status of IP Alias:**

a.) # /nas/sbin/nas\_config -IPalias -list

```
alias           IPAddr      state
eth2:0         172.24.80.9  UP
```

**b.) #server\_ping server\_x 172.24.80.9**

```
PING 172.24.80.9 (172.24.80.9) from 172.24.80.9 : 56(84) bytes of data.
64 bytes from 172.24.80.9: icmp_seq=0 ttl=255 time=52 usec
```

**c.) # /sbin/ifconfig -a**

```
eth2:0 Link encap:Ethernet HWaddr 00:00:D1:20:56:C9
      inet addr:172.24.80.9 Bcast:172.24.80.255 Mask:255.255.255.0
          UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1
          Interrupt:9 Base address:0x1c00
```

**3. Point CIFS Servers to New IP Alias Address:**

- a.) #server\_cifs server\_x -d usrmapper=172.24.80.11
- b.) #server\_cifs server\_x -a usrmapper=172.24.80.9

**4. Test Failover of CS0 to CS1 to verify IP Alias Configuration & CIFS Access:**

**a.) #/nasmcd/sbin/cs\_standby -failover**

**Note:** After issuing command, verify CIFS access

**(3) KEY DATABASE FILES IN EXTERNAL USRMAPPER:**

**usrmapc.db** → Key database that mirrors usrmap.cfg file and shows current increment number for UID/GIDs in last two columns  
# strings usrmapc.db [Use the strings command to examine this file]

10:30:40:50:60:34:58

t2dom3

**VIEWING DOMAIN RANGES USING STRINGS:**

```
# strings --bytes=1 usrmapc.db
*
80000:80001:89999:80001:89999:80001:80001
na
*
70000:70001:79999:70001:79999:70121:70044
dsigus
```

**Note:** Traditional strings of usrmapc.db file does not output Netbios Domain name ranges that are (3) characters or less in length without using above switch

**usrmapusrc.db** → Key database file that reflects UIDs assigned

**#strings usrmapusrc.db**

```
S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b3:*:16:10:user boyo2 from domain t2dom3:/usr/S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b3:/bin/sh S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b3
S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b2:*:15:10:user boyo1 from domain t2dom3:/usr/S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b2:/bin/sh S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-4b2
```

**usrmapgrpc.db** → Key database file that reflects GIDs assigned

**#strings usrmapgrpc.db**

```
S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-200.*:52:domain=20admins.t2dom3:S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-200
S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-65d.*:51:ct4.t2dom3:S-1-5-15-74b49ff8-2a1f6232-7ff7ed83-65d
```

**IMPORTANT USRMAPPER DATABASE FILES:**

Usrmap.cfg----→ Represents domain configuration file with Domains, Domain GIDs, and User and Group ID ranges defined

Usrmapc.db---→ Represents database conversion of the usrmap.cfg file and also tracks next UID/GID to be assigned

Usrmapusrc.db→ Represents User database records

Usrmapgrpc.db→ Represents Group database records

Sidname.db----→ Represents SID-to-Name mappings, used in outputting passwd and group files with correct information

**CELLERRA INTERNAL USRMAPPER:** Introduced NAS 5.2 with Usermapper version 3.1.4

**Note:** Usermapper 3.1.4 was released in NAS 5.1.20.4 (External only) and NAS 5.2.8.x (External or Internal)

Usermapper automatically starts and runs in Universal Mapping mode on Server\_2 for new installations. No manual configuration is required and other data movers will discover the Usrmapper service via broadcast over the internal IP network. No usrmap.cfg file is required, as all mappings come from a universal mapping space, regardless of the domain name. External Usrmapper configurations can also be migrated, or imported, to an Internal Usrmapper configuration [but not prior to NAS 5.2.14-0], in which case it would be

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
called Config Mode—this mode is completely managed manually similar to the rules applied to External Usermapper, hence is less desirable. You can also migrate Usermapper databases to Internal Usermapper without using a usrmapper.cfg file, and thereby maintain the ease of use provided by Universal Mode. Please note that Internal Usermapper is now integrated into DART and is no longer ‘versioned’.

## **VARIOUS INTERNAL USERMAPPER STATES:**

1.) Service Initialized but not currently running:

**# server\_usrmapper server\_2**

server\_2 : Usrmapper service: Initialized

Service Class: Primary

**# cat /nasmcd/quota/slot\_2/etc/usrmapper/usrmap.settings**

Identity=192.168.1.2,192.168.2.2

**Started=off**

2.) Service Running and Enabled:

**# server\_usrmapper server\_2**

server\_2 : Usrmapper service: Enabled

Service Class: Primary

**# cat usrmapper.settings**

Identity=192.168.1.2,192.168.2.2

**Started=on**

3.) Service Not Initialized or Setup on Server\_2:

**# server\_usrmapper server\_2**

server\_2 : Usrmapper service: Uninitialized

4.) Secondary Usermapper Service:

**# server\_usrmapper server\_2**

server\_2 : Usrmapper service: Enabled

Service Class: Secondary

Primary = 10.241.169.26 (c)

**# cat usrmapper.settings**

Identity=192.168.1.2,192.168.2.2

**Master=10.241.169.26**

Started=on

## **INTERNAL USRMAPPER MODES:**

### **Universal Mode & Config Mode**

→Universal Mode is the default mode for all new installs, and requires no manual setup or intervention—user & group assignments are pulled from a common pool of numbers starting at 32768 for Users and 32770 for Groups

→Config Mode is the mode used when a usrmapper.cfg file is used, as in an External-to-Internal Usermapper conversion—as such, the domains & ranges are pre-defined by the config file, and the user and group databases are imported from the External Usermapper system. Config Mode requires manual maintenance of Domains and UID/GID ranges similar to External Usermapper. Usermapper databases can also be imported to Internal Usermapper without the use of a usrmapper.cfg file, and therefore allows the service to run automatically in Universal Mode.

## **INTERNAL USRMAPPER CONFIGURATIONS/RESTRICTIONS:**

→Unlike external Usermapper, Internal Usermapper is completely integrated in DART code

→Only a single Primary Usermapper service is allowed in any namespace environment

→Do not run both Internal & External Usermapper services in the same environment

→Configure Primary Usermapper service first, then Secondary Usermapper services

→Configure only a single IUsrmapper instance on any given Celerra cabinet, with a single overall Primary—one Secondary can be configured for each additional Celerra cabinet in the same namespace environment

→Other Data Movers in a cabinet locate the Primary service via the Internal network using the autobroadcast feature

→For most environments, a single Usermapper service is adequate

→All new installations start IUsrmapper on Server\_2, but a different physical server could be configured manually if desired

→Usrmapper Service cannot be configured on VDM's [configured on a physical server basis only]

→Importing usrmapper.passwd & usrmapper.group files from external files can be done on both Primary & Secondary Usrmapper Servers

→Converting from External to Internal Usermapper is allowed

→Usrmapper will stop mapping UID/GIDs if rootfs reaches 95% capacity

→NASDB backs up the User and Group databases

→Use of IUsrmapper and other mapping methods, such as NIS, are NOT recommended, though can be done

**LOCATION OF INTERNAL USRMAPPER FILES:**

/.etc/usrmapper

**NAS 5.6 CONVERTS USERMAPPER FROM NAMEDB TO BERKELEY DATABASE FORMAT:**# **server\_dbms server\_2 -db -list Usermapper**

server\_2 : done

BASE NAME : Usermapper

Version : 1

State : Opened

Backup enabled : YES

Comment : Usermapper database. It allows to assign a new uid or gid to a given SID.

Creation time : Wed May 20 14:02:15 2009

-----output abridged, other Tables not shown-----

**INTERNAL USRMAPPER BACKUPS:**

**Note:** While the complete directory structure found in /.etc/usrmapper is not backed up, the NAS\_DB backup script does include the following commands [run hourly] to export the User and Group entries into respective files, from which a recovery could be made if required using the server\_usrmapper –Import option—the only problem that might be seen are for sites that have unique ranges defined outside of the “automatic domain mapping” space where a usrmap.cfg file would also need to be imported:

2004-09-08 08:04:13: USRMAP: 3: gID: Cannot put mapping for S-1-5-15-2f61266b-649d4088-496b15a5-3fb (err=-17)

## **SERVER LOG ERROR FOR ROOT INODE 95% FULL:**

**SMB: 3: Usermapper[127.0.0.1](map2unix): error: -20 for user uid request**

**Note:** New Users cannot be mapped to the Usermapper database because the rootfs is 95% full

## **CLIENT ERROR WHEN TRYING TO APPLY PERMISSIONS FOR ROOT INODE 95% FULL:**

Security ID structure invalid error when attempting to assign security for the new user

## **SERVER LOG ERROR FOR MAPPING FAILURES:**

2005-10-10 09:01:19: USRMAP: 3: sid::name: Cannot found sid->name mapping (err=1)

**Note:** Error is logged when DART cannot determine the user or group name related to a SID

## **MAPPINGS CAN FAIL FOR USERS/GROUPS WITH MULTIPLE “.” WITHIN NAMES:**

User or Group Names with leading or multiple dots within the name can fail to map via Usermapper to the Celerra:

S-1-5-15-4862e393-28a68b82-6b635f23-a7170::\*:32780:.amsd.rfs002.imsource\_c.noe:

## **Server Log Errors:**

2005-06-20 16:57:01: USRMAP: 3: Cannot insert gid mapping for group94.bidon-5.bidon-5 (err=28)

1132589685: SMB: 3: Usermapper[192.168.1.2](map2unix): error: -8 for group gid request

**Note:** See primus emc122618

## **INTERNAL USRMAPPER AND NAS 5.2 NEW INSTALLS:**

New installs automatically configure server\_2 as the primary internal usrmapper service for the entire Celerra & enables the service—if data movers have not been configured with ‘-add usermapper=192.10.0.17’, Servers will broadcast over internal network to discover the Usrmapper service that should be used—use Server\_cifs command to verify. Internal Usrmapper will automatically failover properly to a Standby Server in the event of failover.

## **SETTING UP A SECONDARY INTERNAL USERMAPPER SERVICE:**

**Note:** A reason for setting up a Secondary Usermapper Service would be if there are two or more Celerra cabinets sharing the same database space. In this case, leave Server\_2 as the Primary on one of the sites and make Server\_2 of any additional sites as the Secondary.

1. Secondary Site: **\$server\_usermapper server\_2 -enable primary=172.169.2.5** [Point Secondary to IP address of Primary]
2. Primary Site: **\$server\_usermapper server\_2 -disable**
3. Primary Site: **\$server\_usermapper server\_2 -enable secondary=172.143.3.10** [Point Primary to Secondary]

**Note:** Pointing the Secondary Usermapper Service to the primary is all that is required. The Secondary database will update properly as it receives mappings requested from the Primary. In later codes, it no longer appears to be a requirement to specify the Secondary server to the Primary.

## **CONVERTING SECONDARY USERMAP TO PRIMARY ROLE:**

### **BEFORE CHANGE:**

**# .server\_config server\_2 -v "usrmapsvc info"**

```
1146154656: USRMAP: 4: Usrmapper service: Enabled

## CHANGING PRIMARY USERMAPPER SERVICE FROM SERVER 2 to SERVER 3

1. Verify state of current Usermapper Service:

\$ server\_usermapper server\_2

\$ .server\_config server\_2 -v "usrmapsvc info"

2. Disable Usermapper service on server\_2:

\$ server\_usermapper server\_2 -d

3. Set Debug Logging on Server\_3:

\$ .server\_config server\_2 -v "logsys set severity USRMAP=LOG\_DBG3"

4. Export the User and Group databases from Usermapper & do wordcount for number of lines:

\$ server\_usermapper server\_2 -Export -user users\_nov23

\$ server\_usermapper server\_2 -Export -group groups\_nov23

\$ wc -l users\_nov23 groups\_nov23

2415 4405

5. Create Tar Backup of Present Usermapper Directory:

# tar -zcpf /home/nasadmin/bak/usrmap.bak.tar.gz usrmapper

**Note:** Run command from /etc directory--tars & zips usrmapper directory to the location & filename indicated

6. Remove the Usermapper service and associated directory from server\_2:

**\$server\_usrmapper server\_2 -remove -all**

server\_2 : Warning: This operation will erase all user/group mappings.

7. Setup Primary Usrmapper service on Server\_3:

**\$server\_usrmapper server\_3 -enable**

**\$server\_usrmapper server\_3 -Import -user users\_nov23**

**\$server\_usrmapper server\_3 -Import -group groups\_nov23**

**\$server\_usrmapper server\_3**

server\_3 : Usrmapper service: Enabled

Service Class: Primary

8. Export Database files on Server\_3 and validate that line count is at least as great as the imported files:

**\$ server\_usrmapper server\_3 -Export -user users\_exp**

**\$ server\_usrmapper server\_3 -Export -group groups\_exp**

**\$wc -l users\_exp groups\_exp users\_nov23 groups\_nov23**

2415 4405 2415 4405

9. Delete all Internal Usrmapper Settings from netd files, including 127.0.0.1 from Server\_2:

**\$ cat /nas/server/slot\_\*/netd |grep -i usrmapper**

**\$ server\_cifs ALL -d usrmapper=192.168.1.2,192.168.2.2**

**\$ server\_cifs server\_2 -d usrmapper=127.0.0.1**

**Note:** Newer code versions may not require steps 9 or 10. The new primary Usrmapper service will be discovered as mapping requests are issued from each CIFS Server.

10. Add back all Internal Usrmapper settings for Server\_3 to Netd files:

**\$ server\_cifs ALL -add usrmapper=192.168.1.3,192.168.2.3**

**Note:** Delete server\_3's entry and readd as 127.0.0.1 (\$server\_cifs server\_3 -add usrmapper=127.0.0.1)

11. Verify Usrmapper service on Server\_3 by mapping new User/Group,export database if required to verify

12. Turn off debug logging USRMAP on Server\_3

## **INTERNAL USRMAPPER AND UPGRADES—IMPORTING FROM EXTERNAL USRMAPPER:**

**Caution:** External to Internal Usrmapper Upgrades are allowed for an existing “usrmap.cfg” file—see other section for more details. UIDs 1-32768 are reserved—first assignment would be 32768, GIDs start at 32770.

→Users will have a choice to continue using External Usrmapper Service [Defined as preferably a Primary-only service running on the Linux Control Station] or to Upgrade to the new Internal Usrmapper configuration via a procedure outlined in NAS 5.2 Tech Module, “Upgrading From External to Internal Usrmapper” May 2004.

**Migrations both from or to an External Usrmapper configuration are allowed using the following commands:**

**#server\_usrmapper server\_2 -export -user 1 -group <path>** [Import only to a primary Usrmapper server]

**#server\_usrmapper server\_2 -import -user 1 -group <path>** [Import database entries to the primary Usrmapper server]

**Caution:** Use –force only if importing and erasing existing entries—does not append!

**#/usrmap\_control dumpfilesall 3** [Used to output passwd/group files from External Usrmapper database]

## **EXPORTING INTERNAL USRMAPPER DATABASE:**

**# server\_usrmapper server\_2 -Export -user users**

server\_2 : done

**# server\_usrmapper server\_2 -Export -group groups**

server\_2 : done

→Used when migrating from the primary internal service to another source

→Used as a means to backup the database

→Used to collect information for troubleshooting

**Note:** Exports only from Primary Internal Usrmapper into version 3 [SIDs] “group” or “passwd” files.

## **PROCEDURE TO DISABLE SECMAP CACHING AND INTERNAL USRMAPPER:**

1. Disable Secmap Caching and Internal Usrmapper Autobroadcast by setting following params:

**#vi /nas/site/slot\_param**

**param usrmap autobroadcast=0**

**param cifs secmap.enable=0**

2. Create Backup Copy of User and Group Database from Internal Usrmapper:

**#server\_usrmapper server\_2 -Export -user /home/nasadmin/usrmap.passwd** [Export database to file as backup]

**#server\_usrmapper server\_2 -Export -user /home/nasadmin/usrmap.passwd** [Export database to file as backup]

**Note:** Must specify filename as usrmap.passwd and usrmap.group for export to succeed

3. Disable and remove the Internal Usrmapper Configuration:

**#server\_usrmapper server\_2 -disable**

**Note:** Command may not indicate that Internal Usermapper is disabled--ignore this and execute next command

**#server\_usrmapper server\_2 -remove -all**

**Caution:** This command deletes the Internal Usermapper directory from ./etc/usrmapper rootfs of DM. Please do not do this unless you have an alternate form of UID/GID Mapping in place in order to access Celerra CIFS Servers. In this example, customer reverted back to an already populated External Usermapper database. Trying to convert the Internal Usermapper passwd and group files into an acceptable format to accomodate importing into a new External Usermapper configuration is untested and unsupported at this time.

4. Stop CIFS Service

**#server\_setup server\_2 -P cifs -o stop**

5. Reboot Data Mover to put new params into effect and to disable SecMap caching

6. After Server is back up, manually delete the ./etc/secmap directory and all contents [#rm -Rf secmap]

7. Restart CIFS Service on Data Mover

8. Implement alternate means for mapping Users and Groups by UID/GID to the Celerra CIFS Server

**Note:** This procedure should no longer be the norm for NAS 5.2 or 5.3 installations or upgrades.

## **UNIVERSAL MODE OUTPUT:**

**\$ .server\_config server\_4 -v "usrmapserv info"**

## **WHAT DO THE \(32768) and @(32768) FIELDS REPRESENT FOR INTERNAL USERMAPPER:**

### **"usrmapserv info" output:**

**1096316892: USRMAP: 4: \(32768): 2** →This section represents unallocated or unused UID/GID ranges—i.e., ranges avail.

1096316892: USRMAP: 4: UID ffffffff :[0 8010-7ffffef] [1 10-7fff] →Section is where next UID range to be assigned will begin

1096316892: USRMAP: 4: GID ffffffff :[0 8030-7ffffef] [1 10-7fff] →Section is where next GID range to be assigned will begin

**1096316892: USRMAP: 4: @(32768): \* 2** →This section represents any Filled ranges and current UID/GID ranges in use

1096316892: USRMAP: 4: UID 8006 :(0 8000-800f) →Next UID to be assigned; currently allocated UID/GID ranges in use

1096316892: USRMAP: 4: GID 802e :(0 8001-801f) [1 8020-802f] →Next GID to be assigned; GID range filled; GID range used

**HOW DOES USRMAPD.DB FILE ENTRIES CORRESPOND TO USRMAPSVC INFO OUTPUT:****/nasmcd/quota/slot\_2/.etc/usrmapper****# ls -la usrmappc.db**

```
lrwxr-xr-x 1 root bin      54 Feb  7 15:30 @ -> 32768{32774,32814}:32768:32783!32769:32799,32800:32815
lrwxr-xr-x 1 root bin      57 Dec 12 09:01 \-> 32768:32784:2147483647,16:32767:32816:2147483647,16:32767
lrwxr-xr-x 1 root bin      13 Dec  6 13:44 2k3 -> 32768:0:0:0
lrwxr-xr-x 1 root bin      13 Dec 12 09:14 lab -> 32768:0:0:0
lrwxr-xr-x 1 root bin      13 Nov  9 20:06 ntdomain -> 32768:0:0:0
lrwxr-xr-x 1 root bin      13 Dec 12 09:01 w2k -> 32768:0:0:0
```

**Comments:** The @ line represents the default domain @ -> 32768, followed by next UID/GIDs to be mapped, respectively {32774,32814}, followed by currently allocated in-use range for UIDs (:32768:32783), then a separator !, followed by a filled range for GIDs (32769:32799), and the currently allocated in-use range for GIDs (32800:32815). The \-> 32768 line represents the unallocated or unassigned ranges still available for Internal Usermapper's default domain 32768, with :32784:2147483647 and 32816:2147483647 representing the available UID and GID ranges, respectively. The !, :, and ; all represent delimiters in the range lines.

**REPAIRING BROKEN RANGES IN USRMAPC.DB DIRECTORY:****GOOD RANGE ENTRIES:**

```
# ls -alrt /nasmcd/quota/slot_2/.etc/usrmapper/usrmapc.db
lrwxr-xr-x 1 root bin      13 Mar 13 21:07 lab -> 32768:0:0:0
lrwxr-xr-x 1 root bin      57 Mar 13 21:07 \-> 32768:32784:2147483647,16:32767:32784:2147483647,16:32767
lrwxr-xr-x 1 root bin      39 Mar 13 21:07 @ -> 32768{-1,32770}:32768:32783:32769:32783
```

**BAD RANGE ENTRIES:**

```
# ls -alrt
lrwxr-xr-x 1 root bin      21 Feb 28 12:49 \-> 32768:23232:26999:0:0 →This line is incomplete, no value for fields
lrwxr-xr-x 1 root bin      51 Mar  5 15:26 @ -> 27000{23224,-1}!22000:23215,23216:23231!27001:29999
```

**FIXING BAD RANGE LINE:****# mv \ bad-range** →This moves the bad range line called “\” and renames it to “bad-range”**# rm -f bad-range****# ln -s 32768:23232:26999:30000:32999 \** →Adds range back with complete ranges

```
# ls -alrt
lrwxr-xr-x 1 root bin      51 Mar  5 15:26 @ -> 27000{23224,-1}!22000:23215,23216:23231!27001:29999
lrwxrwxrwx 1 root  root    29 Mar  6 00:17 \-> 32768:23232:26999:30000:32999
```

**SETTING UP INTERNAL USERMAPPER IN CONFIG MODE (vs Universal Mode):**

1. Verify that current Internal Usermapper service has not been configured:

**# server\_usermapper server\_2**

server\_2 : Usrmapper service: Uninitialized

2. Import the usrmap.cfg file that defines Domains and Ranges in use for UIDs/GIDs (if needed, define path to the file):

**# server\_usermapper server\_2 -enable config=usrmap.cfg**

server\_2 : done

3. Import the User and Group database files, as originally exported from an External Usermapper configuration &amp; verify:

**# server\_usermapper server\_2 -Import -user usrmap.passwd**

server\_2 : done

**# server\_usermapper server\_2 -Import -group usrmap.group**

server\_2 : done

**# server\_usermapper server\_2**

server\_2 : Usrmapper service: Enabled

Service Class: Primary

4. Review Usermapper Configuration by using the following commands:

**# .server\_config server\_2 -v "usrmapserv info"**

1109605023: USRMAP: 4: Usrmapper service: Enabled

1109605023: USRMAP: 4: Service Class: Primary

1109605023: USRMAP: 4: Database File system: Root

**1109605023: USRMAP: 4: Configuration = usrmap.cfg****1109605023: USRMAP: 4: Mapping mode: config**

1109605023: USRMAP: 4:

1109605023: USRMAP: 4: Usermapper addresses

```
1109605023: SMB: 4:  
1109605023: SMB: 4: Usermapper[0] = [127.0.0.1] state:active (auto discovered)  
1109605023: USRMAP: 4:  
1109605023: USRMAP: 4: Cached enviroments

```

### **INTERNAL USERMAPPER: ADDING OR EXTENDING RANGES FOR CONFIG MODE:**

**Note:** Purpose is to edit the usrmap.cfg to add a new domain range or edit an existing range. The same rules apply to editing the usrmap.cfg as existed for External Usermapper. User or Group ranges can be “extended” using a single comma “,” between the original range and the new range being added.

1. Verify Usermapper Service is running prior to maintenance activity:

**\$ server\_usermapper server\_2**

```
server_2 : Usrmapper service: Enabled →Enabled means Usermapper Service is running normally  
Service Class: Primary
```

2. Export Users and Groups from database prior to making edits of usrmap.cfg file:

**# server\_usermapper server\_2 -Export -user users**

**# server\_usermapper server\_2 -Export -group groups**

3. Disable Usermapper Service prior to any editing of usrmap.cfg file:

**# server\_usermapper server\_2 -disable**

**# server\_usermapper server\_2**

```
server_2 : Usrmapper service: Initialized →Initialized means Usermapper Service has been disabled  
Service Class: Primary
```

**# server\_usermapper server\_2**

```
server_2 : Usrmapper service: Enabled
```

Service Class: Secondary

Primary = 192.1.4.250

**# .server\_config server\_2 -v "usrmapserv info"**

```
1146154500: USRMAP: 4: Usrmapper service: Initialized  
1146154500: USRMAP: 4: Service Class: Secondary  
1146154500: USRMAP: 4: Primary = 192.1.6.202  
1146154500: USRMAP: 4: Mapping mode: undefined  
1146154500: USRMAP: 4:
```

1146154500: USRMAP: 4: Usermapper addresses  
1146154500: USRMAP: 7: Broadcast internal usermapper addresses  
1146154500: USRMAP: 7: Interface broadcast addr #0: 192.168.2.255  
1146154500: USRMAP: 7: Interface broadcast addr #1: 192.168.1.255  
1146154500: USRMAP: 7: Send the usrmapper broadcast request  
1146154502: USRMAP: 4: Broadcast timeout, No answer received  
1146154502: USRMAP: 7: Usrmapper broadcast completed: 0/2

4. Navigate to the Data Mover's `/etc/usrmap` directory, then run the following commands, and compare—though the format is different, the `usrmap.cfg` file should match the `usrmapc.db` output:

**\$ cat usrmap.cfg**

RJ02:130000:130001:139000:139001:139999

**\$ ls -la usrmapc.db**

lrwxr-xr-x 1 root bin 34 Mar 17 11:39 rj02 -> 130000:**130001:139000:139001:139999**

**Note:** Above example shows the UID/GID ranges for the domain called “rj02”. 130001:139000 represents the UID range, while 139001:13999 represents the GID range.

5. Make a backup copy of the `usrmap.cfg` file before editing, then add the new domain range or extend an existing UID/GID range. In the following example we are going to extend the UID range for domain “rj02” using the “,” to separate the original UID range from the new UID range being added. Keep in mind that Usermapper rules do not allow you to use a UID range that overlaps any other UID ranges that may already be defined—same rule applies to GIDs:

**# cp usrmap.cfg usrmap.cfg.bak**

**# vi usrmap.cfg**

**Note:** Add new UID range, 600000-650000, to the domain “rj02”

6. Cat the `usrmap.cfg` file to verify that the edits look correct:

**# cat usrmap.cfg**

RJ02:130000:130001:139000,600000:650000:139001:139999

7. Set Debug Logging for Usrmapper Service:

**\$ .server\_config server\_2 “logsys set severity USRMAP=LOG\_DBG3”**

8. Start the Internal Usermapper Service and verify that it is ‘enabled’:

**# server\_usermapper server\_2 -enable**

server\_2 : done

**Note:** Do not use the ‘config=’ syntax when restarting Usermapper. Usermapper will automatically use the `usrmap.cfg` file in the `/etc/usrmap` directory.

**\$ server\_usermapper server\_2**

server\_2 : Usrmapper service: Enabled

Service Class: Primary

**Caution:** If Service does not restart, verify that the edits were correct and that none of the ranges added overlap. Turn on Debug Logging and run command again. If a range conflict occurs, the Server Log will show it with the following message:

**# server\_log server\_2 -s |grep -i usrmapping |tail**

2005-03-17 12:07:13: USRMAP: 3: Domain: uid, \_history\_sid\_range\_ clashes with the that of domain rj02

2005-03-17 12:07:13: USRMAP: 3: Cannot initialize database context

2005-03-17 12:07:13: USRMAP: 3: Usermapper service not started

9. With Usermapper Enabled, verify output of `usrmapc.db` file:

**# ls -la usrmapc.db**

lrwxr-xr-x 1 root bin 48 Mar 17 12:08 rj02 -> 130000:130001:139000,600000:650000:139001:139999

10. Verify Server Log for any errors or messages related to USRMAP, and have customer test by mapping a new test Windows User to the modified range.

11. Use additional commands to validate newly edited changes:

**# .server\_config server\_2 -v "usrmapping info"**

1111079909: USRMAP: 4: Usrmapper service: Enabled

1111079909: USRMAP: 4: Service Class: Primary

1111079909: USRMAP: 4: Database File system: Root

1111079909: USRMAP: 4: Configuration = `usrmap.cfg`

1111079909: USRMAP: 4: Mapping mode: config

1111079909: USRMAP: 4:

1111079909: USRMAP: 4: Usermapper addresses

1130447354: USRMAP: 7: Interface broadcast addr #0: 192.168.1.255  
1130447354: USRMAP: 7: Interface broadcast addr #1: 192.168.2.255  
1130447354: USRMAP: 7: Send the usrmapper broadcast request  
1130447356: USRMAP: 4: Broadcast timeout, No answer received  
1130447356: USRMAP: 7: Usrmapper broadcast completed: 0/2  
1130447356: USRMAP: 4:  
1130447356: USRMAP: 4: Cached enviroments  
1130447356: USRMAP: 4:  
1130447356: USRMAP: 4: 1 0x1725708 Env ???: Initialized

1130447356: USRMAP: 4:  
1130447356: USRMAP: 4: Cached domains  
1130447356: USRMAP: 4:  
1130447356: USRMAP: 4: \(32768): 2  
1130447356: USRMAP: 4: UID ffffffff :[0 8000-7fffffff] [1 10-7fff]  
1130447356: USRMAP: 4: GID ffffffff :[0 8760-7fffffff] [1 10-7fff]  
1130447356: USRMAP: 4:  
1130447356: USRMAP: 4: pegasus(100000): 1  
1130447356: USRMAP: 4: UID ffffffff :[0 186a1-1a9c8] →Brackets would normally indicate Config Mode range  
1130447356: USRMAP: 4: GID ffffffff :[0 1a9c9-1adaf] →But, UID/GID ffffffff means that no mappings have yet been made  
1130447356: USRMAP: 4: am-sd-nt(50000): 1  
1130447356: USRMAP: 4: UID c36a :[0 c351-e678] →c36a = 50,026 & is the next UID to be assigned from [ ] range  
1130447356: USRMAP: 4: GID e694 :[0 e679-ea5f]  
1130447356: USRMAP: 4: telemar(20000): 1  
1130447356: USRMAP: 4: UID 26169 :[0 4e21-7148] [1 8823-892f] [2 249f0-26d18]  
1130447356: USRMAP: 4: GID ffffffff :(0 7149-752f) (0 8000-8085) (0 8000-875f) (0 26d19-270ff) →This particular line shows the bug. When bug is present, the GID range has become automatically extended. From previous usrmap.cfg file, we know that the other ( ) ranges are correct—the fact that they now have a ( ) around the ranges vs. a [ ] is another indicator of the bug and means that Usrmapper has been stopped and now cannot be restarted, for the GID range goes to ffffffff as it no longer knows what the next GID should be. Meanwhile, the damage here is that 8000-875f has been dynamically assigned by Usrmapper, and conflicts with previous range definitions in the usrmap.cfg file, meaning that range rules have been violated and usrmapper cannot restart:

#### **Server Log Error:**

2005-10-27 14:43:43: USRMAP: 3: Decreasing the max uid or gid for domain telemar below already allocated ranges is not allowed

### **REPAIRING INTERNAL USERMAPPER EMC104375:**

1. Verify current Internal Usermapper state:

**# server\_usermapper server\_2**

server\_2 : Usrmapper service: Initialized -->Indicates Service is not running  
Service Class: Primary

2. Attempt to restart Service:

**# server\_usermapper server\_2 -enable**

3. Review Server Log if service fails to go to "Enabled" state

2005-04-01 15:38:57: USRMAP: 4: Starting usermapper service

2005-04-01 15:38:57: USRMAP: 3: Decreasing the maximum uid or gid for domain karma below already allocated range is not allowed: 200{1122,33128}:1000:10000!1000:2000;32768:33119,33120:33135

2005-04-01 15:38:57: USRMAP: 3: Cannot initialize database context

2005-04-01 15:38:57: USRMAP: 3: Usermapper service not started

2005-04-01 15:38:59: USRMAP: 4: Broadcast timeout, No answer received

**Note:** Output indicates that Internal Usermapper cannot restart because of range violation. See emc104375 for a more complete description—problem is triggered only after Primary Usermapper Server has been rebooted. Once a User or Group range has been filled, Usermapper will revert to Universal Mapping mode and begins assigning UIDs or GIDs from the 32768 range, regardless of whether other domain ranges have been defined to use this range, therefore leading to the problem described herein. Usermapper will continue to run in this condition until the service is stopped. Once stopped, it will not restart.

4. Review output of "usrmapsvc info" to confirm problem:

1112393920: USRMAP: 4: Usrmapper service: Initialized

1112393920: USRMAP: 4: Service Class: Primary

1112393920: USRMAP: 4: Database File system: Root

1112393920: USRMAP: 4: Configuration = usrmap.cfg -->CONFIG Mode

1112393920: USRMAP: 4: Mapping mode: undefined -->Mapping mode undefined indicates problem

5. Export Users and Groups databases from Internal Usermapper:

**\$server\_usermapper server\_2 -Export -user users**

**\$server\_usermapper server\_2 -Export -group groups**

6. Download Users, Groups, & usrmap.cfg files. Take output from "usrmapsvc info" and compare to contents on usrmap.cfg and determine which ranges have been affected by the current problem. Determine whether database can be repaired:

1112393922: USRMAP: 4: karma(200): 1

1112393922: USRMAP: 4: UID 462 :[0 3e8-2710]

1112393922: USRMAP: 4: GID 8168 :(0 3e8-7d0) (0 8000-815f) [1 8160-816f]

**# cat usrmap.cfg**

karma,karma.com:200:1000:10000:1000:2000

**Note:** The range that has reverted to Universal Mapping mode is indicated by the ( ) parentheses, indicating that ranges have been filled, followed by [ ] brackets, indicating that a new range has been dynamically assigned. Checking the hex value for "8168" shows that the last GID assigned was 33,128. In this example, GIDs 32,768 - 33,128 have been assigned to the 'Karma' domain--review the Group file to validate. Also in this example, the fixed domain range "lesskarma.com" has been violated by Universal Mapping mode and is the reason that Internal Usermapper cannot restart. As a matter of record here, the "lesskarma.com" range had not previously been used, meaning that a database repair was feasible without deleting any Group mappings.

7. Modify the usrmap.cfg file to reflect the actual mappings that occurred prior to Usermapper failing and to separate the ranges so that no overlapping occurs in the config file--Usermapper will not start if ranges overlap:

### # vi usrmap.cfg

```
karma,karma.com:200:1000:10000:1000:2000,32768:33127,54801:56000
```

```
lesskarma.com:980:206000:207999:32700:32767,33128:33200
```

**Note:** This example shows a corrected config file and remaps the ranges to reflect what 'Karma' was assigned while removing those assignments from the 'Lesskarma' range.

8. For any User or Group ranges that have been automatically extended, review the appropriate database file for duplicate entries. In this casestudy, all mappings that occurred when Usermapper went into Universal Mapping mode, were duplicated into two separate sections in the groups file. Validate and then remove the duplicated entries.

9. Once the Users, Groups, and usrmap.cfg files have been validated and made ready for a fresh import, test on a lab box to validate the Import process, the usrmap.cfg file, and that Usermapper will 'Enable' properly. Set debug logging for USRMAP and conduct the following steps:

a. # .server\_config server\_2 -v "logsys set severity USRMAP=LOG\_DBG3"

b. # server\_usermapper server\_2 -enable config=usrmap.cfg

server\_2 : done

c. Check Server Log for Success:

```
2005-04-01 19:21:19: ADMIN: 4: Command succeeded: usrmapsvc enable config=usrmap.cfg
```

d. Dump Usermapper Configuration, review output to verify Config Mode, and examine all domain ranges:

# .server\_config server\_2 -v 32768 "usrmapserv info"

```
1112401312: USRMAP: 4: Usrmapper service: Enabled
```

```
1112401312: USRMAP: 4: Service Class: Primary
```

```
1112401312: USRMAP: 4: Database File system: Root
```

```
1112401312: USRMAP: 4: Configuration = usrmap.cfg
```

```
1112401312: USRMAP: 4: Mapping mode: config
```

# .server\_config server\_2 -v 32768 "usrmapserv registry"

```
1112401322: USRMAP: 4: Registry:
```

```
1112401322: USRMAP: 4:           Config = usrmap.cfg
```

```
1112401322: USRMAP: 4:           Identity = 192.168.1.2,192.168.2.2
```

```
1112401322: USRMAP: 4:           Started = on
```

```
1112401322: ADMIN: 4: Command succeeded: usrmapsvc registry
```

e. Import Users & Groups databases & Verify Service:

# server\_usermapper server\_2 -Import -user users

server\_2 : done

# server\_usermapper server\_2 -Import -group groups

server\_2 : done

# server\_usermapper server\_2

server\_2 : Usrmapper service: Enabled

Service Class: Primary

f. Verify Imports in Server Log:

```
2005-04-01 18:49:29: USRMAP: 4: 2884 new users imported
```

```
2005-04-01 18:49:43: USRMAP: 4: 2544 new groups imported
```

```
2005-04-01 18:49:43: ADMIN: 4: Command succeeded: usrmapsvc import
```

g. Re-export databases & verify against original Files:

# server\_usermapper server\_2 -Export -user user\_post

server\_2 : done

# server\_usermapper server\_2 -Export -group group\_post

server\_2 : done

h. Verify Usermapper Service, Check Server Log, ouput Usrmapsvc Info & Server\_Cifs:

\$ server\_usermapper server\_2

server\_2 : Usrmapper service: Enabled

Service Class: Primary

**Server Log:**

2005-04-04 11:04:25: USRMAP: 4: Usermapper[127.0.0.1] now available

**\$ .server\_config server\_2 -v "usrmapserv info" |head -20**

1112703824: USRMAP: 4: Usrmapper service: Enabled

1112703824: USRMAP: 4: Service Class: Primary

1112703824: USRMAP: 4: Database File system: Root

1112703824: USRMAP: 4: Configuration = usrmap.cfg

1112703824: USRMAP: 4: Mapping mode: config

**\$ server\_cifs server\_2**

Usermapper[0] = [127.0.0.1] state:active (auto discovered)

10. Upload modified database & usrmap.cfg files & Rebuild Internal Usermapper on Production System:

a. **# cp -Rf usrmapper /home/nasadmin** (save copy of original database)

b. **# server\_usermapper server\_2 -disable**

c. **# server\_usermapper server\_2 -remove -all**

Yes

**Note:** This will delete the usrmapper directory and completely uninstall Usermapper

d. Follow re-import & verification steps outlined in Step 9 above

11. Verify Internal Usermapper operation with customer

## **NAS 5.2.14 EXTERNAL TO INTERNAL USRMAPPER UPGRADE PROCEDURE**

**Note:** Minimum NAS 5.2.14.0 and External Usrmapper 3.1.4. Upgrade to NAS 5.2.14.0 or higher in order to use External-to-Internal Usrmapper conversion procedure. For NAS Upgrades from 5.1 to 5.2, External Usrmapper will continue to run normally under the control of the nas\_mcd daemon and, by default, will NOT initialize the Internal Usrmapper service on Server\_2.

### **EXTERNAL-TO-INTERNAL USERMAPPER CONVERSION CAVEATS:**

→ Ensure that Data Mover rootfs contains sufficient space and Inodes to support both SecMap Caching and Internal Usrmapper. Each User and Group mapped to the Celerra by Internal Usrmapper requires (4) rootfs inodes to support Internal Usrmapper mappings & (2) rootfs inodes to support SecMap Caching.

**Notes:** Do not convert to Internal Usrmapper without calculating size of current Usrmapper database and available inodes on rootfs of data mover! Be aware that you can disable secmap caching and still use Internal Usrmapper. Be advised that NAS 5.6 eliminates the need for Inodes for Secmap or Usermapper entries, and therefore, the space and Inode limitations are no longer a factor. 5.6 will convert the flat inode-based “namedb” databases to a Berkeley database.

→ Do not convert from External to Internal Usrmapper with NAS Versions prior to 5.2.14-0 [See example of error message seen below] or Usermapper Versions prior to 3.1.4 [With 3.1.3 the -disable command does not work properly]

**#server\_usermapper server\_2 -enable config=/nas/cifs/usrmapperV3/linux/usrmap.cfg**

server-2 :

Error 2225 : server\_2 -enable config=/nas/cifs/usrmapperV3/linux/usrmap.cfg: invalid operation

→ Beginning with NAS 5.2, for installations that are not yet running Internal Usermapper configurations, customers will have the option to continue to use the existing External Usermapper configuration or to upgrade to an Internal Usermapper configuration. However, please note that there are rules, procedures, and limitations to be considered when performing an "External to Internal" Usermapper migration that must be reviewed and understood. It should be understood that the primary documentation for the External-to-Internal Usermapper upgrade is the published Engineering Technical Module--"Upgrading from External Usermapper 3.1 to Internal Usermapper" Version 5.3 August 2004 Rev A01--use this doc as reference material only--use the Engineering Tech Module steps to perform the Upgrade. The Tech Module information should be referenced & available via the CCA [Change Control Activity] Review Process.

## **UPGRADING (CONVERTING) FROM EXTERNAL TO INTERNAL USERMAPPER SERVICE:**

### **1. Verify Status of Current Configuration Prior to Converting:**

**#ps -ef |grep usrm** [verifies that External Usrmapper Service is running]

root 7816 7336 0 May13 ? 00:00:00 /nas/cifs/usrmapperV3/linux/usrm

**#server\_usermapper server\_2**

server\_2: Usermapper Service: Uninitialized

**Note:** Internal Usermapper Service should still be “uninitialized” at this point. If not, run #server\_usermapper server\_2 -disable

**#server\_cifs server\_2**

Usermapper[0] = [10.241.169.43] state:available

**Note:** Verify that DM's point to External Usermapper Service, in this case '10.241.169.43' represents CS0's External IP address

### **2. Enable Server\_2 as a Secondary Usermapper and point to IP Address of External Usermapper Service:**

**#server\_usermapper server\_2 -enable primary=10.241.169.43** [syntax to use when not specifying an existing usrmap.cfg file]

#server\_usrmapper server\_2 -enable primary=10.241.169.43 config=/nas/cifs/usrmapperV3/linux/usrmap.cfg [syntax when using specific usrmap.cfg file settings]

server\_2 : done

**Comment:** You can import usrmap.passwd and usrmap.group databases from an External Usermapper source and allow Internal Usermapper to automatically assign new UID/GIDs from the default 'Universal Mapping' ranges, or, you can reference the path to the external usrmap.cfg file to retain the original ranges and databases defined in the External Usermapper configuration, and then import the usrmap.group and usrmap.passwd files from the External Usermapper database as shown in Step 6 below. Best practices dictates that you DO NOT use the usrmap.cfg file unless absolutely required by the Customer. Usermapper maintenance is virtually eliminated if not using the usrmap.cfg file (CONFIG Mode) and instead running in UNIVERSAL Mode.

### 3. Verify Functionality of Secondary Usermapper Service:

#server\_usrmapper server\_2

server\_2 : Usrmapper Service : Enabled

Service Class: Secondary

Primary = 10.241.169.43 <c> → "c" means that Secondary has contacted the Primary service

### 4. Delete the External Usrmapper Reference from ALL CIFS Data Movers:

#server\_cifs server\_2 -delete usrmapper=10.241.169.43

### 5. Dump the entire External Usrmapper database in Version 3 format (SIDs listed first):

#/nas/cifs/usrmapperV3/linux/usrmap\_control dumpfilesall 3

### 6. Take the Version 3 dumpfiles [usrmap.passwd & usrmap.group] and Import the files one at a time into Internal Usrmapper's database:

#server\_usrmapper server\_2 -Import -user /nas/cifs/usrmapperV3/linux/usrmap.passwd

#server\_usrmapper server\_2 -Import -group /nas/cifs/usrmapperV3/linux/usrmap.group

server\_2 : done

**Note:** If importing to an already existing database, you must use the "-force" switch if you wish to overwrite--otherwise, entries are appended to the existing database. Check Server Log after importing is complete to check for import errors.

### 7. Change Usrmapper Service on Server\_2 from Secondary to Primary to complete conversion to Internal Usrmapper:

#server\_usrmapper server\_2 -disable

#server\_usrmapper server\_2 -enable primary=127.0.0.1

server\_2 : done

**Note:** Above command enables Server\_2 as the Primary Internal Usermapper service and uses its loopback address to reference itself as the Primary. All other Data Movers would 'discover' the Primary Internal Usermapper service via broadcast across the internal IP network.

### 8. Verify Primary Service on Server\_2:

#server\_usrmapper server\_2

server\_2 : Usrmapper service: Enabled

Service Class: Primary

#server\_cifs server\_2

Usermapper auto broadcast enabled

Usermapper[0] = [127.0.0.1] state:active (auto discovered)

### 9. Disable External Usrmapper Service on CS0:

- comment out "Usermapper Service" from /nas/sys/nas\_mcd.cfg file
- Stop & Restart NAS Services and verify that External Usrmapper does not restart
- Rename External Usrmapper executables so that the process does not inadvertently restart
- Conduct tar backup of external usrmapper directory and archive to safe location
- Ensure local passwd and group files are removed from data movers--stop & restart CIFS to flush cache.

### 10. Check SecMap Caching and Internal Usermapper Broadcast Parameters:

**Note:** Run the appropriate commands or check the param files to verify the current settings for the SecMap caching mechanism and the Internal Usermapper Broadcast mechanism. Due to certain limitations of earlier NAS 5.2 versions, either one or both of these parameters may have been disabled--review the 'Upgrade Caveats' outlined at the beginning of this solution prior to changing any params. If the following params are set in the param files, remove them and reboot the Data Mover(s).

param usrmap autobroadcast=0 [Indicates that Internal Usermapper Autobroadcast feature is disabled; =1 to enable broadcast]

param cifs secmap.enable=0 [Indicates that SecMap caching mechanism is disabled; =1 to enable SecMap caching]

### 11. Verify Internal Usrmapper Configuration Files:

- Go to root of datamover and verify contents of "usrmapper" directory [/nasmd quota/slot\_2/etc/ usr mapper]:

#### Typical Internal Usrmapper Directory Contents after Converting from External Usrmapper:

/nasmd quota/slot\_2/etc/ usr mapper

```
drwxr-xr-x 2 root bin 1024 May 14 13:42 aliases.db
drwxr-xr-x 2 root bin 80 May 14 12:52 extidxname.db
drwxr-xr-x 2 root bin 80 May 14 12:52 extuidgidxsid.db
drwxr-xr-x 2 root bin 1024 May 14 13:52 groupmapnamesid.db
```

```
drwxr-xr-x 2 root bin 1024 May 14 13:53 idxname.db
drwxr-xr-x 2 root bin 2048 May 14 13:53 sidname.db
drwxr-xr-x 2 root bin 80 May 14 12:52 uidgidsid.db
drwxr-xr-x 2 root bin 1024 May 14 13:53 usrrpmapnamesid.db
drwxr-xr-x 2 root bin 1024 May 14 13:53 usrmapc.db
-rw-r--r-- 1 root bin 117 May 14 12:52 usrmap.cfg
drwxr-xr-x 2 root bin 1024 May 14 13:52 usrmappc.db
-rw-r--r-- 1 root bin 62 May 14 13:05 usrmap.settings
drwxr-xr-x 2 root bin 1024 May 14 13:53 usrmapusrc.db
```

**Note:** All User and Group mappings that were imported can be found in “usrmapusrc.db” and “usrmapgrpc.db”, respectively.

b.) Verify entries in Usrmap.Settings file:

```
# cat usrmap.settings
```

Config=usrmap.cfg

Identity=192.168.1.2,192.168.2.2

Started=on

c.) Export Internal Usermapper Database and compare beginning and ending entries between External and Internal Usermapper:

```
#server_usrmapper server_2 -Export -user /home/nasadmin/usrmap.passwd
```

```
#server_usrmapper server_2 -Export -group /home/nasadmin/usrmap.group
```

## 12. Test Internal Usermapper with New User Account & Verify UID/GID Counters are incrementing correctly:

```
# ls -la usrmapc.db
```

```
lrwxr-xr-x 1 root bin 57 May 14 12:52 \-> 32768:32768:2147483631,16:32767:32768:2147483631,16:32767 [default ranges]
```

```
lrwxr-xr-x 1 root bin 27 May 14 13:42 _history_sid_range_-> 600:60000:65000:51001:52999 [imported History Sid range]
```

**lrwxr-xr-x 1 root bin 22 May 14 13:53 ts2 -> 10{50,97}:40:80:90:120 ->Imported domain range-next available UID/GID counters are in red**

**Note:** Testing access with New User--UID/GID counters should increment properly, starting at UID/GID number in sequence as found in the imported usrmap.passwd or usrmap.group files. This step is not necessary when using the 'Universal Mapping Mode'. In otherwords, this step would only be prudent if importing an existing usrmap.cfg file when upgrading from External to Internal.

### EXAMPLE OF LAST ENTRY IN EXPORTED PASSWD FILE (From step 11c):

```
S-1-5-15-1f6d0078-63f6f323-65d637a8-488:*:48:10:user mapper8 from domain ts2:/usr/S-1-5-15-1f6d0078-63f6f323-65d637a8-488:/bin/sh
```

**AFTER ACCESS WITH NEW USER:** # ls -la usrmapusrc.db |tail -4

```
23-65d637a8-489 -> S-1-5-15-1f6d0078-63f6f323-65d637a8-489:*:49:10:user mapper9 from domain ts2:/usr/S-1-5-15-1f6d0078-63f6f323-65d637a8-489:/bin/sh
```

```
lrwxr-xr-x 1 root bin 130 May 14 13:53 S-1-5-15-1f6d0078-63f6f3
```

**Note:** Usrmapc.db directory shows that next UID to be assigned for “ts2” domain is {50,97} and next GID is 97

## **DISABLING & REMOVING AN EXISTING INTERNAL USRMAPPER CONFIGURATION:**

1. Verify Existing Usermapper operation:

```
# server_usrmapper server_2
```

server\_2 : Usrmapper service: Enabled

Service Class: Primary

2. Disable Internal Usermapper & Verify:

```
# server_usrmapper server_2 -disable
```

server\_2 : done

```
# server_usrmapper server_2
```

server\_2 : Usrmapper service: Initialized →Note that service goes from “Enabled” to “Initialized”

Service Class: Primary

3. Remove the Usrmapper Database from the Server & Verify:

```
# server_usrmapper server_2 -remove -all
```

server\_2 : Warning: This operation will erase all user/group mappings.

CIFS users may lose access.

Continue(Y/N):

done

**Note:** Prior to deleting, export the Users and Groups from Usermapper, and copy usrmap.cfg, since the –remove –all command will delete the entire usrmapper directory.

```
# .server_config server_2 -v "ls -l .etc" |grep -i usrmapper
```

<directory is not found>

4. Since server\_cifs output still shows Autobroadcast feature enabled, disable by entering the following param and rebooting the Server:

## Usermapper auto broadcast enabled

#vi /has/site/slot\_param

### param usrmap autobroadcast=0

5. Delete the Internal Usermapper Reference from CIFS Configuration on all Data Movers:

**Usermapper[0] = [127.0.0.1] state:available (internal)**

**# server\_cifs server\_2 -delete usermapper=127.0.0.1**

server\_2 : done

6. Reboot Servers as allowed to disable the autobroadcast feature

7. As a final note, disable and delete the SecMap Cache if required by disabling the SecMap feature in the param file, rebooting the Server, then manually removing the ./etc/secmap directory (keep an archive copy if possible)

## USRMAPPER 3.1.4: NAS 5.2.8-2006

**./usrmap\_control -disable** [Disables and stops Usermapper service, temporarily]

The Usermapper server mapping functions are now DISABLED!

**Note:** Usrmapper mappings are disabled and Users cannot map to Celerra. However, the process still shows as running:

#ps -ef |grep usrm

### Usrmapper Log Entry:

“User has DISABLED mapping functions of the Usermapper server.”

**./usrmap\_control status**

Status of local Usermapper Server:

IP Address \_\_\_\_\_ 143.242.14.72

Primary/Secondary \_\_\_\_\_ Primary

Secondary Usermapper IPs\_\_\_\_\_

State \_\_\_\_\_ Enabled

**./usrmap\_control -enable**

The Usermapper Server mapping functions are now ENABLED!

Usermapper Service will now restart...

**Note:** Recognizes that usrmapper is still running under the control of the NAS MCD. Once ‘enabled’, actually stops the Service and lets NAS restart it. If External Usrmapper has been disabled, and Internal Usrmapper enabled for first time, creates following:

**/etc/usrmapper**

(11) default db directories & creates usrmap.settings file

**/etc/secmap**

@gid [Contains GIDs that have been mapped into Secure Map]

S-1-5-15....[Contains SIDs of Users and Groups that have been mapped]

@uid [Contains UIDs that have been mapped]

**Note:** Once Users or Groups have accessed the Celerra and obtained a “secmap” mapping, the Usrmapper Service can be disabled, Users and Groups will still have access to CIFS. The “secmap” database permanently maps a User or Group SID to the data mover and is persistent on Server reboots.

## INITIALIZING INTERNAL USRMAPPER DB WITHOUT “ENABLING” ROLE (i.e., Primary or Secondary):

**Note:** Use following procedure to create Secondary Usermapper server with fully populated database from Primary side

1. Stop CIFS on Secondary Usermapper server

2. Disable Secondary Usrmapper service

**#server\_usrmapper server\_2 -disable**

3. Remove Secondary Usermapper database configuration:

**#server\_usrmapper server\_2 -remove -all**

4. Remove, copy, or tar Secmap directory from ./etc/secmap to /home/nasadmin as a backup

**#rm -Rf secmap**

**# cp -Rip secmap /home/nasadmin/tm/**

**#tar -zcpf /home/nasadmin/bak/usrmap.bak.tar.gz usrmapper** [Run from ./etc directory]

5. Reboot Server\_2 to clear cache

6. Rebuild Secondary Usermapper using “usrmapsrv init” command to create the database structure without starting the Usermapper Service, which in this case is crucial so that the -Export functions will work later on

**# .server\_config server\_2 -v "usrmapsrv init"**

1100566384: USRMAP: 6: Opening the database...

1100566384: USRMAP: 6: Domain cache unloaded

```
1100566384: USRMAP: 7: \domain loaded
1100566384: USRMAP: 6: Usermapper domain manager started
1100566384: USRMAP: 3: Usermapper service not started
1100566384: ADMIN: 4: Command succeeded: usrmapsvc init
# server_usermapper server_2 -Import -user pass_pri [files were uploaded from Primary Usermapper side]
server_2 : done
# server_usermapper server_2 -Import -group gru_pri
server_2 : done
# server_usermapper server_2 -enable primary=161.156.232.22 [Point to IP Address of Primary Usermapper Service]
server_2 : done
# server_usermapper server_2
server_2 : Usrmapper service: Enabled
Service Class: Secondary
Primary = 161.156.232.22 (c) → "c" means that Secondary has contacted the Primary service
7. Start CIFS and verify access using server_cifsstat
8. Export Secondary Usermapper database and verify format of passwd and group files
```

## **REBUILDING INTERNAL USERMAPPER & IMPORTING USERS/GROUPS:**

1. Backup information as needed, then remove any existing traces of Internal Usermapper from your system

**#server\_usermapper server\_2 -disable**

**#server\_usermapper server\_2 -remove -all**

2. Set debug logging for Usrmapper:

**#.server\_config server\_2 -v "logsys set severity USRMAP=LOG\_DBG3"**

3. Re-initialize Internal Usermapper using following command:

**# .server\_config server\_2 -v "usrmapserv init"**

4. First do wordcount and then import the users and groups into the existing internal usermapper db:

**#cat users lwc -l #cat groups lwc -l**

**#server\_usermapper server\_2 -Import -user users**

**#server\_usermapper server\_2 -Import -group groups**

5. Enable the usermapper service:

**#server\_usermapper server\_2 -enable**

6. Check Server Log to see if Imports succeeded and run \$server\_usermapper to see if 'Enabled'

7. Output Usermapper database to see if output files wordcount matches what was imported:

**#server\_usermapper server\_2 -Export -user users\_after**

**#server\_usermapper server\_2 -Export -group groups\_after**

**#wc -l users\_after groups\_after**

8. Run following command to check health of Internal Usermapper, and verify ranges in hex output.

**\$ .server\_config server\_4 -v "usrmapserv info"**

1121362991: USRMAP: 4: Usrmapper service: Enabled

1121362991: USRMAP: 4: Service Class: Primary

1121362991: USRMAP: 4: Database File system: Root

1121362991: USRMAP: 4: Mapping mode: universal

9. Turn off debug USRMAP=LOG\_ERR

10. Map new Users as test & re-export database to verify new mappings

## **SERVERT USERMAPPER COMMAND OPTIONS:**

\$server\_usermapper ALL |-enable primary= | -disable | -remove -all | -import | -export -user -group -force <pathname>

**-enable | -disable:** Starts or stops Usermapper service to allow for configuration changes, maintenance, removal, etc.

**primary=:** Used to create a Secondary Usermapper Service and specifies the Primary Server

**secondary=:** Used by Primary to learn about the newly created Secondary Usermapper Server

**config=:** Used only by Primary Usermapper when migrating from an External to Internal Usermapper configuration

**-remove -all:** Permanently removes Usrmapper directory from Primary or Secondary Usermapper server

**-Import -user | -group | -force:** Imports either Users/Groups to the Data Mover

**Note:** Use the -force option to overwrite the existing /etc/usrmapper database--By default, imported Users or Groups are appended to the existing database.

**-Export -user | -group:** Exports users & groups file from Primary or Secondary Usermapper databases

## \$server\_usrmapper server\_2

server\_2: Usrmapper service: Enabled

Service Class: Primary

**Note:** Used to verify the usrmapper service on a data mover

**\$server\_usrmapper server\_2 -disable** [Used to temporarily disable the Usermapper service]

## INTERNAL USRMAPPER PARAMS:

### NAS 5.6 USRMAPPER PARAMS:

**# server\_param server\_2 -facility usrmap -list**

server\_2 :

|               |          |            |            |            |
|---------------|----------|------------|------------|------------|
| param_name    | facility | default    | current    | configured |
| maxuid        | usrmap   | 2147483647 | 2147483647 |            |
| mingid        | usrmap   | 16         | 16         |            |
| autobroadcast | usrmap   | 1          | 1          |            |
| maxgid        | usrmap   | 2147483647 | 2147483647 |            |
| minuid        | usrmap   | 16         | 16         |            |

**Note1:** Please note that when changing min or max params with NAS 5.5 or 5.6, the Server must be rebooted in order for the change to go into effect. This behavior is different from pre-5.6 NAS versions.

**# server\_param server\_2 -facility usrmap -modify maxgid -value 65535**

server\_2 : done

Warning 17716815750: server\_2 : You must reboot server\_2 for maxgid changes to take effect.

**Note2:** Ranges are only effective when initially creating the database—they have no affect when modifying after a database has already been created.

## CONFIGURING INTERNAL USRMAPPER PORT:

**Note:** Internal Usermapper uses port 12345 by default, hex 3039. Use following procedure to change port.

1. Verify existing port:

**# .server\_config server\_2 -v "param usrmap" |grep -i port**

usrmap.port 0x01721988 0x00003039 0x00003039

**Note:** 3039 is hex value for port 12345

2. Disable Usermapper Service:

**# server\_usrmapper server\_2 -disable**

3. Change usermapper service port:

**# .server\_config server\_2 -v "param usrmap port=1012"**

4. Re-enable Usermapper:

**# server\_usrmapper server\_2 -enable**

5. Verify port changed & service is listening:

**# .server\_config server\_2 -v "param usrmap" |grep -i port**

usrmap.port 0x01676b78 0x00003039 0x00003039

**Note:** Port 3039 is hex for 12345

**# server\_netstat server\_2 -a |grep 12345**

tcp \*.12345 \*.\* LISTEN

udp \*.12345

## INTERNAL USRMAPPER CONFIGURATION OUTPUT:

**# .server\_config server\_2 -v "usrmapserv info"**

1096316892: USRMAP: 4: Usrmapper service: Enabled

1096316892: USRMAP: 4: Service Class: Primary

1096316892: USRMAP: 4: Mapping mode: universal

1096316892: USRMAP: 4: Usermapper addresses

1096316892: SMB: 4: Usermapper[0] = [127.0.0.1] state:available (internal)

1096316892: USRMAP: 4: Cached environments

1096316892: USRMAP: 4: 1 0x218d2504 45 ?: Enabled

1096316892: USRMAP: 4: 1 0x14a8258 Env ?: Enabled

1096316892: USRMAP: 4: Cached domains

**1096316892: USRMAP: 4: \(32768): 2** →This section represents unallocated or unused UID/GID ranges—i.e., ranges avail.

1096316892: USRMAP: 4: UID ffffffff :[0 8010-7ffffef] [1 10-7fff] →Section is where next UID range to be assigned will begin

1096316892: USRMAP: 4: GID ffffffff :[0 8030-7ffffef] [1 10-7fff] →Section is where next GID range to be assigned will begin

**1096316892: USRMAP: 4: @ (32768): \* 2** →This section represents any Filled ranges and current UID/GID ranges in use

1096316892: USRMAP: 4: UID **8004** :[0 **8000-800f**] →Next UID to be assigned; currently allocated UID/GID ranges in use  
1096316892: USRMAP: 4: GID **8029** :(0 **8001-801f**) [1 **8020-802f**] →Next GID to be assigned;GID range filled; GID range used  
1096316892: USRMAP: 4: operations(32768): 1  
1096316892: USRMAP: 4: ops(32768): 1  
1096316892: USRMAP: 4: ohiodom004(32768): 1  
1096316892: ADMIN: 4: Command succeeded: usrmapsvc info

**Note:** Above command represents internal information stored for usrmappc.db file. When in Universal Mode [i.e., not using an imported usrmap.cfg file from a previously used external Usermapper configuration], the domain names do not have a range defined. Usermapper takes the “\” available range to allocate ranges for UID/GIDs, and assigns values to the “@” universal domain as assigned ranges—both \ and @ ranges are complementary and when added together represent the Global mapping range in use.

## **INTERNAL USERMAPPER DEBUG LOGGING:**

**\$ .server\_config server\_2 -v "logsys set severity USRMAP=LOG\_DBG3"**

**\$ server\_usermapper server\_2 -disable**

server\_2 : done

**\$ server\_usermapper server\_2**

server\_2 : Usrmapper service: Initialized

Service Class: Primary

**Note:** Notice that the –disable command changes the service from “Enabled” to “Initialized”. Check Server Log for more details.

**\$ server\_log server\_2 -a |grep -i USRMAP**

1105582533: USRMAP: 5: Usrmapper threads stopped

1105582533: USRMAP: 6: Environment cache unloaded

1105582533: USRMAP: 4: 3: Usermapper service disabled

1105582533: ADMIN: 4: Command succeeded: usrmapsvc disable

## **VARIOUS COMMANDS TO DEBUG USERMAPPER MAPPINGS OF USERS, GROUPS, SIDS:**

**\$ .server\_config server\_2 -v "usermapper if=cge0 user=nas10"**

1105585082: SMB: 4: UserName0='MOUSE\nas10' (0) use=1

S-1-5-15-42f831d9-66417ccd-28a68b82-498 nas10

1105585082: VC: 5: abortCheckWait(smb\_share=0x0)

1105585082: SMB: 4: User mouse\nas10 **UID=32779** →Lookup by User Name returns UID value

**\$ .server\_config server\_2 -v "usermapper if=cge0 group='domain admins'"**

1109767775: SMB: 4: UserName0='MOUSE\domain admins' (0) use=2

S-1-5-15-42f831d9-66417ccd-28a68b82-200 domain admins

1109767775: VC: 5: abortCheckWait(smb\_share=0x0)

1109767775: SMB: 4: Group mouse\domain admins **GID=2000** →Lookup by Group Name returns GID value

**Note:** Use above command to validate that Usermapper can map a User or Group.

**\$ .server\_config server\_2 -v "usermapper if=cge0 group='domain admins'"**

1109767775: SMB: 4: UserName0='MOUSE\domain admins' (0) use=2

S-1-5-15-42f831d9-66417ccd-28a68b82-200 domain admins

1109767775: VC: 5: abortCheckWait(smb\_share=0x0)

1109767775: SMB: 4: Group mouse\domain admins **GID=2000** →Lookup by Group Name returns GID value

**\$ .server\_config server\_2 -v "usermapper if=cge0 gid=2002"**

## **NAS 5.2 AND ROOTFS INODE LIMITATIONS:**

I. NAS Codes prior to 5.2.10.3 support inode densities of 1 inode per 8k block for the rootfs of the Data Mover

II. NAS Codes and new installs of 5.2.10.3 and higher support inode densities of 1 per 1k block

## **INODE USAGE REQUIREMENTS BY USRMAPPER AND SECMAP DATABASES:**

--Each User and Group mapped to the Celerra by Internal Usrmapper will require (4) rootfs inodes

--Each User and Group mapped to the Celerra by the Secmap Cache will require (2) rootfs inodes

### **INODE LIMITATION PROBLEM:**

Default size of the data mover's root file system is 128MB, yielding a total of about 15,464 inodes with a density of 1/8k block

Default size of new file system is still 128MB, yielding 130,871 inodes with a density of 1/1k block.

Systems that are upgraded from any level lower than 5.2.10.3 will not be able to support inode densities of 1/1k block

### **INODE LIMITATION SOLUTION:**

Short and Long-term solutions for sites running out of inodes for the rootfs are as follows:

- I. Cases where customers use very large numbers of shares [8000+], try moving customer to Homedir service to free rootfs space
- II. Extend root file system by 2GB or higher if required—see emc87826

### **CELERRA SECMAP CACHING:**

→DART 5.2 introduced a persistent UID/GID-to-SID cache that is stored in the /.etc/secmap folder of the data mover or /root\_vdm\_x/.etc/secmap for VDM containers

→Secmap Cache was introduced as an efficiency mechanism to cut down on the single-threaded authentication calls made to the DC that often translated into authentication backlogs and slow DM performance during heavy logon periods, etc.

→SecMap Cache consumes (2) Inodes on the Data Mover rootfs for each UID or GID entry

→SecMap is used with Active Directory, NT Credentials for Unix, and SecureNFS features, but not with NFSv4

→Starting with NAS 5.6, Secmap is converted from a nameDB inode reference structure to an internal Berkeley database format

### **NAS 5.6 Secmap Upgrade Issue:**

Upgrade may fail on Task 68 if the secmap service is disabled, and is now checked by the PreUpgrade script:

E000123: Secmap is disabled on Server (server\_2).

**Fix:** Enable secmap on the Data Mover and run the upgrade script again

### **SERVER CIFSSUPPORT SECMAP TOOL:** Introduced with Napa 4 release

**# server\_cifssupport server\_2 -secmap -list | -create | -verify | -update | -delete | -export | -import | -report**

**Note:** Beginning with NAS 5.5.24.2, the server\_cifssupport command allows for reporting and editing of secmap database entries.

### **SECMAP RULES/REQUIREMENTS:**

→Each SID mapping will contain only one UID or GID value

→Each entry is based on the NameDB database and represents a symbolic link file, where the target of the link is the content (applies to all NAS versions prior to NAS 5.6)

→Unix UID/GID Reverse Mappings could have multiple SIDs mapped for each UID or GID

→When Secmap is enabled, the Global Sid Cache is not used

→Secmap uses (3) tables: Domain SID Table, UID Table for Reverse Mappings, GID Table for Reverse Mappings

→Secmap Cache entries are the first source that DART consults when Users/Groups connect to the Celerra

→Data Mover rootfs and all VDM CIFS containers will contain a Secmap cache as CIFS Servers are defined

→SecMap caches each mapping for SIDs upon the first access by that SID to the Celerra, and notes where the mapping originated: i.e., local passwd/group file, NIS, Usermapper, LDAP, etc.

→Subsequent access by the same SID will be mapped & authenticated from the cache, meaning that DART does not have to query the DC's to validate the SID again

→Reverse Mappings are created when using local passwd/group files, NIS, or older versions of Usermapper that use names (DART must take name and query DC's for match for the name to obtain SID), though once cached, subsequent reconnections will map User/Group from SecMap cache based on SIDs-to-UID/GID [See CIFS param quotas.queryNames]

→Reverse Mappings are used by NTCredential for Unix User feature, and for W2K Quotas name lookups

### **CIFS PARAMETER quotas.queryNames:**

**# server\_param server\_2 -facility cifs -info quotas.queryNames -v**

By default, the cifs quotas.queryNames param is set to 0, meaning that User/Group name queries to obtain valid SIDs for W2K Quota enumeration, will use only Usermapper, and once cached in Secmap, then only Secmap to perform the lookup. By setting the param value to 1, DART would use NIS or Local password/group files to perform User/Group name lookups for W2K Quotas

### **TWO TYPES OF MAPPINGS USED IN SECMAP:**

→SID to UID or GID Mapping (most commonly used mapping whenever CIFS users connect to Celerra)

→Reverse UID/GID to SID Mapping (NTCREDENTIAL for UNIX & W2K Quotas)

**Note:** SecMap Caching requires (2) inodes on the DM rootfs for every UID or GID mapping made. One Secmap entry is for the main SID-to-UID/GID mapping and the other entry is for the Reverse Mapping UID/GID-to-SID, which is used when building an NT Credential for UNIX users or when retrieving Users and Groups to get UIDs/GIDs for W2K Quotas.

### **/.etc/secmap**

drwxr-xr-x 2 root bin 1024 May 14 13:52 @gid →GID-to-SID mappings, with GIDs in Hex—no names

drwxr-xr-x 2 root bin 1024 May 14 13:53 S-1-5-15-1f6d0078-63f6f323-65d637a8-ffffffffff →SIDs

drwxr-xr-x 2 root bin 80 May 14 13:53 @uid →UID-to-SID mappings, with UIDs in Hex—no names

**Note:** With secmap caching enabled, default 5.2 installs, directories are populated with hex UID/GID mappings for User/Group SIDs as Users access the system for the first time

# ls -la \*

@uid:

lrwxr-xr-x 1 root bin 39 May 14 13:52 **31** -> S-1-5-15-1f6d0078-63f6f323-65d637a8-489

**Note:** Secmap lists the UID/GID's in HEX [**31 hex = UID 49**], along with the respective Windows SID, but NOT the name.

#cd S-1-5-15-1f6d0078-63f6f323-65d637a8-ffffffffff

# ls -la S\*

lrwxr-xr-x 1 root bin 36 May 14 13:42 **200** -> 162?5a?5a?40a5050b?TS2\Domain Admins →RID & Group Names

lrwxr-xr-x 1 root bin 35 May 14 13:52 **201** -> 162?5b?5b?40a50759?TS2\Domain Users “ “

lrwxr-xr-x 1 root bin 29 May 14 13:52 **489** -> 161?31?a?40a50759?TS2\mapper9 →RID & User Names

**Note:** RID [Relative Identifier—last part of SID 32 bits] of User or Group listed in red

## DUMPING SECMAP CONTENTS TO FILE, LISTING SECMAP DATABASES, INODE USAGE:

# .server\_config server\_2 -v "secmap if=foo list=secmap\_dmp"

# .server\_config server\_2 -v "secmap info"

1153419719: SMB: 4: SecMap: Secure Mapping Database server\_2

1153419719: SMB: 4: SecMap:

1153419719: SMB: 4: SecMap: S-1-5-15-7a50bbc6-60415a8a-6b635f23-ffffffff

1153419719: SMB: 4: SecMap: S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-ffffffff

1153419719: SMB: 4: SecMap: S-1-5-15-242a3a09-6bc5c62-3f32a78a-ffffffff

1153419719: SMB: 4: SecMap:

1153419719: SMB: 4: SecMap: 3 tables defined

# .server\_config server\_2 -v "secmap usage"

1153420014: SMB: 4: SecMap: Database usage

1153420014: SMB: 4: SecMap: Nodes: 101

1153420014: SMB: 4: SecMap: Size: 0

## SECMAP PRIMARY LOOKUP: SID-to-UID/GID:

# .server\_config server\_2 -v "secmap get sid=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6"

1153420211: SMB: 4: SecMap: sid S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6 mapping

1153420211: SMB: 4: SecMap: Mapped from usermapper on Wed Jun 21 12:14:13 2006

1153420211: SMB: 4: SecMap: user=800b(8000)

1153420211: SMB: 4: SecMap: Name=2K3\backup

**Note:** Please be aware that this command only searches cache for a SID match and retrieves the info as is

## SECMAP REVERSE LOOKUP: UID/GID-to-SID:

# .server\_config server\_2 -v "secmap get uid=0x800b"

1153420363: SMB: 4: SecMap: S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6

## WINDOWS ACCOUNT RENAMED--ACCOUNT MAPPED IN USERMAPPER & SECMAP—

### FORCING SECMAP CACHE UPDATE:

**Note:** Names are no longer considered as important for Usermapper or Secmap as the SID. Therefore, if a Windows account was renamed, the SID renames the same, but the account name is NOT automatically updated in SecMap Cache or Usermapper db.

# .server\_config server\_2 -v "secmap get sid=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6"

1153420211: SMB: 4: SecMap: sid S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6 mapping

1153420211: SMB: 4: SecMap: Mapped from usermapper on Wed Jun 21 12:14:13 2006

1153420211: SMB: 4: SecMap: user=800b(8000)

1153420211: SMB: 4: SecMap: Name=2K3\backup

**Note:** This command only searches the secmap cache database for matching SID

# .server\_config server\_2 -v "secmap check sid=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4d6"

1153421283: SMB: 7: ProcessBindReply:cMsRPC\_Bind Pipe,lsarpc to fid=8002

1153421283: SMB: 7: ProcessBindReply:maxFragSizes: Cl=10b8/10b8 Set=10b8/10b8

1153421283: SMB: 7: Request\_enumSIDs:enum 44 4036 1009,1=1

1153421283: SMB: 7: Request\_enumSIDs:done 8988160,895d190 1,1 1,1

1153421283: SMB: 6: ExtractDomain: Domain(0/1)=2K3

1153421283: SMB: 7: ExtractNames:Usr='2K3\backup\_renamed' RID=4d6 U=1 UID=0 T=-1 ((NULL))

1153421283: SMB: 7: Unix user 'backup\_renamed' found with 'SECMAP:backup\_renamed.2k3' UID=32779

1153421283: SMB: 6: FindUserId:Access\_Password 'backup\_renamed',1=800b T=0 (OK)

**Note:** The “check sid” command does a SID-to-Name lookup to the DC and returns the renamed account with the original UID for 2k3\backup, but DOES NOT update the SecMap Cache

**# .server\_config server\_2 -v "secmap fix sid=S-1-5-bfc56af5-d6cf8701-5f67b1a3-4d6"**

1153422090: SMB: 7: ProcessBindReply:cMsRPC\_Bind Pipe,lsarpc to fid=8003

1153422090: SMB: 7: ProcessBindReply:maxFragSizes: Cl=10b8/10b8 Set=10b8/10b8

1153422090: SMB: 7: Request\_enumSIDs:enum 44 4036 1009,1=1

1153422090: SMB: 7: Request\_enumSIDs:done 895b548,8964d28 1,1 1,1

1153422090: SMB: 6: ExtractDomain: Domain(0/1)=2K3

1153422090: SMB: 7: ExtractNames:Usr='2K3\backup\_renamed' RID=4d6 U=1 UID=0 T=-1 ((NULL))

1153422090: SMB: 7: Unix user 'backup\_renamed' found with 'SECMAP:backup\_renamed.2k3' UID=32779

1153422090: SMB: 6: FindUserId:Access\_Password 'backup\_renamed',1=800b T=0 (OK)

**Note:** This command is supposed to validate SID-to-Name lookups with DC and then update SecMap cache with any changed info—did not work with 5.5.22.0.

## **DART MAPPING RESOLUTION ORDER FOR USER/GROUP AUTHENTICATION: MAPPING RESOLUTION ORDER NAS 5.2 & ABOVE:**

1. SecMap Persistent Cache [/etc/secmap] (DART resolves by Group/User SIDs and maps to GIDs/UIDs, respectively)
2. Global Data Mover Sid Cache (DART resolves Group SIDs and maps to GIDs)
3. Local Password & Group files (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
4. NIS Client Service (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
5. Active Directory Mapping Utility (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively)
6. UserMapper Service (External or Internal) (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively for Internal Usermapper, and by Name-to-UID/GID prior to NAS 5.2)

**Note:** Do not use uppercase characters in passwd files or NIS database—use lowercase ASCII for Celerra

## **DISABLING & DELETING SECMAP CACHING (Pre-NAS 5.6):**

1. Set param to disable SecMap caching:

**param cifs secmap.enable=0**

**Note:** Secmap is set to ‘enable=1’ by default.

2. Stop CIFS Service
3. Reboot Data Mover to removed cache from memory
4. Delete SecMap directory, or move to Control Station for archiving:

**# rm -Rf secmap**

5. Start CIFS Service

## **REMOVING ENTIRE SECMAP CACHE WITHOUT STOPPING CIFS:**

**\$ server\_cifssupport server\_x –secmap –list |grep “S-1” | sed ‘s/S-1@/ /’ | awk –F’@’{printf “S-1%\$1\n”, \$2}’ |xargs –i server\_cifssupport server\_x –secmap –delete –sid {}**

**Note:** New method available with 5.5.24.2

## **DELETING SECMAP DB WITH NAS 5.6:**

**Note:** You can edit and delete individual entries using server\_cifssupport, but in order to delete the entire secmap database, use the following steps

1. Stop the CIFS service on the Data Mover in order to “close” the dbms secmap database
2. Delete the secmap dbms database

**# server\_dbms server\_2 –db –delete Secmap**

3. Restart the CIFS service

## **ENABLING SECMAP (Pre NAS 5.6):**

1. Set the param manually in the appropriate /nas/server/slot\_x/param file, or use the server\_param facility:

param cifs secmap.enable=1

**# .server\_config server\_2 -v "param cifs secmap.enable=1"**

**# server\_param server\_2 –facility cifs –modify secmap.enable –value 1**

2. Stop & restart CIFS service to enable the Secmap module

### **Server Log:**

2005-10-27 15:01:42: SMB: 4: SecMap: server\_5 secure mapping DB started

3. After User access, check /.etc directory--Secmap folder should now exist

```
# ls
secmap
```

**DELETING SPECIFIC MAPPINGS FROM SECMAP CACHE (Pre server\_cifssupport 5.5.24):**

```
# .server_config server_2 -v "secmap if=laip1-2a del sid=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-200"
```

1140705748: SMB: 4: SecMap: Mapping removed

1140705748: ADMIN: 4: Command succeeded: secmap if=laip1-2a del sid=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-200

**Note:** Need SecMap enabled and CIFS running in order to run this command. Engineering states that SecMap Cache is checked for GID SID mappings prior to consulting Global Sid Cache. The latter cache does not “expire”, but fills up to capacity, and then uses an LRU algorithm to add new entries while deleting “old” entries. May need to run the following procedure to clean up everything.

**REMOVING SINGLE SECMAP ENTRIES FROM CACHE (Pre server\_cifssupport 5.5.24):**

- Dump secmap cache & check for GID mapping for the Group SID in question

```
# .server_config server_3 -v "secmap if=cge0 list=sec_dump"
#server_file server_3 -get ./etc/secmap/sec_dump sec_dump
```

- Delete SID for GID in Question: →[Domain Guests example]

```
# .server_config server_3 -v "secmap if=cge0 del sid=S-1-5-15-42f831d9-66417ccd-28a68b82-202"
```

1113946407: SMB: 4: SecMap: Mapping removed

- Dump sec\_map again

```
# .server_config server_3 -v "secmap if=cge0 list=mod_sec"
```

- Check to see if mapping has been removed from SecMap cache

- If it has, then stop CIFS to flush Global Sid Cache

- Restart CIFS

**DUMPING & READING SECMAP DATABASE:**

- # .server\_config server\_2 -v "secmap if=172\_25\_9\_200 list=dump.1st" →dumps secmap db to .etc directory

- # server\_file server\_2 -get ./etc/secmap/dump.1st dump.1st

```
# more dump.1st
```

# Secure Mapping Database for server\_2

#

# S-1-5-15-5155eb8a-c0ded414-a9b42a3c-ffffffffff

#

sid S-1-5-15-5155eb8a-c0ded414-a9b42a3c-200 mapping

**Mapped from usermapper** on Wed Jun 30 00:59:19 2004

group=8002 →**Group mapped from Usermapper, hex 8002 = 32770 decimal**

Name=SC\Domain Admins

sid S-1-5-15-2f1e7626-3115e3fc-28a68b82-252d mapping

**Mapped from usermapper** on Mon Aug 23 12:08:23 2004

user=b870(1f40) →**User mapped from Usermapper, hex b870 = 47,216 decimal, group = 1f40 (8000 dec.)**

Name=ALLISON\rd\_tzn2y3

sid S-1-5-15-3e525c04-3373819-101d7ffe-5b3 mapping

**Mapped from etc** on Sun Aug 22 05:42:42 2004

user=13ac(1392) →**User mapped from local Passwd file (uid=13ac; gid=1392 hex)**

Name=GMNMDOMATD02\xz33xp

sid S-1-5-15-8bb001b-20e65643-252c19b2-7bc mapping

**Mapped from nis** on Tue Sep 14 21:21:22 2004

user=8968(1388) →**User mapped from NIS database**

Name=EDSRDATD01\tnz2y3

sid S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4c0 mapping

**Mapped from ldap** on Tue May 16 09:16:37 2006 →**User mapped from iPlanet Directory Server database**

user=b275(fde8)

Name=2K3\W2kU45685

**lrwxr-xr-x 1 root bin 36 May 16 09:16 4c0 -> 171?b275?fde8?4469d0b5?2K3\W2kU45685**

**Note 1:** The “171?b275?fde8?4469d0b5?” shows that the mapping was derived from Ldap iPlanet.

**Note 2:** Reviewing file shows origins of each SecMap mapping (i.e., NIS, Passwd/Group file, Ldap, Usermapper, ADMapping, etc.)

**DUMPING AND RETRIEVING SECMAP DATABASE FROM CIFS VDM:**

```
# .server_config CLKPTDM04 -v "secmap list=sec_dmp"
```

```
# server_file CLKPTDM04 -get ./etc/secmap/sec_dmp sec_dmp
```

CLKPTDM04 : done

**Note:** In this example, NAS 5.4.17.5, the VDM names are all UpperCase, perhaps a result of creation by WebUI

## **DETERMINING ORIGIN OF MAPPING METHOD TO CREATE A SECMAP ENTRY:**

1. Go to Secmap and SID directory for a given Domain SID:

```
#cd /nasmcd/quota/slot_2/.etc/secmap/S-1-5-15-5155eb8a-c0ded414-a9b42a3c-ffffffffff
```

2. Run ls -la:

```
[root@wdseccmcs01 S-1-5-15-5155eb8a-c0ded414-a9b42a3c-ffffffffff]# ls -la lhead
```

```
lrwxr-xr-x 1 root bin 34 Oct 25 08:34 1000 -> 161868d8000417d1cfSC\lozano_v
```

```
lrwxr-xr-x 1 root bin 36 May 16 09:16 4c0 -> 171?b275?fde8?4469d0b5?2K3\W2kU45685
```

**Note:** The “161868d8000417d1” output tells us that this was a mapping derived from a Usermapper call. The “171?b275?fde8?4469d0b5?” shows that the mapping was derived from Ldap iPlanet.

**0 - unknown**

**1 - secmap**

**2 - localgroup**

**3 - etc local files**

**4 - nis**

**5 - active directory**

**6 - usrmapper**

**7 - ldap**

## **USING SECMAP DATABASE TO RECREATE THE INTERNAL USERMAPPER DATABASE:**

**Note:** Use the following procedure to export the User and Group mappings from Secmap, create User and Group import files, then import to Internal Usermapper to repopulate a lost db.

1. Export the Secmap Mappings

```
# server_cifssupport server_x -secmap -export -file secmap_now
```

**Note:** The second colon-delimited field identifies Groups and Users

```
S-1-5-15-32ea1e67-607d8090-79df51a3-a36:2:96:8007:8007:BRCSLAB\LG Teste >> This is a domain group
```

```
S-1-5-15-32ea1e67-607d8090-79df51a3-458:1:96:8000:8000:BRCSLAB\gustavo >> This is a domain user
```

2. Use the following script to parse the output of the exported secmap database to the format the internal usermapper understands. Using vi, create a script file named as usrmap\_imp.sh with the following contents, and use chmod 755 to make the script executable:

```
#!/bin/sh
awk -F: '{
split($6,fld,"\\\"");
if($2!=2){
printf("printf \"%s:*:%%d:%%d:user %s from domain %s:/usr/%s:/bin/sh\\n\" 0x%s 0
x%s\\n",$1,fld[2],fld[1],$4,$5);
} else{
printf("printf \"%s:*:%%d:%s.%s:\\n\" 0x%s \\n",$1,fld[2],fld[1],$4);
}
}'|bin/sh
```

3. Next, use grep to parse the secmap\_now output to create a User file, then a Group file:

```
cat secmap_now |grep :1:./usrmap_imp.sh > usrmap_user.tmp ( This generates the user file )
```

```
cat secmap_now |grep :2:./usrmap_imp.sh > usrmap_group.tmp ( This generates the group file )
```

**Note:** The format of the internal usermapper database files that will be imported should be like this :

```
$ cat user_now
```

```
S-1-5-15-32ea1e67-607d8090-79df51a3-1f4:32769:32768:user Administrator from domain BRCSLAB:/usr/S-1-5-15-32ea1e67-607d8090-79df51a3-1f4:/bin/sh
```

```
$ cat group_now
```

```
S-1-5-15-32ea1e67-607d8090-79df51a3-200:32770:Domain Admins.BRCSLAB:
```

```
S-1-5-15-32ea1e67-607d8090-79df51a3-201:32771:Domain Users.BRCSLAB:
```

```
S-1-5-15-32ea1e67-607d8090-79df51a3-202:32776:Domain Guests.BRCSLAB:
```

4. Use the following steps to import the user and group files into usermapper :

a) Disable internal usermapper :

```
# server_usrmapper server_x -d
```

b) Clean the database :

```
# server_usrmapper server_x -remove -all
```

c) Enable internal usermapper :

```
# server_usrmapper server_x -e
```

d) Import the user and group files :

```
# server_usermapper server_2 -I-user usrmap_user.tmp  
# server_usermapper server_2 -I-group usrmap_group.tmp
```

e) Check the server\_log for any errors. A clean import should look like this :

```
# server_log server_x -a -s |grep USRMAP
```

```
2008-07-31 20:04:10: USRMAP: 4: Starting usermapper service  
2008-07-31 20:04:10: USRMAP: 4: 2: Usermapper service enabled  
2008-07-31 21:58:15: USRMAP: 4: Starting usermapper service  
2008-07-31 21:58:15: USRMAP: 4: 2: Usermapper service enabled  
2008-09-23 11:17:58: USRMAP: 4: 3: Usermapper service disabled  
2008-09-23 11:18:08: USRMAP: 4: 4: Usrmapper database destroyed  
2008-09-23 11:18:18: USRMAP: 4: 1: Usermapper database created  
2008-09-23 11:18:18: USRMAP: 4: 2: Usermapper service enabled  
2008-09-23 11:18:27: USRMAP: 4: Import completed, 60 new users imported  
2008-09-23 11:18:47: USRMAP: 4: Import completed, 883 new groups imported  
2008-09-23 11:50:37: USRMAP: 4: Export last 361 ms
```

## **COMPARING NFS & CIFS PROTOCOLS:**

### **NFS:**

Stateless  
Single filename space  
Host-based “Authentication”; UID’s/GID’s; /etc/Hosts  
Advisory Locking scheme  
DNS & NIS nameservices and User database  
NIS Authentication DB  
RWX file attributes and umask values—no ACL’s

### **CIFS:**

Stateful (i.e., client must recover after server crash)  
Multiple namespace; 8.3/256 [max.path length]/posix\*  
User-Based “Authentication”  
Mandatory locking scheme  
DNS & Wins nameservices  
NT Authentication DB  
Extended file attributes {rwxpdo, file creation date & ACL’s}  
Browsing; Hidden shares; encrypted passwords; HomeDirs

\*Posix is a Unix-based standard called Portable Operating System Interface for computer systems.

**Note:** TCP can be enabled for NFS in /nas/server/slot\_x \*/netd by appending “tcp=1” to “nfs start” line

## **CIFS INTEROPERABILITY ISSUES:**

**Symbolic Links**—an alias, or shortcut for NT; a copy or pointer for Unix

**File Naming**—NT is case preserving, NOT case sensitive

**DOS Attributes**—DOS has file creation date, NOT unix

**Access Checking Policies**—NT or Native affords any NT client access; Secure=Highest security

**File Locking Mechanisms**—Three Options: File Locking occurs when Multiple File System protocols are involved and for CIFS is determined by Applications. Notepad, Wordpad, and Vi Editor do not practice locking, while Word & Excel do.

- 1.) rwlock: A CIFS file lock denies any further access. An NFS file lock will allow access, no 2<sup>nd</sup> lock.
- 2.) wlock: NFS can open an already opened file in Read Only mode.
- 3.) nolock: Either NFS or CIFS can open and write to a ‘locked’ file

## **CIFS ACL's: TROUBLESHOOTING & REPAIR OPTIONS**

**Symptoms:** Loss of access to NT Shares. Specific “Access Denied” message from NT Client when trying to access Celerra Shares through Network Neighborhood or Server Manager, either as Administrator or Ordinary User.

### **Tools to Use:**

View Server\_log--Look for SHADOW file rebuild or other irregularities

Use ACL Dump tool

### **I. Run ACL Check Using .server config Command:**

**Note:** Do not use "aclchk" utility on nas versions under 2.1.32.2

**Revised Procedure:** There is a known issue with running ACLCHK on filesystems when “Exports” are temporarily unexported. Rather than dealing with Exports at all, permanently Unmount the PFS [after noting mount options], create a new mountpoint, and remount the PFS on the new mountpoint to conduct ACLCHKs without interference from Exports.

Step 1. Permanently unmount PFS from original mountpoint. Create new mountpoint for aclchk purposes and permanently remount filesystem to this mountpoint. Conduct aclchk.

**Note:** Filesystem being aclchk’ed is NOT exported

Step 2. Conduct ACL Check on Server\_6:

```
$server_config server_6 "file aclchk /export/htdocs fix"
```

Step 3. Open Server Log to Monitor:

```
$server_log server_6 -s -f [Will show ACL Check completion]
```

Step 4. Permanently unmount File System and remount to original Mountpoint.

Step 5. Re-export all exports:

**\$server\_export server\_6 -a**

## **II. Running the “CIFS UPDATE” on Mountpoint path of affected Share or File System:**

Step 1. Leave the Share Exported for CIFS

Step 2. \$server\_setup server\_2 -P cifs -o stop [Recommended method for Update]

Step 3. Verify CPU Usage: \$server\_sysstat server\_2 [i.e., if heavily utilized, will take more time & possibly panic DM]

Step 4. **\$server\_config server\_2 “cifs update /emcfset12 force level=0”**

Step 5. Monitor CIFS Update in Server Log: \$server\_log server\_2 | tail

**Note:** 'Command Succeeded' will be echoed at commandline--results of Update will be logged:

2001-11-06 23:22:24: SMB: 4: Update of : /emcfset12 completed after 437 s

2001-11-06 23:22:24: SMB: 4: Update of : 219475 files, 21229 dirs

**Note 2:** If Update fails with following error, Stop & Restart CIFS to knock Users off file system:

1005105482: SMB: 3: Error: Update cannot be done on share in use

## **RUNNING CIFS UPDATE ON A FILE SYSTEM:**

**\$server\_cifs server\_6 -update /emcfset12 mindirsize=0 force**

**Note:** Need to run this update if seeing errors in Server Log regarding issues when name info file returns “not found” messages. This command completely rebuilds the Shadow file! A potential drawback of this method is that short filenames may be renamed, depending on the order of the file in the directory as opposed to when they were created:

### **EXAMPLE OF SHORTNAMES:**

**# .server\_config server\_5 -v "shadow readdir \fs28\shortnames"**

1068044303: CFS: 4: name: shortname7.txt 69331000.TXT

1068044303: CFS: 4: name: shortname1.txt SHORTN~1.TXT

1068044303: CFS: 4: name: shortname3.txt SHORTN~3.TXT

1068044303: CFS: 4: name: shortname9.txt 89331000.TXT

### **ALTERNATE SYNTAX:**

**# server\_cifs server\_5 -update /fs40 mindirsize=0 force verbose**

2003-11-05 09:23:34: ADMIN: 4: Command succeeded: cifs update /fs40 mindirsize=0

2003-11-05 09:23:34: SMB: 4: Update of : /fs40 completed after 0 s

2003-11-05 09:23:34: SMB: 4: Update of : 2 files, 3 dirs

### **OTHER SHADOW FIX/CIFS UPDATE METHODS:**

**\$server\_config server\_9 -v “shadow update \ora\ImageArchives”** [Yet another version of update]

**\$server\_config server\_9 -v “shadow fix \volta\f3u2\victor”**

### **The following commands can be useful in troubleshooting and resolving Shadow File problems:**

Step 1. Run ‘Shadow Readdir’ against suspect folder in the file system path—notice the use of backward slashes to define the path:

**\$server\_config server\_x -v “shadow readdir \fs01\users\martin”**

**Note:** If you do not see a listing of all files that you would expect to see, it’s possible that the Shadow File is damaged and needs to be manually repaired. Or, if known subdirectories are seen as 0 Byte files, this also could be an indicator of a damaged Shadow File.

Under certain conditions, such as a full filesystem, the algorithms that dictate how many times the hashing index can be changed before requiring a rebuild operation, can be broken, requiring manual intervention to repair.

Step 2. Use ‘Shadow Fix’ to repair suspect folder, then run the ‘Shadow Readdir’ again to see if the directory contents are ‘visible’.

**\$server\_config server\_x -v “shadow fix \fs01\users\martin”**

**Note:** In some cases, the command will not run because of spaces or other peculiarities in the path—when all else fails, try to determine DOS 8.3 name for the next directory in the path and substitute that name:

**# .server\_config server\_7 -v “shadow readdir \data\userdata\SFISHE3\Sandy's files\Action Plans”**

1131570657: CFS: 3: shadow fix: getAlternateName failed: NotFound

**# .server\_config server\_7 -v “shadow readdir \data\userdata\SFISHE3\SANDY'~1\ACTION~1”**

### **Shadow File Symptoms:**

Loss of Access to Shares by Users

Server\_Log Indicator: SHADOW; forceRebuild; shadow assert failed on line 1740 file ..\shadow\_internal.cxx: 7

### **Server Log Example:**

2001-10-31 10:21:11: SHADOW: 3: ESHADOW: 3: Error from write block: 25 [Error 25 often means File System full]

2001-10-31 10:21:11: CFS: 3: @@@ commit failed: status = 25 [File\_NoSpace]

2001-10-31 10:21:11: SHADOW: 3: Error 25 from writeBlock

Intermittent access to CIFS Shares from different NT Users

CIFS Users see Directories as Files

**Causes:** NT users may lose the ability to access or see files or subdirectories within a file system, yet NFS can still see those files.

**Reasons:** Shadow File has become corrupted in FS and requires 'relinking' the Unix & Cifs filenames. File Systems are at 100% and SHADOW File cannot rebuild itself--File System should be reduced in size, then run the CIFS Update--ENGINEERING recommends that File Systems be kept at 90% or lower. Whenever these conditions occur, the "Shadow File" for a specific NT Share or Upper Level Mountpoint may need to be updated using the following commands:

### **Traditional CIFS Update Fix to Shadow File:**

**\$server\_config server\_2 "cifs update /emc force level=0"**

**\$server\_config server\_2 "cifs update /emc"**

**Purpose of Server CIFS Update Command:** Rebuilds the “shadow” file by relinking all Files and Directories to both their DOS 8.3 and NT Long Names to their Unix counterpart

### **WINDOWS CLIENT FILE SYSTEM FULL “POP-UP” MESSAGE:** 2.2.49.2 +

/nas/server/slot\_x/param

**param cifs sendMessage=0** [Turns off PopUp messages]

**param cifs sendMessage=1** [Default value. Send message on Error only]

**param cifs sendMessage=2** [Send message on Warning only]

**param cifs sendMessage=3** [Send message for both Warnings & Errors]

**param cifs minFreeFS=0** [Default Value is 10, which means that when FS is 90% Full, Pop-Up message is generated. By setting this value to 0, Clients will not be sent PopUp message based on file system capacity]

**Comment:** With both parameters set, a popup message will be sent to any Client connecting to the Share when the minimum Free Space setting is reached. MinFreeFS setting can be modified to any value. “Pop-Up” may not show on Win95 Users unless winpop.exe is turned on

### **CELLERRA CIFS SHADOW FILE:**

The Shadow File is an index containing Unix-to-NT name mappings, consisting of linkages between Unix names and Windows Long Names [M256] and DOS Short Names [8.3]. A separate Shadow File Index is located in every directory on a CIFS file system and is created when CIFS Users access a directory for the first time. Subsequently, the Shadow File is kept up-to-date dynamically as changes to files & subdirectories occur. The Shadow File itself is not visible from ordinary NT or Unix client access.

**Note:** Important to know that a CIFS Shadow File rebuild, whether done by the file system automatically or from a manually initiated CIFS Update, uses the UNIX file name to rebuild and then rename the Windows Long and Short names.

### **SHADOW FILE SYNCRONIZATION:**

One of the limitations of the current file system architecture is that the disk space required to accomodate the shadow file is dependent on the changing structure of the file system itself and cannot be pre-allocated through the use of reserved space or placed in some other location. The effective result of this design means that once a file system reaches the 100% capacity mark, the dynamic mechanism used to keep the shadow file up-to-date and intact can deteriorate. The index is considered out of sync when a file exists in a directory but the corresponding index entry is not yet updated to the Shadow File. This condition triggers a “Shadow Rebuild” operation and under normal circumstances, is quickly rebuilt.

### **THINGS THAT AFFECT SHADOW FILE HEALTH:**

Though events like an unexpected shutdown of a datamover can trigger an out of sync condition, the most common scenario is that of a file system reaching 100% capacity. When file systems reach 100%, it is possible for the shadow file update mechanism to begin to breakdown, especially within directories that support large numbers of files that are rapidly changing. Each time a CIFS host attempts to access files that are determined to be invalid because of changes to the files in the existing directory, a shadow file rebuild operation is initiated for the directory. Under ordinary circumstances, and with adequate free space available, shadow rebuild operations conclude quickly and without visible impact to CIFS clients. However, when file system capacities have been reached and there is limited free-space available, the Shadow rebuild process may force a directory lock while the rebuild is in progress. In extreme cases the rebuild operation can lock-out both NFS and CIFS clients. If the rebuild process is successful, the lock is released and normal access is returned to all Clients. However, if the rebuild is not successful, at some point the lock will be released, allowing NFS clients to access the directory, but denying CIFS users 'visibility' to the impacted directory. Further access attempts will repeat the lock and unlock cycles, and it may be possible that the shadow file cannot regenerate itself under these conditions. The net effect of a failure to rebuild the shadow file is the loss of cifs access from the perspective of Windows Clients. In fact, the overall directory or files within a directory may appear to be "missing" completely, when in reality the files still exist, but are masked from CIFS visibility due to the broken linkages between the underlying Unix file system names and the Windows names--without the linkages intact, files 'disappear' from CIFS view.

### **FUTURE DESIGN CHANGES ELIMINATE THE SHADOW FILE:**

Because of the limitations inherent with the Shadow File design, the Multiprotocol Directory [MPD] structure was been introduced with NAS 5.2—GA on February 9, 2004. The underlying file system improvement eliminates the Shadow File in its entirety, meaning that shadow file information is no longer stored in an auxiliary database, but in the file system inode structure itself, eliminating both the performance bottlenecks and file system full limitations that the previous architecture experienced.

**MAINTAINING A HEALTHY FILE SYSTEM & SHADOW FILE:**

The most effective method for minimizing shadow file issues are to maintain file systems with adequate space to consistently handle the ebb and flow of system and user operations. Ideally, file systems should be monitored so as to maintain 90% or less capacity. As a preventive monitoring measure, current NAS versions have the ability to configure SNMP Traps and Mail Notification alerts in the event that file systems reach a pre-determined plateau.

**KNOWN SHADOW FILE LIMITATIONS:**

--The Shadow File algorithm for calculating rebuilds may fail if the Shadow File tree/leaf structure is greater than 15 levels in depth, causing Shadow Asserts and incorrect computation of hash values. This condition can happen if there are hundreds of thousands of file entries within a file system directory.

--In NAS 4.2 and 5.1.9.4, a problem can occur in the Shadow File Index when files or directories are renamed with the same name [e.g., a Windows client renames a file from all lowercase to uppercase—this really isn't a name change]. Our Unix name mangling function does not check to make sure that the name did not really change and adds a ~ tilde character to the Unix name. Subsequently, a system Shadow rebuild or manual CIFS Update uses the Unix name to rebuild the Shadow file and will rename the NT Long and Short names with the ~ tilde character at the end of the file. See AR30194 and Primus EMC81938.

**SHADOW FILE STRUCTURE: 3 NAME LINKAGES FOR ALL FILES****Shadow file stores following information for each file in a directory:**

**1. DOS 8.3 short names & long M256 names**

**2. UNIX Names**

**3. CIFS Attributes: (5) windows attributes for a file (Archive, System, Hidden, Read-Only, Compression)**

**Symptoms:** Server\_Log: SHADOW; forceRebuild; shadow assert failed on line 1740 file ..//shadow\_internal.cxx: 7  
Loss of Access to Shares by Users [Error 7 means FileNotFound]

**Server Log Example:**

2001-10-31 10:21:11: SHADOW: 3: ESHADOW: 3: Error from write block: 25 [Error 25 means File System full]  
2001-10-31 10:21:11: CFS: 3: @@@@ commit failed: status = 25  
2001-10-31 10:21:11: SHADOW: 3: Error 25 from writeBlock  
2001-11-01 18:08:38: SMB: 4: Update of : /cifs2/share completed after 1940 s  
2001-11-01 18:08:38: SMB: 4: Update of : 1083559 files, 90786 dirs

**Shadow Rebuild Limitation:**

Prior to NAS 2.2.58.1, a file in the Shadow file could only be changed 256 times. Once this limit is reached, file becomes invisible to Client and CIFS Update must be run. Following Log message is indicative of this:

SHADOW: 4: Collision 0xa5,invhash;0x95f1

**HOW TO VERIFY UNIX FILE NAMES & WINDOWS 8.3 NAMES:**

**Note:** The following command will allow you to inspect NT Long Names and DOS 8.3 Short Names—may be useful when determining if a 0 byte file should actually be a folder—confirms whether there has been shadow file corruption

**\$server\_config server\_9 -v "shadow readdir \volta\f3u2\Victor"**

| <b>LONG 256 NAME</b>                           | <b>SHORT 8.3 NAME</b> |             |
|------------------------------------------------|-----------------------|-------------|
| 1041202451: CFS: 4: name: ADMIN                | ADMIN <DIR>           | [Directory] |
| 1041202451: CFS: 4: name: backup_error_ojv.txt | BACKUP~1.TXT          | [File]      |
| 1041202451: CFS: 4: name: USERS                | USERS <DIR>           |             |
| 1041202451: CFS: 4: name: filesystem_ojv.txt   | FILESY~1.TXT          |             |
| 1041202451: CFS: 4: name: profile_ojv.txt      | PROFIL~1.TXT          |             |

**HOW TO FIX SHADOW FILE FOR SPECIFIC FOLDERS:** [Use instead of CIFS UPDATE]

**\$server\_config server\_9 -v "shadow fix \volta\f3u2\Victor"**

**Note:** Shadow collision messages in the Server Log are a good indicator of a hash table problem occurring in the shadow file. If the hashing index reached 0x100 (decimal 256), the algorithm would stop and could no longer rebuild itself, therefore requiring the manual “shadow fix”. You can use this command with CIFS running & shares exported. This command zeroes out the Shadow directory and is rebuilt during next CIFS Client access.

**III. OBTAINING ACL DUMP ON PROBLEM SHARE:**

Step 1. **\$server\_config server\_x -v "acl if=ana0 dump=/export/hs1\_it"** [Full path to Share and Interface Used]

**Note:** If command does not execute, try only the 'sharename' itself in command; "acl if=ana0 dump=/export"

**ACL's are stored on the root of every CIFS file system**

**IV. FIXING ACL's USING SETACL:**

**Purpose:** One of the primary reasons for running the “setacl” command would be if users were experiencing “access denied” problems to CIFS Shares that they previously had access to. Probably the most common example of this problem would be if the Usrmapper databases were changed/deleted, and Users and Groups received totally new UID/GID mappings. Typically, this would be seen by a User as a loss of access to their “Home Directory”, or to a group of users, as a loss of access to a “Share” or “Directory” who’s permissions were based on a Global NT Group for access.

**Note:** When running “setacl”, ensure that CIFS is running—but have an administrator disconnect users from Server Mgr or Computer Management.

### **How does the “SETACL” command work?**

When the “setacl” command is issued against a filesystem mountpoint or CIFS directory, the ACLs are read by the DART to obtain SID information for all Users and Groups included in the ACL List. The DART then queries the DC or AD Server for each User and Group to verify SID information. Once this information is obtained, the DART obtains the latest mapping information from Usrmapper for each User and Group, and then updates the ACL list for that directory, matching User/Groupname/SID to UID/GID.

## **METHODS FOR UPDATING ACL LIST ON CELERRA FILE SYSTEMS:**

### **1<sup>st</sup> METHOD--COMMANDLINE SETACL COMMAND FROM DATAMOVER:**

**\$server\_config server\_2 “cifs update /mnt4 force setacl if=ana0”**

**Note:** This command realigns the UID/GID of a User or Group with the appropriate SID & updates the ACL records on the FS

**Caution:** *Do not run the “setacl” based on this section—review the full SETACL procedure in previous sections.*

### **2<sup>nd</sup> METHOD--WINDOWS NT/2000 GUI:**

As Administrator, view the properties of a particular folder and then “re-apply” the “permissions”—this also does the same thing as issuing the setacl command, though on a less global basis.

**Comment:** Use the ACL Dump command to verify ACLs on a folder BEFORE & AFTER running this command!!!

**\$server\_config server\_2 “acl if=ana0 dump=/mnt4”**

**Caution:** From experience, you may need to reboot the DataMover after each FileSystem after running the “setacl” command. If the command fails to execute [Error 4020], reboot the Server and try again.

**PREFERRED SYNTAX:** **\$server\_config server\_x “cifs update /mnt4 force setacl if=fsn0”**

**ALTERNATE SYNTAX:** **\$server\_config server\_x “cifs update /mnt4 setacl if=fsn0”**

**2002-10-01 18:20:53: SMB: 4: Update of : /shared completed after 630 s**

**2002-10-01 18:20:53: SMB: 4: Update of : 463771 files, 30447 dirs, 494218 Acl**

### **STOPPING CIFS UPDATES:**

**Note:** Use the following command to stop any of the commands that use CIFS Update

**#server\_config server\_x “cifs update abort”**

### **OUTPUTTING ACL DUMP INFORMATION:** Directory or File Permissions on Celerra File Systems

**\$server\_config server\_6 -v “acl if=fsn0 /personal/its/DParker”**

### **USING INLINE SCRIPTS TO RECURSIVELY DUMP ACLS:**

**\$for i in `find ftest /testdata/RMS`;do .server\_config server\_4 -v “acl if=fsn0 dump=\$i” >> /tmp/fptest.acldump; done**

## **V. RESETTING ACL’s ON CIFS SHARE OR SUBFOLDER TO ‘EVERYONE’ FULL CONTROL:**

**Note:** Apply to the “toplevel” CIFS Share only as it will reset the acl’s to “Everyone FULL CONTROL”. Otherwise, you can use this command discretely by running against a specific subfolder. The permissions would then have to be manually reassigned and built by the system admin. If you have the opportunity, conduct an “acl dump” prior to resetting ACL’s so that an analysis can be done on the share in question.

--If Administrator has Mask=1f01ff & Rights=RWXPDO, they have Full Control, no problem

--If Everyone has Mask=0x100000 & Rights=RWX, they have “No Access”

**\$server\_config server\_x “cifs update /mntpoint resetacl”**

**Note:** Can also run against subfolder

**\$server\_config server\_x “cifs update /share/subfolder resetacl”**

### **“SECURITY ID STRUCTURE INVALID”:**

Windows Client Pop-Up Error Message

**Cause:** ACL’s are corrupt, missing, or not populated with User/Group permissions

--Use ACL DUMP to examine ACLs on Folder or File

--Set Server Logon Traces: “param NTsec logonTraces=6” & have User retry

--Examine Server Log for SMB Error Code message for User & debug using “ntstatus 0xc0000007”

--Look at Celerra Security Event Log for “failure” messages in Event Viewer

## **CIFS ACL CHANGES IN NAS CODE:**

**Effective Rights:** RWXPDO    NAS Code 2.1.5 thru 2.2.46 uses algorithms to convert Effective Rights to Extended

**Extended Rights:** Bit-masked 4-byte value: NAS Code 2.2.46+ uses only Extended Rights, as does Win2k

|                                  |                                   |                                        |
|----------------------------------|-----------------------------------|----------------------------------------|
| Bit 1 = List/Read                | Bit 2 = Create files/Write Data   | Bit 3 = Create folders/Append data     |
| Bit 4 = Read Extended attributes | Bit 5 = Write Extended Attributes | Bit 6 = Traverse Folders/Execute Files |

## **CELERRA AND ACCESS CONTROL LISTS:**

For Celerra, each file or directory object or Share contains an ACL [Access Control List], which consists of ACE's for Users and Groups. The ACE contains the permission set for the User or Group, the SID, Effective, and Extended NT Rights, as depicted in the values above.

**--ACL's are stored on the root of every CIFS file system!!**

## **VIEWING CIFS PARAMETERS:**

**\$server\_config server\_2 -v 32768 "param cifs"** [from 2.2.46.6 code]

Note: With NAS 5.3, the .server\_config commands are wrapped in XML so as to be able to output the full contents of commands to screen, as the older RPC had 16k limitation. Beginning with NAS 5.4, the 32k output will be the default.

**TO DUMP COMPLETE PARAM LIST TO SERVER LOG: \$server\_config server\_2 "param cifs"**

## **CIFS PROTOCOL[Common Internet File System]:**

CIFS is a file sharing and network access protocol based on the Server Message Block (SMB) protocol, adopted by Microsoft to run on top of NetBIOS (Network Basic Input/Output System)--the building blocks upon which traditional Windows-based Microsoft Networks are built. NetBIOS served as a 'Session Layer API' that provided (3) basic functions for a Microsoft Network: 1) Name Service host resolution 2) Datagram Delivery Service using UDP 3) Session Service that established & maintained point-to-point connection-oriented NetBIOS sessions over TCP/IP between 'networked' computer systems.

More recently Microsoft redesigned CIFS to be the native file sharing protocol for Windows 2000 and implemented SMB directly over TCP/IP using Port 445 (traditional networks used SMB over NBT over TCP/IP using Port 139), making CIFS 'transport independent.'

CIFS is implemented as a Client/Server request & response protocol that supports File Sharing Services, Messaging, File Locking, Security, Authentication, & Short/Long File Naming conventions using communication mechanisms related to File Sharing, API's, Named Pipes, & Mail Slot communications. Client systems issue SMB commands that are handled by the local 'redirector' to connect to 'remote systems' or resources using connection establishment messages. After authentication & security considerations, clients receive access to Shares for opening, reading, writing, and executing files. Other forms of messages between Client & Server are Mail Slots and Named Pipes [Mail Slots is a connectionless broadcast delivery service often used in Browsing services, while Named Pipes is a form of connection-oriented messaging via a virtual circuit or 'pipe', established between client & server, so that two applications or processes can communicate with each other. Data is passed as output from (1) host process to input on the other host].

Remote Procedure Calls (RPC) are the basic mechanism by which a Client computer can make a network request to use the processing capabilities of a Server--both Client/Servers use an End Point Mapper service to listen on Port 135 for TCP/IP connection requests. Clients must then conduct an RPC-bind to an interface before it can begin making SMB or other types of procedure calls.

Celerra implements the CIFS file sharing protocol to allow network access for Windows-based Users--CIFS is implemented inside the Operating System kernel for better performance and is layered on top of DART (Data Access in Real Time).

**Note:** With NAS 5.2, Celerra now supports "SMB Signing", a form of host-based authentication [See MS--Q161372].

## **SMB2:**

Celerra began supporting Microsoft's new and improved SMB2 CIFS protocol with NAS 5.6.42

## **TROUBLESHOOTING CIFS:**

**# server\_cifssupport server\_2** [Excellent CIFS troubleshooting utility added to 5.5.24.2—Napa 4]

**# server\_checkup server\_2** [New CIFS configuration troubleshooting utility to be released with GrandNapa 5.5.27.x]

**\$server\_config server\_3 "cifs stop"** [Use command to stop cifs when other command fails]

**\$server\_cifs server\_3 -o audit** [Returns open connections to data mover]

**\$server\_cifsstat server\_3 -full** [-summary; -z to zero] {SMB Statistics--Open Connections to DM, SMB calls, ops per second; total operations}

**\$server\_cifsstat server\_x -s** [Provides shortened version of stats]

**\$ server\_cifsstat ALL -s |grep -A 1 -i open**

Open connection Open files

130 340

### \$server\_config server\_3 -v "cifs audit full" or "cifs audit full debug"

```
1147962378: SMB: 4: ||| AUDIT Ctx=0xd827c004, ref=1, XP Client(XP1) Port=1811/445

Note: Dumps information on User connections and open files, but only if Users are connected to Server

### \$server\_config server\_3 -v "param NTsec logonTraces=6" [Increases logon levels; set 'logonTraces=3' when done]

Note: With 5.6, you may need to use \$ server\_log server\_x -i option to see trace output in the server log

\$server\_sysstat server\_3 # of threads in Use--should be a low number

\$server\_config server\_3 -v "printstats cifs"

\$server\_config server\_3 -v "param cifs"

\$ .server\_config server\_2 -v "cifsThrd" [new facility with NAS 5.4]

1110213490: SMB: 4: cifsThrd: checking blocked threads

minimum: 0/256 threads, 5 seconds

\$server\_config server\_3 -v "printstats meminfo" or "printstats mem"

\$server\_config server\_3 -v "acl if=ana0 dump=/fsdata/prod"

\$server\_config server\_3 -v "ntcred client=0x384dom user=robin" [Dumps perms for user 'robin' to server\_log]

\$server\_config server\_3 -v "ntcred client=168.244.127.17" [or machinename]

\$server\_config server\_3 -v "ntcred user=watson"

\$server\_config server\_3 -v "ntcred credp=0x6b87c04" [Dumps perms for user 'robin' to server\_log]

\$ .server\_config server\_2 -v "ntcred all"

# .server\_config server\_2 -v "samr if=10\_241\_169\_49 user=nas1"

1099322602: SMB: 4: RID=0201 GID=2002 A:7 U:2 ='Domain Users'

1099322602: SMB: 4: RID=0462 GID=2009 A:7 U:2 ='NAS Users'

\$server\_config server\_3 -v "sidcache global status" [Look for High Cache Miss rate]

Sid cache status

Enable:1

DefaultSize:53

Hits:0

Miss:2

Count:0 Collisions:0

Total of collisions:0 Total of hash OK:0 Compare:0

\$ .server\_config server\_5 -v "sidcache if=ana0 global dump"

\$server\_config server\_5 -v "srwpwd dump" [Checks machine account trust relationship between Server and Domain by verifying machine passwd against DC—used for IPC\$ netlogon and membership in domain]

\$server\_config server\_2 -v "tcp audit" [Useful to see what Ports datamover listening to & IP Addresses]

Caution: Use this command in conjunction with "cifs audit" output to identify the hex value for the User account in question. An incorrect hex value entered here could panic the datamover!

\$server\_config server\_3 "logsys set severity SMB=LOG\_DEBUG" [Debugging SMB problems]

\$server\_config server\_3 "logsys set severity SMB=LOG\_PRINTF" [Turn off SMB debug mode]

### VERIFYING CURRENT LOGGING LEVEL FOR CATEGORIES:

# .server\_config server\_2 -v "logsys get severity SMB"

1158591814: LIB: 4: Server log severity for facility SMB is 4

### IMPORTANT CIFS TROUBLESHOOTING TOOLS:

1. \$ server\_cifssupport utility added with NAS 5.5.24.2

2. \$ server\_checkup utility to be added with NAS 5.5.27.x (Spring 2007)

3. Set Server Log Debugging: "logsys set severity SMB=LOG\_DBG3" [\_ERR to turn off]

4. Increased Logon Traces: "param NTsec logonTraces=6" [=3 to turn off]
5. Audit User Accounts: 16384 "cifs audit full"
6. Debug Server Log SMB Errors: "ntstatus 0xc0000073" →NONE\_MAPPED
7. Dump Folder/File Permissions: "acl if=ana0 dump=/fsprod/prod2"
8. Dump User Credentials: "ntcred client=MACHINENAME or IP user=thomas" | "ntcred all"
9. View Event Viewer "Security Event Logs" on DataMover and increase Log Size [Access via Event Viewer NT Program]
10. Verify Usrmapper Process, Database entries, check Usrmapper.log, Server Log for errors
11. Verify PDC Connections: -v "pdc dump"
12. Look at Server CIFS output to verify CIFS configuration [crosscheck with /nas/server/slot\_x/netd file]
13. Observe User Connections/Activities: "server\_cifsstat ALL -s" [SMB Load, Open Files & Connections]
14. Observer CPU/Memory Activity: "server\_sysstat ALL"
15. Run setacl, resetacl, cifs update of Shadow File if required
16. Verify Shadow File and/or Fix using: "shadow readdir \personal\its" & "shadow fix \personal\its"
17. Windows commandline Utility to debug NT Errors: err.exe
18. Windows DOS prompt help utility: C:>net helpmsg 1208  
An extended error has occurred.
19. MS Windows Errors—link to website:  
<http://msdn2.microsoft.com/en-us/library/ms681381.aspx>
20. Checking for blocked CIFS Threads: "cifsThrd"

### **DEBUGGING SMB SERVER LOG ERRORS:** SMB: 3: NetLogon::buildSecureChannel=7 E=0xc0000022

**Run Following Command:** **\$server\_config server\_2 -v "ntstatus 0xc0000022"**

1023977569: SMB: 4: NT status 0xc0000022: **ACCESS\_DENIED**  
1023977569: ADMIN: 4: Command succeeded: ntstatus 0xc0000022

**\$server\_config server\_2 -v "ntstatus 0xc000023"**

1108730617: SMB: 4: NT status 0xc0000233: DOMAIN\_CONTROLLER\_NOT\_FOUND

**\$server\_config server\_2 -v "ntstatus 0xc0000bb"**

1108730807: SMB: 4: NT status 0xc00000bb: NOT\_SUPPORTED

### **COMMON SMB ERROR MESSAGES:**

"ntstatus 0xc0000073" → NONE\_MAPPED  
"ntstatus 0xc0000016" → MORE\_PROCESSING\_REQUIRED  
"ntstatus 0xc000015b" → LOGON\_TYPE\_NOT\_GRANTED  
"ntstatus 0xc000006d" → LOGON\_FAILURE  
"ntstatus 0xc0000022" → ACCESS\_DENIED  
"ntstatus 0xc000018c" → TRUSTED\_DOMAIN\_FAILURE  
"ntstatus 0xc0000078" → INVALID\_SID  
"ntstatus 0xc00000e5" → STATUS\_INTERNAL\_ERROR

### **CIFS STATISTICS:**

**\$server\_cifsstat ALL -s \$server\_cifsstat ALL -z**

Compare "cifsstat" 'State info:' & 'Open connection Open files' to the cifs audit output [server\_cifs server\_x -o audit]  
→server\_cifsstat reports Open Connections to Data Mover, not total number of "SMB Sessions"—each Session can involve use of multiple connections, such as a Client connecting to several different Shares on the same Server. SessUsers param defines the number of SMB Sessions that can be established from a specific client system—observe Sessions from Computer Manager.

#### **Note "SessSetupX" Times:**

**SessSetupX 167997 0.04 13869.96 4.13** [Indicates healthy and fast Session Setups]

"Opened files/dirs=0" Indicates an "Open connection" but not an 'Open files'

"Opened files/dirs=1" Indicates an "Open connection" and an "Open files"

"Total Trans2Smb/NTSmb"

--Trans2 and TransNT are special commands--Trans2 are used mainly to get/set information on filesystem and files. TransNT are used to Create/open files with NT clients and send special request like IOCTL and Notification requests.

--TransNTCreate requests are not specifically outlined in Cifsstat Output, but are used in backup/restore applications

### **SERVER CIFSSTAT OUTPUT:** # server\_cifsstat server\_6

#### **SMB statistics:**

| proc    | ncalls   | %totcalls | maxTime | ms/call |

## **SETTING UP CELERRA EVENT LOG AUDITING:**

1. From the Application and Tools CD, install the Celerra Management MMC snapins on the Windows management station
2. From Windows, go to Programs>Administrative Tools>Celerra Management, to open the snapin
3. Rightclick 'Data Mover Management', select 'Connect to Data Mover...', and enter compname, "Name: Harry"
  - a.) Under Data Mover Security Settings, select Audit Policy, rightclick and "Enable auditing"
  - b.) Doubleclick the Events to Audit, such as "Audit Object Access", and set policy for 'Success and/or Failure' of the event
  - c.) Close interface
4. Go to a drive mapped to the Celerra Share where file or directory objects are to be audited, rightclick, select Properties>Security tab>Advanced>Auditing>Add [Add the Group or User to be audited, such as the group Everyone, if auditing access on objects for all Users]
5. Select the type of attributes to audit [such as Read, Write, Delete, Change Ownership, etc] and apply
6. Auditing is now in place.
7. To verify & view auditing events for Celerra "objects", open Event Viewer on Windows: Start>Run: eventvwr>highlight Eventviewer>Rightclick and "Connect to Another computer">Type in name of CIFS Server>Click on "Security" and observe Events that are recorded in the righthand window pane

**Note:** In Event Viewer, look at the "Properties" of the "Security" item to observe the default settings and location of the security.evt file [Default is Overwrite Events older than 10 days, 512kb is Security Log size, and default location of "security.evt" log for Celerra Server is c:\security.evt]. The size of the security event log can be increased, but only when moving the log off the roots of the Data Mover to a dedicated file system.

## **CHANGING THE LOCATION AND SIZE OF THE CELERRA SECURITY EVENT LOG:**

**Note:** This procedure illustrates how to create a dedicated file system for use with Celerra Event Logging, how to change the current location of the security.evt log file from the roots of the Data Mover to a dedicated file system, and finally, how to change the default Log size from 512KB to some larger size.

1. Using Celerra Manager, create a file system called "event\_log" and a custom mountpoint called "/winnt"

Custom

Pathname: **/winnt**

2. As Administrator, create a hidden share to the /winnt mountpoint called "winnt\$" on CIFS server 'Harry'

3. Map to the hidden share "winnt\$" from a Windows system, and create the following directory structure underneath the \winnt mountpoint:

\harry\winnt\$

\system32\config

4. Open the Registry Editor from a Windows system (Start>Run>Regedit), go to Registry>Connect Network Registry>type in the name of the Celerra CIFS server name (Harry)

**Note:** Ignore the popup that says "Unable to connect to all the roots of the computer's registry"

5. Navigate from the CIFS server name registry hive to the Security key:

HKEY\_LOCAL\_MACHINE>System\CurrentControlSet\Services\Eventlog\Security

6. Doubleclick and edit the "File" data location, changing the location from the default "c:\security.evt" to the new file system location and path:

**Default location:**

**c:\security.evt**

**New location:**

**c:\winnt\system32\config\security.evt**

7. Close the Registry Editor and open Event Viewer (Start>Run>eventvwr)

8. Highlight Event Viewer, rightclick and "Connect to another computer", type in CIFS Server name>Highlight the "Security" item, rightclick and "Clear all events" (Click o.k. to close the dialogue without saving any events)

**Note:** The new log location will not go into effect without first clearing all events from the old log

9. Rightclick "Security" >Properties, and change the 'Maximum log size' from the default 512kb to the desired new value (e.g., 512000KB = 512MB)

10. Finally, for the section "When maximum log size is reached:", select the appropriate setting to overwrite or not to overwrite events, etc.

## **VIEWING CELERRA SECURITY EVENT LOG:**

1. Copy msaudite.dll from Windows system to Control Station and push file to .etc of Data Mover

2. Connect to Data Mover registry using regedit & and modify the following keys:

HKLM>System>CurrentControlSet>Services>Eventlog>Security>Security>CategoryMessageFile

HKLM>System>CurrentControlSet>Services>Eventlog>Security>Security>EventMessageFile

Add c:\etc\msaudite.dll to each key

3. Close registry editor

## **GPO POLICY ALLOWS DEFAULT EVENT LOG SIZE TO BE > THAN 512kb:**

The historical size restriction for all Event Logs (Security, Application, System) for DART has been defined as 512kb when the logs are located on the roots of the Data Mover. The reason for this restriction is because the rootfs is traditionally very small in size (typically between 16 and 128MB). Even with rootfs extensions, this limitation has not been lifted. Under normal circumstances, changes made to increase the size of the log from 512kb to a higher value (when the logs reside on the rootfs) are restricted by DART code for Event Log or Registry changes. However, for GPO policies, DART fails to enforce the size restriction and it becomes possible to create a log size larger than the 512kb default on the rootfs of the Data Mover.

**Note:** See emc123515 and AR71688—issued resolved with 5.4.21.0

## **\$server\_security server\_3 -info -policy gpo**

2002-10-05 14:28:29: SMB: 4: addNewNTGids 15/84=-16

**DEFAULT TIMEOUT VALUES FOR DC CONNECTIONS (CIFS TIMEOUTS):**

**NTsec.DCConnectTimeout=1388 = 5000 decimal = 5 secs.** [length of time waiting to connect to DC]

**NTsec.DCTimeout=4e20 = 20000 = 20 seconds** [length of time waiting for reply from DC before trying another]

cifs.NTsec.DCTimeout 0x015d6b54 0x00004e20 0x00004e20

**Note:** DataMover will reselect next DC on its list after the 20-second timeout value if no further communication is occurring. In certain situations, such as for orphaned SIDs, or SIDs that cannot be resolved in other domains because of Trusts or firewall issues, Clients may experience long “pauses” as directories are traversed—this is because of the 20sec CIFS timeout value. In extreme cases, setting this value to 1388=5000=5 secs may help speed things up, but could have adverse impact & cause DC cycling.

**SECURE CHANNEL COMMUNICATIONS AND NTLMv2 SUPPORT:** NAS 5.4.16.0/5.3.18.0 +

With the implementation of native NTLMv2 support and subsequent fixes provided in AR59648, the first CIFS server of the Data Mover will open a secure channel connection to a Domain Controller. Other CIFS servers will open a separate secure channel whenever the first client connects only if that client is using NTLMv2--this behavior is different from the default behavior in the past, when the Celerra only opened a single secure channel to the Domain Controller that was used as the security context for all CIFS servers on the Data Mover. If NTLMv2 is not being used by the Client, then client connections to other CIFS servers on the Data Mover will piggyback over the first secure channel session that was opened without opening a separate secure channel. Clients that connect to the Data Mover using WINS name resolution, or direct IP address mappings, will default to NTLM, or NTLMv2 if set.

**EXAMPLE:**

**# .server\_config server\_2 -v "pdc dump"**

DC\*DC9a6c600c USADC50[USA](157.184.147.198) ref=42 time(getdc184)=0 ms

Pid=100c Tid=0800 Uid=0800

Cnx=NO\_TRUST\_SAM\_ACCOUNT,17 logon=Authenticate2InvalidReply 3 SecureChannel(s):

[LEXFILE16] Fid=0x801 CallID=0xa Status=SUCCESS/SecureChannelOK

[LEXFILE1] Fid=0x802 CallID=0xb Status=SUCCESS/SecureChannelOK

[LEXFILE13] Fid=0x803 CallID=0xa Status=SUCCESS/SecureChannelOK

**USING PDC DUMP TO VERIFY DM CONNECTIONS TO DC's:**

**\$server\_config server\_x -v 16384 "pdc dump"**

**Note:** Windows 2000 datamovers can have multiple “>DC” connections established. (1) for Kerberos AD Services, (1) for LDAP Directory Services, etc. PDC Dump can also tell you how the DataMover discovered the DC--BROADCAST, WINS, DNS

**EXAMPLE:** [Server Cifs Output and PDC Dump Output]

DOMAIN NETWORK FQDN=network.lan

SID=S-1-5-15-f407b588-8201be4d-bda18164-ffffffffff

>DC=UTIL002(172.19.3.254) ref=136 time=3 ms

DC=UTIL003(172.19.3.253) ref=240 time=0 ms

>DC=UTIL004(172.19.3.252) ref=33 time=0 ms

**# .server\_config server\_2 -v 16384 "pdc dump"**

### PDC INVALIDATE/VALIDATE COMMAND:

**\$ .server\_config server\_5 -v "pdc invalidate=10.64.25.101"**

1058881433: SMB: 4: TSWORKSTATION DC invalidate  
1058881433: SMB: 4: DCInvalidate TSWORKSTATION from cmdLine  
1058881433: ADMIN: 4: Command succeeded: pdc invalidate=10.64.25.101

**Note:** Use command to invalidate or validate a specific DC

### SERVER CIFS OUTPUT AFTER RUNNING INVALIDATE COMMAND:

DOMAIN TS\_NAS

SID=S-1-5-15-209b5669-55a118ba-7e4b2f8f-ffffffffff

>DC=SNEEZY(10.64.25.106) ref=4 time=0 ms

**DC=TSWORKSTATION(10.64.25.101) ref=2 time=136 ms INVALID**

**\$ .server\_config server\_5 -v "pdc validate=10.64.25.101"**

**Note:** Removes the “INVALID” designation for DC if successful

### VALIDATING MACHINE ACCOUNT PASSWD IN THE WINDOWS DOMAIN:

**\$ .server\_config server\_5 -v "srwpwd dump"**

1068222796: SMB: 4: srwpwd V=1 fileV=1 1 records  
1068222796: SMB: 4: Entry:4[tech] @ 12[SEINFELD.COM]  
1068222796: SMB: 4: Time: 0x3f79a7f7 Now=0x3fabc94c D=0x322155  
1068222796: SMB: 4: Account: 5[TECH\$]  
1068222796: SMB: 4: Password:15[LWbegMgTBxzB48r]  
1068222796: SMB: 4: GUID: 5de1e21f-9b6a-426b-b971-0ff657eba7d3  
1068222796: ADMIN: 4: Command succeeded: srwpwd dump

**Note:** Verifies machine account trust relationship between Server and Domain by verifying machine passwd against DC—used for IPC\$ netlogon and establishes membership in domain

### SERVER PASSWORD COMMANDS (Pre-NAS 5.5):

**\$ .server\_config server\_5 -v "srwpwd dump"**

**\$ .server\_config server\_5 -v "srwpwd display"**

**\$ .server\_config server\_4 -v "srwpwd compname=DM4 change"**

1095873609: SMB: 7: DomainJoin::modifyServerPassword: Reset server password dm4@MOUSE.COM using 'DM4\$' -  
machineAccount: DM4\$

**\$ .server\_config server\_4 -v "srwpwd compname=DM4 minutes=8640"**

**Note:** Changes frequency of password change from default 10020 minutes to 8640 minutes, or every 6 days.

### DATA MOVER MACHINE ACCOUNT PASSWORD (NAS 5.2):

→Windows NT/2000/2003 computers use a machine-account password to establish & maintain a ‘trust’ relationship with the Domain  
→The computer account password is used to authenticate the server during communication with the DC  
→Password is also the hash base for generating the Server’s Kerberos service keys  
→AD stores the password for each computer and generates Kerberos Service tickets for clients that wish to access the Server  
→NT 4.0 systems automatically change their passwords every 7 days while Windows 2000 changes every 30 days  
→Password is generated during Join process using either Kerberos set password protocol, or MSRPC SAMR set password call  
With the introduction of NAS 5.2, Celerra CIFS Servers automatically change their machine-account password every 7 days by authenticating to a Domain Controller, changing the password, then recalculating their Kerberos Encryption/Decryption keys based on the new password. Typically, Clients cache their Kerberos Service Tickets and may need to request new tickets after the CIFS Server has changed its password. A problem can occur if the Clients connect to a DC that does not yet have the Data Mover’s latest password change (i.e., replication not completed yet), meaning that the Client’s Service Ticket will still be invalid and DART will reply with MORE\_PROCESSING\_REQUIRED.

### NAS 5.5:

Please be aware that NAS 5.5 has completely revamped the machine account password system on DART so that a configurable number of passwords can be retained on the Data Mover in a history file, and that by default, the actual password change mechanism itself is not enabled. To put machine account password change in effect, provide a value in minutes to the param updMinutes.

### WORKAROUND FOR CIFS SERVER PASSWORD CHANGE ISSUES:

**param cifs srwpwd.updtMinutes=0**

**Note:** Set the above parameter to disable the weekly CIFS password change, then reboot the Data Mover to put into effect—this is the only way to make this param effective. See Primus emc92464 for more details. The automatic password change can also induce a race condition panic with DART, and more recently has been directly tied to a loss of domain trust as a result of the passwd change attempt failing, requiring Rejoining the compname to the domain via Unjoin/Rejoin or resetserverpasswd command.

### # server\_param server\_2 -facility cifs -i srvpwd.updtMinutes -v (NAS 5.5)

server\_2 :

```

name          = srvpwd.updtMinutes
facility_name = cifs
default_value = 0
current_value = 0
configured_value =
user_action    = reboot DataMover
change_effective = reboot DataMover
range         = (0,4294967295)
description    = Time interval between password changes
detailed_description

```

Defines the time interval between two server password changes in minutes, by default, it is 0 (not enabled). The Windows default value is 7 days - 1 hour (0x2724).

## TROUBLESHOOTING CIFS OUTAGE PROBLEM WITH CFS 2000 DM: NAS 4.2.9.0

**Intro:** Case 8715047, AR28374

**Scenario:** Customer experiences periodic CIFS Outages because DC is running out of resources

**Problem:** Data Mover uses its netlogon connection to IPC\$ share on the DC using NULL SMB session, then opens communication channel via RPC ‘named pipes’ in order to bind to DC’s LSA Interface [Local Security Authority for authentication calls]. However, rather than conducting multiple “\lsarpc” calls [OpenPolicy2/LookupSIDs2] down a single pipe, we are opening pipes for each command, which eventually consume the DC’s memory resources, and a CIFS outage occurs. Problem could be exacerbated by DM calls to DC to try and resolve local machine account SIDs. DC’s, however, do not know local machine account SIDs for individual Windows systems and cannot answer DM correctly. DM “switching” to alternate DC could then occur, as DM seeks to find a DC that can resolve the unknown SID [STATUS\_NO SUCH\_USER].

### How DM Queries DC When Client Makes Network Request for Resources:

As with any member Server, DM must query DC for username associated with SID of Client making Network Resource request. Data Mover uses its connection to default IPC\$ share on DC to communicate & issue commands via named pipes. DM sends SMB NTCCreateAndX calls to open the \lsarpc “magic” file via names pipes, which is used to talk to the DCERPC/LSA authority on the DC. DM queries DC for username of SID by opening “magic” \lsarpc file via LSA service and issues “OpenPolicy2” command to DC, and “OpenPolicy2/LookupSIDs2()” command via SMB-Transaction/Named Pipes to obtain username from SID. DM opens a new pipe for each call if required.

### DM-to-DC AUTHENTICATION CALLS:

DM→connected to DC via IPC\$ share

DM→binds to LSA interface on DC

DM→sends \lsarpc call OpenPolicy2 to DC \\AUS

DM→sends \lsarpc call LookupSIDs2 for SIDs of users/groups

### Symptoms:

1. Most obvious is a CIFS outage on DM, as well as port 445 “Too many connections open in listen queue”
2. Windows 2000 ADUC Interface sees hundreds of Pipe\LSARPC connections to DC
3. Netmon Traces show “STATUS\_PIPE\_NOT\_AVAILABLE” & “STATUS\_IO\_TIMEOUT” errors, which are indicators that there is a resource issue with the affected DC.

### Troubleshooting Commands:

1. \$server\_config server\_x -v “pdc dump”
2. \$server\_cifs server\_x
3. \$server\_config server\_x “param NTsec logonTraces=6” | Traces=3 [to turn off trace after done collection]
4. **\$server\_config server\_3 -v “pdc trace=1”** [Trace of DC actions] | trace=0 [to turn off PDC tracing after collection]
5. \$ .server\_config server\_3 -v “sidcache if=ana0 global status” [Shows health of SID Cache for User/Group lookups]

## HOW DM CHOOSES FASTEST-RESPONDING DC or LOCAL SUBNET DC:

Normally, DataMover will select the fastest-responding Domain Controller, but in 4.1, this may not always work. Set following parameter to make DataMover select DC on local Subnet, if available:

### /nas/server/slot\_x/param

**param cifs DC.useFastest=0** [Default Value is 1 for selecting “fastest-responding” DC]

**Note:** NAS 4.1 does not recompute DC List every 15 minutes as previous CIFS code did. NAS 4.2 does recompute DC list every 15 minutes and uses new mechanism for selecting DC on local Subnet, and then only (1) DC for all AD Services required

### **DUMPING ACLS [permissions] ON FOLDERS/FILES:**

**.server\_config server\_2 -v "acl if=ana0 dump=/mnt30/andy"**

### **DUMPING LOCALGROUPS FILE TO SCREEN:**

**.server\_config server\_2 -v 16384 "lg list vs=nas46"** [where nas46 = netbios name]

**.server\_config server\_2 -v 16384 "lg list"** [Dumps all Localgroups for DM]

### **RUNNING NTCRED TO VERIFY USER CREDENTIALS:**

**\$server\_config server\_4 -v "ntcred client=machinename user=rparsons" | "ntcred all"**

**\$server\_config server\_4 -v "ntcred client=172.19.8.10"**

### **COMMAND TO FIND CLIENT IP ADDRESS:**

**\$ server\_cifs cldm2 -o audit**

|||| AUDIT Ctx=0x8beae04, ref=0, Client (168.244.127.17) Port=1340

||| MTESTNET[LOWES] on if=int1

||| CurrentDC 0x8b0d904=DCCSC

||| Proto=NT1, Arch=Win2K, RemBufsz=0xffff, LocBufsz=0xffff

||| Uid=63 NTcred(0x8bc7904 RC=1) 'LOWES\mstestblephew\$' [User logged into Celerra]

||| Uid=64 NTcred(0x8bc6a04 RC=1) 'LOWES\celerraav' CHECKER [User logged into Celerra]

|| Cnxp(0x8c2f404), Name=IPC\$, Tid=63, Ref=1

|| readOnly=0, umask=22, opened files/dirs=0

|| Cnxp(0x8b90004), Name=CHECK\$, Tid=64, Ref=1

|| readOnly=0, umask=22, opened files/dirs=0

**Note:** Meaning of some values seen with cifs audit feature

Ctx = address in memory of the Stream Context

Arch = type of client O/S

RemBufsz = max buffer size client

LocBufsz = local buffer size negotiated

FNN/FNNlist = number blocked files not yet checked by VC

NbCnx = number connections to shares for this TCP connection

cUid = User ID who has opened the connection first

Tid = Tree ID representing share connection

### **CIFS RIGHTS & PRIVILEGES:**

Logon Rights: Controls who is authorized to log onto a computer and how [allow logon and deny logon]

Privileges: Controls access to system resources and override permissions on the local computer—manage via group membership

Permissions: Shares, Directories, Files

**\$ .server\_config server\_2 -v "ntcred user=administrator"**

1190081463: SMB: 4:

- SeOpenLocally = 0x1 → 0x3 is a combination of the two logon rights
- SeNetworkLogonRight = 0x2

## **COMMENT ON OWNERSHIP & MEMBERSHIP IN LOCAL ADMIN GROUP:**

If a User is a member of the local Administrators group on a Server, the SID S-1-5-20-220 is used in the Owner field, and not the UID of the User. This mimics Windows behavior. So, file ownership is held by the Administrator group and not the User.

### **NTCRED OUTPUT:**

→Shows the cumulative credentials for a User, based on domain and local group memberships

principal type 1, key version: 1, encryption type 3

End of keytab entries.

**Note:** A Keytab is a Key Table file that contains “keys” that can be used by a Host or Service

**\$ server\_kerberos server\_2 -ccache**

**Note:** Displays credential cache on Data Mover

### # .server\_config server\_2 -v "kerberos listrealms"

1158590830: KERBEROS: 4: Kerberos realm configuration:

1158590830: KERBEROS: 4:

1158590830: KERBEROS: 4: realm name: 2K3.PVT.DNS

1158590830: KERBEROS: 4: kdc: george.2k3.pvt.dns

1158590830: KERBEROS: 4: admin server: george.2k3.pvt.dns

1158590830: KERBEROS: 4: kpasswd server: george.2k3.pvt.dns

1158590830: KERBEROS: 4: default domain: 2k3.pvt.dns

### # .server\_config server\_2 -v "kerberos"

1158591016: KERBEROS: 4: usage:

kerberos <listrealms | addrealm | delrealm | keytab> listrealms

addrealm realm=<realm name> kdc=<fq kdc name>[:port][kdc=...] [kadmin=<kadmin fqdn>] [kpasswd=<kpasswd fqdn>]  
[domain=<dns domain>] defaultrealm delrealm realm=<realm name> addrel realm=<realm name> domain=<dns domain>  
delrel domain=<dns domain> [realm=<realm name>] keytab

## **VIEWING USER INFO & GROUP MEMBERSHIP ON NT 4.0/WIN2K DOMAIN:**

**C:>net user dparker /DOMAIN**

## **HOW TO VIEW GROUP MEMBERSHIP NT 4.0/WIN2K:**

**C:>net group Everyone /DOMAIN**

## **OTHER CIFS TOPICS:**

### **Creating Trust Relationship between NT 4.0 Domains (1-way trust):**

Example: Netinfo (“trusting”) {aka, Resource...}domain -----→trusts Netcentric (“trusted”)

Step (1): Netcentric adds Netinfo in UserMgrDomains to the “Trusting Domain” box and assigns Password

Step (2): Netinfo then adds Netcentric to its “Trusted Domain” box using the provided password to establish the trust.

**Accessing PDC from NT Machine:** run: \\superman\c\$\winnnt\system32\srvmgr {usrmgr,winsadm,cmd,etc}

## **USING USER MANAGER INTERFACE ON WIN2K STYLE CIFS SERVER:**

### **# server\_param server\_3 -facility cifs -info majorVersion**

server\_3 :

name = majorVersion

facility\_name = cifs

default\_value = 0

current\_value = 0

configured\_value =

user\_action = restart Service

change\_effective = restart Service

range = (0,4294967295)

**Note:** Set value to 4 on Celerra to allow usrmgr interface to manage CIFS server

## **MULTIPLE NT DOMAINS:**

Each DataMover Interface can be a member of different NT Domains [Create interfaces & CIFS Services]

Use VLAN IDs to provide security & separation between multiple DOMAINS defined on a single Data Mover [VLAN Tagging]

**NT 4.0 & Celerra:** Celerra uses NTLM 0.12, or NT1, a dialect of CIFS using SMB’s [MD4 encryption]. Celerra supports NTLMv2 with NAS 5.4.18/5.3.16 and higher

## **LOTUS DOMINO/NOTES R5.0.3:**

**Intro:** Domino & Notes applications are sensitive to network disruptions, with CIFS outages of 10 seconds and NFS outages of 30 seconds causing potential database corruption. However, automatic recovery can be done with transaction logging and restarting of the Lotus database.

### **Lotus R5.0 Support in NAS Environments:**

1. Enable Transaction Logging for databases
2. Turn off CIFS Oplocks [Use nooplocks for mounts]
3. Use Lotus Administrative Client to remotely administer Celerra resource, as we do not support ‘null sessions’ local db account
4. Stop Domino Server before making snapshot or checkpoint

## **SQL SERVER SUPPORT:**

Microsoft generally recommends only running SQL databases over SAN or direct-attached storage. If you have to use NAS solution, however, Microsoft requires specific “write ordering” and “write-through” guarantees. By default, you cannot create SQL database link over the network—a special setup is required using the ‘Trace flag 1807’ option. Key I/O considerations for SQL are I/O Aggregated Bandwidth (measured in MBps); I/O Latency (measured in ms); and CPU Cost (Host cpu in microseconds/operation).  
--CIFS oplocks should be disabled—that is, use “nooplocks” to help prevent corruption if using SQL databases  
--SQL 7.0 is intolerant to network interruptions and a file system unavailability > than 10 secs. will cause database corruption  
--SQL 2000 is more tolerant to network disruptions—up to 45 secs, but “nooplocks” rule still applies

## **RATIONAL CLEARCASE SUPPORT: 4.1**

Supported only via links from ClearCase Server’s storage for Unix/NFS & NT/CIFS—Celerra hosts the VOB (Versioned Object Database) pools [Special setup & Clearcase User account required]

## **IIS 4.0 (NT 4.0, IIS 5.0 (Windows 2000) IIS 6.0 (Windows 2003) SUPPORT:**

**Intro:** There are unique challenges presented when running an IIS Server with Celerra. Because Internet Information Servers rely on “content caching” of web pages to work properly, it requires that “NAS file servers” [Celerra, NetApps] notify IIS whenever Files or Directory content changes—hence the terms “File Change Notification”, “Directory Watch”, “Notify”, “WatchTree Bit”, “WatchSubTree”. IIS 4.0 can only cache ASP files—IIS 5.0 caches both ASP & HTML files. In older versions of NAS that did not provide for a “notify” function and “WatchSubTree” bit, the only way that IIS could update its cache would be to stop & start the IIS Service. IIS 6.0 introduces file caching from remote NAS servers using last-modified times (mtime) for files, as well as the traditional file state change notification feature.

### **IIS 6.0 & Windows 2003 Constrained Delegation:**

IIS 6.0 also supports a concept for 2003 native domains called “Constrained Delegation” which allows a Domain Administrator to delegate specific services on a target NAS Server, for access by individual Users connecting through an IIS 6.0 Server. Essentially, Constrained Delegation (aka, Service4User2Proxy) allows an IIS server to pass User credentials (e.g., Kerberos) to the remote NAS Server (pass-through authentication) so that NTFS permissions can be used to control file access, as opposed to the traditional method of allowing a “designated” user access via IIS (can configure this for NTLM, Basic Digest, Kerberos, etc.). The IIS Server is also responsible for controlling access to a specific list of Services on the Remote NAS Servers. Remote Servers authorize access based on the delegated Service Tickets sent by IIS and grants access based on ACLs. Kerberos Integrated Windows Authentication, is an example of a protocol that supports delegation, allowing for application of NTFS permissions through the use of Domain Users or Domain Groups.

Constrained Delegation is a Windows 2003 capability that allows Active Directory to delegate, via Administrative configuration, certain Services for access from an end User via an intermediary Server, to a remote Server (i.e., NAS) using Kerberos Pass-through Authentication. In the case of NAS and IIS 6.0, there is an MS Kerberos Extension called "S4U2Proxy" that allows a Web Server to present an end User's Service Ticket for the connection to the Web Server, to the KDC, in order to obtain access to a remote NAS Server. Essentially, the KDC returns the TicketGrantingService ticket to the Web Server, which contains the end User's authentication data. The Web Server then presents the Service Ticket to the remote NAS Server on behalf of the end User. One of the key reasons for using 'Constrained Delegation' is that this allows Customers to secure NTFS permissions on remote NAS devices using Domain-based Users and Groups, as opposed to traditional IIS designation of a special User account with unrestricted UNC access. See emc142136 & emc132863 for more information.

### **Constrained Delegation has been tested and approved, though with certain caveats:**

--Use only Compname and not IP Address when configuring Celerra Virtual Web Directory (Kerberos requires Compname)  
--Only the Shortname & FQDN for the CIFS & HOST Services should appear in the Delegation properties tab for the IIS Server—if there are extra instances present, delete them

## **CONFIGURING W2K3 DELEGATION:**

ADUC>rightclick Domain>Raise Domain Functional Level (only W2k3 and is irreversible)

ADUC>Computers>IIS Server properties>Delegation tab>select ‘Trust this computer for delegation to specified Services only’ & add other authentication schemes such as Kerberos.

Click Add>Add Services>Select Users or Computers>enter NAS Server

Select services for the NAS Server that are registered with SPN's, select Host & CIFS for Service Type list

## **CONSTRAINED DELEGATION CONFIGURATION PROCEDURE FOR CELERRA WITH IIS 6.0:**

1. Configured NAS 5.5\* CIFS Server running with exported Shares
2. Windows 2003 Domain must be running in native mode

3. Configure Virtual NAS Directory to Celerra using IIS Manager:

a.) Create new Virtual Directory or use existing Home Directory tab on Default Web Site Properties tab

Default Web Site>new>Virtual Directory

b.) Enter alias for the UNC location

c.) Enter UNC path for the remote NAS Share path

**Note:** Do not use IP address here--must specify the Compname of the Data Mover since Kerberos is required

d.) Keep the setting, 'Always use the authenticated user's credential when validating access to the network directory'

e.) Set the appropriate Virtual Directory access permissions to be allowed

4. Set Directory Security on Virtual NAS Directory using IIS Manager:

a.) Highlight Virtual NAS Directory>Directory Security>Authentication and access control>Edit>Uncheck 'Enable anonymous access' and ensure that 'Integrated Windows authentication' is checked

5. Configure Constrained Delegation using Active Directory for Computers (ADUC) MMC Interface:

a.) Open ADUC>highlight IIS Server>properties>Delegation tab>select 'Trust this computer for delegation to specified services only' and 'Use Kerberos only'>Click on 'Expanded' box and add CIFS & HOST services of the Data Mover using 'Add' button (if services not already listed)

**Note:** One known issue is that multiple entries may appear in the Delegated Services box--remove any duplicated entries.

**Examples of Correct Service Entries for NAS--Shortname & Fully Qualified Domain Names required:**

Service Type User or Computer

cifs dm2

cifs dm2.pvt.dns

host dm2

host dm2.pvt.dns

## **IIS 6.0 TUNING PARAMETERS:**

|                                                                             | Default Values | Max Values |
|-----------------------------------------------------------------------------|----------------|------------|
| HKLM>System>CurrentControlSet>Services>LanmanWorkstation>Parameters>MaxCmds | 50             | 65535      |
| HKLM>System>CurrentControlSet>Services>LanmanServer>Parameters>MaxMpxCt     | 50             | 65535      |
| HKLM>System>CurrentControlSet>Services>LanmanServer>Parameters>MaxWorkItems | 4096           | 65535      |

## **CELLERRA IIS SUPPORT:**

Only NT Security Mode is supported (security=NT)

**Note:** Not supported with Unix or Share Security modes

## **SETTING UP CELERRA WITH IIS:**

IIS User account must be defined for IIS and also the Passwd/Group file for the DataMover (or Usrmapper database)—not the IUSR Anonymous User account created by default for IIS Servers. Map Celerra Shares for IIS using 1.) Network Drive 2.) UNC Path

## **FILE CHANGE NOTIFICATION COMPONENT: FileChangeNotify**

File Change Notification is implemented by Windows Applications using SMB that allows for Applications to setup a “watch” on single or multiple directories [or whole subdirectories] so that any File or Directory changes that are made are then sent back to the IIS Server from the Celerra File Server as a ‘file change notification’. Main purpose here is to have Applications “register” their requests for change notification with the File Server so that constant ‘polling’ of the File Server is not required. Changes are usually based on creation or modification times.

### **NAS 4.2 FCN EXAMPLE:**

IIS Server sends file change notification request for each virtual directory to monitor, to the File Server using SMB sessions. File Server will reply only when a change occurs by using a watch bit subdirectory flag.

‘Changes’ to IIS Web Server content [hosted on Celerra Shares] are buffered so that multiple notifications can be satisfied with a single response. By default, the file system level for ‘notifications’ is 512 subdirectories down from the root. This can be changed by using the Server Mount command to set the “triggerlevel” option:

**\$server\_mount server\_2 -o “triggerlevel=0x000000f” fs01 /fs01**

**Note:** Example sets notification down 15 directories from root

### **DISABLING TRIGGER NOTIFICATION ON FILE SYSTEM:**

**\$server\_mount server\_2 -o “triggerlevel=-1” fs01 /fs01**

**Note:** Negative value disables file change notification feature

### **Directory Notifications OnAccess & OnWrite:**

CFS Windows Environment Guide [NAS 4.2 page 4-9,], suggests that the "notifyonaccess" and "notifyonwrite" values are disabled by default for file systems, meaning that they would have to be setup if you wanted to have notification by access time of a modification and notification of write access to a file system [same for NAS 5.2].

**\$server\_mount server\_x -o notifyonaccess,notifyonwrite fs1 /fs1**

**IIS Limitations:** When using "Share Security" with IIS, you might encounter an "HTTP Error 401" from the Clientside. This is due to 'unauthorized' access on ACL. To correct this condition, convert to "NT Security" on CIFS Server. Celerra also does not recognize the built-in IIS anonymous User account. The workaround here is to specify a regular NT User as the "anonymous user" account.

**WatchSubTree Functionality:** Setting this "bit" allows for applications to notify Celerra of directory changes, such as in IIS Only supported with NT Security, not 'Share-level'

**NAS 2.2.40 & Below:** NO SUPPORT FOR WatchSubTree function

**NAS 2.2.40-46.x:** Limited support for “Directory Change Notification” by using WIN32 API. Monitors (8) directories below root by default & can be specified on File Systems using the ‘mount’ command to monitor down (15) levels: \$server\_mount server\_2 -o "triggerlevel=0x0000000f" fs01 /fs01

**NAS 2.2.47 & Above:** Trigger level extended down to 512 directories [also the default setting]

### **"Notify" WatchSubTree 'bit' Restrictions:**

- NOT SUPPORTED on NFS, FTP, or MPFS [ONLY FOR CIFS]
- SHARE-LEVEL SECURITY MODE NOT SUPPORTED
- ONLY NT "User-level" SECURITY MODE SUPPORTED

### **SETTING TRIGGER LEVELS FOR FILE CHANGE NOTIFICATION:**

\$server\_mount server\_2 -o "triggerlevel=0x0000000f" fs01 /fs01 [Hex value specifying (15) directory levels]

### **DISABLING FILE CHANGE NOTIFICATION:**

\$server\_mount server\_2 -o nonotify fs01 /fs01

### **DISABLING IIS DYNAMIC AND STATIC CACHING:**

**Disabling Dynamic Cache:** Open IIS Manager, rightclick ‘Computername’>Properties>Edit WWW Service Master Properties>Go to ‘Home Directory’>Click on ‘Configuration’>Process Options’ tab and select “Do not cache ASP files”>Apply>o.k., Stop & Restart the IIS Service to put changes into effect.

**Disabling Static Cache:** run: regedt32>HKLM>System>CurrentControlSet>Services>Inetinfo>Parameters>Add following value to registry with value of 1: “DisableMemoryCache”: REG\_DWORD: 1

**Note:** Must reboot IIS Server to make changes effective

### **Disabling Caching on IIS 4.0 Web Servers:**

1. Open Internet Service Manager on IIS Web Server
2. Rightclick Server name>Properties>WWW Service Master properties>Edit>Home Directory>Configuration>Process Options: “Do no cache ASP files”
3. Apply change
4. Stop & Restart IIS Service
5. Make following Registry Change on IIS Server: HKLM>System>CurrentControlSet>Services>Inetinfo>Parameters>Add following value: “DisableMemoryCache” with value of REG\_DWORD:1
6. Reboot IIS Server

### **SOME REASONS FOR FILE CHANGE NOTIFICATION TO FAIL:**

- Loss of network connectivity
- lack of permissions
- invalid user accounts
- MaxCmds limit has been exceeded on Client Redirector
- MaxWorkItems context has been exceeded on the Server
- File Server not returning notifications completely
- File Server not returning any notifications at all

### **IMPLEMENTING NONOTIFY FOR ROOT FILESYSTEM ON DM:**

#### **root\_fs\_2 on / ufs,perm,rw,nonotify**

**Purpose:** Also called the NetShareEnum issue in that Windows 9x clients can only browse 64k in buffer size for Shares. Problem can occur when a Client browses the root filesystem of the data mover, placing a ‘notify’ request for any changes to the .etc directory. This in turn causes poor performance on the data mover and locks up browse and notify threads. Symptoms are poor browse performance.

**Fix:** Apply the “nonotify” option to the root filesystem of the DM

1. #vi /nas/server/slot\_x/mount
- ufs rw / 48=2 rw,nonotify
2. Reboot server

**Note:** This fix should not be applied with Engineering/GNS diagnosis and recommendation

### **COMMON CIFS PORTS & PROTOCOLS:**

#### **PORT USAGE**

| PORT | USE      | Transport               |
|------|----------|-------------------------|
| 53   | DNS      | TCP [DNS over TCP]      |
| 88   | Kerberos | UDP [Kerberos over UDP] |

|     |               |     |                                                                                                     |
|-----|---------------|-----|-----------------------------------------------------------------------------------------------------|
| 138 | Netbios-DGM   | UDP | [Netbios datagram service using SMB over Netbios over UDP-broadcasting [SMB Browser Svc]            |
| 137 | Netbios-NS    | UDP | [NetBIOS Name Service, broadcast or directed IP—NBT WINS over UDP]                                  |
| 139 | MicroSoft-SSN | TCP | [Netbios sessions using SMB over Netbios over TCP [typical Win9x, NT client authentication/traffic] |
| 389 | LDAP          | UDP | [Default LDAP Port over UDP or TCP]                                                                 |
| 389 | LDAP          | TCP | “ “                                                                                                 |
| 445 | Microsoft-DS  | TCP | [SMB encapsulated on top of TCP [Win2k client port and Win2k forwarding Directory Services]]        |
| 464 | DNS           | UDP | [DNS over UDP]                                                                                      |
| 135 | Endmapper Svc | RPC | Similar to Unix Portmapper service, maps services to ports                                          |

## **WINDOWS 2000 & CELERRA SUPPORT:**

### **MIXED MODE SUPPORT:**

**Intro:** By definition, "Mixed Mode" means that there is still a legacy NT 4.0 Domain Controller on the network that can replicate with the Active Directory Mixed Mode Server. However, all that is required for a CIFS NT 4.0 Server to be established on a Windows 2000 domain is the running of the PDC Emulator Service, which runs by default on the first Active Directory Server installed. There is one PDC Emulator for every Domain in the Forest. PDC Emulator supports NT Clients, Member Servers, Domain Controllers, Windows 9x Clients via the following:

- Windows 9x & NT 4.0 Clients are supported for Password Changes & Checking & AD Writes via the PDC Emulator
- NT 4.0 BDC's replicate from PDC Emulator
- PDC Emulator servers as NT 4.0 Domain Master Browser (0x1B)

**Note:** With the installation of the ADClient package, Windows NT & Windows 9x Clients can write to AD to any AD Server

## **CIFS & WINDOWS 2000 ACTIVE DIRECTORY SUPPORT:**

**Intro:** First of all, it is important to note that NAS 4.0 and above will support CIFS as either a legacy "NT 4.0-style" Server or as a native "Windows 2000-style" Server without regard to "Mixed v. Native Mode". The common misconception is to refer to this behavior as "Mixed-Mode" v. "Native-Mode". Strictly speaking, "Mixed-Mode" means only that there are still NT 4.0 Domain Controllers operating within the Windows 2000 Domain. "Native-Mode" means that there are only Windows 2000 Active Directory Servers in the Windows 2000 Domain space.

### **CIFS 2000 SERVER SUPPORT:**

- Supports Kerberos MD5 (128-bit hash output), NTLM, or NTLMSSP [NTLM Security Support Provider] Domain Authentication Modules
- CIFS Service created from commandline [\$server\_cifs server\_x –add compname=]
- Computer Name is "Joined" to Active Directory Domain from commandline with the use of Dynamic DNS Support as a 'native' Windows 2000 type server
- Uses Dynamic DNS for Name Resolution and Active Directory LDAP queries for locating network resources
- By definition operates only within the Windows 2000 Domain

### **CIFS 4.0 SERVER SUPPORT:**

- Supports only NTLM Version 1.2 Domain Authentication [Which AD Servers support by default for NT 4.0-style Clients]
- CIFS Service created from commandline [\$server\_cifs server\_x –add netbios=]
- Requires manual creation of CIFS Computer Account [i.e., Netbios name] using Server Manager or AD Users & Computers Snap-in & participates as an 'NT-4.0' type server
- Requires use of NetBIOS protocol for WINS Name Resolution and Network Browsing
- Participates in either an NT 4.0 or Windows 2000 Domain environment
- Data Mover broadcasts name and comment field every 15 minutes to Browse Service [initial startup broadcasts 5x in first minute]

## **CELERRA AUTHENTICATION SUPPORT FOR MICROSOFT WINDOWS NT, 2000, 2003:**

### **NTLM    NTLMSSP    NTLMV2**

Typically, NT 4.0 Domains/Clients use NTLM authentication on Port 139 → Celerra Supports NTLM

Typically, Windows 2000 Domains/Clients use NTLMSSP (SPNEGO) authentication on Port 445 → Celerra Supports NTLMSSP

**Note:** SSP is a Security Support Provider, and SSP Negotiate is a special authentication protocol based on the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO). By default, Win2k SSP Negotiate will select Kerberos authentication, but if no NDS is available, or a service SPN name is not registered, will fall back on NTLMv2, NTLMv1, LAN Manager, etc.

If Windows 2003 Domain Security Policy is set for 'NTLMV2' only, Celerra does not support & cannot negotiate until 5.3.18+

**Note:** 5.1.24.1/5.2.12.0/5.3.4.0 allows NTLMSSP even if Port 139 is used by Clients.

## **MIGRATING CELERRA SERVERS TO WINDOWS 2000 ACTIVE DIRECTORY: CONVERTING NT 4.0 CFS DM's TO CIFS 200:**

**Background:** Customer running Usrmapper with “\_SID\_HISTORY” turned on. Both NT 4.0 Domain Groups and Windows 2000 Domain Groups are defined in Usrmapper & the DataMover’s localgroups file

Step 1. Disconnected all Users from CIFS Shares using NT 4.0 Server Manager interface

**Note:** For busy systems, if this first step was not done, CIFS could hang when trying to stop

Step 2. Stopped CIFS Service on DataMover to be converted

Step 3. Deleted WINS entries from CIFS

**\$server\_cifs server\_2 -d wins=172.19.3.254,172.19.3.253**

Step 4. Deleted NETBIOS Name from CIFS:

**\$server\_cifs server\_2 -d netbios=file014**

**Note:** Make sure that the Netbios name is also deleted from the NT 4.0 Domain using Server Manager!

Step 5. Verify netd file: /nas/server/slot\_2/netd [In some cases, discovered that WINS entries were not removed].

**#vi /nas/server/slot\_2/netd**

**cifs add wins=172.19.3.254 wins=172.19.3.253 [Deleted this line]**

Step 6. Point DataMover to NTP Server:

**\$server\_date server\_2 timesvc start ntp 172.24.80.11**

**\$server\_date server\_2 0209041130** [Run to correct Time if not in sync—Year, Mnth, Day, Time]

Step 7. Setup or Add Windows 2000 DNS Domain & Servers—leave entry for old DNS Domain:

**\$server\_dns server\_2 -p tcp network.lan 172.19.10.254,172.19.10.253**

**Note:** You can point to multiple DNS Domains per DM—limited to 3 different domains from GUI, & 3 servers per domain.

Step 8. Enable ASCII Filtering for Non-UTF-8 [Non-I18N] Implementations:

**#vi /nas/server/slot\_2/param**

**param shadow asciifilter=1**

Step 9. Reboot DataMover—always reboot DataMover after “editing” either the “netd” or “param” files!

**Note:** For those Customers that can, turn I18N On!

**\$/nas/sbin/uc\_config -setup**

**\$/nas/sbin/uc\_config -on -mover server\_2**

Step 10. Add Computer Account to Active Directory:

**\$server\_cifs server\_2 -add compname=dm2,domain=network.lan,netbios=file014,interface=fsn0**

Step 11. Join CIFS Server to Active Directory Domain:

**\$server\_cifs server\_2 -Join compname=dm2,domain=network.lan,admin=migratory**

**Password: \*\*\*\*\***

Step 12. Start CIFS Service

**\$server\_setup server\_2 -P cifs -o start**

Step 13. Reboot Datamover—verify CIFS Service & access to Shares

**Comments:** In this example, did not have to edit usrmap.cfg file because the “network,network.lan” entry was already added. Nor did the localgroups.db file require editing or updating because both the NT 4.0 & WIN2K Domain Groups had already been added.

## **MIGRATING NETBIOS SERVER FROM NT 4.0 TO WIN2K—“ALIAS METHOD”:**

**Prerequisites:** NAS 4.2 and higher. Migrating from old to new Server while retaining old Server’s name.

Trust relationship between NT 4.0 & Windows 2000 domains. Sid History configuration on Usrmapper.

1. Setup Windows 2000 CIFS Server with a different netbios name than the NT 4.0 Server to be migrated

2. Migrate localgroups database from NT 4.0 to Windows 2000 CIFS Server using LGDUP

3. Migrate data using EMCopy

4. Migrate Shares using SHAREDUP

5. Delete original Netbios name from NT 4.0 domain

6. Create alias on Win2k server with old netbios name from NT 4.0 domain

## **MIGRATING NETBIOS SERVER FROM NT TO WIN2K WITHOUT ALIAS:**

**Prerequisites:** Migrating from old to new Server, but retaining old server’s name. Ensure that Usrmapper is configured.

1. Setup Windows 2000 CIFS temp Server with a different netbios name than the NT 4.0 Server to be migrated [not as the default]

2. Migrate localgroups database from NT 4.0 to Windows 2000 CIFS Server using LGDUP

3. Migrate data using EMCopy

4. Migrate Shares using SHAREDUP

5. Delete original Netbios name from NT 4.0 domain

6. Create CFS 2000 Service using original netbios name on same Windows 2000 Data Mover

7. Migrate localgroups, data permissions, and Shares from temp Win2k to new service with original netbios name

8. Delete temporary name [i.e., if not the default CIFS service]

## **TROUBLESHOOTING CIFS NT 4.0 & WINDOWS 2000 'JOIN' ISSUES:**

**Note:** Computer Name is created using "-a compname=mickey, domain=t2dom3.local, interface=ana0" command

**AD Account & DNS Updates occur during "-J compname=mickey, domain=t2dom3.local, admin=tmatta" command**

--Are WINS entries properly registered on WINS Server for CIFS netbios name?\* [Workstation & Server Service: 00h/20h]

--Are WINS entries properly registering the NT Domain & Domain Controller that the DataMover uses for authentication?\*

[NT DOMAIN: 00h [Workgroup service]/1Bh [Domain Master Browser]/1Ch [Domain Controller]/1Eh [Normal Group Name]  
[PDC/AD Server: 00h/20h/03h]

--Are Broadcast & Subnet Masks correct for Celerra? [Incorrect entries will not allow for proper network communications]

--Are switches configured to allow for Port 137 [Netbios Name Service], 138 Netbios UDP Service], 139 Netbios TCP Service], 445 [Secure SMB over TCP Service], and 135 [TCP Port Service Locator Service] for Netbios-related services?

--Is Windows 2000 Active Directory Server Security Template set to 'Highly Secure'?\*

[Will prevent DM from communicating because of lack of support for digital encryption communications]

--Does AD Server have '\*Enable netbios over TCP/IP' set?\* [Netbios will not communicate with AD Server]

--Verify PDC Emulator Service is configured by checking 'Operations Master' properties on Active Directory Users & Computers\*

--Does AD Server have multi-homed Network Interface Card?\* [Can cause netbios name resolution to fail]

--Run NBTSTAT -r on AD Servers

--Ensure Reverse & Forward LookUp Zones for DNS are setup properly and using 'Allow Dynamic Updates--Yes'\*\*  
[Cannot properly Join domain without]

--Ensure Reverse Lookup Zone is created for DataMover

--Ensure Time Service setup on DataMover to allow for Kerberos participation\*\* [Without will not properly Join Domain]

--Ensure valid Domain Admin account is used for 'Join' command, as well as a valid password\*\*

\*CIFS NT 4.0 Legacy Server only

\*\*CIFS WIN2K Native-mode Server only

### **KERBEROS ENCRYPTION ERROR:**

...KDC has no support for encryption type

LDAP: 3: LDAP bind: Security negotiation failed

**Note:** KDC fails to issue TGS ticket with DES-cBC-MD5 encryption & DM cannot Join Domain. Run following command to reset:  
c:>nlttest.exe /server:kdc\_computer\_name /SC\_CHANGE\_PWD:DC\_domain\_name

### **JOIN PROBLEM IF DC USES UPNs (Universal Principal Names):**

Join fails with error: 'Message Stream modified' [LDAP fails to bind during Join command]

**Note:** Use LDP to verify UPN name; Use adsedit utility to delete UPN name; reset computer account using nlttest

### **JOIN ISSUE REGARDING KERBEROS UDP PACKET SIZE LIMITATION OF 2K:**

Microsoft limitation for Kerberos over udp is 2k. Often, a Server's Kerberos packet information [User's group information, compnames, IP Addresses] may exceed the 2k size limit and prevent a Join from working for a new compname. NAS 5.2 supports Kerberos over TCP, which will resolve this issue.

### **KERBEROS OVER UDP 2K SIZE LIMITATION FOR JOIN COMMAND:**

Prior to NAS 5.2, we used UDP protocol for transmitting Kerberos data to DC's. If a User is a member of many groups, or has a large number of interfaces already defined, a "Join" for a new compname might fail with following Server Log message due to Kerberos Ticket Size:

**2004-04-02 09:40:50: KERBEROS: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure  
KRB5 error code 52**

### **POSSIBLE WORKAROUNDS:**

→Create new Admin User and make member of only Domain Admins so as to have fewest possible Group memberships

→If Server contains large number of defined interfaces, 'down' all other interfaces except for Compname being Joined

→Upgrade to NAS 5.2 so as to take advantage of Kerberos Over TCP, which removes Kerberos ticket size limitation

### **JOIN FAILS WHEN STRONG LDAP AUTHENTICATION IS SET ON AD SERVERS:**

**Note:** NAS 5.5 fully supports LDAP Signing and LDAP Privacy

### **SERVER LOG LDAP ERRORS IN DEBUG MODE:**

2004-05-26 16:14:57: ADMIN: 3: Command failed: domjoin compname=ph11s domain=my.domain.com admin=paasol password=7\_init

2004-05-26 16:15:03: ADMIN: 3: Command failed: domjoin compname=phl1s domain=my.domain.com admin=paasol password=7\_init

## **CAUSE:**

### **LDAP Bind ‘Strong Authentication’ is set on AD Servers:**

**HKLM>System>CurrentControlSet>Services>NTDS>Parameters>LdapServerIntegrity=2** [LDAP Enabled]

**Note:** Customer upgraded to Windows 2003 Domain Controllers and hardened LDAP Bind security settings for Active Directory Services. Celerra does not currently support hardened LDAP Bind Security for either NAS 5.1 or 5.2. With LdapServerSecurity=2 set in the registry of each Domain Controller, LDAP Bind requests to AD will fail for any authentication mode that does not use SASL or TLS/SSL, which is what occurs when trying to conduct a Join. Celerra does not support the use of SASL (Simple Authentication and Security Layer Protocol) or TSL/SSL (Transport Layer Security). The only current solution for this problem is to disable 'Strong LDAP Authentication' on all Domain Controllers in which the Celerra CIFS Servers are a member of--emc87712.

**Note:** TLS is SSL version 3.1.

### **DISABLING STRONG LDAP AUTHENTICATION ON AD SERVERS:**

**HKLM>System>CurrentControlSet>Services>NTDS>Parameters>LdapServerIntegrity=1** [LDAP disabled]

**LDAP BIND SETTINGS:** Values are as follows for LDAP server (ldapagnt.lib) handling of LDAP bind command requests

**LdapServerIntegrity=1** Default or not defined—LDAP Server supports client request for LDAP traffic signing when handling a LDAP bind command request which specifies a SASL authentication mechanism.

**LdapServerIntegrity=2** LDAP Server requires LDAP traffic signing, unless LDAP bind request is already protected with TLS/SSL. It rejects the LDAP bind command request if other types of authentication are used.

## **HOW TO CREATE CORRECT COMPUTER ACCOUNT AND JOIN ACTIVE DIRECTORY IF DNS NAME AND WINDOWS 2000 DOMAIN NAMES ARE DIFFERENT:**

**Intro:** By default, when creating Windows 2000 Domain, the DNS Domain is the same. However, this does not have to be the case and there are legitimate times when a Customer will have a different DNS FQDN than WIN2K FDQN. If this is the case, in order to properly Join AD, use following (2) Steps and Syntax:

### **Step 1.**

**\$server\_cifs server\_2 -add compname=fei0018s009, domain=ds.ferg.com, interface=fsn2, dns=hq.ferg.com -comment "dm2"**

### **Step 2.**

**\$server\_cifs server\_2 -Join compname=fei0018s009, domain=ds.ferg.com, admin=backup**

### **CIFS OUTPUT EXAMPLE OF DIFFERENCES:**

CIFS Server (Default) FEI0018S009[FEI-NT]

Full computer name=**fei0018s009.ds.ferg.com** realm=DS.FERG.COM [FQDN with AD]

Comment='dm2'

if=fsn2 l=172.16.104.41 b=172.16.104.255 mac=0:60:cf:20:a6:9e

FQDN=**fei0018s009.hq.ferg.com** (Updated to DNS) [FQDN with DNS]

### **Error Message for Unsuccessful Join:**

If above syntax is not used, Server CIFS output will show a “DNS Opcode Failure/Error” message

## **CIFS AND WINDOWS 2000’S REVERSE LOOKUP ZONE FOR DNS:**

NAS 4.0 & 4.1 Releases depend on an MIT implementation of Kerberos, which relies on determining the real FQDN of hosts for Kerberos services based on using the IP Address of the Host to perform a Reverse Zone Lookup [request for PTR record]. In actuality, the Join process may work without this Zone being configured, as the DNS query will generally still provide the correct FQDN—In short, best practices require that this Zone be setup.

**Change Update: NAS 4.2.6.x + no longer requires that Celerra use the Reverse Lookup Zone “PTR” Record. Only the “A” Record for Hostname & IP in the Forward Lookup Zone is required.**

**Caution:** If both Zones are configured, however, the Join process will not work if the two Zones contain conflicting records for the Host as a Kerberos Ticket will not be issued to the DataMover.

### **Disabling Dynamic Reverse Lookups for Celerra:**

Set the following parameter to disable Reverse Zone Lookups if using “Static DNS” records:

/nas/server/slot\_x/param or /nas/site/slot\_param

**param dns updatePTRrecord=0 | 1=enable** [enables reverse zone lookups]

**Note:** NAS 4.2 & higher are no longer dependent on Reverse Lookups as DART implements DNS the same as native Win2k Client.

### **REVERSE LOOKUP ZONE PTR RECORD RULE:**

--Reverse Lookup FQDN & IP Address must be the same as in Forward Lookup Zone

--Ensure that multiple/old entries are removed if using Static DNS entries!

--Remove DNS ‘suffix’ option from AD Server—allows interface to register real DNS name

--Use alternate DNS suffix for DM Interfaces by using “dns=” option in server\_cifs [Use this if WIN2K name is different than DNS!]

**Change Update: NAS 4.2.6.x no longer requires that Celerra use the Reverse Lookup Zone “PTR” Record. Only the “A” Record for Hostname & IP in the Forward Lookup Zone is required.**

### **Symptoms:**

Users cannot access Shares & DC List changes to “\*SMBSERVER”

**Server cifs Output:** “Update of “PTR” record failed during update”

**Server Log:** DNS update ERROR: Opcode not implemented in name server while registering..; Primary name server not found...”

## **NORMAL SERVER LOG/SCREEN MESSAGES FOR SUCCESSFUL MACHINE**

### **ACCOUNT CREATION AND JOIN COMMAND:**

#### **SERVER LOG RESULTS WHEN ADDING NEW COMPUTER NAME FROM COMMANDLINE:**

\$server\_cifs server\_5 -add compname=dopey, domain=t2dom2.local, interface=ana0

2002-03-14 14:34:34: SMB: 4: CIFS Server DOPEY[T2DOM2] created (0)

2002-03-14 14:34:34: SMB: 4: Full computer name todd.t2dom2.local, Realm T2DOM2.LOCAL

2002-03-14 14:34:34: SMB: 4: Interface ana0 added into CIFS Server DOPEY[T2DOM2]

2002-03-14 14:34:34: SMB: 4: Interface ana0 added into CIFS Server DOPEY[T2DOM2]

2002-03-14 14:34:34: ADMIN: 4: Command succeeded: cifs add compname=DOPEY domain=T2DOM2.LOCAL interface=ana0

### **JOINING WINDOWS 2000 AD/DNS FROM COMMANDLINE:**

# server\_cifs server\_5 -Join compname=dopey, domain=t2dom2.local,

admin=tmatta

server\_5 : Enter Password:\*\*\*\*

done

### **Corresponding Log Entry:**

2002-03-14 14:41:25: SMB: 4: Dart account todd not registered with DNS.

2002-03-14 14:41:25: ADMIN: 4: Command succeeded: domjoin compname=dopey domain=t2dom2.local admin=tmatta password=7?!? init

2002-03-14 14:41:25: LIB: 3: dns\_updateMessage: unable to get hostname of DNS server : Domain not exists

2002-03-14 14:41:25: LIB: 3: DNS update ERROR: Domain not exists while registering dopey.t2dom2.local

**Comment:** DNS Update Error is normal until CIFS service is started!!

## **USING NON-ADMIN USER ACCOUNT TO JOIN COMPUTERS (OR DMs) TO DOMAIN:**

### **Step 1. Create User account to be used for this process:** [User account called “Join”]

a.) As Administrator, open Active Directory Users and Computers & highlight “EMC Celerra” container

**Optionally:** Use the default “Computers” container

b.) Rightclick “EMC Celerra” container and select “Delegate Control”

c.) Select “Next”, then choose “Add” under “Selected users and groups”

d.) Add User called “Join” (A User account used for this test) and click on “o.k.”

e.) Select “Next” and then: \*Create a custom task to delegate

f.) Keep radial button selection: “Delegate Control of: \*This folder, existing objects in this folder, and creation of new objects in this folder

g.) Select “Next” and then check all three of the following boxes:

\_x\_General; \_x\_Property Specific; \_x\_Creation/deletion of specific child objects

h.) On same window, select “\_x\_Full Control” under section for “Permissions:”

i.) Select “Next” and “Finish”

**Note:** The “Computers” container underneath “EMC Celerra” will inherit the rights delegated above to the user “Join”

### **Step 2. Force AD replication update—Test user account “Join” by creating Computer account in ADUC MMC:**

### **Step 3. Create CIFS service and add compname from CLI using “Join” user account:**

a.) #server\_cifs server\_3 -add compname=phoenix, domain=t2dom3.local, interface=ana1

b.) #server\_cifs server\_3 -Join compname=phoenix, domain=t2dom3.local, admin=join

**Step 4.) Verify Status of new Compname:**

- a.) Check Server Log
- b.) Check CIFS output
- c.) Map drive to new compname “Shares” and access data
- d.) Highlight compname in Active Directory Users and Computers interface and select "manage"

**Note:** By default, only Domain Admins can create new compnames or join computers to AD Domains

**SYSTEM/MACHINE-ACCOUNT PASSWORD:**

Native Win2k changes machine password every (7) days. Celerra passwd set to infinity by default with NAS versions prior to 5.2 (NAS 5.2 defaults to weekly password changes). NAS 5.5 has re-implemented passwd change feature and a passwd history cache so that the Data Mover can decrypt Kerberos tickets that may still be sent to it based on the previous passwd.

**param cifs srvpwd.updtMinutes=10020** [Sets param from default to 6 days, 23 hours]

**Note:** Use above param to set different password interval change than the default for DM's in Windows Domain

**PASSWORD CHANGES AND VIRUSCHECKER PROBLEM:**

Issue in NAS 5.2 where password change would cause VC to stop working and create a CIFS outage. See AR45264.

**param cifs srvpwd.updtMinutes=0** & stopping/restarting CIFS will disable Server Password change as workaround.

**CFS 2000 SERVER: COMMON ERRORS WHEN JOINING WINDOWS 2000 DOMAIN CLOCK TIME TOO GREAT BETWEEN AD SERVER & CFS SERVER:**

Kerberos Security Mechanisms will fail if clock skew is greater than 5 minutes

**COMPUTER NAME CREATION COMMAND FAILS:**

2002-04-08 10:50:48: ADMIN: 3: Command failed: domjoin compname=monday domain=t2dom2.local admin=tmatta password=##=?=7%- init

2002-04-08 10:50:55: SMB: 4: Dart account monday not registered with DNS.

2002-04-08 10:50:55: KERBEROS: 3: krb5\_sendto\_kdc: unable to send message to any KDC in realm T2DOM2.LOCAL.

2002-04-08 10:50:55: KERBEROS: 4: krb5\_gss\_release\_cred: kg\_delete\_cred\_id failed: major GSS\_S\_CALL\_BAD\_STRUCTURE or GSS\_S\_NO\_CRED, minor G\_VALIDATE\_FAILED

2002-04-08 10:50:55: KERBEROS: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure

Preauthentication failed

**JOIN COMMAND FAILS DUE TO TIME SERVICE ISSUE:**

2002-04-08 10:50:55: ADMIN: 3: Command failed: domjoin compname=monday domain=t2dom2.local admin=tmattha password=Å1!3575 init

2002-04-08 10:51:05: SMB: 4: Dart account monday not registered with DNS.

1969-12-31 19:01:05: KERBEROS: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure  
Clock skew too great

**RESOLUTION:** Sync datamover to NTP server [troubleshoot & check Time Service, etc]

**KERBEROS DECRYPT INTEGRITY CHECK FAILURE:**

--Following error can result from a TIME SYNCHRONIZATION problem between DM & AD Server, resulting in an expired KERBEROS Authentication Key, or it could indicate a COMPNAME PASSWORD DESYNCHRONIZATION ERROR—either situation would prevent communicating or integration into Active Directory & loss of CIFS Access or failure to “Join” Domain:

**SERVER LOG:**

2002-04-08 11:01:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328351

2002-04-08 11:01:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328351

2002-04-08 11:01:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328351

**Note:** Entry is populated in Server Log everytime a User tries accessing via Explorer or AD Computer Management Interface, etc

**RESOLUTION:**

--Verify and correct Time Desynchronization problem [Verify NTP Service, DM Timesvc, AD Server Timezone to CS0 Timezone]

**REJOINING\RESETTING DATAMOVER SERVER PASSWORD ACCOUNT:**

**\$server\_cifs server\_4 -Join compname=suncor, domain=network.lan, admin=migratory -o  
resetserverpasswd**

**Note:** This option can be used when it becomes clear that the data mover can no longer connect to AD with valid Kerberos credentials. Resets the server's password and encryption keys with the principal. Please note that if using Celerra Manager to perform the Join, it will automatically use the reuse or resetserverpasswd option and complete the Join—NAS 5.4 & 5.5.

**SERVER LOG ENTRIES FOR SERVER THAT CAN LONGER AUTHENTICATE TO DOMAIN:**

### **COMMON JOIN ERRORS FROM SERVER LOG:**

**CommandLine Error:** Failed to complete command

**Client not found in Kerberos Database**→Computer account created in AD but not yet replicated to KDC; Or, could mean that Kerberos Server is different than AD Server that DataMover is communicating with [Use DC= command to JOIN]

**Server not found in Kerberos Database**→Common with 4.0.12.0; Need to force DM to use specific KDC; or, install DNS Service for DataMover

**DomainJoin::connect:** Unable to connect to the LDAP service on win2k.t2dom3.local - result code Sasl protocol violation. → Again, try using DC=FQDN command to Join Domain

**DomainJoin::getAdminCreds:** gss\_acquire\_cred\_ext failed: Miscellaneous failureKDC has no support for encryption type → Reset Administrator's password and try again

**Note:** When AD Server is first setup, it's Admin password is encrypted using DES encryption. The password needs to be changed after Installation so that Kerberos encryption is used.

## **PREVIOUSLY KNOWN JOIN ISSUES:**

- DNS Reverse Lookup Zones & Forward Lookup Zone entries for DataMover FQDN must match or else Join process will fail!
- Once DataMover is “Joined” to Domain, Users will be able to map to Celerra Shares, but Administrator may not be able to “manage” the DM when using the Active Directory Users & Computers MMC Interface
- Windows 2000 Groups may not be mapped in Usrmapper Database. DM will obtain User UID's without issue, but may not serve up Group GID's. Workaround at present is to use Localgroups.db file.
- DNS Domain is usually same as WIN2K domain but can be different! Use “dns=” option in server\_cifs to specify DNS suffix for datamover interfaces
- Known issue where Kerberos ticket is too large due to the number of Groups that the admin user is a member of, causing Join to fail
- Known issue where tpc stack mishandles Kerberos tickets and ignores certain bytes, rejecting the Kerberos ticket and causing Join to fail (turn param tcp doRFC1323=0 to zero to disable)

## **COMMON JOIN FAILURES & CORRECTIVE ACTION REQUIRED:**

### **JOIN FAILURE:**

Invalid User account used to conduct Join

#### **Server Log Error:**

2006-04-03 11:59:53: KERBEROS: 4: Warning: Client principal "schmuck" not found in Kerberos realm "2K3.PVT.DNS" database - KDC 0.0.0.0.

2006-04-03 11:59:53: SMB: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure. Client not found in Kerberos database.

2006-04-03 11:59:53: ADMIN: 3: Command failed: domjoin compname=bestbuy domain

=2k3.pvt.dns admin=schmuck password=\*\*\*\*\* ou="ou=Computers,ou=EMC Celerra" init

#### **Corrective Action:**

Select a valid account and conduct Join.

### **JOIN FAILURE:**

Correct Admin User account used to conduct Join, but password wrong or entered wrong

#### **Server Log Error:**

2006-04-03 12:12:08: SMB: 3:[VDM\_UPPERCASE] DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure. Preauthentication failed.

2006-04-03 12:12:08: ADMIN: 3:[VDM\_UPPERCASE] Command failed: :4 domjoin compname=bestbuy domain=2k3.pvt.dns admin=tmatta password=\*\*\*\*\* ou="ou=Computers,ou=EMC Celerra" init

#### **Corrective Action:**

Verify password or reset User's password in ADUC and retry Join.

### **JOIN FAILURE:**

Correct Admin User account and password used, but the wrong fully qualified domain name was entered

#### **Server Log Error:**

2006-04-03 12:28:48: SMB: 3: DomainJoin::findServer: Unable to locate a Domain Controller in domain 2k3.svt.dns

2006-04-03 12:28:48: SMB: 3: DomainJoin::findServer: Unable to contact any domain controller in domain 2k3.svt.dns

2006-04-03 12:28:48: ADMIN: 3: Command failed: domjoin compname=bestbuy domain

=2k3.svt.dns admin=tmatta password=\*\*\*\*\* ou="ou=Computers,ou=EMC Celerra" init

#### **Corrective Action:**

Delete CIFS compname for “2k3.svt.dns” using GUI, then attempt new Join using correct FQDN, “2k3.pvt.dns” for the Compname.

### **JOIN FAILURE:**

Compname already exists in the netd file on Data Mover

#### **Server Log Error:**

2006-04-03 12:34:04: SMB: 3: Cifs error: Bad domain name

2006-04-03 12:34:04: ADMIN: 3: Command failed: cifs add compname=BESTBUY domain=2K3.PVT.DNS netbios=bestbuy interface=vdm\_test

#### **Corrective Action:**

Delete compname from CIFS Service and re-attempt Join.

### **JOIN FAILURE:**

DNS Service not running, not configured, or misconfigured on the Data Mover

#### **Server Log Error:**

2006-04-03 12:41:09: SMB: 3: DNS is required for domain w2k.pvt.dns, it is actually not configured or it is not running, please configure DNS

2006-04-03 12:41:11: SMB: 3: DomainJoin::findServer: Unable to locate a Domain Controller in domain 2k3.pvt.dns

2006-04-03 12:41:33: SMB: 3: ActiveDirectoryServer::connectToDc: No Domain Controllers found for domain 2k3.pvt.dns.interface=laip1-2a

2006-04-03 12:41:33: SMB: 4: ActiveDirectoryServer::initiate: Couldn't open anonymous LDAP connection to domain 2k3.pvt.dns.interface=laip1-2a

**Corrective Action:**

Verify DNS Service configuration, correct configuration, start DNS client on Data Mover. Conduct Join.

**JOIN FAILURE:**

NTP Service may not be running Data Mover, or, Service is running but time is still out of sync, wrong NTP Service, etc. Clock skew too great

**Server Log Error:**

2006-04-02 12:49:31: SMB: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure. Clock skew too great.

2006-04-02 12:49:31: ADMIN: 3: Command failed: domjoin compname=bestbuy domain

=2k3.pvt.dns admin=tmattha password=\*\*\*\*\* ou="ou=Computers,ou=EMC Celerra" init

**Corrective Action:**

Verify NTP service and make sure Data Mover time and AD Time are in sync. Conduct Join.

**JOIN FAILURE:**

A valid, but non-admin User tried to Join compname to domain

**Server Log Error:**

2006-04-03 13:18:21: SMB: 3: DomainJoin::addHostToDomain: AD Account creation for computer account 'bestbuy' failed. LDAP response code = Insufficient access rights, error message = '00000005: SecErr: DSID-03151E04, problem 4003 (INSUFF\_ACCESS\_RIGHTS), data 0'.

2006-04-03 13:18:21: ADMIN: 3: Command failed: domjoin compname=bestbuy domain=2k3.pvt.dns admin=dodo3 password=\*\*\*\*\* ou="ou=Computers,ou=EMC Celerra" init

**Corrective Action:**

Verify that user account is member of Domain Admins (or has correct delegated privileges), and attempt new Join.

**LEGACY NT 4.0 CIFS SERVER PREREQUISITES FOR WINDOWS 2000:**

**I. Requires at a minimum the PDC Emulator Service:**

[Also could include an NT 4.0 Domain Controller, but is not required]:

**Verifying the PDC Emulator Service:**

Programs>Administrative Tools>Active Directory Users & Computers>Rightclick AD Server>Select "Operations Masters">PDC Tab>Operations Master: win2ksrvdom2.t2dom2.local [PDC Emulator Server is listed in this box]

**II. Requires that NetBIOS Communications be Enabled for TCP/IP for Legacy Servers on AD Server:**

Network & Dial-up Connections>Local Area Connection>Properties>Select "Internet Protocol (TCP/IP)"

Properties>Advanced>WINS Tab>\*Enable NetBIOS over TCP/IP [Enabled by default]

**III. Windows 2000 Security Template Cannot Be Set to 'Highly Secure' for Machines Using NTLM:**

Using Windows 2000 "Highly Secure" templates are designed for pure Windows 2000 networks that use digitally signed and encrypted network communications and are not supported by legacy NT 4.0 Servers. The default 'Security Template' for a Windows 2000 Domain is "Basic", but there are also "Secure" and "Compatible" templates as well.

**CIFS & WINDOWS 2000 /WIN2K/ ACTIVE DIRECTORY SUPPORT:**

**NAS CODES SUPPORTING WIN2K:** NAS 2.2.35.4; NAS 2.2.49.0; NAS 4.0.12.1; NAS 5.0, 5.1

**NAS 4.0.12.1:**

When looking for DC, LDAP, or Kerberos Services, will use the first DC in the list as returned from DNS

For multi-Domain environments, requires Enterprise Admins rights—needs to have authority to obtain a User's Group credentials from other Domain Controllers in the Forest

This version often suffered problems in multi-domain environments, especially if there were synchronization issues

**NAS 4.0.16.100:**

Tries to use DC on same subnet first, then first one listed in DNS query

Requires use of Enterprise Admins rights to interoperate in multi-domain environments

**NAS 4.0.18.0/4.1.6.0/4.2.4.1:**

No longer requires Enterprise Admins rights in multi-domain environments

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Reverse DNS Zone entries no longer required to validate canonical name of KDC upon lookup—Celerra obtains correct information for real host name from forward DNS queries.

Locates services in same manner as native Win2k systems—using “use\_ds” file for local KDC, LDAP services

### **NAS 4.2 & Above:**

Data Mover decodes the PAC [Privilege Attribute Certificate] for ‘joins’ as do Win2k systems

**Best Practices:** Try to have DC on same subnet as any single NetBIOS names on an interface  
Use the SNTP Service on the AD Server for Time Synchronization

## **HOW DATAMOVER DISCOVERS DC’s IN ACTIVE DIRECTORY ENVIRONMENT:**

--DNS Query for \_ldap.tcp.REALM SRV records

--NetBIOS Name Query Broadcast for 0x1C & 0x1B or directed IP to WINS Server

**Note:** The NetBIOS Name Query method is the default method for Windows NT CIFS Servers but is still used with the CFS 2000 implementation. The DC List is recomputed every 15 minutes by default. The “Join” process uses only DNS & will also use the closest DC determined from LDAP-UDP ping.

### **DATA MOVER-to-DC COMMUNICATION:**

--Celerra uses LDAP-UDP queries to all DC’s that are returned from DNS

--In the absence of Site information from AD, Celerra will use the closest DC as determined from the LDAP-UDP ping RTT

--DM will also use closest DC for KDC service, unless the AD Server does not know the “principal” that the DM is trying to service, then the DM will resort to querying other KDC’s in the realm.

**Rule:** Data Mover will always use the closest DC for all LDAP operations!

--Join requests use LDAP over TCP

## **HOW DART DISCOVERS AND SORTS LIST OF AD SERVERS:**

**param ds useDCLdapPing=1** [default DM setting]

**param ds useDCLdapPing=0** [Sorts by order that DNS returns AD List, or as set by DM in directoryservices file]

**Note:** Dart uses Ldap Ping to AD Servers returned from DNS in order to sort the DC’s. Default behavior is to sort based on site information from LDAP queries to AD and on response time to the ping. The LDAP ping is used every 15 minutes to help data movers maintain current DC preference list and whenever CIFS service is started. When CLOSEST\_SITE bit is set, 0x8000 is ADDED to the final preference calculation. The response time is SUBTRACTED from the final preference calculation (So if you have 2 DCs with the same preference number at this point, the response time will be the tie break). See DS Dump example:

1082056734: LIB: 4: IP:19.59.116.46 server:fresca.ford.com

1082056734: LIB: 4: **Preference:0x00057ffc**

**Note:** Data Mover will not be truly “Site” aware until NAS 5.4

## **WINDOWS 2000 ACTIVE DIRECTORY MIGRATION TOOL (ADMT.EXE):**

### **Intro:**

Tool used for migrating User, Group, Computer, Service Accounts, and other Network Resources from one Domain to another. The “admt.exe” executable is installed on the Target Domain’s PDC Emulator. The Target Server must be running Windows 2000 Active Directory in Native Mode. For our purposes, we are mainly concerned with migrating from an NT 4.0 to a Windows 2000 Domain. ADMT is used to migrate “security principals” in the following situations:

- a.) From one Forest to another Forest (Copying or Cloning accounts from Source to Target)
- b.) From one Domain to another within the same Forest (Moving accounts from Source to Target Domain)

### **SID History:**

The ADMT process migrates the User or Group SIDs from the Source Domain and assigns a new SID in the Windows 2000 Domain. The new WIN2K SID contains an attribute called “SIDHistory” that stores the User’s original SID and access rights [Security Principals] to the Source Domain’s resources as long as proper 2-way Trusts have been established. In otherwords, until the original Source Domain is deactivated, a User should be able to log in to either “Source” or “Target” domain after the migration and have equivalent access rights to the original Source Domain resources.

**Note:** NAS 4.2.13.0 and higher now integrates the SID History function correctly into the Usrmapper database

### **Utilities:**

To view or delete SIDHistory entries after a “migration”, use “ldp.exe” from Resource Kit. To view SID identities, use “getsid.exe”. Other useful Utilities include apimon.exe, dumpel.exe, xcacls.exe. The “netdom” utility is useful for managing computer accounts, such as Adding, Removing, or Querying, and also to establish and manage Domain Trusts. It also can be used to verify and reset a computer’s “secure channel” communication to the DC.

## **SECURITY ACCESS TOKENS (SAT):**

The ‘SAT’ serves as the basis for allowing a User ‘Network Access’ to resources. The Access Token itself is constructed each time a User logs into the Domain and consists of a User’s SID & all the Group SIDs to which the User belongs. The basis of “permissions”

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
is determined by the Operating System when comparing a User's SAT to the Network Resource's Security Descriptor, which consists of an Access Control List (ACL) and Access Control Entries.

## --Access Tokens equate to User Authentication to Network Resources based on User's SID, Group SID, and SIDHistory...aka 'access'.

## --Security Descriptors are attached to all Network Resources and equate to Authorization based on ACLs (and ACE entries) and SIDs and Access Rights. Authorization = verification of SAT SID to ACL on SD.

**Note:** Access Tokens are limited to 1023 SIDs. Users with membership in 500 or more Groups may experience log on or access problems under WIN2K. Corrective action may be to consolidate or reduce the number of Groups a User is a member of; Turn off the SID History function after the migration is completed; Remove the SIDHistory entries.

## **CELERRA SID HISTORY SUPPORT:**

Celerra Supports SIDHistory with the following "usrmap.cfg" entry, which must always be the last line of this file:

**\_history\_sid\_range\_:600:17500:18500:18600:19600**

**Comment:** SID History range optional in NAS prior to 4.2.13.0. 4.2.13.0 and higher requires SID History range configured in all "usrmap.cfg" files. Usrmap will no longer work properly without this entry. The SID History range will now map correctly, whereas in versions prior to 4.2.13.0, the SIDs were mapped from regular Domain ranges & not the SID History range. SID History was never implemented correctly in any NAS version prior to 4.2.13.0 due to a Netbios name limitation of 15 characters and a real "**\_history\_sid\_range\_**" of 19 characters.

## **RUNNING THE ACTIVE DIRECTORY MIGRATION TOOL:**

1. Download "ADMT.EXE" from Microsoft: 9 Mar 2000 Windows NT to Windows 2000 Active Directory Migration Tool (ADMT) Version 1.0 2543kb. Installed on PDC Emulator (Creates new MMC Snap-in)
  - a.) Verifying PDC Emulator: ADUC>Rightclick "T2DOM2.LOCAL">Operations Master>PDC:
- Operations Master: win2ksrvdom2.t2dom2.local**
2. Must have 2-Way Trusts established between Target & Source Domains
  - a.) User Manager for Domains>Policies>Trust Relationships: Add T2DOM2 to "Trusting Domains" on T2DOM1 NT 4.0
  - b.) Active Directory Domains and Trusts>Rightclick "T2DOM2.LOCAL">Properties>Trusts>Add T2DOM1 to "Domains trusted by this domain" [Listed as an External Trust]
  - c.) Add T2DOM1 to "Domains that trust this domain" on AD Server
  - d.) Add T2DOM2 to "Trusted Domains"
- Note:** If having difficulty establishing Trusts, make sure that WINS defines the Windows 2000 Domain Controller and the Domain Name for the NT 4.0 Domain.
3. Choose a User account that has Domain Admin privileges on Source Domain
  - a.) Add Target "Domain Admins" group to local group "Administrators" on NT 4.0 Domain
  - b.) Add Target "Domain Users" group to local group "Users" on Source Domain
4. Run the Active Directory Migration Wizard: Programs>Administrative Tools>Active Directory Migration Tool>Rightclick>User Migration Wizard; Group Migration Wizard; Computer Migration Wizard; Reporting Wizard; Service Account Migration Wizard; Trust Migration Wizard; Group Mapping & Merging Wizard
  - a.) User Migration Wizard>Welcome to the User Account Migration Wizard>Next
  - b.) Test or Make Changes → \*Test the migration settings and migrate later?  
→ o Migrate now?
  - c.) Domain Selection>Source Domain: T2DOM1 Target Domain: T2DOM2.LOCAL
  - d.) User Selection>Add>T2DOM1>select Users to migrate>Next
  - e.) OU Selection>Users>Next: LDAP://T2DOM2/CN=USERS,DC=T2DOM2,DC=LOCAL
  - f.) Password Options: \* Complex Passwords \*Same as User name
  - g.) Account Transition Options: \*Disable Source Accounts \*Disable Target Accounts \*Leave both accounts open  
\_\_x\_\_Migrate User SIDs to target domain [This is SID History]

## **PREREQUISITES HANDLED BY ADMT MIGRATION WIZARD:**

- 1.) --Auditing is not currently enabled on Target domain. Enable? Yes

**Note:** NT Auditing must be turned on for both Source & Target Domains

Source: User Manager>Policies>Audit>Select Audit These Events: \*Success \*Failure User and Group Management

Target: AD Users & Computers>DC Container>Group Policy tab>Default DC Policy>Edit>Computer Config>Group

Policy>Windows Settings>Local Policies>Audit Policy>Audit Account Management: Select "Define these Policy Settings" \*Success \*Failure [Use SECDEDIT to refresh policy: c:>secedit /refreshpolicy machine\_policy]

- 2.) --The Local Group 'T2DOM1\$\$\$' does not exist on T2DOM1. This group is required to migrate SIDs. Would you like to create it? Yes

- 3.) --TcpipClientSupport registry key is not set on the Source domain. Would you like to add this registry key? Yes

**Note:** This entry is required to allow the Lsa of the Source Domain to communicate with the Target Domain

## **HKLM>System>CurrentControlSet>Control>Lsa>TcpipClientSupport: REG\_DWORD: 0x1**

- 4.) --Would you like to reboot the PDC to insure changes will take effect? Yes.
  - h.) User Account To add SID history, you must supply a user account with the proper permissions:  
Username: nasadmin  
Password: \*\*\*\*\*  
Domain: T2DOM1
  - i.) User Options. You can migrate user groups, profiles, and security settings. Please select the following options to customize your migration task.  
 Translate roaming profiles [Leave blank]  
 Update User Rights  
 Migrate associated user groups (recommended)  
 Update previously migrated objects  
Select how all migrated accounts should be moved.  
 \*Do not rename accounts  
 \*Rename with prefix:  
 \*Rename with suffix:
  - j.) Naming conflicts. To select how you like to resolve group account name conflicts, click an option below.  
 o Ignore conflicting accounts and don't migrate [Change to select this]  
 \*Replace conflicting accounts [Default choice, unselect this]  
 \_x\_Remove existing User rights  
 \_x\_Remove existing members of groups being replaced  
 o Rename conflicting accounts by adding the following: o Prefix: o Suffix:
  - k.) You have successfully completed the User Account Migration Wizard. Finish. Migration Progress... Status: In progress. Completed. The "Viewlog" will document results of the Migration.

**Migrating Groups:** Rule of thumb—always migrate Users and Global Groups together. Groups—migrate Global Groups as “closed sets” when migrating Users    Ignore conflicting accounts and do not migrate    Replace conflicting accounts    Rename conflicting accounts

**Group Mapping & Merging Wizard:** Migrates Group membership from Source to Target; Merge multiple Groups into one

**Tools:** usrstat; showmbrs; showgrps

## **WIN2K ACTIVE DIRECTORY PREREQUISITES and CELERRA CIFS:**

Nas 2.2.35.4/2.2.49.0/4.0.12.1 [See notes below for details on specific support per code level]

Kerberos Authentication for Win2k network client/server authentication using secret key cryptography

Dynamic DNS--mechanism which DataMover uses to register on the WIN2K domain, as well as for Host Name resolution

**Important Point:** Celerra CIFS must use the "reverse zone lookup" feature of DNS, which is not setup by default for DNS--therefore, ensure that it is setup--this is the only way a CIFS DataMover can join the WIN2K Active Directory Domain as a "Windows 2000 CIFS Server". If running Windows 2000 native mode & you have multiple Domains, then DNS must be able to resolve the Global Catalog Service [port 3268] in order to authenticate users [the Gobal catalog authenticates all Users]. Each Domain runs its own Active Directory and has its own namespace in DNS. Trusts are created automatically if within same 'forest' or by specifying each other as the secondary DNS server for the other's zone DC's TCP/IP properties; configure to allow Zone Transfers.

Network Time Protocol [NTP]--Standard Internet Time Service required for implementing Kerebos Network Authentication

Active Directory--requires use of LDAP [Lightweight Directory Access Protocol] protocol between Clients and WIN2K Servers

**Note:** Active Directory is stored in NTDS.DIT and can hold up to 1.5 million objects

Windows NT 4.0 & Celerra CFS 2.2.49.2 +/4.0.12.1 cannot use IPSec for encrypted network communications

## **FORCING ACTIVE DIRECTORY REPLICATION:**

Programs>Administrative Tools>Active Directory Sites & Services>doubleclick the Domain Controller>Select NTDS Settings & rightclick in right window pane on <auto generated> Replicate Now

## **FORCING AD REPLICATION FROM RUN BOX:**

**c:> repadmin /syncall <dest dsa> [<naming context>] [<flags>] <dc name>**

**C:\2k3tools>repadmin /syncall george.2k3.pvt.dns**

CALLBACK MESSAGE: SyncAll Finished.

SyncAll terminated with no errors.

**c:> repadmin /showconn /showmeta <object dn> [DSA] [/nocache]**

## **Replication Monitor GUI:**

**c:>replmon** [Add AD Servers—use tool to verify Operations Master and Global Catalog Roles]

## **WINDOWS 2000 SUPPORT TOPICS:**

**Organizational Unit:** A container used to organize and store objects in the domain

### **Forest:**

AD Schema contains all forest objects & attributes, stored in Global Catalog of Domain Controllers. Multiple Trees can be created to form a “Forest”. Multiple forests can be trusted.

### **Tree:**

Multiple domains combined into hierarchical trees. All Domains within a Tree & Forest share a common Schema & Global Catalog. Domain Structure usually goes from a Parent to Child domains.

### **Sites:**

Multiple domains can be in a single site; Single Domains can be in multiple sites

Used to service client requests for network resources

Used for AD replication among Domain Controllers

Generally based on geographic locales & IP Subnets

Minimum of (1) DC running the Global Catalog Service in each site

### **Global Catalog:**

Separate db from AD and contains partial RO replica of AD objects in entire forest. Used to provide Universal group membership information during logon process and also when using UPN name to logon

### **Operations Master Roles:**

Schema Master (updates & mods to AD Schema) and Domain Naming Master (domain name space changes) in the forest  
PDC Emulator, RID Master, and Infrastructure Master in the domain

## **ACTIVE DIRECTORY:**

AD database uses ESE (Extensible Storage Engine) and is similar to Exchange transactional logging & online db maintenance. AD database contained in a file called Ntds.dit

Comprised of multiple sites

Schema contains list of object classes & attributes in the Forest--stored in Global Catalog; View Schema using MMC AD Schema snap-in after registering a dll: run: regsvr32 schmmgmt.dll. Also edit AD objects using ADSI Edit Snap-in; register the dll: run: regsvr32 adsedit.dll

Contains Domain, Schema, and Configuration data directory partitions

Information about Users, Groups, Machines in a logical and hierarchical tree structure

User Name Format Changes from NT 4.0 Style to Win2k Style: UPN (Universal Principal Name): [tmattha@t2dom2.local](mailto:tmattha@t2dom2.local)

AD Replication conducted by KCC (Knowledge Consistency Checker) Service in AD using IP or SMTP protocols

Global Catalog represents central repository of all AD Objects in Tree or Forest—required for network logon

REPADMIN tool used to monitor and diagnose replication of AD

### **AD Names:**

Logon Names: UPN=User Principal Name ([user1@t2dom2.com](mailto:user1@t2dom2.com)) SAM=legacy (user1)

GUID: Globally Unique Identifier number

LDAP Names: DN=Distinguished Name (/DC=com /DC=t2dom2 CN=users /CN=user1)

RDN=Relative Distinguished Name (CN=user1);

URL=Universal Resource Locator Name (LDAP: //t2dom2.com/cn=user1,cn=users)

Canonical Name=t2dom2.com\users\user1

SID=Security Identifier for Users, Groups, & Computers

Security Principal Name (user1)

LDAP name components commonly used in AD: DC (Domain Component), OU (Organizational Unit), CN (Common Name)

### **UPN (Universal Principal Name):**

→Domains have default current Domain and root Domain User Principle Name suffixes for User accounts. Companies can use alternative UPN suffixes to provide more logon security and to simplify the logon name for a User.

**Active Directory Domains and Trusts>Properties:** Alternative UPN suffixes (Add)

→The alternative UPN suffixes do not need to match the current or root domain naming structure

### **Example of UPN Use:**

Internal Windows Domain Name: iq.no

External Internet Domain Name: iqas.no

Pre-Win2k Name: iq\pin (uses NTLM authentication)

FQDN: [pal.innvik@iqas.no](mailto:pal.innvik@iqas.no) (uses Kerberos authentication)

→UPN's for Users in the base domain “iq.no” can be assigned any suffix name: [tm@network.com](mailto:tm@network.com), and still maps to the same underlying User SID in the “iq.no” domain

## **WIN2K Trusts:**

Within “forest” trusts are 2-way Transitive between “parent” and “child” domains

“Shortcut Trusts between child domains within forest are 1-way trusts, but can have 1-way trust in each direction

Between “forests” of other external domains, trusts are “external”, with 1-way trusts in each direction

## **WIN2K Groups:**

### **Local Groups:**

Contains Local, Global, Universal groups from parent domain; Global & Universal Groups from Trusted domains; Global Groups from NT 4.0 Domains

### **Domain Local Groups:** Cross forest oriented

Contains Users, Universal & Global Groups from any domain in Forest; other Domain Local Groups from same domain only

Nesting of Domain Local Groups within Local Groups now supported at 4.2.14 +

**NAS 5.1.9.4 Bug:** Adding “Domain Local Groups” to Administrators group on DM fails—‘...Member has wrong account type.’

### **Global Groups:** Domain oriented (Nest Global Groups into Universal Groups for replication reasons)

Contains Users or other Global Groups from same domain

### **Universal Groups:** Forest oriented

Contain Users, Universal and Global Groups from any Domain in Forest; other Universal Groups

## **GROUP POLICY OBJECT (GPO):**

Manages software configurations based on Group Policy Objects & applied during User Logon and Machine Startup

Stored on a Domain basis

GPO’s are applied to Sites, Domains, OUs, are cumulative, and are inherited from Top down

Domain Admins, Enterprise Admins, local system have Full Control permissions to modify GPO’s by default

Celerra supports machine account GPO’s in NAS 5.0 and higher—use \$server\_security server\_x -i -p gpo

## **TWO TYPES OF GPO’s:**

### **COMPUTER SETTINGS:**

Settings processed when domain member system starts up

### **USER SETTINGS:**

Settings processed when user logs onto domain member

### **GPOs ARE LINKED TO AD CONTAINERS:**

AD Site

AD OU

AD Domain

### **ORDER OF PRECEDENCE FOR GPOs:**

Local GPO, Site GPO, Domain GPO, OU GPO (gPLink & gPOptions attributes)

### **DFS PATH REFERRALS SYSVOL SMB SHARE:**

[\\domainname\sysvol\domainname\Policies\GPO\\_GUID & gpt.ini](\\domainname\sysvol\domainname\Policies\GPO_GUID & gpt.ini) file \Machine\registry.pol; \User\registry.pol

## **GPO LOOPBACK POLICY:**

Certain special-use computers, such as Terminal Servers, can have the Loopback Policy applied so that all Users logging into the computer will have GPO’s applied to their User accounts. GPO’s can be applied in a Merge Mode (User gpo’s are gathered using GetGPOList call, and computer’s GPO’s are called last and added to the User’s list) or Replace Mode (only computer GPO’s are used). For applying GPO’s to Terminal Servers, you might chose to put the computers into a separate OU or use the Loopback Policy settings mentioned here.

## **DATAMOVER & WINDOWS 2000 JOIN PROCESS:**

1. Celerra needs to discover which DC’s are closest in proximity—uses LDAP over UDP queries to DC’s to accomplish this
2. Will use ping if needed to help determine closest DC’s [shortest round-trip]
3. Actual Join to AD is done using closest ‘available’ DC using LDAP over TCP
4. Celerra will also attempt to contact closest KDC server first, but if the KDC does not know the principal “administrator” or ‘server’ name, will contact others in the KDC ‘realm.’ Kerberos & Kpasswd services are used to obtain a Kerberos Ticket used in Join Process & setting server password, and thereafter for renewals.
5. List of DC’s seen in “server\_cifs” output is regenerated every 15 minutes [Not in 4.1, but in 4.2 & 5.0]
6. > carat symbol in “server\_cifs” means only that DataMover has a current TCP connection with the DC

## **DATAMOVER JOIN PROCESS:**

1. DM queries DNS for list of DCs and returns fastest DC list
2. DM queries DNS for LDAP “SRV” records and replies with Service & listening Port number
3. DM queries DC’s using LDAP null query to make sure that LDAP service is up
4. DM queries DNS for Kerberos and Kpasswd services
5. DM binds and unbinds to LDAP again to verify that authentication works
6. DM binds to LDAP to find out supported security layer to use for authentication, then unbinds
7. DM logs in to AD with ‘Guest’ account to make ADSI calls [DM establishes defaultNamingContext & encryption type]

8. DM obtains TGT for specified User in Join (KRB\_AS\_REQ to KDC to obtain Kerberos ticket and receives KRB\_AS REP?)
  9. DM sends KRB\_TGS\_REQ for ‘Service Ticket’ for LDAP service to prepare to modify LDAP db
  10. DM binds using SASL and initiates direct calls to ADSI using LDAP bind [Checks for existence of compname and creates OU’s]
  11. DM checks for name and creates new one if does not exist.
  12. Service principals for compname are modified and AD is populated with DM compname and other information such as SAM account and ObjectGUID
  13. Account password is changed for compname using kpasswd protocol & unbinds from LDAP service
- Note:** /etc directory populated with krb5.account, krb5.conf, krb5.conf.old, & krb5.keytab
- krb5.account: database file holding Kerberos information
- krb5.conf: holds encryption support types or TGS
- krb5.conf.old: backup file
- krb5.keytab: file contains information from current Authentication session with KDC

## **HOW DATAMOVER DISCOVERS DC & SRV SERVICES IN AD:**

- DM uses a locator service, similar to Windows 2000, to query Windows 2000 DNS Domain/Realm & determine Site
- DM requests list of services (SRV records) for Domain from DNS
- DC’s are validated via LDAP\_Ping, then sorted based on SITE and LDAP ping response times [server\_cifs list]

## **WINDOWS NT/2000 LOGON AUTHENTICATION:**

NTLM/NTLM v2 for NT/Kerberos & NTLM [NTLM & NTLM V2] for Windows 2000

**Note:** Legacy NT 4.0 systems use traditional NTLM for User logon authentication, while Windows 2000 uses MIT’s version 5 (RFS1510) implementation of Kerberos. Authentication protocols allow computers to mutually identify each other on the network.

## **WINDOWS 2000 MACHINE LOGON PROCESS:**

- Client→Boots Up & Obtains IP configuration from DHCP Server [APIPA—Auto Private IP Addressing]
- Client→Locator “DsGetDcname” Service collects information needed & passes to Local NETLOGON Service
- Client→NETLOGON uses “DsGetDcName” service to “DNSQuery” to obtain A & **SRV records** for LDAP Server [ldap.tcp.dc.\_msdcs.win2kdomain.com]
- Client→NETLOGON Service retrieves list of Domain Controllers & caches list
- Client→Uses **locator service** to find Site and list of DC’s; ldap.tcp.Default-First-Site-Name.\_sites.dc.\_msdcs.win2kdomain.com]
- Client→Queries list of DC’s using LDAP UDP datagrams to determine which DC to log into
- Client→Uses **netlogon** process to create Secure Channel for ‘logon’ & ‘authentication’ to DC [SMB & RPC End Port Mapper svc]—LDAP protocol is used to establish logon via local SAM to Directory Service Agent
- Client→Kerberos Session Ticket from KDC to then create an “IPC\$” connection to DC [Queries KDC service and negotiates Ticket]
- Client→Queries **LDAP RootDSE** for standard directory information
- Client→Uses LDAP query to locate Group Policy Objects & then loads policies from DC’s “SYSVOL” share & ‘autoenrolls’ cert.
- Client→Time synchronization over Port 123 with NTP Server
- Client→Updates Dynamic DNS with its name
- Client→Breaks down connections with DC using SMB Tree disconnect

## **CLIENT LOGON ABBREVIATED:**

DHCP Networking→Site & DC Info→Secure Channel to DC→Kerberos AS/TGS Tickets→Load Group Policies→Enroll Client Certificates→Time Sync→Dynamic DNS Updates→Completion

## **WINDOWS 2000 USER LOGON PROCESS:**

User→initiates logon using SAM Account Name, Domain, & Password; User Principle Name (UPN); or FQName--user@win2kdom.com]

**Note:** UPN logon only supported in Native Mode and uses Global Catalog to lookup User Account

User→Logon process generates Kerberos Authentication request for Session Ticket from KDC via Ticket Granting Service

User→Group Policy Object information downloaded from “SYSVOL” share

User→Closes SMB Port 445 connection to DC after logon process completed

## **UPNs & SPNs (User Principal Names & Service Principal Names):**

UPNs are unique in a forest, and consists of a User’s Principal name, @ symbol, and DNS domain name. SPNs are also unique in the forest and represent a unique service for each machine account in the domain—consists of ServiceClass, Host, Port, Service name. Use the setspn –list Resource Kit tool to see registered SPN service names for Servers.

## **PROBLEM WITH SPNs, DNS ALIASES, and WINDOWS 2003:**

→Users unable to connect to Celerra shares after DCs upgraded from W2K to W2K3, when the client is trying to use a DNS alias and SPNs are in use in AD. Users can access if they use the real “compname”. Problem is that with W2K3, the KDC may not provide the canonical compname of the CIFS server to the client requesting the access ticket, and the connection to the DM will fail. See emc158629, AR92558 for more detail.

**Resolution:** Upgrade to NAS 5.5.29 or higher and set the following parameter to 1

## # server\_param server\_2 -facility cifs -info LanmanServer.disableNameChecking

server\_2 :

```
name      = LanmanServer.disableNameChecking
facility_name = cifs
default_value = 0
current_value = 0
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range      = (0,1)
description = Disables checking of the server's principal name of the client's kerberos ticket.
```

## **COMMON TCP/IP PORTS USED FOR WINDOWS 2000:**

|           |                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------|
| Port 42   | WINS Replication                                                                                          |
| Port 53   | DNS Service                                                                                               |
| Port 68   | DHCP (UDP only)                                                                                           |
| Port 88   | Kerberos                                                                                                  |
| Port 135  | RPC; RPC EndPoint Mapper; Wins Manager                                                                    |
| Port 137  | NetBIOS Name Service: Logons; Browsing; NT 4.0 Trusts, Secure Channel (UDP only); WINS Registration (TCP) |
| Port 138  | NetBIOS Datagram Service: Logons, NT 4.0 Trusts, NetLogon; Browsing (UDP only)                            |
| Port 139  | NetBIOS Session Service: NTB; SMB; File Sharing; NT 4.0 Secure Channel/Trusts; Logons (TCP)               |
| Port 389  | LDAP                                                                                                      |
| Port 445  | SMB or CIFS                                                                                               |
| Port 464  | Kerberos Kpasswd (UDP)                                                                                    |
| Port 636  | LDAP over SSL                                                                                             |
| Port 3268 | Global Catalog Search for LDAP                                                                            |

## **KERBEROS BASICS:**

- In networking parlance, Kerberos is a protocol designed for ‘distributed security’
- Kerberos is implemented as an SSP (Security Support Provider) using SSPI interface
- NTLM & SSL are also implemented as SSP authentication solutions on MS networks, using SSPI interface
- Basic Kerberos v5 protocol implements 56bit DES (Data Encryption Standard) encryption by default
- MS networks use 128bit RC4 encryption with their version of Kerberos
- Kerberos offers delegation and mutual authentication, which NTLM does not
- Kerberos assures security for authentication and network services using encryption based mostly on secret key encryption (aka private key, symmetric keys, or shared secrets)
- Password-based keys are only used during login process, and even then, the Principal’s (user) logon is a hash of their password, aka message digest or checksum. The bitstring cannot be used to recover the original input value, i.e., the password itself, and is called a one-way hash. On the KDC, the passwords of all users and computers are hash values and not the actual password itself!
- Users, servers, and other workstations all have passwords, known as security principal
- Kerberos tickets contain encrypted & unencrypted information

### **Unencrypted portion of ticket:**

Name of Windows 2000 domain (realm) and name of principal of the ticket (user or computer)

### **Encrypted portion of ticket:**

Encryption session key, used to encrypt data being exchanged; encrypted copy of principal name & domain name; start & end times for ticket validity; IP addresses identifying user system; User authorization data (SIDs, etc); other fields

### **BASIC KERBEROS SERVICES:**

- Authentication of Clients & Servers
- Data integrity and data privacy

**Note:** Checksums use HMAC with RC4 encryption, session keys between Client & Server are shared

## **CELERRA WIN2K AUTHENTICATION SUPPORT:**

- With NAS 5.5, Celerra uses Kerberos v5, NTLM, or NTLMv2 as valid authentication packages on MS domains
- In general, Windows 2000/XP/2003 clients should use Kerberos authentication

→ NT Clients will be authenticated using NTLM v. 1.2 if within the same or trusted Domain as the Celerra

**Note:** Celerra does not provide native NTLMv2 support until NAS 5.3.17.x & NAS 5.4

→ In addition, Celerra supports SMB & LDAP Signing

## **CELERRA DOES NOT SUPPORT SChannel (SSL/TLS):**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Celerra does not support the ability to use SChannel (SSL/TLS, Secure Socket Layer/Transport Layer Security) as an authentication SSP module (Security Support Provider). Celerra supports only the Kerberos and NTLM (LAN Mgr, NTLM v1, NTLM v2) SSP authentication mechanisms.

## **PURPOSES FOR DATA MOVER COMMUNICATES WITH DOMAIN CONTROLLERS:**

- Kerberos service ticket validation
- Pass-through authentication, as in case of NTLM clients
- Retrieving GPO information for the domain
- Listing out trusted domains to domain Joined to
- Resolving names to Windows SIDs, resolving SIDs to Windows names

## **KERBEROS VERSION 5:**

- Security principal name for Windows domain is called krbtgt, and is used by KDC
  - A network authentication and security protocol in use by Windows 200/2003 Domains [Kerberos V5—based on the MIT Version 5] which replaces the NT 4.0 NTLM Netlogon Services protocol---supported by 4.0.12.1
  - Kerberos allows for mutual authentication between computers on a network (NTLM does not)
  - Kerberos provides for faster network connections between C/S (NTLM requires communication to DC each time Client connects)
  - Uses UDP/TCP over IP Port 88 for legacy computers and W2k/W2k3 systems for both Client & Server
  - Kerberos V5 is default authentication protocol for Windows 2000—see RFC 1510
- Note:** Celerra supports only Kerberos over UDP until NAS 5.2
- Kerberos Tickets are built to include User name & User SID
- “Realm” serves a single Kerberos database and set of KDCs. Realm names are displayed in uppercase and usually correlate to the Windows 2000 Domain name. A Realm consists of the Kerberos db of all security principals in the domain, therefore the Realm is usually equivalent to the Windows domain.

## **TYPICAL CLIENT WORKSTATION KERBEROS LOGON PROCESS:**

- I. Client logs into AD with password and sends “AS” [Authentication Service] request to KDC AS Service, receiving Ticket Granting Ticket [TGT]
- II. Client requests access to Service or Resource on network by sending TGS [Ticket Granting Service] to TGS on KDC. Individual TGS is returned to the Client.
- III. Client submits TGS to Server using AP messages, with SIDs and PAC as part of the ticket sent to the Server. If Client requests mutual authentication for this exchange, Server will respond with Authenticator Timestamp.

## **KERBEROS AUTHENTICATION SERVICE:**

Only portion of Kerberos communications that requires a password, or pre-shared secret, to be verified between Server and Client, typically invoked during logon. A TGT (Ticket-Granting Ticket) is provided to the client logging into the domain, from the KDC, which can then be used to obtain additional service tickets. AS exchange uses KRB\_AS\_REQ from client to server. Preauthentication data is included in the Client’s secret key timestamp and KDC realm must match. Applications, or the O/S, can specify the type of SSP to use [i.e., NTLM or Kerberos], over Port 88. Clients secret keys are 64-bit hash of the client’s password and are replicated to all DC’s, whereas private keys are not shared with other DC’s. Server’s KRB\_AS REP consists of encrypted data that cannot be read by a Client except for server name and realm. Client presents server name and realm when presenting Authorization Ticket to Server. Data block encrypted to client’s secret key and holds session key for client.

## **WHAT IS MUTUAL AUTHENTICATION?:**

- System whereby communication partners share crypto keys, called ‘Shared Secrets’ in order to verify each other
- Shared Secret Keys are symmetric, meaning that a single key can be used to both encrypt and decrypt keys
- Use of Authenticator contains info based on name & timestamp and encrypted based on client’s master key, which receiving system can decrypt to prove identity, sending back an Authenticator with portion of key encrypted with its master key and original timestamp, proving its identity to Client.

## **(3) KERBEROS PROTOCOLS IN OPERATION FOR WINDOWS NETWORKS:**

### **I. Authentication Service Exchange (AS Service):**

Provides logon session key & TGT’s to Clients, using the TGS exchange (Ticket Granting Service)--KRB\_AS\_REQ & KRB\_AS REP

Used by the KDC to provide a Client a logon session key and a Ticket Granting Ticket (TGT) for further communication between Client & KDC. When a User logs on, their password is encrypted using DES-CBC-MD5 encryption, from which a Master Long-term Key is derived. Client sends KRB\_AS\_REQ message, containing User’s information, name, and service requested, as well as pre-authentication data (Preauth Data is usually the timestamp encrypted with Client’s longterm key). The KDC retrieves a cached copy of the User’s Master key from AD to decrypt pre-authentication data and review timestamp, and creates logon session key and

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
credentials for the user. KDC returns logon session key encrypted with User's longterm key, and another copy of the logon session key in the form of the TGT, which contains the user's Session Key encrypted with the User's Master Key, which is also encrypted by the KDC's long-term master key & returned to client via KRB\_AS REP. Client decrypts logon session key using User's master key, and stores in ticket cache. TGT is also extracted and stored in local ticket cache. For further communications to KDC for the current logon session, Client uses the Session Key. The TGT has a special authorization data field that contains the User's SID, SIDs from Domain Groups, and in multiple domains, SIDs from Universal Groups (queries the GC for this info).

## **II. Ticket Granting Service Exchange (TGS):**

### **Provides Service Tickets for Network Resources—KRB\_TGS\_REQ/\_REP**

Client sends Kerberos TGS (KRB\_TGS\_REQ) to KDC for access to a network service (supplying Session Key, Authenticator, TGT). Request include's User's name, Authenticator encrypted with logon Session Key, and TGT obtained during original AS Exchange, name of service requested, and Preauthentication data to prove User's ID, encrypted timestamp from Client's Master Key. KDC decrypts the TGT using master key, extracts User's logon session key, which is then used to decrypt the User's authenticator. KDC then creates new Session Key to be used for the TGS, encrypting one copy of the Session Key with Client's logon session key, and embeds another copy of Session Key in the TGS, that contains User's authorization data (SIDs, etc) encrypted with Server's longterm Session Key (KRB\_TGS REP). User decrypts target Server session key using logon session key, and stores session key in local cache, along with target Server's ticket.

### **Multiple Domain Communications:**

If a Client User exists in a Child domain, and needs to communicate to another child domain Server, user would request TGS from KDC, which would in turn refer User to KDC in the other domain, and process may need to be repeated until the KDC in the Server's domain in contacted, which can then provide the TGS to the Client.

## **III. Client Server Authentication Exchange (CS):**

### **Client & Server mutual authentication—KRB\_AP\_REQ/\_REP**

Client sends Application Request (KRB\_AP\_REQ) to Server, which contains an Authenticator encrypted with Session Key for the service and the TGS ticket from the KDC, encrypted with Server's master key. Server retrieves authorization data and decrypts session key with secret key, extracts the Session Key, and decrypts Authenticator, reviewing timestamp for validity. Server returns timestamp encrypted with Session Key in form of Application Reply (KRB\_AP\_REPLY) to authenticate itself. The Session Ticket contains Domain name, User name, and time of ticket validity.

## **KERBEROS PREAUTHENTICATION:**

KerberosV5 uses preauthentication using encrypted timestamps by clients to prove their password when going to the KDC for a TGT.

## **KERBEROS AND GPO POLICIES:**

GPO settings for Kerberos can only be defined once, at the AD Domain level—never at the OU or SITE level

## **KERBEROS TICKET DEFAULTS:**

Forwardable flag is set, used for delegation (Client's authentication key can be forwarded to multiple systems using same credentials)

Ticket renewal flag is set

Preauthenticaion flag is set

TGT has initial flag set

## **DEFAULT KERBEROS TICKET PARAMETERS FOR WINDOWS 2000:**

**Note:** Enforced by default Domain policy template

MaxServiceTicketAge: 10 hours (Service Ticket)

MaxTicketAge: 10 hours (User Ticket TGT)

MaxRenewAge: 7 days (Service or TGT Ticket)

MaxClockSkew: 5 minutes (time skew between Kerberos authenticator timestamp and current KDC or Resource Server time)

Enforce Logon Restrictions: On by default—KDC checks validity of User account every time a ticket request is submitted

## **DEFAULT CELERRA KERBEROS PARAMETERS:**

|                                  |                                                                             |
|----------------------------------|-----------------------------------------------------------------------------|
| Enforce User Logon Restrictions: | Default=enabled [Check validity of User each time ticket request submitted] |
| MaxServiceTicketAge:             | Default=600 minutes [Kerberos service ticket]                               |
| MaxTicketAge:                    | Default=10 hours [User Ticket lifetime for the TGT]                         |
| MaxRenewAge:                     | Default=7 days auto-renewal for User TGT per GPO if User remains connected  |
| MaxClockSkew:                    | Default=5 minutes clock synchronization, or per Domain GPO                  |

## **WINDOWS 2000 SUPPORTED KERBEROS ENCRYPTION TYPES:**

RC4-HMAC 128-bit [Default encryption type for Windows Clients]

DES-CBC-MD5 56-bit [When using DES encryption, Win2k Clients use this encryption type for session tickets]

DES-CBC-CRC 56-bit [Used only for MIT Kerberos, not Win2k Clients]

**Note:** DES stands for the Data Encryption Standard, a block cipher algorithm using 56-bit keys. Triple DES (TDES) is a more secure combination of three sets of 56-bit DES encryption keys [168-bits]. AES (Advanced Encryption Standard) is largely replacing DES and has much better performance characteristics than TDES. The block cipher is 128-bits, but has different key sizes of 128, 192, or 256 bits. Celerra does not use TDES or AES encryption at this time.

## **KERBEROS CACHE ON WINDOWS CLIENTS:**

Tickets are cached for User logon sessions by the LSA

Use ResKit Utilities klist.exe or kerbtray.exe to verify

**C:\>klist tgt | tickets**

Cached TGT:

ServiceName: krbtgt

TargetName: krbtgt

FullServiceName: mattat

DomainName: CORP.EMC.COM

TargetDomainName: CORP.EMC.COM

AltTargetDomainName: CORP.EMC.COM

TicketFlags: 0x40e00000

KeyExpirationTime: 256/0/29920 0:100:8048

StartTime: 7/22/2005 7:21:19

EndTime: 7/22/2005 17:21:19

RenewUntil: 7/29/2005 7:21:19

TimeSkew: 7/29/2005 7:21:19

## **KERBEROS TROUBLESHOOTING UTILITIES:**

mytoken.exe →Display contents of User's access token, including user rights & group memberships

klist.exe →Examines local ticket cache, purges cache

kerbtray →GUI version of ticket cache

netdiag →netdiag /test:Kerberos

netdom →manages domains and trusts; reset member accounts; verify, reset time, etc.

setspn →View current SPNs, reset, add or delete

Network Monitor: nltest →discover trusted domains, DC's, DC for a particular Trusted Domain User

## **SUPPORTED KERBEROS INTERFACES USED BY WINDOWS:**

SSPI (Security Support Provider Interface)—very similar to GSSAPI (General Security Service Application Prog. Interface)

LsaCallAuthenticationPackage—used to retrieve tickets from Kerberos cache. Windows 2000 uses the SSP as its Authentication Protocol for Kerberos, and also supports an SSP for NTLM authentication. Windows 2000 AD Servers stores Tickets and Keys in a credential cache managed by Kerberos SSP (LSA authority).

## **HOW TO RESTRICT AUTHENTICATION TO KERBEROS ONLY:**

**\$server\_cifs server\_x -add compname=swift, domain=mover.com, authentication=kerberos**

**Note:** Use this option to restrict authentication to Kerberos only—most secure mode for Celerra.

## **MICROSOFT SP3 ISSUES:**

**MICROSOFT KERBEROS MAXTOKENSIZE ISSUE & HOT FIX:** Primus emc62537, emc74207, & emc80211

Celerra code versions prior to 4.2.14.403; 4.2.16.0; 5.0.16.0; 5.1.12.0; 5.1.9.100/300; and 5.2.1.0 all have potential to cause Rolling Data Mover panics after application of SP3 or SP4 to Windows 2000 Domain Controllers, or any of the MS Hot Fixes for Kerberos “MaxTokenSize” that allow for greater numbers of Group SIDs in the Kerberos Tokens of Users—prior to the fix, a User could only be a member of about 70-80 groups before running out of buffer. The main impact of this limitation is related to GPO’s, and certain GPO’s could not be applied properly. From Celerra perspective, the original corrective action required removing Hot Fix, Unjoining & Rejoining DM to Domain. Latest guidance suggests that applying the latest 4.2.17.2 nas.exe is sufficient to stabilize environment without further action.

**Cause:** Q263693/Q280830 Microsoft HotFix addresses Kerberos Token size limitation and increases large group support.

**Microsoft Registry Fix to Increase MaxTokenSize on AD Servers:**

HKLM>System>CurrentControlSet>Control>Lsa>Kerberos>Parameters> Add new parameter called "MaxTokenSize" and set in DECIMAL to 100000

**Note:** Limitation is approx 70-80 groups but can vary considerably

**Symptoms:** Data Movers panic continuously; Server\_log errors→SSXAK=c000006d origin=600 stat=d0000; Mapping drives to CIFS Shares causes DM Panics

**Common Panic Headers:**

A.) Page Fault Interrupt..

**Solution:** Apply NAS code to stabilize Servers. In some cases, may need to Unjoin and Join Data Movers back to Domain. In one case, fsn's needed to be un-joined and re-joined to AD Domain & the Hot Fix backed out of AD Servers. A workaround might entail disabling the default FSN Interface, then un-joining and re-joining the other interfaces, followed by re-enabling the default interface. In rare cases this problem has resulted in memory corruption and subsequent file system corruption, requiring fsck.

**MICROSOFT KERBEROS MAXPACKETSIZE LIMITATION FOR UDP:**

Microsoft has a well known limitation of 2000 bytes when transmitting Kerberos information over UDP, resulting in various authentication and GPO issues. Kerberos tickets should use TCP by default if the ticket size is larger than 2kb, which can easily occur because Kerberos tickets carry PAC data.

**DATA MOVER SYMPTOM:** Cannot Join Domain

2004-02-20 14:27:31: ADMIN: 3: Command failed: domjoin compname=mercury domain=aba.ad.abanet.org admin=administrator password=19asee init

2004-02-20 14:27:49: KERBEROS: 3: DomainJoin::getAdminCreds: gss\_acquire\_cred\_ext failed: Miscellaneous failure KRB5 error code 52

**TYPICAL CELERRA WORKAROUND:**

Create temp User account and add only to Domain Admins Group [i.e., delete from Domain Users], then do the Join.

**EMC & MS INFORMATION:**

Primus Articles that address this issue are: emc74207 and emc80211

**Microsoft Articles that address this issue:**

Q-244474 Max Packet Size Limitation when using Kerberos over UDP

Q-320903 addresses a subsequent issue with using Kerberos Over TCP that is fixed in Win2k SP4

**Registry Fix:**

HKLM>System>CurrentControlSet>Control>Lsa>Kerberos>Parameters> Add new value called "MaxPacketSize" and set to "1" to force Kerberos Over TCP

**SMS & WINDOWS 2000 SP4:**

Changes have been made to the way clients and DC's communicate. Clients that use local SMS accounts cause DM to try to authenticate them with AD Server, causing delayed logon performance, as these are not domain accounts. Disable ability of SMS Servers to find DM in MS registry.

**USERS CONNECT TO DM FROM LOCAL CLIENTS WHILE LOGGED IN AS A NON-**

**DOMAIN/LOCAL USER OR SMS ACCOUNT:**

AR30449 identified the problem where Users would log into a local machine domain with a local user account, then attempt to connect to the Celerra. The effects of this were that the DM would try to have the AD server authenticate the local User account & match the local machine's Domain with a known AD domain, resulting in a 20 second timeout, which, when combined with many User logon attempts, would slowdown logons to the Celerra.

**Following new parameters were added to code stream:**

**param NTsec.logonOptions=1** (default) →Check to avoid bad local domain and use DC timeout value

**param NTsec.logonOptions=0** [Prevent Celerra from treating local machine name as a domain but allow local machine User-accounts to log into the Celerra if the Guest Account param is enabled]

**param NTsec.guestLogon=1** (default) →Allow Guest account to logon local Users from local machine domains

**param NTsec.guestLogon=0** [Disable the guest logon feature to the Celerra, especially for Guest accounts]

Fixed in 4.2.19.0, 5.1.16.0, and 5.2.1.0

AR33286 identified a memory leak regression introduced by AR30449 that caused Data Mover panics when local User accounts such as SMS attempted to log onto the Celerra. Fixed in 5.1.18.8, 4.2.22.2, 5.2.1.0

**DEFAULT BUILTIN USER ACCOUNTS IN WINDOWS 2003:**

Administrator

Guest

Help Assistant (used for Remote Assistant sessions)

Support\_388945a0 (used in running signed scripts from Help and Support Services)

**Note:** The default Domain and builtin Guest user account is disabled in Windows 2000, 2003, & XP. Be advised that the account, if enabled, does not have any password assigned.

### **(3) TYPES OF WINDOWS USER ACCOUNTS:**

Local User accounts defined in SAM on local system only

Domain user accounts

Default builtin User accounts

### **DEBUGGING USER LOGON ISSUES:**

**\$server\_config server\_3 -v "param NTsec logonTraces=6"** [=3 to turn off]

**\$server\_config server\_3 -v "pdc trace=1"** [=0 to turn off]

### **PAC DECODING FOR CLIENT AUTHENTICATION:**

With NAS 4.x, Data Mover will use Kerberos authentication field (PAC—Privilege Attribute Certificate) to obtain information about client Users or Groups, as opposed to using LDAP queries to AD for the same information. This more closely emulates native Windows behavior.

Clients use the Kerberos PAC to obtain Kerberos tickets from KDC for the Server that they are connecting to.

PAC Certificates are the Kerberos Tickets used for system/user calls to access network resources. ‘Marshalling’ is a term applied to the manner in which variable data [such as User.name, User.password, User.SID, User.GroupID] is serialized into a data stream for transmission across the network. Unmarshalling is the decoding of this variable data stream on the receiving end and reconstructing the appropriate fields of data. Celerra has had issues with the ‘unmarshalling’ process because the format was not as the DM expected to see, resulting in a filling in of the variable data fields with incorrect data. This would later result in a system crash.

### **MS PRIVILEGE ATTRIBUTE CERTIFICATE (PAC):**

PAC credentials are created by the KDC during an AS request that has been validated by a pre-authentication or by a TGS request from a client that has no PAC and the target resource is a service in the domain or a ticket granting service (referral ticket). PAC information contains a digitally signed User’s logon ID and group membership list, and is unique for the User’s logon session—i.e., a new one would be created only if User logged off domain and logged back on.

PAC is part of the Kerberos V5 authorization data field that is used by the Windows O/S to provide User Logons and to create Access Tokens. The PAC is of C data type with integers encoded in little-endian order. PAC\_INFO\_BUFFERS are structures that hold PAC\_LOGON\_INFO information for the client’s credentials inside the Kerberos ticket. The PAC contains two digital signatures, one using master key of the Resource Server and one using the master key of the KDC.

### **RECENT CODE ISSUES WITH NEW PAC RECORDS:**

Recent PAC changes in Windows 2003 have caused a number of Celerra issues. See emc132863 (AR76179) & emc126516 (AR73457) for KRB and ASN errors seen in Server Logs and network traces, resulting in loss of CIFS access and panics.

#### **EXAMPLE:**

CIFS Server (Default) FILE026[NETWORK]

Full computer name=dm6.network.lan **realm=NETWORK.LAN**

**KDC:** Key Distribution Center—trusted agent in the protocol—holds account information for network users and resources  
KDC runs on every Domain Controller and is started by LSA—provides Authentication Service and Ticket-Granting Service  
Obtains account database from AD

Registered in DNS as as SRV Record (\_kerberos.\_udp.t2dom2.com)

LSA=Local Security Authority—loads the SSP (Security Support Provider) DLL’s which support authentication protocols (Kerberos/NT LAN Manager)

SSP—manages “credential cache” on AD server (stores tickets & keys from KDC)

LTK=Long-Term Key—used to establish security between KDC and “Security Principal” (User)—built during log-on process by passing password through 1-way hashing function

STSK=Short-Term Session Key—used for normal network communications between parties

TGT=Ticket Granting Ticket—a special STSK, usually granted for a 10-hour period

***Note: Can view Client Tickets using the ‘Kerbtray’ Resource Kit Utility!***

### **HOW CLIENTS & KDC SERVER COMMUNICATE DURING USER LOGON PROCESS:**

1. User on Client computer logs on with Username & Password using Kerberos client, which sends an Authentication Service (AS) request to KDC using pre-shared secret known only to Server and Client—AS Service validates the user and then returns a “Ticket Granting Ticket” (TGT) that validates the user’s credentials.
2. Client then requests session to a “service” or “resource” using TGS (Ticket Granting Service) to KDC—ticket for service returned
3. Client can then use this TGS to access the resource or service that it needs

**Note:** Kerberos does not provide authorization to access resources—only authorization to the ‘system’. Celerra uses only Kerberos over UDP Port 88—support for Kerberos over TCP will be added with NAS 5.2

## **HOW WINDOWS CLIENTS LOCATE KDC’s:**

Clients discover DC’s via SRV records after querying DNS. Clients then resolve *ldap.tcp.dc.\_msdcs* SRV records to resolve the KDC Server to contact

**Kerberos consists of (3) sub protocols:** AP--TGS--CS { Application Exchange--Ticket-Granting Service--Client/Server Exchange} NTLM Legacy Authentication for NT and Windows 2000 Mixed Mode Domains--supported by 4.0.12.1

Key Distribution Center for Long-Term Key and Short-term Session Keys

KDC provides Authentication Services and Ticket-Granting Services

Supports UDP port 88 and TCP port 88

**Note :** Celerra only supports Kerberos over UDP—Kerberos over TCP will be supported at NAS 5.2]

## **KERBEROS UDP vs. TCP Packets:**

By default, Windows 2000 Clients use UDP datagrams to Port 88 of KDC Server. Because UDP size is limited to 2000 bytes, there is potential for Domain NETLOGON to fail [Event Log Error 5719]

## **PREVENTING USE OF UDP PACKETS FOR KERBEROS COMMUNICATIONS:**

**HKLM>System>CurrentControlSet>Control>Lsa>Kerberos>Parameters**

To create ‘Parameters’ Key; Edit>Add Value>REG\_DWORD Value=1

## **HOW KERBEROS AND TIME SERVICES INTERACT:**

--Kerberos Client presents Kerberos ticket to Server to prove identity on the network, and includes encrypted authenticator information that contains a secret key and timestamp that proves the presenter’s validity, and prevents replay attacks.

--Server decrypts authenticator and extracts Client’s clock time & checks for allowable time skew against Server time, and also checks that the time is not the same or earlier than another authenticator message, then returns modified authenticator to client

## **CLOCK SKEW:**

Servers check to make sure that client time is within an allowable skew limit [5 minutes by default, or as defined with GPO] before sending authenticator back. If greater than skew limit, return ‘Clock skew too great’ error. Clients can compensate for skew error by adjusting their time used to communicate back to the Server—up to 4 attempts to authenticate are allowed before Kerberos forces a Client to resync its clock, provided that the skew is within the lifetime of the Kerberos ticket.

## **COMMON WINDOWS 2000 KERBEROS ERRORS:**

### **0x6 (KRB\_ERR\_C\_PRINCIPAL\_UNKNOWN) "Client not found in Kerberos database"**

KDC could not translate client principal name into an AD account. AD replication problem--error generated by DC trying to auth.

### **0x7 (KRB\_ERR\_S\_PRINCIPAL\_UNKNOWN) "Server not found in Kerberos database"**

KDC could not translate server principal name into an AD account. AD replication problem--error generated by DC trying to auth.

### **0xE (KDC\_ERR\_ETYPE\_NOTSUPP) "KDC has no support for the encryption type"**

Client does not have proper encryption key; KDC (cross-realm trust) does not have proper encryption key; Also, if Administrator’s account has never been changed, then password change must occur for the MIT-compatible key to be available.

### **0x18 (KDC\_ERR\_PREAMTH\_FAILED) "Pre-authentication information was invalid"**

This indicates failure to obtain ticket, possibly due to the client providing the wrong password.

### **0x25 (KRB\_AP\_ERR\_SKEW) "Clock skew too great"**

#### **When there is a time discrepancy between client and server or client and KDC:**

2003-10-28 12:37:54: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328347

2003-10-28 12:39:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328347

From Kerberos web site, this means: 37 -1765328347 Clock skew too great

<http://www.net.berkeley.edu/kerberos/k5msgs.html>

"KDC has no support for the encryption type": Client lacks correct encryption key type

"Pre-authentication information was invalid": Client failed to obtain KDC ticket, possible due to wrong password

"Clock skew too great": Time or Timezone discrepancy client/server or client/KDC

## **USING SERVER KERBEROS COMMANDS TO VERIFY KERBEROS:**

**\$ server\_kerberos server\_2 -l**

Kerberos realms configuration:

realm name: NETWORK.LAN

KDC: util002.network.lan

admin server: util002.network.lan

default domain: network.lan

kpasswd server: util002.network.lan

## **\$ server\_kerberos server\_2 -keytab**

Dumping keytab file  
keytab file major version = 5, minor version 2  
realm: NETWORK.LAN, principal: host, host: FILE014,  
    principal type 1, key version: 1, encryption type 3  
realm: NETWORK.LAN, principal: host, host: DM2.NETWORK.LAN,  
    principal type 3, key version: 1, encryption type 3  
realm: NETWORK.LAN, principal: cifs, host: FILE014,  
    principal type 1, key version: 1, encryption type 3  
realm: NETWORK.LAN, principal: cifs, host: DM2.NETWORK.LAN,  
    principal type 3, key version: 1, encryption type 3  
realm: NETWORK.LAN, principal: user, host: dm2,  
    principal type 1, key version: 1, encryption type 3  
End of keytab entries.

## **USING KERBEROS COMMAND TO ADD SPECIFIC KERBEROS REALM TO DM:**

**\$server\_kerberos server\_2 -add**

**realm=T2DOM2.LOCAL,kdc=win2k.t2dom2.local, domain=t2dom2.local**

**Comment:** In certain situations, Data Mover may not be able to “Join” AD Domain because the Kerberos info is different than the AD Domain name. Use this command to specify the correct “kdc” domain suffix.

**Symptoms:** DM seeks krbtgt for certain domain suffix but receives “Server not found in Kerberos database” message.

## **MICROSOFT KERBEROS TROUBLESHOOTING TOOLS:**

**Kerbtray:** Displays ticket information, purges Tickets

**Klist:** CLI tool to display or purge Kerberos tickets and tgt

**Setspn:** List, add, delete SPNs objects

**W32tm:** Use to verify client time with DC, Timezone, etc.

**Kerberos Logging:** Add the following registry value

HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Parameters

Registry Value: LogLevel

Value Type: REG\_DWORD

Value Data: 0x1

## **MICROSOFT SUPPORT TOOLS:** From Server CD>Support>Tools

**Adsedit.msc:** Useful GUI to observe and edit Active Directory OU's, Containers, and Objects

Domain NC → OU's

Configuration Container → CN's

Schema → AD Objects

**Ldifde Utility for AD Dumps :** Used to import or export all or specific portions of Active Directory into text file [LDAP Data Interchange Format]

**Ldifde -f c:\usersdump.txt -d CN=Users,DC=buzzsaw,DC=com** [dump Users container only]

**Ldifde -f domain.ldf -d "DC=buzzsaw,DC=com" -s 10.76.10.160** [dump entire domain partition]

**repadmin Utility for AD Replication:** Use to replicate AD Servers

**run: repadmin /syncall /e /d /P <adservername>**

## **NTP SERVICE (RFC1305):**

--Required for successfully implementing a CIFS 2000 Server in a WINDOWS 2000/2003 Active Directory Domain

--NTP Service Version 2 [Up to (4) NTP servers can be specified]

--Default clock skew of 5 minutes allowed to retain Kerberos ticket validity, or tighter tolerances if using GPO Policies

--W32Time is default SNTP Service (RFC 1769) on Windows 2000 based on UTC (Coordinated Universal Time) atomic time scale

--W32Time meets NTP requirements for W2k3/XP

--W32Time synchronizes every 45 minutes until synch successfully 3 times, then once every 8 hours thereafter

--Use an external Time Service if needing tighter time sync specs, or for PDC Emulator service at domain root, or child domains, etc.

## **SNTP:**

RFC 1769 was used by MS to implement W32Time for Kerberos V5 authentication and is called “loose synchronization”. SNTP protocol guarantees clocks within 20 secs of each other in the enterprise, or 2 secs between sites.

**Best Practice:** Use the AD Server as the NTP Server [Most AD's are configured as such by default]

**Note: Celerra uses SNTP for time synchronization within fractions of a second—as opposed to the NTP Implementation which is within milliseconds**

**Automatic NTP Detection:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
If not manually configured, Celerra datamovers will automatically detect & synchronize with up to (4) NTP sources  
Normal time corrections between local clock and NTP clock are done by “clock slewing”—time is gradually increased or decreased to bring back within synchronization. Normal slew rate is 10%, or about (6) minutes to correct an hour’s time difference

### **CELERRA NTP COMMANDS:**

```
$server_date server_x timesvc  
$server_date server_x timesvc start ntp 192.10.4.5  
$server_date server_x timesvc set ntp      [Immediately synchronizes with NTP server]  
$server_date server_x timesvc update ntp  [begins updating system time to NTP]  
$server_date server_x timesvc stats ntp  
$server_date server_x timesvc delete ntp
```

### **CELERRA DATABASE FILES: DNS/NIS/NTP**

**/nas/server/slot\_x/misc**

#### **DYNAMIC DNS: Default mode for Windows 2000**

--A FQDN must be defined on DM and added to "Enterprise Admin Group" in order to use LDAP for credentialing

--Namespace based on DNS--root Domain Controller is also root DNS server for domain

--DNS updates occur whenever CIFS is started and at regularly scheduled times

#### **WINDOWS 2000 DCLIST BUILD BEHAVIOR FOR CELERRA:**

When joined as a W2K Server, Celerra uses DNS exclusively to get the list of Domain Controllers to use & sorts the list based on LDAP ping response time, site information, and subnet information. Param is enabled by default—when the param is disabled, Celerra will use the list obtained from WINS to build its DC list:

```
# server_param server_2 -f cifs -info NTsec.getDCfromADServices -v
```

server\_2 :

```
name          = NTsec.getDCfromADServices  
facility_name = cifs  
default_value = 1  
current_value = 1  
configured_value =  
user_action    = restart Service  
change_effective = restart Service  
range         = (0,1)  
description   = Use DNS to get list of Domain Controllers
```

#### **DNS is a distributed database that provides name & service resolution services for datamovers:**

1. Mapping machine names to IP addresses    2. Mapping protocols    3. Mapping NT Domain names for client applications

4. Mapping IP Addresses to hostnames [Reverse Zone Lookups]

#### **DNS RULES:**

→DNS protocol runs over TCP or UDP Port 53[UDP is the default] and can point to (3) DNS Servers per DOMAIN for the datamover. DNS uses UDP by default, but if response is greater than 512 bytes, a TC bit is set and the Resolver knows to query again, this time using TCP.

→Default timeout is 60 secs if first DNS Server does not respond.

#### **Configure more than one DNS domain if the following conditions exist:**

--CIFS Services with DNS Domains that are in different forests

--CIFS Services with different DNS servers

```
$server_dns server_4 -protocol tcp t2dom2.local 192.10.3.2
```

--CIFS 4.0 Server will first try to resolve computernames by DNS, then NETBIOS Broadcast, then WINS [if configured]

--CIFS 4.0 Server also supports resolving Windows Service Names via DNS [such as LDAP, Kerberos, etc.]

--Dynamic DNS allows for automatic registration/un-registration of CIFS 4.0 Server—Secure Dynamic Updates are the default

**Note: 4.0.12.1 works when "Allow Dynamic Updates?" is set to "Yes"**

--With successful JOIN, the 'COMPNAME' is created by default in the "ou=Computers,ou=EMC Celerra" organizational unit (AD)

--CFS Servers retrieve list of supporting LDAP, Kerberos, & other services from the DNS Server

--Zones are stored in the AD database if using the “Integrate DNS with Active Directory” mode [not the default mode]

--Windows 2000 FQDN can only be 15 characters in length

#### **TURNING OFF DYNAMIC DNS FOR SERVER:**

Why do this? Data Mover automatically registers NetBIOS/COMPNAMES on all interfaces to all DNS Servers in its list--might be desirable to configure DNS Servers with A & PTR records manually, especially if DNS lookups are causing performance problems due to slow Name Resolution.

```
param dns updateMode=0  [Turns off dynamic DNS and introduces Static DNS behavior]
```

## **DNS-RELATED UTILITIES:**

```
C:>netdiag /v /l /test:dns [testing individual Servers]  
C:>dig <ip of NS> <resource record name> <type record>  
C:>dnslint  
C:>dnscmd 10.241.169.16 /zoneinfo mouse.com
```

## **MICROSOFT DNS:**

As long as DNS is BIND (Berkeley Internet Name Domain) 8.1.2 compliant, can be used with Windows 2000 (8.1.2 meets RFC2052 spec for Service Resource Records & RFC2136 for dynamic dns updates). ISC BIND 8.2.4 will run on NT 4.0 or Windows 2000. Microsoft DNS is based on BIND standards.

### **DNS BASICS:**

DNS is a distributed database similar to an inverted ‘tree’—the ‘root’ of DNS is at the top & is represented by the ‘null’ zero-length label “”, or more commonly by a dot “.” in Unix. Windows represents ‘root’ with a backslash \. In DNS, an ‘absolute name’ is synonymous to a FQDN. FQDN’s are read from left-to-right as Node→Subdomain→Parent Domain→TopLevel Domain→Root. Top-level or first-level domains are known as .com, .edu, .net, etc. Domains beneath top-level domains are called sub-domains or child domains.

## **TROUBLESHOOTING DNS ISSUES/DNS BEST PRACTICES:**

→Ensure that clients are pointing to correct DNS Server or they will not be able to use their Locator service to find SRV Service records that advertise DC services, such as Kerberos, LDAP, and Global Catalog—with the SRV records, clients will not be able to authenticate and operate within the domain. DC’s use their Netlogon service to register SRV records

→Default TTL for cached DNS entries on the DNS Server is one hour

→TCP/IP Properties, ensure DNS Resolver Suffix is correctly chosen for the intended purpose:

**Primary DNS Suffix:** Obtained from the TCP settings defined for the local host, appended to the local host’s ‘flat’ name

**Append Parent Suffix:** If the ‘Append primary and connection specific DNS suffixes’ option is checked, a DNS query will use first the Primary Suffix, then the Parent Suffix

### **EXAMPLE:**

ts2.emc.com →Primary suffix

emc.com →Parent suffix

**Interface Suffix:** With this setting checked, means that a DNS query will use first the Primary Suffix, then any unique suffixes that might be defined in the TCP settings [Static or DHCP-provided], then the Parent Suffix

**Search Table:** If the ‘Append these DNS suffixes’ is checked, the local DNS Resolver will not use the Primary, Connection-Specific, or Parent Suffixes, rather, will use whatever suffixes are defined in the table, in order from the top to bottom entry. If using this method, ensure that local FQDN is defined first.

→Use DNS Forwarding to reduce recursive DNS queries. During normal operation, if a client submits a request for a resource record from an outside domain, the DNS Server will assume responsibility for contacting a nameserver from the target domain to submit the query and provide the results—recursive queries. But, recursive queries can tie up Server resources, so using a Forwarder to conduct the recursive work for the Client is better. Even if using AD-integrated DNS, DNS forwarding information needs to be defined on the Forwarder as this is a local Registry entry, not an AD value.

→When configuring Zone Transfers between DNS Servers, allow transfers only to specified Name Servers, and ensure that Port 53 is not firewalled, as Zone Transfers use TCP ports 53 and ports above 1023

→When configuring AD-integrated zones, make sure all Secondary Zones are removed from DC’s & dns service is restarted

→Clients register their A & PTR records with Start of Authority (SOA) DNS Server (With AD-integrated DNS, any DC running DNS can update a Zone record)

→Improperly Delegated Child Zones can lead to ‘lame delegation’ and ‘replication’ issues

AD identifies Domains and DC’s in DNS via CNAME records correlated to GUID & FQDN

With delegation, Parent DNS Zone contains A Records and Names of Child DNS Servers—if the Child DNS Server is offline, then lame delegation and replication issues can occur. Check Event Logs for RPC connection errors and KCC problems. Win2k3 Servers use Stub DNS Zones to help avoid lame delegation issues.

## **CONFIGURATION CHECKING UTILITY: dnsllint**

C:>**dnsllint** is a utility that can test DNS configurations to see if they correctly support an AD domain, and also to test if DNS configuration meets standard practices for zones

→As a Best Practice, do not use your public DNS server as a Forwarder. Instead, install a Caching-Only DNS Server in the DMZ and use this as the Forwarder, and Disable Recursion for all Public DNS servers

→Best practice, if using BIND-style DNS Servers, do NOT allow dynamic updates. Only allow Dynamic Updates if using AD-integrated DNS Zones, then permit only SECURE updates

## **NAMESERVERS:**

NameServers are used to administer the DNS ‘namespace’ in subdomains called “zones”. NameServers are ‘authoritative’ for Single or Multiple Zones if they’ve been given ‘delegated’ authority. For example, a Parent Windows 2000 Domain called “gm.com”

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
[Windows 2000 Domains by default are DNS Domains] is authoritative for “gm.com” but might not be for “sub-domains” or ‘child domains’ such as “corp.gm.com”, which would have its own authoritative NameServer while the “gm.com” NameServer would contain pointers to it. If a NameServer is Authoritative for a Zone that it receives a Query for, it will either provide the data or return an error that the requested data does not exist. If not Authoritative, it would use Iterative Queries to other NameServers to obtain answer.

## **DNS ZONES:**

Zones contain all domain names for a Domain for which it is ‘authoritative’, represented by the SOA Record (Start of Authority). Every DNS Zone has at least one NameServer that is authoritative & one SOA record. Domain names and data that are located in subdomains that have been given their own ‘delegated authority’ (SOA) will not be found in the parent domain. NameServers load DNS Zones as either a Primary or Secondary Servers. A ‘Zone Transfer’ means that a Primary DNS Server provides a Secondary with dns records upon request.

>**ls t2dom2.local** [Conducting a Zone Transfer using nslookup]

**Forward Lookup Zones:** Contain “A” Address Records. A Records provide resolution for “names” to its corresponding IP Address.

**Reverse Lookup Zones:** Contain “PTR” Pointer Records. PTR Records provide resolution for “IP Addresses” to a ‘name’.

## **TYPICAL ZONE RECORDS:**

SOA Record—one per Zone to indicate that it is authoritative for its Zone

NS Record—one per Zone to identify the NameServer for the Zone

A & PTR Records

CNAME—Canonical Names or “aliases” –are aliases to the Address or Host Record.

## **PRIMARY vs. SECONDARY NAMESERVERS:**

Primary NameServers load the DNS Zone directly from local zone files. Secondary NameServers obtain their Zone records from the Primary via a “zone transfer” over the network. The purpose of Secondaries are for adding redundancy, spreading out the load, and also to have a DNS server as close to its Client systems as possible.

**Important Point:** Secondary NameServers are also authoritative for the Primary Zone.

## **DNS NAME RESOLUTION:**

Primary or Secondary NameServers provide data about the Zones for which they are authoritative. When resolving queries for data to which they are not “authoritative”, the process is called “name resolution”. In DNS, there are two major types of Queries from Client “Resolver” systems.

### **RECURSIVE DNS QUERY:**

Recursive queries instruct the NameServer to return an authoritative answer, or query Remote DNS Servers until it obtains an answer, or returns an error message. If the local DNS Server does not contain the authoritative data being requested, it will then most likely contact other DNS Servers using Iterative Queries until it finds the right answer for the Client.

### **ITERATIVE DNS QUERY:**

Local DNS Server will consult its own database first, then provide a list of NameServers to the Client ‘Resolver’ as a ‘referral.’

### **I18N SUPPORT:**

MS DNS supports all characters from UTF-8 Unicode character set

### **Native Windows 2000 Clients Startup Process:**

During startup & logon, native WIN2K clients use DNS to locate LDAP & Kerberos services, obtain address of DC, and registers its Hostname & IP Address with DNS.

### **DNS UPDATE MODES FOR WIN2K:**

Celerra works with "Secure Updates Only" [Default Mode]; 'Allow Dynamic Updates'--"Yes", or "No"[Insecure & No Updates].

**Note:** DM will automatically use Secure Updates if configured on DNS

### **DEFAULT DNS IS SECURE UPDATES:**

To configure Insecure or No Updates, use following params:

**param dns updateMode=0 [No Updates]**

**param dns updateMode=1 [Insecure Updates]**

**param dns updateMode=2 [Secure updates—default]**

## **REFRESHING DNS RECORDS ON AD SERVER:**

**Command Prompt: c:>ipconfig /refreshdns**

Admin Tools>DNS: Action>Update Server Data Files

## **QUERYING DNS RECORDS ON WINDOWS HOST—“Resolver”:**

**C:>ipconfig /displaydns                   c:>ipconfig /flushdns**

## **DATAMOVER DNS CACHE:**

**\$server\_config server\_8 -v “dns dump”**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
**Note:** Outputs dump of datamover DNS cache. Useful for displaying DC A Records & SRV records for LDAP, KERBEROS, KPASSWD

**Note:** Standard Unix implementations use cache on the Server, not the Resolver Client system

## **SETTING UP DNS CLIENT ON CONTROL STATION:** Facilitates DNS testing of Windows environment

Step 1. #vi /etc/resolv.conf file and add DNS Domain

```
domain t2dom3.local  
search t2dom3.local  
nameserver 192.10.4.4
```

Step 2. Use #nslookup server\_x [verifies Server DNS name resolution and IP Address]

**Note:** Other tools are "dig"; dnswalk; etc

**Comment:** Other files to check—

```
# cat /etc/nsswitch.conf |grep hosts  
hosts: db files nisplus nis dns  
hosts: files nisplus nis dns [order of host resolution—i.e., /etc/hosts, nisplus, nis, dns]
```

## **VERIFYING HOST NAME RESOLUTION:**

```
#nslookup 192.168.51.22
```

```
Server: 192.168.26.10  
Address: 192.168.26.10#53  
22.51.168.192.in-addr.arpa name = .  
22.51.168.192.in-addr.arpa name = ogcovsrv01.ocfl.net.
```

```
# /usr/bin/host 192.168.51.22
```

```
22.51.168.192.in-addr.arpa domain name pointer .  
22.51.168.192.in-addr.arpa domain name pointer ogcovsrv01.ocfl.net.
```

## **COMMON WINDOWS 2000 DNS PROBLEMS:**

--Domain Controller is not pointing to itself for DNS resolution in its TCP/IP Properties>DNS Tab page

--A “root” [ . ] Zone exists in the Forward Lookup Zone [Having this set as a “Root” DNS Server will prevent Internet lookups]

**Solution:** Do not have a “. .” Zone unless only used for a closed network

--Ensure that Client Systems point to the DC DNS Server for DNS Name Resolution

--‘Disjointed Namespace’—when the DNS Domain Suffix differs from the Windows 2000 Domain Suffix

--Incorrectly configured Child Domains:

**Solution--Configuring the Parent DNS Domain with a Child DNS Domain:**

→Create Delegation Record on Parent DNS Server for Child DNS Server>Create Secondary Zone of Child DNS Server & configure to transfer from the Parent DNS Zone>Point Secondary Child DNS Server to itself only

## **WINDOWS 2003 ISSUE WITH CELERRA:**

If aliases are being used with W2K3, as set with SPNs, the KDC will include the alias name in the Kerberos ticket instead of the real compname, and the Data Mover will reject the client connection. W2K does not behave like this and is fine. A NAS workaround is built into 5.5.29.x, AR92558, by setting the following param, the name in Kerberos ticket does not need to match real server name, when checking Kerberos keys during authentication:

```
param cif's LanmanServer.disableNameChecking=1
```

## **DNS SRV RECORDS:**

**Intro:** Perhaps the single most important feature in making DNS & Active Directory function smoothly together is the registration of “SRV” Service Records. If the AD DNS Server points to its own IP Address in TCP/IP Properties for DNS, upon startup the “NETLOGON” Service will register SRV records and create the following (4) Records in the Forward Lookup Zone:

```
__msdcs  
__sites  
__tcp  
__udp
```

→Records contained within these folders are vital for Windows 2000 [CFS 2000 Servers] to register themselves and query AD!

## **LOCATION OF SRV RECORDS ON DC:**

c:\winnt\system32\config\netlogon.dns

## **VERIFYING REGISTRATION OF DNS SERVICE (SRV) RECORDS ON AD SERVER & HOST “RESOURCE RECORDS” (A & PTR) FOR CELERRA USING NSLOOKUP:**

**Comment:** There may be a need to ensure that Windows 2000 Services & Host Resource Records are properly registered with DNS. One tool for verifying these records is “nslookup”. Other tools can also be used, such as the Unix “dig” command.

**Change Update:** **NAS 4.2.6.x no longer requires that Celerra use the Reverse Lookup Zone “PTR” Record. Only the “A” Record for Hostname & IP in the Forward Lookup Zone is required.**

### **DNS RESOURCE RECORDS:**

Each host system on the network requires a minimum of (2) Resource Records for integration as a Active Directory client for Windows 2000 Domains.

#### **Forward Lookup Zones:**

**A=Address Records**—these records resolve Hosts by converting “Host Names-to-IP Addresses”

Every Host must have an “A” record for proper DNS registration and Name Resolution.

**nas.us.dg.com →**      **Name**      **Type**      **Data**  
                              cpc233120      A      10.240.16.113

#### **Reverse Lookup Zone:**

**PTR=Pointer Records**—these records resolve Hosts by converting “IP Addresses-to-Host Names”

**16.140.10.in-addr.arpa →** **Name**      **Type**      **Data**  
                              113      PTR      cpc233120.nas.us.dg.com

## **USING NSLOOKUP TO VERIFY IF AD SERVICES ARE REGISTERED:**

**#nslookup**

**>set type=SRV**

**> \_ldap.\_tcp.dc.\_msdcs.nas.us.dg.com**      [Shows DC List, IP Addresses, Port 389]

Server: cpc233120

Address: 10.240.16.113

\_ldap.\_tcp.dc.\_msdcs.nas.us.dg.com      SRV service location:

    priority      = 0  
    weight      = 100  
    port      = 389  
    svr hostname      = cpc233120.nas.us.dg.com

cpc233120.nas.us.dg.com internet address = 10.240.16.113

### **VERIFYING LDAP SERVICE IN DNS:**

**> \_ldap.\_tcp.nas.us.dg.com**      [Shows LDAP Servers]

Server: cpc233120

Address: 10.240.16.113

\_ldap.\_tcp.nas.us.dg.com      SRV service location:

    priority      = 0  
    weight      = 100  
    port      = 389  
    svr hostname      = cpc233120.nas.us.dg.com

cpc233120.nas.us.dg.com internet address = 10.240.16.113

### **VERIFYING KERBEROS SERVICE IN DNS:**

**> \_kerberos.\_udp.nas.us.dg.com**      [Shows list of Kerberos Services & Port 88]

Server: cpc233120

Address: 10.240.16.113

\_kerberos.\_udp.nas.us.dg.com      SRV service location:

    priority      = 0  
    weight      = 100  
    port      = 88  
    svr hostname      = cpc233120.nas.us.dg.com

cpc233120.nas.us.dg.com internet address = 10.240.16.113

### **VERIFYING KERBEROS PASSWORD SERVICE IN DNS:**

**> \_kpasswd.\_tcp.nas.us.dg.com**      [Shows list of Password Servers Port 464]

Server: cpc233120

Address: 10.240.16.113

\_kpasswd.\_tcp.nas.us.dg.com      SRV service location:

    priority      = 0

```
weight      = 100
port       = 464
svr hostname = cpc233120.nas.us.dg.com
cpc233120.nas.us.dg.com internet address = 10.240.16.113
```

**VERIFYING PTR RECORD OF DATAMOVER:** [Also called “Reverse Lookup Zone Record”]

```
#nslookup -sil
```

> **set type=PTR**

> **10.240.16.113**

```
Server: cpc233120
Address: 10.240.16.113
113.16.240.10.in-addr.arpa name = cpc233120
```

**VERIFYING DATAMOVER A RECORD IN DNS:** [Also known as Host Record for Forward Lookup Zone]

> **set type=a**

> **10.240.16.113 [or Hostname ‘cpc233120’]**

```
Server: cpc233120
Address: 10.240.16.113
Name: cpc233120
Address: 10.240.16.113
```

**USEFUL WINDOWS RESKIT TOOLS OR UTILITIES:**

**TROUBLESHOOTING ACTIVE DIRECTORY: Q247811**

**TROUBLESHOOTING, REPAIRING, TESTING “SRV” RECORDS IN DNS FOR AD SERVER:**

**Note:** Quickest way to rebuild an AD Server’s DNS SRV records is to stop its netlogon service, then dns, restart Netlogon & dns  
Use Microsoft WIN2K Resource Kit tools to troubleshoot and fix: c:>dcdiag.exe & netdiag.exe

**C:>netdiag.exe /fix** [This utility helps re-register the AD Server’s SRV Records in DNS]

**C:>dcdiag.exe /fix** [Utility to analyze state of domain controllers in a forest or enterprise and reports problems. Also used to help repair Domain Controller records, problems, etc.]

**C:>nlttest /dsgetdc:win2kdomain** [Verify that Domain Controller can be located for specific domain]

**C:>nlttest /dsgetdc:example.com /force**

**C:>nlttest /dbflag:0x2000ffff** [Turns on Debug Log in AD Server’s “Netlogon” directory>netlogon.log]

**C:>ldp.exe** [Use this utility to connect & bind to DC to verify LDAP connectivity]

**C:>netdom.exe /network.lan:network.lan** [Use to verify Trust relationships]

**C:>setspn.exe -l server\_x** [Lists Service Principal Names of AD Object]

**C:>setspn.exe -r server\_x** [Resets SPN to default; Use -a to add new SPN]

**#nslookup**

**>movername.umb.umbbank.com** [Use to verify that DataMover is registered correctly with DNS]

**>guid.\_msdcs.umbbank.com** [Use to verify that GUID SRV record for Parent Domain can be resolved]

**DCDIAG TOOL:**

Verifies connectivity, replication, topology, DS partitions, DS records, Inter-site health, External trusts only  
dcdiag /s:SERVER1 /c /v [Use these switches to verify whether critical DC Services are running on the AD Server]

**NETDOM UTILITY:**

Use this tool to verify Kerberos v5 Trusts

**Symptoms:**

Celerra Server cannot obtain SID after successful “Join”

**Server Log Indicates SRV Records Not Found:**

2002-07-11 20:16:56: KERBEROS: 3: krb5\_locate\_srv\_dns: DNS returned no KDC for service \_kerberos at realm DSUNET.COM

**NSLOOKUP Fails to Find SRV Records:**

**C:>nslookup**

> **set type=SRV**

> \_ldap.\_tcp.dc.\_msdcs.nas.us.dg.com [Shows DC List, IP Addresses, Port 389]

**Note:** In this example, no SRV record is returned for the LDAP service

**SETSPN [ServicePrincipalName] TOOL:**

Win2k Reskit tool to locate target principal name for a service—“Service Principal Names” of an AD Object

**C:>setspn -l pc10corp**

Registered ServicePrincipalNames for CN=PC10CORP,OU=Laptops,OU=US Clients,

DC=corp,DC=emc,DC=com:

HOST/ PC10CORP

HOST/ PC10CORP.corp.emc.com

**Note:** Details of ServicePrincipalName for computername “pc10corp”

**C:>setspn -r pc10corp**

**Note:** Resets default SPN for host “pc10corp”

**C:>setspn -a http/pc10corp pc10corp**

**Note:** Sets a new SPN for “pc10corp”

#### **NAS SYSTEM:**

C:\Program Files\Support Tools>setspn -l mview\_dm2

Registered ServicePrincipalNames for CN=mview\_dm2,OU=Computers,OU=EMC Celerra,DC=2k3,DC=pvt,DC=dns:

cifs/mview\_dm2.2k3.pvt.dns

cifs/mview\_dm2

host/mview\_dm2.2k3.pvt.dns

host/mview\_dm2

### **USING LDIFDE UTILITY TO VIEW ACTIVE DIRECTORY DATABASE OBJECTS:**

**C:>\Ldifde -f domain.ldf -d “DC=buzzsaw,DC=com: -s 10.7.10.160**

**Note:** Dumps the entire AD partition from the AD Server indicated to a text file

Ldifde -f c:\domaindump.txt -d DC=buzzsaw,DC=com →dumps domain

Ldifde -f c:\usersdump.txt -d CN=Users,DC=buzzsaw,DC=com →dumps Users container

#### **SUBINACL.EXE:**

Useful tool to display security information on files or services, change ownership on objects, replace security from one SID to another, migrate security information on objects, modify any part of ACL.

#### **SUBINACL SYNTAX:**

c:>subinac /noverbose /output=filename subinac command

**Example:** To backup NTFS ACLs on all files on c:\ drive

**c:>subinac /noverbose /output=c:\aclbackups.txt /file c:\\***

→ Subinac /noverbose & /output parameters allows for snapshot of ACLs on objects--the /playfile option lets you restore ACLs.

→/output param will report on ACLs and dump to file

→/playfile will restore ACLs from a previous backup

**c:>subinac /playfile c:\aclbackups.txt**

### **USING NLTEST UTILITY:**

**C:>nltest /DOMAIN\_TRUSTS**

List of domain trusts:

0: ASSDPS (NT 4) (Direct Inbound)

1: ZAPPA (NT 4) (Direct Inbound)

2: ASD (NT 4) (Direct Inbound)

3: PSOLAB2 psolab2.emc.com (NT 5) (Direct Inbound)

**C:>nltest /DCLIST:corp**

Get list of DCs in domain 'corp' from '\\CORPMAHO1'.

gen1dc1.corp.emc.com [DS] Site: CorpEUGENuernberg1

bebr1dc1.corp.emc.com [DS] Site: CorpEUBEBrussels1

uksy3dc1.corp.emc.com [DS] Site: CorpEUUKLondon1

**C:>nltest /SC\_QUERY:corp**

Flags: 30 HAS\_IP HAS\_TIMESERV

Trusted DC Name \\corpmawe1.corp.emc.com

Trusted DC Connection Status Status = 0 0x0 NERR\_Success

**C:>nltest /dcname:corp**

PDC for Domain corp is \\CORPMAWE2

The command completed successfully

### **TROUBLESHOOTING DIRECTORY SERVICE INFORMATION:**

**\$server\_config server\_8 -v “ds dump”**

**Note:** Useful for showing CIFS FQDN, DOMAIN GUID, FOREST name, SITE name, DOMAIN name, capabilities of Domain Controllers for each AD Server, CIFS Services information, etc.

### **CODE CHANGES AFFECTING CELERRA & ACTIVE DIRECTORY INTEGRATION:**

**NAS 4.0.12.1:**

- DM will use first DC, LDAP, or KDC server returned by DNS without further processing
- Required “Enterprise Admins” rights in multi-domain environments for Join

**NAS 4.0.16.100:**

- Uses DC on same subnet first, then first returned from DNS list
- Still required “Enterprise Admins” rights in multi-domain environments for Join

**NAS 4.0.18.0, 4.1.6.0, 4.2.4.1:**

- No longer requires “Enterprise Admins” account to Join multi-domain environments

**NAS 4.2.6.1/5.0.9.2:**

- Now locates DC Services in same manner as Windows 2000 Client
- No longer requires Reverse DNS Entry to validate the DM Host Record

## **CONFIGURING DATAMOVERS TO USE SPECIFIC AD SERVERS (DSFile):**

**Note:** The 'directoryservices.tmp' file represents the basic outline of the AD Servers & Services in use on the network, as seen by the DM. Edit the file as necessary, deleting AD Servers/Services that are not desired--retaining DC's and Services that are desired. This option was introduced with NAS 4.2.10.x. You would need to execute this file for each domain in multi-domain environments & build a list of preferred DC's in the directoryservices file.

1. Create the Directory Services File by executing the following command:

**\$ .server\_config server\_4 -v "ds domain=ts2.mouse.com makeDsFile"** [Use cmd to create DS File in .etc]

**Note:** Creates a file called “directoryservices.tmp” in the ./etc of the DM:

-rw-r--r-- 1 root bin 3140 Apr 5 10:07 directoryservices.tmp

1081174049: SMB: 4: The list of services is stored in file ./etc/directoryservices.tmp.

2. After editing the directoryservices.tmp file to reflect the AD Servers & Services desired, rename as “directoryservices”

3. Add following parameters to data mover slot:

**param ds useDSFile=1** [Enables the use of the 'Directory Services' file by the DM]

**param ds useDCLdapPing=0** [Disables default behavior of using DC's sorted by Site & LDAP Ping response times]

4. Reboot Server

**Note:** By using this file, DART will access only DC's for Services configured here, and in the order listed. For Services not listed here, DART will use DNS.

## **EXAMPLE OF AN ‘ABBREVIATED’ CONFIGURATION FILE: ./etc/directoryservices**

#Domain: alpa.com – Domain Controller: alpadc1

```
_ldap._tcp.dc._msdcs.alpa.com 0 100 389 alpadc1.alpa.com  
_kerberos._udp.alpa.com 0 100 88 alpadc1.alpa.com  
_kpasswd._udp.alpa.com 0 100 464 alpadc1.alpa.com  
_kpasswd._tcp.alpa.com 0 100 464 alpadc1.alpa.com
```

**Note:** Configure the above services for each Domain Controller to be used by Data Mover

**EXAMPLE ‘DIRECTORIEServices’ FILE**—Caution: File abridged—do not use as real file!

**\$ cat /nas/rootfs/slot\_4/.etc/directoryservices.tmp**

```
#  
# File ./etc/directoryservices.tmp  
#  
# This file is a temporary file created by the Dart.  
# It contains service descriptions for the services: ldap, Kerberos,  
# and kpasswd, which are provided by a Windows 2000 domain/realm.  
#  
# For each Windows 2000 Domain, modify the list of Domain Controller(s) to  
# keep the servers the Data Mover will access and are geographically close.  
#  
# For each Windows 2000 Domain Controller you can create manually other entries, one for each of the following services:  
# _ldap._tcp.dc._msdcs  
# _kerberos._udp  
# _kpasswd._udp  
# _kpasswd._tcp  
#  
# For the configured services, Dart will try to access only the Domain Controllers  
# configured and in the order the Domain Controllers have been configured.  
#
```

```
# When trying to access a Domain Controller for a service NOT configured,
# Dart will use regular DNS mechanisms to locate the Domain Controllers that provides
# the service.
#
# Each service is defined with the syntax below:
#
# <service_fqdn_path> <priority_value> <weight_value> <port> <domain_controller_FQDN>
#
# Where:
#   <service_name> : full DNS path of the service, in the form: service_name.server_fqdn
#           Example: "_kerberos._udp.mydomain.com"
#
#   <priority_value> : The priority of the server.
#           Dart attempt to contact the server with the lowest priority
#
#   <weight_value> : Used for load balancing. Use the same value for all the
#           Domain Controllers in a Windows domain.
#
#   <port> : TCP/UDP port where the service listens for connections (decimal)
#           "_ldap"   listens on port 389
#           "_kerberos" listens on port 88
#           "_kpasswd"  listens on port 464
#
#   <domain_controller_FQDN> : fqdn of the Domain Controller that provides the service
#
# All numeric values are decimal.
#
# Lines starting with "#" are considered as comment.
#
# NOTE: Dart 'param'
# =====
# To activate service lookup using this file,
#   - rename this file in /etc/directorieservices
#   - set the 'param' ds.useDSFile to 1
# In the file /nas/server/slot_x/param , add:
#   param ds useDSFile=1
#
# Reboot the Dart using the 'server_cpu' command
# =====
# Services for domain ts2.mouse.com
#
# Domain controller(s):1
_ldap._tcp.dc._msdcs.ts2.mouse.com 0 100 389 minnie.ts2.mouse.com
#
# Global catalog server(s):0
# Kerberos server(s) over UDP protocol:1
_kerberos._udp.ts2.mouse.com 0 100 88 minnie.ts2.mouse.com
#
# Kerberos server(s) over TCP:1
_kerberos._tcp.ts2.mouse.com 0 100 88 minnie.ts2.mouse.com
#
# Kerberos admin server(s) over TCP protocol:0
# Kerberos password change server(s) over UDP protocol:1
_kpasswd._udp.ts2.mouse.com 0 100 464 minnie.ts2.mouse.com
#
# Kerberos password change server(s) over TCP protocol:1
_kpasswd._tcp.ts2.mouse.com 0 100 464 minnie.ts2.mouse.com
# -----
```

## WINDOWS SMB PROTOCOL:

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Resource-sharing protocol used in client-server operations to access files, printers, mail slots, named pipes, and API's.  
Current version is known as CIFS (Common Internet File System)--slightly different than NT LM 0.12—and is the native file sharing protocol for Windows 2000. Two Windows 2000 computers use NTLM 0.12, which allows exchanges to use Unicode for file names,, resource, and user names.

**SMB Commands fall into four categories:** Session Control; File Commands; Print Commands; Message Commands

Supports Two Levels of Security:

Share Level: password

User Level: files, user access and rights

#### **How does the Protocol Work?**

CIFS uses commands packaged via “redirection” requests to remote computers or the local computer. Connection establishment messages start & end “redirection” connections to remote resources. Namespace & File Manipulation messages are used to gain access to files and to read & write. Printer messages are used by redirection to send data to a print queue. Other messages send redirection requests to mail slots and named pipes.

#### **MICROSOFT RPC:**

- RPC is a protocol that permits a Client computer using a process to make a network (or local) request to use the processing resources of a Server. Thus, Client requests execution of instructions by another process located on a remote Server on the network.
- End Point Mapper listens on Port 135 for TCP/IP
- Client must RPC-bind to an interface before it can make procedure calls to Server
- RPC over SMB is also done

### **MICROSOFT NETWORK NAME RESOLUTION:**

#### **WINS & NT 4.0 Domains:**

Windows Internet Name Service & DNS uses TCP Port 134 for Name Resolution

#### **WINS/DNS for WIN2K Domain:**

WINS & DNS can still use TCP Port 134 for Name Resolution

SMB CIFS & NetBT can also travel directly over TCP/IP using TCP Port 445

#### **LDAP:**

- Clients submit LDAP requests to Servers—Servers can refer Client to other Servers for information
  - Celerra runs LDAP version 3.0 as an agent on DART to query & access Active Directory in Windows 2000 Domains
  - Windows 2000 supports LDAPv3 defined in RFC 2251 and LDAPv2 as defined in RFC 1777
  - Lightweight Directory Access Protocol allows clients to query, create, update, delete information stored in Active Directory.
  - LDAP Clients submit requests for operations based on entries for objects that are comprised of specific attributes. Entries have attributes consisting of a ‘type’ with one or more values [ASCII strings; URL’s; Public Keys]. Attribute values and distinguished names are defined by ISO 10646 character set.
  - LDAP protocol is carried over TCP or UDP
  - LDAP Versions 3 & 2 are used for Windows 2000
  - LDAP replaces ‘named pipes’ SMB communication with Domain Controllers
  - SASL (Simple Authentication and Security Layer) mechanisms can be used with LDAP to provide security services.
- Include DataMover in "Enterprise Admins" account  
Enable "Authenticated Users" to have read access to user account in all domains in forest that will be accessing datamover  
Distinguished Names; Universal Resource Locator name; Globally Unique Identifier

#### **LDAP over TCP:**

LDAP PDUs (Protocol Data Units) are mapped directly to TCP byte stream, usually listening on Port 389. AD also supports port 636 for LDAP Secure Sockets Layer communications. Global Catalog AD Servers listen on ports 3268 for LDAP & 3269 for LDAP SSL.

**LDAP Referral:** If a DC does not have the requested object during a query, will refer them to a different DC.

**RootDSE:** Consists of top portion of LDAP search tree containing logical namespace. Identifies domain, schema, and configuration directory partitions for a single DC and the forest root domain directory partition. Clients connect to the “rootDSE” when making LDAP inquiries. RootDSE publishes information about LDAP Servers, such as versions, SASL mechanisms, etc.

**Client→LDAP RootDSE→Server provides standard information in reply**

#### **How LDAP is Used During Windows 2000 Client Startup & Logon:**

Clients use LDAP locator process to locate DC to use for logon. LDAP is also used to find Group Policy Objects for computer or user. Also locates certificates if used.

#### **LDAP SERVICE OPERATIONS:**

BindRequest; BindResponse; UnbindRequest; SearchRequest; SearchResponse; ModifyRequest; ModifyResponse; AddRequest; AddResponse; DelRequest; DelResponse; ModifyRDNRequest; ModifyRDNResponse; CompareRequest; CompareResponse; AbandonRequest

→BindRequest is made by Client to Server

→BindResponse from Server

→LDAP Operation sent to Server

## **CELERRA CIFS SERVICES LIMITATIONS:**

- No physical limit to number of CIFS services that can be configured [just practical limit due to finite resources—old limit was 29]
  - Use multiple IP interface configurations for a single CIFS service for High Availability and Network Redundancy
  - Shares can be local to a specific Netbios name or Global across all netbios names for a specific Server
  - Each CIFS Service can participate in a separate NT Domain or Forest
  - Each CIFS Service can have its own DNS domain defined [up to (1) Primary & (2) Secondary DNS Servers]
- Note:** Use \$server\_dns command to add DNS Service & \$server\_cifs –add compname=, domain=, dns= to specify DNS domain  
--VLAN tagging can also be used to ensure security of packets when using CIFS Services in multiple NT Domain environments on the same DataMover

## **LOCALGROUPS SUPPORT:**

Celerra maintains a localgroups database similar to other Windows Servers

CIFS 4.0 Servers → The localgroups database can be managed by either User Manager or Computer Management Snap-in

CIFS 2000 Servers → Can use only Computer Management snap-in [also manages Shares & Event Viewer]

\\\172.19.3.22\compmgmt.msc

## **SPARSE FILE SUPPORT:**

Celerra frees unused space from 'sparse' files--these files allocate a logical size, but may only take up a small physical portion

## **NAMED STREAMS SUPPORT: aka, Alternate Data Streams (ADS), Multiple Data Streams, Named Data Streams, etc**

Every file uses a main, unnamed stream associated with it for 'data'. Alternate Data Streams are hidden files that are linked to the normal data stream file, and contains various information used by some applications and operating systems. For file systems that provide ADS capability, applications can write data at specific offsets within a stream as an alternate sequence of bytes, and then access the streams via their names. Thumbnail bitmaps and Summary Tab information on files with Windows NT/2000 are examples of files containing ADS. Name Streams (ADS) was introduced by Microsoft in the 1990's as a way to support Macintosh platforms as a file server. Macintosh files use a Data Fork and Resource Fork—the Resource Fork is used to store information about how the file was created, and by what application, allowing the correct application to subsequently reopen the file—whereas Microsoft uses file extensions to determine which application opens a file.

Celerra supports ADS with NAS 5.0 and higher. 'Streams' consist of data associated with a main file or directory. In FAT file systems, this data stream was called an "unnamed stream". NTFS introduced the concept of multiple data streams (MDS/ADS) within a file called 'named streams'. 'Named Stream' data is a hidden file—even Windows Explorer itself does not have the ability to see 'named streams'. To create an example of a 'named stream' within a file on an NTFS system, at the command prompt type the following:

**C:>echo hello > test:stream**

Opening "test" in notepad shows an empty file. Using **c:>more < test:stream** from prompt shows word "hello" inside the file.

### **Enabling Streams for NAS 5.0:**

**param cifs.multipleStreams=1**

Alternate Data Streams works on files with no spaces in name, but not with directories—param no longer found in NAS 5.5.

### **VERIFYING ADS NAMED STREAMS ON WINDOWS DATA:**

Download freeware utility called 'streams v1.53' from [www.sysinternals.com](http://www.sysinternals.com)

### **PROBLEMS WITH ADS:**

NAS 5.0.9.1 and 5.1.9.4 have problems when Clients try to create files with null strings, resulting in CIFS deadlock condition and loss of CIFS access to users. NAS 5.1.9.301 fixes problem in 5.1 family. A bug also exists in 5.1 in which NFS clients can corrupt a file system if they access files that contain ADStreams, causing panics. Issue first seen at Thales, 9660961, AR33615 and is fixed in 5.1.19.0.

### **Use the following param to turn off ADS and prevent FS corruption prior to 5.1.19.0:**

**param shadow stream=0**

### **SIDHistory:**

Migration capability from NT 4.0 Domains to WIN2K

## **WINDOWS PLATFORMS SUPPORTED BY CELERRA:**

NT 4.0 SP 4-6a → CIFS 2.1 and higher

Windows 2000 SP 1-3 → CIFS 2.2.35.4 and higher

Windows XP SP1 → CIFS 4.1.7 and higher

Windows 20003 Server (W2K3) → Not yet supported with any version NAS

**Note:** NAS 5.1M2 will have W2K3 Client Support; NAS 5.2 will include Domain Controller support

#### **Issues with 2003 Server:**

Default Domain Controller security policies require that clients use encryption and digital signatures via the secure channel socket between DC and Client, aka “SMB Signing”. DM does not yet support this mode and therefore cannot effectively “Join” the Domain, perform NETLOGON, or obtain SID [DART supports SMB Signing with NAS 5.2].

#### **Symptoms:**

Server Log →NETLOGON fails with “STATUS\_ACCESS\_DENIED” or “SMB: 3: SSXProcessReply: TreeXError=c0000022

Server\_Cifs output does not show SID

Users cannot map successfully to Celerra Shares

Network Traces show that Celerra cannot access the IPC\$ share on the 2003 DC's

## **BASIC STEPS IN CONFIGURING CELERRA AS A WINDOWS 2000 CIFS SERVER:**

- Step 1. Mount File System with relevant CIFS options [Locking Policies and Accesspolicies]
- Step 2. Start the Time Service on the DataMover [server\_date timesvc start ntp -i 0800:mn host] [Up to (4) Time Servers]
- Step 3. Configure DNS on the DataMover [server\_dns] **[Up to (3) DNS Servers can be specified per Data Mover]**
- Step 4. Enable I18N or ASCII Filtering [Note: Strongly recommended to enable I18N!]
- Step 5. Add CIFS Server to WIN2K Domain [server\_cifs -a compname=four0, domain=T2DOM2.LOCAL.COM, interface=ana1]
- Step 6. Join DataMover to Domain [server\_cifs -Join compname=four0, domain=T2DOM2.LOCAL.COM, admin=administrator]
- Step 7. Implement Usrmapper 3.0/NTMigrate/Manual Passwd/Group files
- Step 8. Start the CIFS Service [server\_setup]
- Step 9. Create CIFS Shares

**NTMigrate Note:** NTMigrate is supported for Windows 2000 Active Directory & produces same (3) output files that are then merged with a Unix Passwd/Group file or NIS database using "ntmiunix.pl" perlscript utility.

## **SETTING UP THE CIFS 2000 DM:**

### **I. Mount & Export File Systems:**

**Mount Options:** Mount Type; File Locking; Opportunistic Locks; File Change Notification; Access Checking Policies

**Mount Type:** rw [default] ro \$server\_mount server\_4 -o rw fs3 /mnt3

**File Locking:** nolock [default] wlock rwlock \$server\_mount server\_4 -o nolock fs3 /mnt3

**Opportunistic Locks:** nooplock [on by default] \$server\_mount server\_4 -o nooplock fs3 /mnt3

**File Change Notification:** on by default \$server\_mount server\_4 -o nonotify fs3 /mnt3

**Access Checking Policies:** NT UNIX SECURE NATIVE [default] \$server\_mount server\_4 -o accesspolicy=NT fs3 /mnt3

### **II. Configure NTP Time Service for CIFS Server:**

a.) **Start Time Service on DataMover:** Default clock delay is 60 minutes

\$server\_date server\_4 timesvc start ntp 172.24.80.11

\$server\_date server\_4 timesvc [Status of Time Service]

\$server\_date server\_4 timesvc stop | start | update ntp

\$server\_date server\_4 timesvc delete ntp

#### **UPDATING SERVER TIME MANUALLY:**

\$server\_date server\_4 0209041130 [Year, Mnth, Day, Time]

**Note:** In practical terms, best to use the NTP Service already running on one of the Windows 2000 Active Directory Servers!

**Important:** Ensure that Data Movers time is synchronized with Windows 2000. If not synchronized, CIFS Servers will not “Join” Active Directory properly or function properly after “Joining”—you would lose ability to “manage” the system from “Active Directory Users and Computers”. Authentication will not occur if the Time differential is greater > 5 minutes!!

### **III. Configure DNS Service for CIFS Server:** [Up to (3) DNS Servers can be listed]

**Note:** Windows 2000 and “Dynamic DNS” replaces “WINS”--when configured properly, this service will automatically register the CIFS Server in the WIN2K domain.

#### **NAS 4.0/4.1 REQUIRES REVERSE LOOKUP ZONE IN DNS:**

**CAUTION:** Make sure that the Windows 2000 Server’s DNS Service is configured with a “Reverse Lookup Zone”—the CIFS Server will not be able to register without this “zone” enabled. However, if Reverse Lookup Zone is used, it must match entries in Forward Lookup Zone or else the Join will fail—Celerra requires this because in a multi-protocol environment, this zone lookup is used to determine if we are communicating with the correct hosts. More specifically, we use an implementation of Kerberos used for mixed Unix & Windows environments—this MIT-based Kerberos obtains actual Host names by querying the Host’s IP Address in the Reverse Lookup Zone. In reality, if this Zone is not configured, the Kerberos Service may still obtain the correct name from the DNS query. NAS 4.0 & 4.1 may fail to obtain Kerberos ticket if Host names in Forward & Reverse Lookup Zones do not match. NAS 4.2.6.1 & higher no longer requires use of Reverse Lookup Zone for DM. See Microsoft Q174419 for info on setting up MS DNS.

Note: Reverse Lookup Zone is not enabled by default with Windows 2000 Server installations of DNS.

a.) **Setup the DNS Service on the DataMover:**

**\$server\_dns server\_4 -p tcp | udp t2dom2.local 192.10.3.2** [UDP is default protocol used]

Note: Recommendation is to use UDP protocol

**\$server\_dns server\_4 -o stop | start | flush**

**\$server\_dns server\_4 -delete t2dom3.local**

*Windows 2000 Domain:* t2dom2.local

*Default DNS Zone:* t2dom2.local

*Windows 2000 Active Directory Server FQDN:* win2ksrvdom2.t2dom2.local

b.) **Setting Up DNS on Windows 2000 Active Directory Server: REVERSE LOOKUP ZONE!**

1. Programs>Administrative Tools>DNS>View>Advanced>WIN2KSRVDOM2: Expand Folders

2. Reverse Lookup Zone: Rightclick and select "New Zone"

3. Welcome to the New Zone Wizard: Next

4. Zone Type: Select "Active Directory-integrated"

\*Active Directory-integrated

\*Standard Primary

\*Standard Secondary

5. \*Network ID: Enter: 192.10.3

6. You have successfully completed the New Zone wizard.

Name: 3.10.192.in-addr.arpa

Type: Active Directory Integrated Primary

Lookup Type: Reverse

FINISH [Shows up under "Reverse Lookup Zones" as "192.10.3.x Subnet"]

7. Highlight DNS Server & Stop/Restart DNS: WIN2KSRVDOM2>All Tasks: Stop | Start

8. FORWARD LOOKUP ZONES>t2dom2.local>Properties>General: Allow Dynamic Updates? Change to "Yes"

9. REVERSE LOOKUP ZONES>3.10.192.in-addr.arpa>Properties>General: Allow Dynamic Updates? Yes

**Example of Correct Entry for Datamover in Reverse Lookup Zone:**

Note: PTR Record for Datamover should look like the following entry:

DNS SERVER>Reverse Lookup Zones

100.168.192.in-addr.arpa 100 PTR dm2.dsunset.com

Rightclick entry for datamover>Properties>

Pointer (PTR)

Subnet:

100.168.192.in-addr.arpa

Host IP Number:

100

Host Name:

dm2.dsunset.com

**Important!** If AD Server is multi-homed, it most likely will have "A" Records for each IP Address in the Forward Lookup Zone. Make sure that it has only (1) PTR record in the Reverse Lookup Zone and reflects the IP Address of the Interface being used by the Datamover for Active Directory. When adding cifs server and 'joining' to domain, entries will show up immediately in DNS if successful. If a version other than Microsoft Windows 2000 DNS is being run on the network, ensure that it is Unix BIND 8.2.2 compliant to support Dynamic DNS. If Dynamic DNS is not being used, then add the CIFS Server manually to the DNS Servers by adding an "A" Record in the Forward Lookup Zone and a "PTR" Record in the Reverse Lookup Zone.

**Best Practice:** With NAS 4.2.6.1, no longer need the "PTR" record to function in AD

**IV. Enable I18N or SetUp the ASCII Filter Parameter:**

Note: If I18N is not used, then the following ascii parameter is defined in the DataMover "param" or Celerra Global "slot\_param" file

**Best Practice:** Engineering strongly recommends that I18N be configured by default on all new installations!

Why? Because all CIFS clients normally negotiate UNICODE on connection to File Servers. And, later 'conversions' tend to present a majority of the problems here.

a.) **Setting the ASCII Filter on a DataMover Basis:**

**#vi /nas/server/slot\_4/param**

**param shadow asciifilter=1**

b.) **Setting the ASCII Filter on the Whole Celerra:**

**#vi /nas/site/slot\_param**

**param shadow asciifilter=1**

Note: By default, ASCII filtering limits "Share" names to 12 characters

### c.) Enabling I18N on DataMovers:

1. **\$/nas/sbin/uc\_config -setup** [Normal→“Common Unicode translation subdirectory already exists.”]
2. **\$/nas/sbin/uc\_config -update** [Run this if the Customer has other Code Pages to load on the Servers]
3. **\$/nas/sbin/uc\_config -on -mover ALL | server\_2**

**Note:** After this command, Server\_2 will show "I18N Mode=UNICODE"

**Additional I18N Commands:** \$/nas/sbin/uc\_config -setup -i | -l

## V. Add CIFS Service Computer Name to Celerra Database:

- a.) **\$server\_cifs server\_4 -add compname=bubba, domain=t2dom2.local, interface=ana0**

**Note:** Adds the computer account to CIFS

Can only choose to hide the netbios name from Network Neighborhood [hidden=y]

Authentication=kerberos | all ["all" is default for both Kerberos & NTLM]

Netbios=legacy [use this option when you need to have a different netbios name than the FQDN]

#### Corresponding Server Log Entry:

2002-03-15 14:01:33: SMB: 4: CIFS Server TODD1[T2DOM2] created (0)

2002-03-15 14:01:33: SMB: 4: Full computer name todd1.t2dom2.local, Realm T2DOM2.LOCAL

2002-03-15 14:01:33: SMB: 4: Interface ana0 added into CIFS Server TODD1[T2DOM2]

2002-03-15 14:01:33: ADMIN: 4: Command succeeded: cifs add compname=TODD1 domain=T2DOM2.LOCAL interface=ana0

**Error Seen When DNS Not Setup Properly:** Note that Join command still works!

2002-03-14 14:41:25: SMB: 4: Dart account todd not registered with DNS.

2002-03-14 14:41:25: ADMIN: 4: Command succeeded: domjoin compname=todd domain=t2dom2.local admin=tmattha password=7?!?7 init

2002-03-14 14:41:25: LIB: 3: dns\_updateMessage: unable to get hostname of DNS server : Domain not exists

2002-03-14 14:41:25: LIB: 3: DNS update ERROR: Domain not exists while registering todd.t2dom2.local

## CHANGING DEFAULT COMMENT FIELD FOR COMPNANE:

Add Computer account to Create CIFS Service Using Following Syntax:

**\$ server\_cifs server\_6 -add compname=denver, domain=t2dom3.local, interface=ana1 -comment 'Look Out World'**

#### Server CIFS Output:

CIFS Server DENVER[T2DOM3]

Full computer name=denver.t2dom3.local realm=T2DOM3.LOCAL (domain not joined !)

Comment='Look Out World'

if=ana1 l=192.10.3.29 b=192.10.3.255 mac=0:0:d1:1f:61:2f

FQDN=denver.t2dom3.local (Updated to DNS)

## EXAMPLE OF USE OF OPTIONS FOR SERVER\_CIFS:

**\$server\_cifs server\_2 -add  
compname=cel2k, domain=ts2.emc.com, hidden=y, authentication=Kerberos, netbios=Celerra, interface=ace0, wins=192.168.3.2, dns=emc.com -comment 'EMC\_Celerra'**

**Note:** For no comment at all, leave a space between tic marks: -comment ‘ ’

## HOW TO REMOVE 'EMC-SNAS' FROM DRIVE MAPPINGS TO CELERRA ON XP CLIENTS:

**HKeyCurrentUser>Software>Microsoft>Windows>CurrentVersion>Explorer>ComputerDescriptions:**  
→edit and remove the 'EMC-SNAS' comment

## VI. Joining the CIFS Server to the Windows 2000 Domain:

- a.) **\$server\_cifs server\_4 -Join**

**compname=bubba, domain=t2dom2.local, admin=tmattha, DC=win2k.t2dom2.local**

**server\_4 : Enter Password:\*\*\*\***

**done [Use -U to unjoin a domain]**

**Note:** This command adds computer account to AD 'OU' & DNS Forward & Reverse Lookup Zones

#### JOIN PROCESS DEFINED:

1. **Join Command Issued→DART queries DNS Server for list of LDAP Services [DM→DNS→DM]**
2. **DART queries LDAP Server via UDP to obtain attributes of Domain Controllers [DM→LDAP→DM]**
3. **DART queries DNS for Kerberos Information [DM→DNS→DM]**
4. **DM obtains Session ticket with KDC [DM→KDC→DM]**
5. **DM uses LDAP via TCP to request add of Compname and Celerra 'OU' to AD [DM→LDAP→DM] & obtains SID**

#### Corresponding Server Log Entry:

2002-03-15 14:03:24: SMB: 4: Dart account todd1 not registered with DNS.

2002-03-15 14:03:24: ADMIN: 4: Command succeeded: domjoin compname=todd1 domain=t2dom2.local admin=tmattha password=7?!?7 init

2002-03-14 14:41:25: LIB: 3: dns\_updateMessage: unable to get hostname of DNS server : Domain not exists

2002-03-14 14:41:25: LIB: 3: DNS update ERROR: Domain not exists while registering todd.t2dom2.local

**SERVER LOG MESSAGES FOR UNSUCCESSFUL JOIN:**

2002-03-15 13:26:35: ADMIN: 3: Command failed: domjoin compname=todd domain=t2

dom2.local admin=tmatta password=7?!?7 unjoin

2002-03-15 13:49:01: KERNEL: 4: Time set

2002-03-15 13:52:30: SMB: 4: LGDB: Database started

2002-03-15 13:52:30: SMB: 4: ShareDB: DART database started

2002-03-15 13:52:30: ADMIN: 4: Command succeeded: cifs start

2002-03-15 13:52:44: KERBEROS: 3: krb5\_sendto\_kdc: unable to send message to any KDC in realm T2DOM2.LOCAL.

2002-03-15 13:52:44: KERBEROS: 4: krb5\_gss\_release\_cred: kg\_delete\_cred\_id failed: major GSS\_S\_CALL\_BAD\_STRUCTURE or GSS\_S\_NO\_CRED, minor G\_VALIDATE\_FAILED

2002-03-15 13:52:44: LDAP: 0: LdapGssAuthenticator::getCredentials: gss\_acquire\_cred\_ext failed: @ = 0x83d0f04, for principal user/todd@T2DOM2.LOCAL - GSS-API

major error: Miscellaneous failure

2002-03-15 13:52:44: LDAP: 0: LdapGssAuthenticator::getCredentials: gss\_acquire\_cred\_ext failed: @ = 0x83d0f04, for principal user/todd@T2DOM2.LOCAL - GSS-API

minor error: Preauthentication failed

2002-03-15 13:52:44: LDAP: 3: LdapBinder::bind: SASL\_PROTOCOL\_VIOLATION

2002-03-15 13:52:44: SMB: 4: Unable to connect to Active Directory server win2ksrvdom2.t2dom2.local, port 389

2002-03-15 13:52:44: SMB: 3: smb\_threadCtx::SSXAuth\_KERBEROS: Failed to obtainattributes for: user Administrator - realm T2DOM2.LOCAL - server todd@T2DOM2.LOCAL

**RESETTING COMPUTER PASSWORD ACCOUNT IN DOMAIN:**

-o reuse | resetserverpasswd [Used when migrating from Mixed to Native Mode using same computer account; Resets CIFS compname password and encryption keys]

**Example of Syntax:**

**\$server\_cifs server\_4 -Join compname=suncor, domain=network.lan, admin=migratory -o  
resetserverpasswd**

**Following Error Indicates a Password or Computer Account Desynchronization With Domain:**

2002-11-09 20:44:50: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328246

**Comment:** Server does not register with DNS until CIFS started! If error messages persist, check DNS Forward & Reverse Lookup Zones and Allow Dynamic Updates setting!!

**PURPOSE OF ADDING CELERRA TO 'ENTERPRISE ADMINS' GROUP IN AD:**

By default, the Celerra CIFS 2000 Server is added to the "Enterprise Admins" group by default so that the datamover will have the capability to query any Domain Controller in the Forest so as to validate Users accessing Celerra shares. While not a requirement, this is our default behavior. Celerra no longer requires the "Enterprise Admins" group for NAS 4.x or 5.x

**Misc. Notes:**

--Join command creates a machine account in Active Directory & adds Server to an "Organizational Unit" called "ou=Computers,ou=EMC Celerra". Celerra becomes member of both "Domain Computers" and "Enterprise Admins" for T2DOM2.LOCAL/Users. Compname can be up to (63) UTF8 characters in length and represents the FQDN. 'Admin=' account is an Administrator with rights in the Domain Forests to add a member to 'Enterprise Admins' Group.

--Join command also immediately creates entries in DNS Forward and Reverse Lookup Zones

**USING JOIN COMMAND TO JOIN SPECIFIC "OU" CONTAINERS IN ACTIVE DIRECTORY:**

**\$server\_cifs server\_2 -Join  
compname=dm4, domain=network.lan, admin=migratory, ou="ou=energy:ou=suncor"**

**Note:** Last "ou" added by this command is actually the first "ou" that is created [i.e., OU=Suncor, followed by OU=Energy]

**\$server\_cifs server\_2 -Join  
compname=dm4, domain=network.lan, admin=migratory, ou="ou=energy,ou=suncor"**

**Note :** Alternative syntax for OU's

**VII. Setup UID/GID Mapping Service:**

**VIII. Start the CIFS Service:**

a.) #server setup server 4 -P cifs -o start

b.) Access the Netbios Name and Check for SID Generation in "server\_cifs" Output.

**SERVER LOG ENTRIES WHEN STARTING CIFS FOR FIRST TIME:**

2002-03-14 15:11:55: SMB: 3: LGDB: New Database created

2002-03-14 15:11:55: SMB: 4: LGDB: Database started

2002-03-14 15:11:55: SMB: 4: Registry initialization OK

2002-03-14 15:11:55: CFS: 3: Init new log file

2002-03-14 15:11:56: CFS: 3: attempt to set a zero-length filename

2002-03-14 15:11:56: SMB: 4: ShareDB: DART database started

2002-03-14 15:11:56: ADMIN: 4: Command succeeded: cifs start

2002-03-14 15:11:57: LIB: 3: dns\_updateMessage: unable to get hostname of DNS server : Domain not exists

**Example CIFS Output:**

DOMAIN T2DOM2  
DC=WIN2KSRVDOM2(192.10.3.2) ref=1 time=0 ms  
CIFS Server (Default) TODD[T2DOM2]  
Full computer name=todd.t2dom2.local realm=T2DOM2.LOCAL  
Comment='EMC-SNAS:T4.0.12.2'  
if=ana0 l=192.10.3.26 b=192.10.3.255 mac=0:0:d1:1f:83:1e  
FQDN=todd.t2dom2.local (Update of "A" record failed during update: Domain not exists)

**Note:** Above example reflects incorrect DNS configuration! Troubleshoot separately.

**Example of CIFS Output After Rebooting DataMover:**

CIFS Server (Default) TODD[T2DOM2]  
Full computer name=todd.t2dom2.local realm=T2DOM2.LOCAL  
Comment='EMC-SNAS:T4.0.12.2'  
if=ana0 l=192.10.3.26 b=192.10.3.255 mac=0:0:d1:1f:83:1e  
FQDN=todd.t2dom2.local (Retrying DNS update...)

**AFTER CHANGING FORWARD & REVERSE LOOKUP ZONES PROPERTIES TO:**

Allow Dynamic Updates: Changed from "Allow Dynamic Updates 'Secure Updates Only' to 'Yes'  
Stopped & restarted DNS, then CIFS and following DNS Update made to DNS & CIFS OUTPUT.

\$ server\_cifs server\_5

32 Cifs threads started  
Security mode = NT  
Max protocol = NT1  
I18N mode = ASCII  
Home Directory Shares DISABLED  
Usermapper[0] = [172.24.80.11] last access 0  
Enabled interfaces: (All interfaces are enabled)

DOMAIN T2DOM2  
SID=S-1-5-15-323e04be-36d67c9a-32eac016-ffffffffff  
DC=WIN2KSRVDOM2(192.10.3.2) ref=1 time=0 ms  
CIFS Server (Default) TODD[T2DOM2]  
Full computer name=todd.t2dom2.local realm=T2DOM2.LOCAL  
Comment='EMC-SNAS:T4.0.12.2'  
if=ana0 l=192.10.3.26 b=192.10.3.255 mac=0:0:d1:1f:83:1e  
FQDN=todd.t2dom2.local (Updated to DNS)

**Note:** If successful, DNS entries show up immediately in DNS REVERSE & FORWARD ZONES  
And, can now "manage" the account "todd1" in Active Directory

**IX. Create CIFS Shares:**

a.) **From CommandLine: Control Station**

\$server\_export server\_4 -P cifs -n share /mnt3

b.) **From WIN2K: "Computer Management" Interface**

Programs>Administrative Tools>Active Directory Users and Computers>T2DOM2.LOCAL>EMC Celerra>Computers  
>todd1: Rightclick netbios name and select "manage">Computer Management (TODD1.T2DOM2.LOCAL)>System Tools>  
**Shared Folders>Shares:** Rightclick & select "New">File Share>Folder to Share>C\$>mnt4 [Name Share & assign perms]

C\$ C:\  
CHECK\$ C:\  
cmdshare C:\todd  
IPC\$ \etc

**Shared Folders>Sessions**

administrator 192.10.3.2  
win2ksrvdom2\$ 192.10.3.2

**Shared Folders>Open Files**

\etc\PIPE\srvsvc administrator

**X. UNJOINING/DELETING CFS 2000 SERVER FROM WINDOWS 2000 DOMAIN:**

**Step 1. Unjoin the Server from the Domain:**

\$server\_cifs server\_4 -Unjoin compname=win2k, domain=t2dom2.local, admin=tmatta

Enter Password: xxxxxxxx

Removes from Active Directory and DNS

## **Step 2. Deleting the CIFS Service from the Data Mover:**

**\$server\_cifs server\_4 -delete compname=win2k [Deletes CIFS Service configuration]**

**Note:** Must have DNS service running on DataMover to do this

## **NOTE ABOUT "REALM" IN WINDOWS 2000:**

The word "realm" refers to the Kerberos Security space of Windows 2000 active directory piece. Therefore, any errors referencing "realm" would most likely be related to a problem with Kerberos security

## **JOIN PROCESS FOR WIN2K:**

1. FQDN request and response
2. Bind & query LDAP server for DC's
3. Kerberos session between DM & KDC
4. LDAP add request/response

**Note:** When the Netbios name is different than the prefix name for the FQDN, then the "netbios" parameter needs to be specified using the "server\_cifs -add" command

## **MOVING COMPNAME FROM ONE “OU” TO ANOTHER IN ACTIVE DIRECTORY:**

**NAS 4.2.9.0:** Moving CIFS “compnames” from default location, “EMC Celerra : Computers” to a different Organizational Unit [OU] Process of moving a compname using the Active Directory Users and Computers is very straightforward.

1. As Administrator, go to Start>Programs>Administrative Tools>Active Directory Users and Computers
2. Expand the “EMC Celerra>Computers” OU and highlight the Celerra compname to be “moved”.
3. Rightclick the compname and select “move” and select the appropriate OU container to move the computer account to.
4. Verify data and administrative access to the compname

## **CREATING CIFS “SHARE” FROM WINDOWS 2000 SERVER:**

Step 1. Computer Management>Action>Connect to another computer>Look in Entire Directory

Step 2. Highlight Celerra Machine Account: “win2k (user/win2k@t2dom2.local) T2DOM2.LOCAL/EMC Celerra/Computers”

Step 3. Expand ‘System Tools’>Shared Folders>Shares>rightclick and select “New”>File Share>Folder to Share>C\$>mnt4  
[C:\mnt4 = path for cifs file system]

- Step 4. Name the New Share and Assign Network Access Permissions
- \* All Users have Full Control [Default Value assigned]
  - Administrators have Full Control; Others Read Only
  - Administrators have Full Control; Others No Access
  - Customize Share and Folder Permissions
- “Finish”

## **HIDING COMPNAME FROM NETWORK NEIGHBORHOOD:**

Use hidden=y option with server\_cifs command

## **WINDOWS 9x LIMITATION ON RETRIEVING NETWORK SHARES INFO: Q202892**

By default, Windows 9x Clients are limited in the amount of info that can be retrieved, to 65,536 bytes. If the NT Server or Datamover delivers more than that, then not all shares will be displayed by Client. This is a LAN Manager 2.1 limitation.

### **Condition Represented by Following Irritating Server Log Message:**

"Max buf Size of Client too small"

## **WIN2K RESTRICTED LOGON ACCESS PROBLEM:**

NAS Code prior to 4.2--Client uses port 445 to connect to Celerra and we used IP Address of Client in place of machine name. Therefore, if access is restricted based on machine name of client, then connection will be refused by Server.

## **USING NFS TO COPY FILES TO A CIFS FILE SYSTEM:**

If Customer conducts a data migration from another Unix system to a CIFS filesystem, using strictly NFS CPIO or RSYNC operations, the “Ownership” of the directories copied will probably be the Unix Root User, indicated as “UNIX Uid=0x0” when examining folder permissions after the migration. Similarly, the default NT Permissions should be for “EVERYONE Full Control” Properties>Advanced>Owner **UNIX UID=0x0”**

If required, the Administrator can “Take Ownership” of files and re-permission directories as needed.

## **COMMON ERRORS WHEN CIFS SERVER ACCOUNT NOT ‘JOINED’ WITH WIN2K DOMAIN:**

Indicators: Missing DNS entry for Server/Server not ‘manageable’ from Active Directory Users and Computers Menu

**I. WINDOWS 2000 SERVER POPUP ERROR:**

Manage Computer>todd1>Shared Folders>Shares

"MMC The System encountered the following error while reading the list of shares: Error 5: access is denied"

**II. SERVER LOG ENTRIES:**

2002-03-22 13:06:02: SMB: 4: >DC=WIN2KSRVDOM2(192.10.3.2) R=2 T=0 ms S=0,1/-1

2002-03-22 13:06:02: KERBEROS: 3: krb5\_sendto\_kdc: unable to send message to any KDC in realm T2DOM2.LOCAL.

2002-03-22 13:06:02: SMB: 3: KC\_ComputeBlob Status=70000,0

2002-03-22 13:06:02: SMB: 3: DC\_GetBlob T2DOM2.LOCAL\todd1 WIN2KSRVDOM2\HOST=70000 -2045022973

**III. ACCESS FROM NT CLIENT [CORRESPONDING SERVER LOG ERROR]: [Line logged each time access to CIFS Server attempted]**

SMB:3:SSXAK=c000006d origin=600 stat=d0000, -1765328347

**IV. EXAMPLE OF SERVER "ALPHADM2" WITH BROKEN SECURITY TRUST:**

"Network path not found" from clients:

2002-03-28 16:43:31: SMB: 4: >DC=NTSRVDOM1(192.10.2.2) R=2 T=0 ms S=0,1/-1

2002-03-28 16:43:31: SMB: 3: NetLogon::buildSecureChannel=7 E=0xc000018b

2002-03-28 16:43:31: SMB: 3: NetLogon::buildSecureChannel=7 E=0xc000018b

2002-03-28 16:43:31: SMB: 3: NLogon\_SecureChannel not OK=7

2002-03-28 16:43:31: SMB: 3: No more valid DC (currDC=6ecbc04 6ecbc04/6ecbc04)

2002-03-28 16:43:31: SMB: 4: DC=\*SMBSERVER(192.10.2.2) R=2 S=15,c000018b/-1

2002-03-28 16:43:31: SMB: 3: No nextDC available, keep DC=6ecbc04

**Resolution:** Stopped CIFS, then UsrMapper, deleted Netbios Name & Readded back to Domain for Success

**RESETTING MACHINE ACCOUNT FROM ACTIVE DIRECTORY GUI:**

**Note:** There are situations whereby the "trust" account for the CIFS Server may need to be reset with the Windows Domain From Windows 2000 Active Directory Users and Computers Menu:

Manage Computer>rhombus: Rightclick, select "Reset Account"

**WINDOWS 2000 POPUP MESSAGE:**

"Active Directory Are you sure you want to reset this computer account? Yes  
Account rhombus was successfully reset. OK"

**LOSS OF CIFS ACCESS WHEN CELERRA TIME SERVICE BECOMES UNSYNCHRONIZED**

**WITH KERBEROS KDC SERVER:**

**Users have lost access to a CIFS Share and the Server Log is logging the following error(s):**

2002-04-08 11:01:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328351

2002-04-08 11:01:32: SMB: 3: SSXAK=c000006d origin=600 stat=d0000,-1765328351

Clock skew too great

**Users See Following Errors from Windows Clients:**

a.) My Network Places>Computer>CIFS2000>"Enter Network Password: Incorrect Password or unknown username for: \CIFS2000"

b.) The Following Error is encountered when using the "Active Directory Users and Computers" interface to "manage" the CIFS2000 Netbios name: "Computer Management" "Computer \CIFS2000 cannot be managed. The network path was not found."

c.) Or, when trying to "manage" the CIFS2000 Server from within the "Active Directory Users and Computers" interface, the following errors are encountered: "Error 5: Access is denied"

**Note:** You may see several different messages, all resulting in an "Access Denied" message. Also, you may see certain elements of the CIFS2000 Netbios name circled with a red X around the subject, such as in "Local Users and Groups"; all these are indicators that the CIFS Server has lost the ability to login to the Windows 2000 Domain using Kerberos Security.

**Cause:**

By default, the Kerberos Key Distribution Center [KDC] Time Clock requires that Client Computer Systems Clocks on a Windows 2000 Active Directory Domain be synchronized to within a 5 minute variance. When Client Systems become unsynchronized, they can no longer successfully establish secure network communications using Kerberos Security and are effectively 'denied access' to services on the network until the Time Synchronization problem is corrected.

**Resolution:**

Resynchronize the DataMover's Time Service with that of the Customer's Network Time Service:

\$server\_date server\_5 timesvc stop | start

**TROUBLESHOOTING WIN2K ISSUES:**

1. Verify NTP Service and Time Synchronization
2. Encryption issues related to RC4 v. DES [see Q248808]
3. DNS Zones properly created [FWD & REVERSE] and non-authenticated updates enabled!

## **IMPROPER DNS SETUP=WIN2K CLIENT ERRORS:**

**"Reverse & Forward Lookup Zones" "Allow Dynamic Updates?": "Only Secure Updates"**

**Comment:** With "Only Secure Updates" set, you can add the CIFS Server and "Join" the Windows 2000 Domain, Create a "Share" from the commandline that is network accessible, Obtain a SID, but the appropriate DNS Entries will not be made and you will not be able to "Manage" the cifs server from "Active Directory Users & Computers"--if you try, you obtain a client error:

- a.) No entries in DNS Forward or Reverse Zones for CIFS server
- b.) Active Directory Users and Computers>Manage Computer>todd>Shared Folders>Shares:

## **WINDOWS 2000 POPUP ERROR:**

Microsoft Management Console

"The System encountered the following error while reading the list of shares:  
Error 5: access is denied"

Computer Management

"Computer <\\todd1.t2dom2.local> cannot be managed. The Network path was not found. Choose 'Connect to another Computer' from the Action menu to manage a different computer."

"WIN32: The RPC Server is unavailable"

## **SERVER LOG DNS ERRORS:**

1. CIFS Stopped or 2. REVERSE & FORWARD LOOKUP Zones not set properly; Allow Dynamic Updates? Yes!!!

2002-03-14 15:38:28: LIB: 3: DNS error: unable to get SOA to update todd.t2dom2.local entry

2002-03-14 15:38:28: LIB: 3: DNS update ERROR: Primary name server not found while registering todd.t2dom2.local

2002-03-14 15:41:16: LIB: 3: dns\_updateMessage: unable to get hostname of DNS server : Domain not exists

2002-03-14 15:41:16: LIB: 3: DNS update ERROR: Domain not exists while registering todd.t2dom2.local

2002-03-14 15:43:04: LIB: 3: DNS ERROR: no response from name server 192.10.3.2 after 2 seconds

## **WIN2K DNS PROPERTIES:**

DNS>WIN2KSRVDOM2>Forward Lookup Zones><t2dom2.local>><todd1>>Doubleclick netbios name for "Properties"

### **Host(A) Tab:**

Parent Domain: t2dom2.local

Host: todd1

IP Address: 192.10.3.26

Update associated pointer (PTR) record

Delete this record when it becomes stale

Record time stamp: 3/14/2002 5:00:00 PM

Time to Live (TTL): 0:0:20:0

### **Security Tab:**

Administrators (T2DOM2\Administrators)

DnsAdmins (T2DOM2\DsAdmins)

Domain Admins (T2DOM2\Domain Admins)

Enterprise Admins (T2DOM2\Enterprise Admins)

ENTERPRISE DOMAIN CONTROLLERS

Everyone

Pre-Windows 2000 Compatible Access

SYSTEM

Permissions: Full Control Read Write

Allow inheritable permissions from parent to propagate to this object

## **SYMPTOMS SEEN WHEN DNS NOT CORRECT:** 'Allow Dynamic Updates?' is set to "Only Secure Updates"

1. Cifs Service can be successfully added using \$server\_cifs server\_4 -add compname=todd1, domain=t2dom2.local, interface=ana0
2. FQDN is added to Active Directory: \$server\_cifs server\_4 -Join compname=todd1, domain=t2dom2.local, admin=tmatta
3. Name "todd1" is not added to DNS Forward or Reverse Zones; Server Logs give errors; Server\_Cifs output also indicates failure
4. Name "todd1" is added to Active Directory, but cannot be 'managed'; GUI Errors; Server\_Log errors, etc
5. Active Directory Users and Computers>todd1>Properties can be viewed but Shares cannot be created [Access Denied]
6. Shares can be created from CommandLine and then successfully mapped from Windows Clients!
7. SID is also obtained

### **Windows Client Errors:**

"Computer <\\todd1.t2dom2.local> Cannot be managed. The Network Path was not found. Choose 'Connect to another Computer' from the Action menu..."

## **WINDOWS 2000 DOMAINS:**

Each Domain contains its own "Active Directory". Multiple Domains comprise a "forest". The Global Catalog Service is the common denominator. Likewise, each Domain contains its own "DNS Zone" and trusts are automatic within the forest. Otherwise, create trusts between "forests" by configuring each Domain as a Secondary DNS Server for the other [New Zone Type>Standard Secondary]. Note, must have a working Global Catalog Service [first DC in the forest] for authentication/logons to work.

**SETTING WINDOWS 2000 USER RIGHTS/POLICIES:**

Programs>Administrative Tools>Domain Security Policy>Local Policies>User Rights Assignments | Security Options  
 >Domain Controller Security Policy>Local Policies>User Rights Assignments | Security Options  
 >Local Security Policy>Local Security Settings>Security Settings>Local Policies>User Rights Assignment>Security Options

**WINDOWS 2000 DNS INTERFACE:****Programs>Administrative Tools>DNS>WIN2KSRVDOM2>Properties**

| <u>Interfaces</u>                                                                                                                                                                                                                                                                                                                                                                                                                                      | <u>Forwarders</u>                                                                                                     | <u>Advanced</u>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <u>Root Hints</u>                |

**CIFS OUTPUT WITHOUT DNS CONFIGURED FOR DYNAMIC UPDATES:**

\$ server\_cifs server\_5  
CIFS Server (Default) CIFS1[T2DOM2]

Full computer name=todd.t2dom2.local realm=T2DOM2.LOCAL

Comment=EMC-SNAS:T4.0.12.2'

if=ana0 l=192.10.3.26 b=192.10.3.255 mac=0:0:d1:1f:83:1e

**FQDN=cifs1.t2dom2.local (Update of "A" record failed during update: Domain notexists)**

## **CIFS OUTPUT AFTER ALLOWING DYNAMIC UPDATES IN DNS FWD & REVERSE ZONES:**

Changed from "Allow Dynamic Updates 'Secure Updates Only' to 'Yes'

DOMAIN T2DOM2

SID=S-1-5-15-323e04be-36d67c9a-32eac016-ffffffff

DC=WIN2KSRVDOM2(192.10.3.2) ref=1 time=0 ms

CIFS Server (Default) CIFS1[T2DOM2]

Full computer name=todd.t2dom2.local realm=T2DOM2.LOCAL

Comment=EMC-SNAS:T4.0.12.2'

if=ana0 l=192.10.3.26 b=192.10.3.255 mac=0:0:d1:1f:83:1e

**FQDN=cifs1.t2dom2.local (Updated to DNS)**

## **DFS NAMESPACE (Replaces Distributed File System name) SUPPORT:**

--DFS's are Shared folders that can map to more than one root target, or Servers, which in turn can map to Links underneath the root

--Each Namespace is seen as a Shared folder, with subfolders underneath

--Celerra supports DFS as “leaf volume” only—DFS Server must be configured to see Celerra as a leaf volume [Native Windows supports ‘root volumes’]

--Celerra does not support File Replication service

--Since NAS 5.4, we only support Standalone DFS Root, which means there is only one root target

--Windows 2003 R2 changes from DFS to DFS Namespace, replaced DFS File System snap-in with DFS MMC Snap-in, and introduced DFS Replication. Windows 2008 added domain namespaces and other improvements.

**Note:** Celerra does not currently support DFS Replication, which replaced the File Replication Service (including NAS 6.0)

## **ACCESSING WIN2K OR NT SERVER FROM UNIX:**

Setup an "rshd" service on the Windows machine to enable a Unix Host to connect & use "rsh" and "rcp"

## **ENABLING RSH ON DATA MOVER:** /usr/bin

**# .server\_config server\_2 -v "rshd"**

1090516820: ADMIN: 4: Command succeeded: rshd

**Note:** To stop the RSH daemon on the DM, must reboot! No other way to turn off from CLI.

#rsh server\_x “pdc dump” or #rsh server\_x pdc dump

#rsh server\_x ls

## **ENABLE/DISABLE CIFS NETWORK INTERFACE:**

**\$server\_cifs server\_2 -Enable ana0 |Disable ana0**

**Note :** Use to associate a specific interface with the default CIFS configuration

## **CFS 4.0 32-BIT GID SUPPORT:**

**NFS support introduced with 2.2.35.4 +[new min NAS 2.2.46.x]**

Celerra supports 32-bit GID values (2 Billion--old values were 16-bit or 64k), but the actual value is still capped at a total of 64K GIDs per FS [0 – 2147483647]

16-Bit FileSystem Values range from 0 – 65,534

32-Bit FileSystem Values range from 0 – 2,147,483,647, but are still limited to a total of 65,534 GIDs per filesystem

**Note:** GID values are stored in the ushort of the inode, which is limited to 64k unique values, but are mapped differently for 32-bit so that the values can range from 0 – 2 billion (Using a 31-bit mapping scheme)

**Note:** Solaris, HP-UX, Netapps, AIX all support 32Bit GIDs or more

--Implement only during filesystem creation & not during mounting

--/etc/gid\_map file is created On-Disk at time of 32-bit file system creation [Superblock misc flag value FS\_GID\_32 0x20] to support translation between 32-bit values to 16-bit on-disk values

--Initial support only pertains to NFS file systems

--Linux 6.2 Control Station only supports 64k GID's [therefore you will not be able to see the 32-bit GID values]

--Linux 7.2 Control Station kernel now supports 2 Billion UID/GIDs

--Disable 'Quotas' prior to setting up 32-bit GID filesystem

--If NIS is being used, the GID can be resolved to a Group name

**Note:** A DataMover can mount and handle a 32-bit file system even if the 32-bit feature has not been enabled

## **NAS 5.3:**

32-bit GID support on by default

#nas\_fs -G [used to verify 32-bit fs]

**\$ nas\_fs -G fs06**

FS GID = 32BIT

### **32-BIT GID MAP:**

The gid\_map file is a way of mapping a 32 bit gid to a 16 bit gid and is unique for every file system. GIDs are only allocated sequentially on-disk, meaning that freed gid's have to be cleaned up from the database. The server\_mount option –o gid32Rebuild fs1 /fs1 frees up unused on-disk GIDs and puts a sentinel free value in unused slots in gid\_map file.

**# server\_mount server\_2 -o gid32Rebuild fs05 /fs\_repS**

**Note:** Each file system and rootfs that are 32bit will have the following gid\_map file. The gid\_map file is not visible in Versions 5.2 or 5.3, but is visible in 5.4:

```
-r--r--r-- 1 root bin 262144 Nov 9 16:45 gid_map
```

### **RECOVERING GID MAP FILE IF DAMAGED BY FSCK OR OTHERWISE:**

1. Mount the affected file system with the gid32Ignore option:

**\$ server\_mount server\_2 -o gid32Ignore home /home**

2. Verify the file system is mounted with the option:

```
$ server_mount server_2 | egrep home
```

```
home on /home uxf5,perm,rw,gid32Ignore
```

3. Check to see if the gid\_map file was moved to lost+found directory of the 'home' file system. The size of the gid\_map file is always 262144 bytes and the inode number of the file should be a low order number. If the gid\_map is found in the lost+found directory, or the gid\_map file needs to be obtained from a different file system\*, first copy the gid\_map to a temporary directory on the Control Station (e.g., /tmp), then copy the file back to the appropriate file system's hidden /etc directory using the server\_file command, as demonstrated in Step 4. The reason for this two-step process is that the /etc directory is hidden and only accessible via the server\_file command:

**Note:** The gid\_map is not universal and each file system will be unique—however, there are rare occasions where Eng. may propose restoring a gid\_map from one file system to another.

4. [root@laip1 lost+found]**# cp -ip gid\_map /tmp**

5. Copy the file to /etc (not /.etc) of the affected file system:

```
$ cd /tmp
```

**\$ server\_file server\_2 -put gid\_map /home\\Vetc/gid\_map**

```
server_2 : done
```

6. Umount the file system and remount without gid32Ignore option.

```
$ server_umount server_2 -p /home
```

```
server_2 : done
```

```
$ server_mount server_2 home /home
```

```
server_2 : done
```

7. Verify access and re-export for NFS and CIFS if required.

### **Example of what typical listing of the gid\_map file should be:**

```
$ ls -ail
```

```
7 -r--r--r-- 1 root bin 262144 Nov 9 16:45 gid_map
```

### **VERIFYING WHETHER FILE SYSTEM IS 16 or 32-BIT SUPPORTED?**

**\$server\_config server\_5 -v "file query /metro"**

```
1058875245: CFS: 4: fsRawSize = 4418808
```

```
1058875245: CFS: 4: inodes = 535294
```

```
1058875245: CFS: 4: kbytes = 4350792
```

```
1058875245: CFS: 4: used = 248
```

```
1058875245: CFS: 4: avail = 4350544
```

```
1058875245: CFS: 4: refCount = 13
```

**1058875245: CFS: 4: gid = 16**

```
1058875245: ADMIN: 4: Command succeeded: file query /metro
```

**Note:** Superblock contains a misc flag value of FS\_GID\_32 0x20 when 32-bit support is enabled

**\$ nas\_fs -G fs06**

FS GID = 32BIT

### **CIFS SUPPORT FOR 32-BIT GIDs:**

--Introduced with NAS 4.1

--Usrmapper Version 3 also supports

**Note:** NAS 5.2.9.6 still defaults to 16-bit file system support

## **32-BIT GID BACKUP SUPPORT:**

**NDMP:** Veritas & Legato NDMP supports 31-bit GID's for Backups [emctar; ustar; cpio; bcpio; sv4cpio; sv4crc; tar does not] --Server\_archive emctar also supports 31bit UID/GID Backups --Other Backup Formats: ustar=21bit; tar=18bit; cpio=15bit; bcpio=16bit; sv4cpio=21bit; sv4crc=21bit

## **MODIFY PARAM FILE TO ENABLE 32-BIT VALUES:**

```
param ufs gid32=0 [default value=16-bit GID's]
param ufs gid32=1 [Sets 32-bit values]
$ .server_config server_2 -v "param ufs"
ufs.gid32      0x00e0f734  0x00000000  0x00000000
```

## **CREATING A FILESYSTEM TO SUPPORT 32-BIT GID's:**

1. #vi /nas/server/slot\_13/param  
**param ufs gid32=1**
2. Reboot Server\_13
3. Create 32Bit FileSystem Using Server\_13:  
**#nas\_volume -n metav\_d91\_32bit -c d91,d92**  
**#nas\_fs -n 32bitfs01 -c metav\_d91\_32bit -o mover=server\_13**
4. Create mountpoint & export for NFS:  
**#server\_mountpoint server\_13 -c /32bitfs01**  
**#server\_mount server\_13 32bitfs01 /32bitfs01**  
**#server\_export server\_13 -o anon=0 /32bitfs01**

**Note:** Turn Off the param after the filesystem is created! [gid32=0]

5. Verify that FileSystem was created as 32-bit by checking Server Log:

### **SERVER LOG ENTRY:** UFS: 4: Creating GID MAPS

**Note:** NAS Version 5.1 and higher requires use of “mover=server\_x” in order to create 32-bit file system support—previous versions would default to Server\_2, but this is no longer the default behavior.

```
$server_config server_5 -v "file query /metro"
```

## **GID's GREATER THAN 65,535 ARE WRITTEN TO ACL's ON DISK WITH INCORRECT GID VALUES—HOW TO MIGRATE FROM 16-BIT TO 32-BIT FILE SYSTEMS:**

### **EXAMPLE OF FILE SYSTEM ISSUE WHEN USING UID OR GID VALUES > THAN 64k:**

If GID value of 75000 is used, unless 32-bit support is enabled for all file systems, the value will be truncated and written to disk as “9464”. 75,001 will be written as “9465”, etc. The meaning of this should be clear—actual GID values will be written to ACL records with the “new” truncated value, not the value that Usermapper has assigned. If a file system has encountered this problem, the following is one method for correcting:

1. Set following parameter on Data Mover that will be used to create 32-bit File System support:

```
/nas/server/slot_4/param
```

```
param ufs gid32=1
```

2. Reboot Server\_4 and create 32-bit File System:

```
#nas_fs -n newfs32 -c mtvfs32 -o mover=server_4
```

**Note:** Must specify the Server to be used for File System creation!

3. Migrate data from 16-bit file system to new 32-bit file system:

```
$server_archive server_4 -J -rw /oldfs /newfs32
```

**Note:** Server\_archive can only be used to migrate data located on the same Server. The above syntax preserves CIFS attributes. Sticky bit values and Quotas are also preserved. Data migration rate using server\_archive is only 16-18GB per hour.

4. Verify ACL's on 16-bit file system with known GID problem

```
# .server_config server_4 -v "acl if=fsn1 dump=\fs00620\0\GRPF-KPC-4-15-03"
```

Default values:

Interface 'elv0' Addr='0.0.0.0'

```
===== UNIX =====
```

USER 4196 GROUP **45007** mode=rwxr-xr-x

```
===== NT =====
```

Owner=USER 4196 UNIX UID=0x1064 ".:S-1-5-12-1-1064

Group=GROUP **110543** UNIX GID=0x1acf ".:S-1-5-12-2-1acf

**Note:** The NT Value for the Group in this example is 110,543—this is the value assigned by Usermapper service. Problem is that this value translates/truncates to “45007” when written to UNIX record on file system that has only 16-bit support enabled.

5. After a successful data migration from 16-bit to 32-bit file system, update the “on-disk” ACL records for all Users and Groups by

running Setacl--this will update the “UNIX value from “45007” to “110,543” in the above example:

**#server\_config server\_4 "cifs update /newfs32/testfolder force setacl if=ace0"**

6. Run ACL Dump again to validate the setacl repairs

## **RECOVERING 32-BIT GID MAP FILE IF FSCK REMOVES TO LOST+FOUND:**

**Note:** On rare occasions the gid\_map of a file system can become corrupted and require recovery—use following procedure

1. Remount file system with gid32Ignore option

**\$ server\_mount server\_2 -o gid32Ignore fs1 /fs1**

2. Locate gid\_map file from lost+found (if FSCK moved) or use same file from another 32-bit file system—gid\_map file size is always 262144 bytes

3. Copy gid\_map to /tmp directory

4. Copy gid\_map to /etc directory of the appropriate file system (NOT .etc)

**#server\_file server\_2 -put /tmp/gid\_map /fs1\etc\gid\_map**

5. Unmount file system and remount with normal mount options

## **NFS Protocol:**

Client-Server model where Server exports local directories for remote NFS Clients. NFS is a Session-layer protocol [RFC 1057], but with RPC used with NFS running over UDP or TCP. Data values are encoded using XDR. A Remote Procedure Call passes data to a function and awaits a reply [or value] to be returned. RPC can also conduct Host and UID authentication, and supports DES encryption. NFS is stateless in the sense that a server does not keep track of the dialogues it conducts with remote clients. NFS uses a number of Procedures, called synchronous, as the ‘server’ blocks additional requests until a valid reply is sent. Asynchronous requests generally lead to higher performance.

## **COMPONENTS USED WITHIN NFS:**

→RPC protocol RFC1057

→XDR protocol RFC1014

→NSM Network Status Manager for statd, crash & recovery, client reboot notification to Server, lock re-claim

→NLM Network Lock Manager for lockd, advisory locks only [NLMv1, 3 for NFSv2, NLMv4 for NFSv3]

→Port Mapper

→Mountd

→Xid, xid cache

## **NFS RETRANSMISSIONS:**

Duplicate XIDs are seen by the RPC layer and indicate that UDP packets have been lost and requires retransmission.

## **NFS NETWORK LAYERS:**

NFS v2 or v3 uses RPC Client-Server calls over TCP/UDP and IP. Portmapper service [RPCBind] registers applications. RPC Calls are assigned unique XID numbers.

## **NFS OPERATIONS:**

**NULL:** NULL does not perform real work, but is used to allow Server response testing and timing

**GETATTR:** Get File Attributes; retrieves attributes for file object by file handle [fhandle] from Server in response to a LOOKUP, CREATE, MKDIR, SYMLINK, MKNOD, READDIRPLUS

**SETATTR:** Used to change attributes of file system or directory object on Server; new attributes specified by sattr3 structure.

**LOOKUP:** Searches directory for specific name & returns file handle for file system object

**ACCESS:** Check Access Permission; Determines Client access rights for a File Object [ACCESS3\_READ--read from file or directory; ACCESS3\_LOOKUP--lookup name in directory; ACCESS3 MODIFY--Rewrite file date or modify directory; ACCESS3\_EXTEND--Write new data or add directory entries; ACCESS3\_DELETE--Delete directory entry; ACCESS3\_EXECUTE--Execute a file]; Client encodes permissions in bit mask, Server checks permissions & returns "NFS3\_OK" with enclosed bitmask permissions if o.k.

**READLINK:** Reads data from symbolic link as ASCII string.

**READ:** Reads data from file in 8-Kbyte blocks

**WRITE:** Writes data to file/or cache in NFS v3 in 8-Kbyte blocks

**CREATE:** Creates regular file

**MKDIR:** Create new subdirectory

**SYMLINK:** Creates symbolic link

|                     |                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------|
| <u>MKNOD:</u>       | Create new special file for block, device, named pipes, or socket                                                  |
| <u>REMOVE:</u>      | Removes entry in directory                                                                                         |
| <u>RMDIR:</u>       | Removes a subdirectory                                                                                             |
| <u>RENAME:</u>      | Rename a file or directory                                                                                         |
| <u>LINK:</u>        | Creates hard link from file to link name in directory                                                              |
| <u>REaddir:</u>     | Retrieves variable number of entries in sequence from directory & returns name & file identifier (reads directory) |
| <u>REaddirplus:</u> | Extended read from directory for variable number of entries; enhanced REaddir (reads directory)                    |

FSSTAT: Retrieves dynamic/volatile file information

FSINFO: Retrieves non-dynamic or non-volatile information

PATHCONF: Retrieves POSIX information, pathconf information for a file or directory

COMMIT: Commit cached data to stable storage using WRITE procedure

**NFS runs over IP using UDP for NFS v2 and both UDP [port 2049] and TCP for NFS v3.**

Note: Must run NFS v3 if you are using CIFS! [Uses RPC over TCP]

CIFS runs only over TCP/IP [No UDP support here!]

DataMover can support both NFS & CIFS simultaneously

XDR—External Data Representation: A Presentation Layer protocol acting as RPC translator between disparate Hosts and is equivalent to the CIFS Unicode protocol.

ACCESS3\_READ: Read data from file or directory

ACCESS3\_LOOKUP: Look up name in directory

ACCESS3 MODIFY: Rewrite existing file data or directory entries

ACCESS3 EXTEND: Write new data or add directory entries

ACCESS3\_DELETE: Delete an existing directory entry

ACCESS3\_EXECUTE: Execute a file

## **UNNAMED PIPES:**

Way for processes to share data, usually in the context of the login Shell in use.

# ls | wc -l

Note: Example of unnamed pipe where the std-out of ls process is sent to std-in of wc process

## **NFS CALLS:**

NFS Packets that include RPC & NFS Headers, along with the IP fragment of the datagram. Biode's are Client NFS processes that communicate with Server nfsd processes (aka RPCBIND)—typical Unix systems run 8-16 biode processes. Threads spawn processes that conduct work. Modern NFS requests are typically multiplexed over a single TCP connection—note, if too many NFS requests are channeled over a single TCP stream, could create a performance issue—this is called a lack of I/O Concurrency. In otherwords, may need to implement multiple streams to improve performance.

## **NFS CLIENT-SERVER MODEL:**

Client always issues the Commands or Calls to the Server (NFS Commands (C))

Server always sends NFS Replies or Responses (R)

Clients always “write” to the Server or “read” from the Server

## **NFS PROCESSES:**

--“Biodes” are process threads that run on NFS Clients that send NFS Read or Write requests to the Server. Multiple Biodes allow for concurrent I/O requests. Each biod uses a different originating port number, but destination port number is always 2049. Normally 4-8 biodes running on a Client.

--Asynchronous Requests are when Client biod processes send multiple NFS requests prior to receiving reply from previous requests.

--Concurrent Requests are when multiple biod requests occur simultaneously.

--“Nfsds” are process threads running on the Server that handle NFS Client “biod” requests.

--Safe Asynchronous Writes occur when using NFS V3—Server replies with “Reply OK” to Client before writing to disk [Uses new COMMIT procedures].

--NFS Streaming is only supported when using TCP and Record Marking Standard markers for NFS. When NFS Streaming is used, multiple requests can be sent in a single packet, as well as multiple replies from the Server.

--NFS does not support the use of ‘nested mountpoints’ by design so that clients cannot see the same file across different mountpoints

## **ASYNCHRONOUS vs. SYNCHRONOUS NFS CALLS:**

Async requests, especially writes, are faster than synchronous because the client is not waiting for replies for every call, but making multiple write calls, which is more efficient and leads to greater throughput.

## **NFS MOUNTS:**

Mount is used to get the file handle of the directory being mounted. The “timeo” mount option specifies the NFS retransmission timer, defined in tenths of a second—often set as 11/10ths of a second for connectionless transports and 600/10ths for a connection-oriented transport. The “retrans” option sets the number of NFS retransmissions—default is 5 [when using TCP, this option does not normally have any effect]. The “rsize” and “wsize” options are used to set maximum data transfers for Read and Write requests, but Server negotiates with client during FSINFO call—maximum Celerra “wsize” is 64k. Mount protocol always uses UDP.

#### **Soft and Hard Mounts:**

These mount options determine how Clients react whenever the Server is overloaded or crashes. By default, all NFS filesystems are mounted Hard, meaning that Client RPC calls that timeout will retry indefinitely. The effect of this is to make the Server appear as a “local disk” to the Client. A side effect of Hard Mounting is that processes can “hang” or block other requests while waiting for an NFS RPC call to complete. Soft mounts allow NFS operations to fail and crashed Servers will return system calls with error messages. Do not use Soft Mounts whenever writing data or running executables from the Server [i.e., wouldn’t use soft mounts if filesystems are mounted RW]

**Hard Mount Error:** NFS server jassoc not responding, still trying

**Soft Mount Error:** NFS read for server jassoc: error 5 (RPC: Timed out)

### **NFS PERFORMANCE ISSUES:**

#### **TYPICAL NFS THROUHPUT ON 507 DATA MOVERS USING GbE:**

Single Client Reads: 15 MBps

Single Client Writes: 20 MBps

Multiple Clients Writing to DM: 35MBps

#### **TYPICAL NFS THROUHPUT ON 510 DATA MOVERS USING GbE:**

Single Client Writes: 35-40 MBps

Multiple Client Writes: 60 MBps

**Comment:** Data Mover DART is tuned to handle multiple Client requests more efficiently than a Single Client. So, best practice performance testing on DMs should be done using multiple Clients, as is more realistic of a network environment.

### **TESTING NFS WRITES TO NS600 FROM NFS RED HAT 8.0 CLIENTS:**

```
10.32.3.10:/fs1 /fs1 nfs      noauto,rw,hard,intr,proto=udp,rsize=32768,wsize=32768 0 0  [Using UDP mount on NS600]
10.32.3.10:/fs1 /fs1 nfs      noauto,rw,hard,intr,proto=tcp,rsize=32768,wsize=32768 0 0  [Using TCP mount on NS600]
dd if=/dev/zero of=/fs1/test/terminal1-1.dat bs=32k count=32000      [Crontab jobs from clients]
dd if=/dev/zero of=/fs1/test/terminal1-2.dat bs=32k count=32000
```

### **HOW TO CHANGE NUMBER OF NFS DAEMONS ON EACH DATAMOVER:**

**Background:** Sun Servers run 1024 nfsd daemons by default. Celerra DataMovers run 96 by default. The number of daemons can be changed but as a caution, this should be done carefully and in small increments to assess system impact

Step 1. Go to /nas/server/slot\_x/netd and vi

Step 2. **nfs start openfiles=15360 nfsd=96** [change nfsd=96 to nfsd=124, etc...]

### **CELLERRA NFS DAEMONS :**

Nfsd—manages the transfer of traffic across the network

Biod—manages the disk writes to FileSystems at the Block level

Lockd—processes file lock requests for NFS clients

Statd—maintains lock status and crash recovery [statd & NLM work to allow clients to reclaim previously held locks]

Mountd—manages mount characteristics of NFS filesystems

Portmapper [port 111]—Client requests Port for a transaction; Server provides port for communications; Occurs for every transaction

**Note:** Portmap provides a mapping service to network ports for services such as mountd, nfsd, etc.

### **NFS CLIENT DAEMONS:**

LOCKD & STATD daemons keep track of locks on NFS files

Client maintains list of FileSystems to mount on bootup, in the /etc/fstab file, via the /etc/rc.boot script

Alternatively, can manually mount the Fstab FileSystems: \$/usr/etc/mount -a -t nfs

### **NFS SERVER DAEMONS:**

RPC.MOUNTD daemon answers requests from Clients for NFS files and maintains /etc/rmtab file of FileSystems currently mounted NFSD daemon also processes Client requests

LOCKD & STATD daemons keep track of locks on NFS files

Exports FileSystems in the /etc/exports file, via the /etc/rc.local script [#exportfs]

Showmount -e -d shows exported filesystems [Solaris]

## **UNIX-BASED EXPORTS FOR NFS:**

# showmount -e [Shows how a server is exporting its file systems]  
# exportfs # exportfs -a

## **NFS VERSIONS:**

### **NFSv2 or NFSv3:**

Both have UDP/IP or TCP/IP support and can support 2000 Connections by default.

Both use Mount protocol, Status Monitor, and Network Lock Manager via RPC calls.

NFSv2 supports maximum data transfer size of 8k; supports UDP & TCP, but mostly uses UDP, & max file size of 2GB [NFSv2 uses 32-bit file sizes/offsets]

NFSv3 max data transfer size with UDP is 64k, supporting filesizes >than 2GB; NFS over TCP supports larger transfer sizes [Data transfers negotiated with FSINFO]. With NFSv3, safe asynchronous writes are supported using COMMIT. Clients have to wait for the Server to reply using NFSv2 before issuing more commands, with NFSv3, Client knows data is written to disk when “Reply OK” received to a COMMIT request. NFSv3 also returns file attributes with each call, reducing need for explicit “GETATTR” calls that NFSv2 requires [NFSv3 supports 64-bit filesizes/offsets]

### **NFSv4 Protocol:**

Through the use of “Open/Close Operations”, this version now makes NFS a “stateful protocol”, and implements File Locking & Delegation. NFSv4 introduces OPEN operation for file lookup, creation, and share reservation to become “stateful”.

Other Improvements: Enhanced access & performance across Internetworks; Strong security; Cross-platform interop.

NFS is still considered a “system” that is “Operating System” independent, using RPC procedures. NFS4 is now a single protocol with a well-defined port that uses RPC in “operations” v. “procedure calls”.

Mandatory Locking Introduced: Concept of “stateid” to block I/O operations by applications that record a lock on a file [similar to the way Windows locks files]

### **CELLERRA NFSv4:** (see Configuring NFS on EMC Celerra 300-004-152)

→ NFSv4 Clients can manage file system objects by ACLs when Celerra file systems use accesspolicy of MIXED or MIXED\_COMPAT

→ Celerra requires use of Unicode with UTF8 encoding

→ NFSv4 requires the use of UTF-8 encoded Usernames and Groupnames, as well as an NFSv4 domain

**Note:** File & Directory structure still maintains the UID/GID

→ Built on ONC RPC—RFC1831, uses XDR—RFC1832, TCP-Only

→ Supports CIFS, NFSv2-NFSv4, & FTP

→ NFSv4 RFC 3530, uses port 2049, connection-oriented only, i.e., TCP [Does not use UDP as NFSv2 or NFSv3 can]

→ NFSv4 uses 32-bit NFS clients (param nfsv4 32bitClient)

→ Use of Read/Write Client Delegation for caching data, metadata, & locking to improve network performance, is enabled by default on a per file system basis

**Note:** Celerra delegation levels are None (No file delegation granted); Read (Only Read delegation); and Read/Write (Read/Write delegation granted)

→ Support for Share reservations

→ Enhanced security as NFSv4 supports KerberosV5 user authentication

→ Offers better WAN performance than previous NFS protocols

→ Mount, NLM, Status, ACL protocols are removed

→ MKDIR & RMDIR replaced by CREATE & REMOVE

→ File locking now built into the NFS protocol, hence no more NLM

→ File System object names, owners, owner groups, & metadata are UTF-8 encoded

→ Mandatory attributes will be supp\_attr, type, lease\_time, others

→ Access Control Lists will be compatible with CIFS ACLs, requires MIXED mode for Client, requires synchronization between mode-bits and ACLs (Owner, Owner\_group, Everyone)

→ RPCSEC\_GSS layer built for AUTH\_SYS or KERBEROS v5 security via GSS-API

→ Access to file systems will be through a pseudo-root “/” construct instead of using mount protocol

→ NFSv4 adds mandatory locks, byte ranges and share reservations

→ NFSv4 Open/Close operations are Stateful, ensures atomicity of Share reservations, Exclusive creates, delegate authority to Clients

→ NFSv4 is stateful, required for proper locking and recovery from failures, but doesn't require constant connection—CIFS requires continuous TCP connection to maintain state, NFSv4 does not, will recover

→ Both mode bits for Unix and ACLs will be allowed for NFSv4

→ Set param nfsv4 domain=xxx & /nas/server/slot\_x/netd→hivers=4 and reboot Data Mover to enable NFSv4

→ Export a file system using “nfsv4only” option

- Configure name service (iPlanet, NIS, etc.) and configure NSSwitch
- Use Unicode and MIXED accesspolicy file systems in order to fully support NFSv4 ACLs
- Use NIS if using both CIFS & NFS to access file systems, NFSv4 uses user & group names for mappings, and has to then translate to UID/GIDs [using mapid daemon]

### **NFS VERSION 4 RESTRICTIONS/LIMITATIONS:**

- NFSv4 supported only for Server-side, not Client-side, hence CDMS migration from NFSv4 to Celerra is not supported, nor Celerra FileMover to NFSv4 Secondary storage
- SecMap caching cannot be used with this feature
- HighRoad MPFS is not supported
- NMFS file systems are not supported
- Only pseudo-roots supported at this time, not pseudo file systems
- Access Control will be through Windows SIDs
- Configuration support not provided by Celerra Manager
- Celerra does not yet support Volatile File Handles
- Blocking locks not supported
- No public key authentication yet [SPKM-3, Lipkey]

### **NFSv4 Clients:**

Solaris 10+ patches, AIX 5.3 ML-2 + patches, Linux, Hummingbird, HPUX

### **NFSV4 PARAMS & SETTINGS:**

**param nfsv4 domain=nfsv4.net** (use this param to set the NFSv4 domain)

/nas/server/slot\_2/netd file

**nfs start openfiles=240000 nfsd=256 hivers=4**

**Note:** Must specify the hivers=4 to set NFSv4—NFSv3 will remain the default

param dns updatePTRrecord →use when Windows is Kerberos environment

param cifs acl.sortAces →used to reorder ACEs per Windows Explorer model

\$server\_nfs server\_2 ALL | -v4 | -service -start | -stop | -client -list | -info | -release | -stats

**# server\_nfs server\_2 -v4**

server\_2 :

NFSv4 is not enabled

Restart system and use nfs option hivers=4

**\$ server\_nfs server\_2 -v4 -client -info index=0xef400000**

**\$ server\_nfs server\_2 -v4 -client -list**

**\$ server\_nfs server\_2 -secnfs -user -list** (Secure NFS stats)

**\$ server\_nfs server\_2 -v4 -secnfs -user -info handle=32**

**\$ server\_nfs server\_2 -v4 -service -start | -stop** (Cleans up NFS v4 state and recalls delegations)

**\$ server\_param server\_2 -facility nfsv4 -info domain -v**

**\$ server\_param server\_2 -facility nfsv4 -info 32bitClient -v** (return attribute values in 32-bit only)

**\$ server\_param server\_2 -facility nfsv4 -info leaseDuration -v** (duration server maintains client state)

**\$ server\_param server\_2 -facility nfsv4 -info recallTimeout -v** (timeout for recall delegations)

**\$ server\_param server\_2 -facility nfsv4 -info delegLeaseDuration -v**

**\$ server\_param server\_2 -facility dns -info updatePTRrecord -v** (use dynamic updates for PTR—is not by default)

**\$ server\_param server\_2 -facility cifs -info acl.sortAces -v** (sort ACEs in the ACL in the order Explorer expects)

**# server\_param server\_3 -facility nfsv4 -list**

| param_name    | facility | default | current | configured |
|---------------|----------|---------|---------|------------|
| recallTimeout | nfsv4    | 10      | 10      |            |
| vnodePercent  | nfsv4    | 80      | 80      |            |
| leaseDuration | nfsv4    | 40      | 40      |            |
| domain        | nfsv4    |         |         |            |
| 32bitClient   | nfsv4    | 1       | 1       |            |

### **Disabling Delegations:**

**\$ server\_mount -o nfsv4delegation=NONE**

**\$ server\_export server\_2 -P nfs -option nfsv4only /mnt** (restrict access from NFSv2 or 3 clients to NFSv4 only)

### **Problems:**

NFS v4 clients do not have a standard way of setting and interpreting ACLs

### **FILE SYSTEM DEFINITIONS:**

**File System Identifier [fsid]:** 128-bit unique per-server identifier of a single file name space.

**Regular File:** A simple byte stream.

**Filehandle:** Identifies a unique file on a per-server basis on a fs. NFSv2 & v3 had persistent filehandles. NFSv4 uses volatile filehandles to handle client caching operations.

## **IMPLEMENTING NFSv4 ON CELERRA:**

1. Enable a Name Mapping mechanism on the Celerra, using either local passwd/group files, NIS, or LDAP

**Note:** NFSv4 uses names in ACLs, not UID/GIDs

2. Edit /nas/server/slot\_x/netd and change “nfs start” line to read:

**nfs start openfiles=240000 nfsd=256 hivers=4**

3. Reboot Data Mover

4. Set the NFSv4 domain on the Data Mover:

**\$ server\_param server\_x -f nfsv4 -m domain -v europe.local**

5. Set the file system accesspolicy to mixed to support ACLs:

**\$ server\_mount server\_x -o accesspolicy=MIXED fs1 /fs1**

## **COMPARISON OF NFS VERSIONS:**

### **NFS Version 2   NFS Version 3   NFS Version 4**

|      |      |      |
|------|------|------|
| NULL | NULL | NULL |
|------|------|------|

#### **Compound Operations:**

COMPOUND/NVERIFY/VERIFY

#### **Open/Close Operations:**

## **SERVER NFSSTAT:** NFS & RPC stats for NFSv2 & v3; Server cache statistics

**\$server\_nfsstat server\_4 [lists all statistics]**

-z {zeroes stats} -r [zeroes out RPC stats] -n [zeroes NFS stats] -s -c {server client}

**\$ server\_nfsstat server\_2 -s**

server\_2 :

Read/write size and alignment distribution (v3):

| size   | read | crossed | write  | crossed |
|--------|------|---------|--------|---------|
| 1 - 1  | 0    | 0       | 183    | 0       |
| 2 - 3  | 3    | 0       | 400586 | 0       |
| 4 - 7  | 39   | 0       | 12430  | 0       |
| 8 - 15 | 102  | 0       | 18140  | 0       |

|               |         |       |          |       |
|---------------|---------|-------|----------|-------|
| 16 - 31       | 100     | 0     | 4281     | 0     |
| 32 - 63       | 191     | 0     | 12464    | 0     |
| 64 - 127      | 330     | 0     | 94552    | 1125  |
| 128 - 255     | 538926  | 9992  | 751543   | 5791  |
| 256 - 511     | 490406  | 88200 | 10726464 | 6775  |
| 512 - 1023    | 3666    | 0     | 2078183  | 0     |
| 1024 - 2047   | 271057  | 15049 | 541734   | 9618  |
| 2048 - 4095   | 181237  | 0     | 1110809  | 0     |
| 4096 - 8191   | 5210239 | 0     | 1587799  | 32689 |
| 8192 - 16383  | 1552627 | 21820 | 407415   | 32985 |
| 16384 - 32767 | 79206   | 620   | 60851    | 5     |
| 32768 - 65535 | 3024210 | 981   | 3607389  | 1     |

**Clientside:** Large difference between “timeout” and “badxid” values may indicate client, server, network problem  
Use nfsstat –c from different clients to compare results

## **TROUBLESHOOTING NFS PROBLEMS:**

### **NFS & Client Mounting Process:**

1. Client initiates request to Server by contacting “portmap” daemon to discover service & port to communicate
2. Server returns list of services and ports
3. Client makes request to “mountd” daemon on Server to export a file system or directory
4. Server reads /etc/vfstab to verify availability and check permissions to directory and then returns a File Handle pointer to the file system or directory to the Client’s NFS kernel

### **NORMAL SEQUENCE OF EVENTS FOR MOUNTING FS NFS:**

1. PORTMAPPER/GETPORT/MOUNT [Mount executable tries to find mount Server]
2. MOUNT/NONE [Mount executable pings mount Server to verify that mount service is available]
3. MOUNT/MNT [Mount executable finds filehandle for the share]
4. PORTMAPPER/GETPORT/NFS [Mount executable finds NFS service]
5. NFS/NONE [Mount executable pings NFS server to verify service; after mounting, Mount executable notifies Client OS]
6. NFS/FSINFO [Client OS sends commands to Server querying for FileSystem info]

### **NFS CLIENT FILE ATTRIBUTE & READ BUFFER CACHING:**

Client caching is used in NFS for performance reasons, preventing some RPC calls to the Server. Operations such as ‘getattr’ and ‘ls’ collect metadata information and reuse it without always having to go back to the Server. File attributes, such as mod time & file size remain valid when read by a Client for 3 seconds, and if the attributes remain static, for 60 seconds before cache is flushed. Directory attributes typically remain valid for 30 seconds, up to 60 seconds before cache is flushed. Cache is also flushed whenever writes occur. Attribute changes created by write operations on the clientside are typically sent back to the server in a single setattr. Certain client operations, such as a chmod, are never cached on the client.

Cache consistency is used to ensure that the cached copy of file data is consistent with what is on the Server. The file’s modification time is used as a check to make sure that cached data is newer than the mod time—if mod time is newer, data is flushed.

Async threads typically perform read-ahead and write-behind operations for NFS clients. Data is read and uses cache consistency to keep track of changes, while writes are collected into buffers until a full page is collected or the buffer is filled, then written back to disk. With flush-on-close, NFS buffers are written to the Server. NFSv3 clients using write stable flag will force Server to write to disk using commit operation.

NFS file locking should be used in situations where overlapping Reads & Writes occur on the same file. File locking disables caching, meaning that writes are written back to the Server instead of local client cache.

#### **Attribute Caching can be disabled using following from Clientside:**

**# mount -o noac nfs\_server:/files/home /mnt**

**# mount -o actimeo=1 nfs\_server:/files/home /mnt** (use this to change attribute cache timeout on files & directories)

**Note:** Disabling attribute caching does not disable Read caching for NFS aysnc threads or VM system for consistency caching, but does require new getattr RPC call to Server for each check.

### **NFS CLOSE-to-OPEN CACHE CONSISTENCY:**

NFS Client applications opens files using GETATTR or ACCESS and write back any pending changes to Server when closing file, as well as provides opportunity for Server to report any write errors that may occur. This is done to provide Close-to-Open cache consistency. Weak Cache Consistency (WCC) is an NFSv3 feature that allows clients to check for attribute changes to a file before and after operations are made, though this method is not 100% reliable and can lead to stale data, though Linux no longer uses WCC. Linux uses NOAC mount option to achieve cache coherency by disallowing client file attribute caching, forcing the Client to check with the Server before changes are made.

## **NFS SERVER CACHING:**

- Inode cache, containing file attributes (speeds up NFS get and set operations)
- Directory Name Lookup Cache (DNLC)—caches directory entries to reduce pathname resolution—works at VFS layer
- Buffer cache used for data read from files—for NFSv2, writes are not cached, for NFSv3 writes are not cached unless the NFS stable flag is set to off

## **CELERRA NFS LOCKS:**

Celerra notifies Clients of locks that they previously had, after failover or failback. This is normal NFS Server behavior. Clients receive a 45sec grace period to reclaim locks. Implications here are that failover + grace period = about 75sec. Some applications may not respond to this length of outage. The 45sec “grace period” is not yet configurable.

## **UNCACHED WRITE MECHANISM:**

**\$ server\_mount server\_2 –option rw,uncached fs1 /fs1**

**Note:** Use this mount option to enhance performance for database applications with many connections to a large file for NFS.

**NFSSTAT:** Generally used for troubleshooting Networking/Performance Issues

**Badxid ~timeout:** Usually an indicator of a slow Server

**Badxid ~0:** Dropped packets between NFS Client & Server in Call or Reply

**Nfsstat -m:** Useful to determine NFS mount options

**Server Statistics:** **\$nfsstat -s** [displays server stats, # NFS RPC Calls Received and Rejected {badcalls}]

Calls=total RPC calls from clients

Badcalls=number of calls rejected by RPC layer [Might indicate overloaded network]

Nullrecv=number times RPC call not available

Badlen=number RPC packets truncated or damaged

Dupreqs=number duplicate RPC calls

Xdrccall=number RPC calls whose XDR header could not be decoded (External Data Representation)

writes>than 5% may indicate a problem

readlink>than 10% may indicate excessive symbolic links problem

getattr>than 40% indicates need to increase DNLC [Directory Name Lookup Cache--Speeds up name to inode mapping lookups]

\$vmstat -s for cache hit rate] and Inode Cache

**Client Statistics:** **\$nfsstat -c**

Calls=total calls made to NFS

Badcalls=number of calls rejected by RPC layer

Retrans=number calls retransmitted due to timeouts [>than 5% of total calls means requests aren't reaching server]

Badxid=number of times Server's reply was taking too long; Server Not Responding or other NFS Program Errors [If this value is approx. 0 may mean network is dropping requests [reduce rsize and wsize]; If value is large, then Server is taking too long

Timeouts=number times call timed-out while waiting for Server reply

Null>0 means Automounter retrying to mount too frequently

**NFS Statistics for Mounted FileSystems: \$nfsstat -m [Client mount status information]**

**\$nfsstat -m** [Useful for determining Server name and address, current NFS Read/Write sizes, retransmission count, hard/soft mount, and other mount status information of Client]

“NFS Server Not Responding”—Increase “timeo” parameter in /etc/vfstab by doubling the value to start with

Lookups>80; Reads>150; or Writes>250—Requests are taking too long to service [slow network or slow server]

**Note on NFSSTATs:** High Client “retrans” and “Timeouts” may indicate networking issues

## **USING NFSSTAT ON SOLARIS/LINUX CLIENTS:**

**#nfsstat -m** [Will show remote mounted filesystems, protocol in use, NFS Version 2 or 3, and Read/Write Transfer Size, such as 32k; It will also tell you what the NFS timeout values are for minor & major timeouts]

**#nfsstat -rc** [Will display BadXid and Timeout Stats for NFS—if these two values are equivalent, may indicate Server Not Responding problem, resulting in Clients sending duplicate NFS requests; If BadXid near zero but Timeout value is large, would indicate a network problem resulting in packets being dropped]

**#nfsstat -cz** [If gathering statistics, run this command first to zero out historical information]

## **Other NFSSTAT Switches:**

**#nfsstat -cnr** [Client NFS & RPC Information, such as NFS & RPC Calls made and rejected; -n NFS -r RPC]

**#nfsstat -snr** [Server NFS & RPC Information; -n NFS -r RPC]

**#nfsstat -z** [zeroes out statistics]

**SOFT MOUNTS:** Soft-mounts are typically used for Read-Only mounts—a key indicator of a soft-mounted filesystem would be an NFS “RPC Timeout”—client retries a number of times before giving up.

## **NFS TIMEOUT MESSAGES:**

SERVER NOT RESPONDING—Client sees major timeout error on hard-mounted systems

RPC TIMEOUT—Client will only retry the connection a number of times before timing out—soft-mounted systems

**Note:** Timeout Errors can be adjusted via the “timeo” option on the Client

## **INCREASING NFS PERFORMANCE:**

### **USING NFSv3 V. NFSv2:**

#### **Use of TCP v. UDP Transport Protocol:**

Since UDP is connectionless, this transport protocol works best over clean and pristine networks. For WAN networks, or busy networks with slower servers, TCP might be best because it will reduce number of retransmissions. TCP only has to retransmit the frame that was lost—UDP needs to retransmit the whole Datagram, which can be a large number of packets. Duplicate XIDs as seen by the RPC layer would indicate a need to retransmit UDP. Also with UDP, Server cannot slow down or ‘flow control’ the Client, meaning that datagrams will be discarded and all needed to be retransmitted. TCP can use congestion avoidance, slow start, and zero window advertisement to control flow, UDP does not. TCP can use fast retransmission at Layer 4 where UDP relies on Layer 7.

#### **Write Throughput:**

Increased because the number of write requests made to server are aggregated, then written to server cache as “safe asynchronous writes”, which can reduce number of overall disk I/O requests to a Server

#### **Read Throughput:**

Sequential ‘read’ operations on client can be enhanced by caching file data locally from Server

Reduced File Attribute Requests: NFSv3 Servers return file attributes for all operations—Clients cache this information and less likely to have to ‘re-request’ file attribute information as a result

#### **Increased NFS BufferSize:**

NFSv2 only supported NFS buffer sizes of 8192kb

NFSv3 supports larger data transfer sizes for “read/writes” of 32k—provides better “read/write” performance

#### **Reduced Directory Lookups:**

Server returns all File Names listings and File Attributes in one operation v. piecemeal method in NFSv2

## **NFS VERSION 2 ERRORS:**

NFSERR\_PERM=1, Not owner--Caller does not have the correct ownership to perform the requested operation.

NFSERR\_NOENT=2, No such file or directory--does not exist.

NFSERR\_IO=5, Some sort of hard error occurred when the operation was in progress--disk error, etc.

NFSERR\_NXIO=6, No such device or address.

NFSERR\_ACES=13, Permission denied. The caller does not have the correct permission to perform the requested operation.

NFSERR\_EXIST=17, File exists. The file specified already exists.

NFSERR\_NODEV=19, No such device.

NFSERR\_NOTDIR=20, Not a directory. The caller specified a non-directory in a directory operation.

NFSERR\_ISDIR=21, Is a directory. The caller specified a directory in a non-directory operation.

NFSERR\_FBIG=27, File too large. The operation caused a file to grow beyond the server's limit.

NFSERR\_NOSPC=28, No space left on device. The operation caused the server's file system to reach its limit.

NFSERR\_ROFS=30, No space left on device. The operation caused the server's file system to reach its limit.

NFSERR\_NAMETOOLONG=63, File name too long. The filename in an operation was too long.

NFSERR\_NOTEEMPTY=66, Directory not empty. Attempted to remove a directory that was not empty.

NFSERR\_DQUOT=69, Disk quota exceeded. The client's disk quota on the server has been exceeded.

NFSERR\_STALE=70 The fhandle given in the arguments is invalid--the file referred to by that file handle no longer exists, or access to it has been revoked. The fhandle is the file handle passed between the server and the client. All file operations are done using file handles to refer to a file or directory. The file handle can contain whatever information the server needs to distinguish an individual file. A filehandle that consists of 32 zero bytes is called the public filehandle. It is used by WebNFS clients to identify an associated public directory on the server.

NFSERR\_INVAL The fhandle given in the argument does not refer to a symbolic link.

NFSERR\_NOSPC No space left on device. The operation caused the server's file system to reach its limit.

**Note:** We no longer support WebNFS!

## **NFS VERSION 3 ERRORS:**

NFS3\_OK = 0 Indicates the call completed successfully.

NFS3ERR\_PERM = 1 Not owner. The caller does not have the correct ownership to perform the requested operation.

NFS3ERR\_NOENT = 2 No such file or directory. The file or directory name specified does not exist.

NFS3ERR\_IO = 5 I/O error--a hard error occurred when the operation was in progress. This could be a disk error, for example.  
NFS3ERR\_NXIO = 6 No such device or address.

NFS3ERR\_ACES = 13 Permission denied. The caller does not have the correct permission to perform the requested operation. Contrast this with NFS3ERR\_PERM, which restricts itself to owner permission failures.

NFS3ERR\_EXIST = 17 File exists. The file specified already exists.

NFS3ERR\_XDEV = 18 The caller attempted to do a cross-device hard link.

NFS3ERR\_NODEV = 19 No such device.

NFS3ERR\_NOTDIR = 20 Not a directory. The caller specified a non-directory in a directory operation.

NFS3ERR\_ISDIR = 21 Is a directory. The caller specified a directory in a non-directory operation.

NFS3ERR\_INVAL = 22 Invalid argument or unsupported argument for an operation. Two examples are attempting a READLINK on an object other than a symbolic link or attempting to SETATTR a time field on a server that does not support this operation.

NFS3ERR\_FBIG = 27 File too large. The operation would have caused a file to grow beyond the server's limit.

NFS3ERR\_NOSPC = 28 No space left on device. The operation would have caused the server's file system to exceed its limit.

NFS3ERR\_ROFS = 30 Read-only file system. A modifying operation was attempted on a read-only file system.

NFS3ERR\_MLINK = 31 Too many hard links.

NFS3ERR\_NAMETOOLONG = 63 The filename in an operation was too long.

NFS3ERR\_NOTEMLTY = 66 An attempt was made to remove a directory that was not empty.

NFS3ERR\_DQUOT = 69 Resource (quota) hard limit exceeded. The user's resource limit on the server has been exceeded.

NFS3ERR\_STALE = 70 Invalid file handle. The file handle given in the arguments was invalid. The file referred to by that file handle no longer exists or access to it has been revoked.

NFS3ERR\_REMOTE = 71 Too many levels of remote in path. The file handle given in the arguments referred to a file on a non-local file system on the server.

NFS3ERR\_BADHANDLE = 10001 Invalid NFS file handle. The file handle failed internal consistency checks.

NFS3ERR\_NOT\_SYNC = 10002 An update synchronisation mismatch was detected during a SETATTR operation.

NFS3ERR\_BAD\_COOKIE = 10003 A REaddir or REaddirplus cookie is stale.

NFS3ERR\_NOTSUPP = 10004 The operation is not supported.

NFS3ERR\_TOOSMALL = 10005 The buffer or request is too small.

NFS3ERR\_SERVERFAULT = 10006 An error occurred on the server, which does not map to any of the valid NFS Version 3 protocol error values. Clients based on an XPG system may choose to translate this to EIO.

NFS3ERR\_BADTYPE = 10007 An attempt was made to create an object of a type not supported by the server.

NFS3ERR\_JUKEBOX = 10008 The server initiated the request, but was not able to complete it in a timely fashion. The client should wait and then try the request with a new RPC transaction ID. For example, this error should be returned from a server that supports hierarchical storage and receives a request to process a file that has been migrated. In this case, the server should start the immigration process and respond to client with this error.

## **CELLERA NFS ERRORS AND CAUSES:**

2006-05-02 13:05:34: NFS: 3: checkExportedByHandle: nodeFromHandle failed with status 9 for client 10.203.3.53

**Note:** checkExportedByHandle message can occur for a number of reasons:

→Occurs when Quotas treeid conflict is on the mountpoint of the file system

→Can occur if path is no longer exported

→Can occur if file system is no longer mounted

2006-04-13 13:21:09: UFS: 3: foundNode(valid), with treeId 5 different than passed treeId 1,please umount & re-mount fs 237 from nfs clients

**Note:** Can occur if Quotas treeid conflict is on the filehandle and mountpoint is o.k.

## **CELLERA BACKUP SOLUTIONS:**

### **I. MANUAL/LOCAL TAPE BACKUPS:**

--backups based on "server\_archive" PAX [Portable Archive Interchange] and standard unix formats such as CPIO/TAR

--backups do not go over network, thus, no network traffic

--direct Symm to Celerra to Tape connections via SCSI or Fibre

--no Scheduling, Cataloging, or TLU support or Media control

--provides for multi-protocol support, backing up both CIFS & NFS attributes using "server\_mt" commands

--conducted as either a Full or Incremental "Logical" backup

--Fibre Channel tape support only for LUNS 0-7

--MD5 authentication for NDMP now supported with CFS 4.0

--CFS 4.0 supports Level 10 NDMP Incremental Backup

--Celerra supports (2) tape drives per controller for a total of (4) Tape Drives per DM

## **MULTI-PROTOCOL BACKUP SUPPORT:**

Celerra supports Backup & Restore of multiple protocols (CIFS & UNIX) using Server\_Archive or NDMP

### **NDMP PAX:**

TAR-like archive protocol based on standard UNIX tape formats, provides file-level backup and recovery [server\_archive]

### **TAR:**

PAX format traverses file tree in depth-first order

### **NDMP DUMP:**

Veritas-style PAX backup by inode order vs. tar tree-style backup (mixed width-first depth-first order)

### **NDMP CCB:**

High-speed raw image backup

## **SERVER ARCHIVE COMMANDS:**

#server\_archive commands using tar/cpio/emctar formats. Uses Dart PAX technology [Portable Archive Interchange]

**Note:** Default format used with server\_archive is “ustar”. Ustar is an extended tar interchange format from the -p1003.2 standard, with a default block size of 10,240 bytes.

**\$server\_archive server\_2 -w -e device -x emctar -tvN /fullpath**

[contents of tape]

**\$server\_archive server\_4 -v -e device**

[Write to tape]

**#server\_archive server\_2 -w -e tape1 -x emctar -tvN /home/user/file**

[restore archive]

**#server\_archive server\_2 -r -f /fullpath -e device**

**Note:** Server\_archive -v -e functions broken in NAS 5.2/5.3—requires server reboot

## **SERVER MT COMMAND: \$server\_mt**

Used to perform manual tape operations--rewinding, unloading, etc, & to verify status of communications to tape drive.

### **REWINDING TAPE DRIVE:**

**\$server\_mt server\_4 -f c1t4l0 rewind**

**\$server\_mt server\_4 -f tape2 rewind**

### **COMMUNICATING TO TAPE DRIVE:**

**\$server\_mt server\_4 -f c128t0l1 status**

Device name: /dev/c128t0l1

Product Id: ULTRIUM06242-XX

Block size: 0

Block number: 1

**Note:** Following output means that the tape device cannot be read—i.e., empty, not defined, not cabled, etc.

Device Not Ready

Device Not Ready

## **CAN THE SERVER MT COMMAND DETERMINE & SET TAPE DENSITIES ON MEDIA?**

Answer: NO. Some Unix O/S's allow for the querying and setting of tape compression attributes, aka "multi density support".

### **With Solaris the following (4) commands can determine density settings for a DLT/7000:**

mt -f /dev/rmt/0l status -->20GB Uncompressed

mt -f /dev/rmt/0m status -->20GB Compressed

mt -f /dev/rmt/0h status -->35GB Uncompressed

mt -f /dev/rmt/0u status -->35GB Compressed

**Note:** When using these commands, only one will return without error, indicating the compression density mode on that tape.

How do I force a specific mode, usually the highest performance mode available for the tape?

On Solaris, just append an "l", "m", "h", or "u" to the /dev/rmt/{n} format device name to specify tape density.

l=20GB m=20GB compressed ~40GB h=35GB u=35GB compress ~70GB [DLT7000 Example]

**Cause:** Celerra uses "auto-sense" mode and defaults to tape density being loaded—it cannot manipulate or force specific densities

**Fix:** The "server\_mt" command can only manipulate & detect tape drives for the Celerra. A workaround is to load all tapes onto a general purpose Unix or NT system and write a dummy record, selecting the proper density/compression pseudo-device alias name. Once these tapes are pre-formatted, then they can be unloaded, and assigned to the Celerra NDMP media pool.

## **CELERRA SERVER ARCHIVE:** [For more detail on server\_archive, use #info server\_archive]

--Server\_archive reads, writes, and lists archive files and directory hierarchies & supports a variety of different formats

--Cannot be used to backup or restore between Servers

--Server\_archive uses PAX (Portable Archive Interchange) & other standard UNIX tape formats—TAR, CPIO

--Server\_archive offers multiprotocol backups of both Unix & Windows attributes

--PAX is the subsystem that provides both NDMP & Server\_archive services for Celerra

**Note:** *Default format used with server\_archive is “ustar”.* Ustar is an extended tar interchange format from the -p1003.2 standard, with a default block size of 10,240 bytes.

## **BACKUP ARCHIVE FORMATS:**

**Ustar:** Unix Standard called 'extended tar interchange'—Celerra's Default format referenced in -p1003.2

Default blocksize is 10,240 bytes and max pathnames are 250 characters (150 char. for basename, 100 for filename)

**Emtar:** EMtar is the format of data written to disk or tape through PAX, and is not valid for Veritas or other vendor applications. Can be used to backup CIFS attributes. Not compatible with "ustar". Can "archive" files > than 8GB to an archive name. Pathnames are limited to 3070 characters. Not -p1003.2 compatible. Otherwise performs as Ustar.

**Caution:** Backing up Celerra filesystems to an NT box destroys UNIX file attributes

**Cpio:** Extended interchange format found in -p1003.2 standard. Default blocksize is 5120 bytes.

**Tar & PAX:** Tar is the old BSD format found in BSD4.3 and is what is used by Backup vendors. Default block size is 10240 bytes. Pathnames must be 100 characters or less. Only regular files, directories, & hard & soft links are archived. Backup methodology goes from bottom of directory tree to top—depth first order. Tar sends file details with full path names.

**Dump:** This is also the "server\_archive" format and traverses file system in mixed width-first, depth-first order. Dump sends file history in form of inodes and file names as a tree.

**NDMP:** NDMP Backups generate “emtar” data images or NDMP Dump formats, which can be read by ‘server\_archive’

## **TYPICAL SERVER ARCHIVE FORMAT RESTRICTIONS:**

--file pathname length

--file size

--link pathname length

--file type

## **ARCHIVING FILES TO TAPE:** [Tape direct-attached to DM]

**\$server\_archive server\_4 -w -f /dev/c1t4l0 -v /fs01** [Backs up files to tape device file]

**\$server\_archive server\_4 -f /dev/c1t4l0 -v** [Lists files from tape device file]

**\$server\_archive server\_4 -r -f /dev/c1t4l0 /fs01** [Restores file to tape device file]

**\$server\_mt server\_4 -f c1t4l0 rewind** [Rewinding tape]

**\$server\_mt server\_4 -f c1t4l0 status** [Tape drive status]

## **MIGRATING & ARCHIVING DATA TO TAPE:** [Using either Tar or Cpio formats]

**Note:** Useful for backing up files from network computer to tape, & then restoring to Celerra Filesystem

### **Archiving Using Relative Path:**

\$tar cvf /dev/rmt/0

### **Archiving Using Absolute Path:**

\$tar cvf /dev/rmt/0 /full\_pathname

### **Listing Archive Files from Tape:**

\$tar tvf /dev/rmt/0

### **Listing Archive Files from Tape Using Server Archive:**

\$server\_archive server\_2 -r -f c1t4l0 -v

### **Restoring From Tape Using Server Archive & Relative Path:**

\$server\_archive server\_2 -r -f c1t4l0 -s, ^ ., /path\_name\_new,

### **Restoring From Tape Using Server Archive & Path Beginning with Dir:**

\$server\_archive server\_2 -r -f c1t4l0 -s, ^ ., /path\_name\_new,

### **Restoring From Tape Using Server Archive & Absolute Path:**

\$server\_archive server\_2 -r -f c1t4l0 -s, ^ /path\_name\_new,

## **USING SERVER ARCHIVE TO LIST EMCTAR CONTENTS:**

**\$server\_archive server\_3 -f /fs01**

## **USING SERVER ARCHIVE TO BACKUP & RESTORE:**

### **Writing From Tape to FileSystem:**

**\$server\_archive server\_x -w -J -e tape1 /cifs/homedirs**

**Note:** This will backup UNIX/NT Names + Special NT Attributes + ACLs

**Archiving CIFS Attributes From One FileSystem to Another:**

**\$server\_archive server\_3 -J -rw /fs01 /emc** [-J switch preserves CIFS Attributes]

**Archiving NFS Attributes From One FS to Another:**

**\$server\_archive server\_3 -w /fs01 -f /emc** [Backs up /fs01 using emtar to /emc]

**Restoring EMCTAR Archive to Original Location:**

**\$server\_archive server\_3 -r -f /emc /fs01** [Restores archive to original location]

**Archiving From FileSystem to Tape:**

**\$server\_archive server\_3 -w -f /dev/c128t0l1 /fs\_d3** [Backs up /fs\_d3 using emtar to tape]

**USING "SERVER\_ARCHIVE" TO BACKUP & RESTORE FROM TAPE:**

**Conducting BackUp From File System to Tape Drive:**

1. Insert tape into drive and run status command

**\$server\_mt server\_4 -f c128t0l1 status**

2. Rewind Tape & run status command again [Need to see "Block number: 0"]

**\$server\_mt server\_4 -f c128t0l1 rewind**

3. Conduct Backup To Tape:

**\$server\_archive server\_4 -w -f /dev/c128t0l1 /fs\_d3**

4. Restoring from Tape to File System:

**Note:** Run steps 1 & 2 prior to conducting restore

**\$server\_archive server\_4 -r -f /dev/c128t0l1 /fs\_d3**

**CAUTION:** In practical terms, "server\_archive" is an "all or nothing" Restore, meaning that it is impractical to restore individual files if you have a large backup file. "Server\_archive" can only "restore" to the original location as well.

**USING "SERVER\_ARCHIVE" TO BACKUP & RESTORE FILES:**

**Backups:** \$server\_archive server\_2 -v -w -f /fleetmnt/archive /testfs [Archive Name and Source Folder, respectively]

**Restores:** \$server\_archive server\_2 -r -i -f /fleetmnt/archive /testfs

**Note:** Using the "i" interactive switch will prompt you for each file that you would like restored [i.e., impractical if you had thousands of files because you cannot specify an individual file by path]

**SERVER\_ARCHIVE SWITCHES:**

-r      Reads archive file from "archive name" and extracts specified files  
-w      Writes to "archive name" in standard input or format specified  
-r -w    Copies  
-0      Full referenced backup put into a reference file stored ./etc/BackupDates  
-e      archive\_name [Specifies archive name when it is a streamer]  
-f      archive\_file [Specifies archive name when it is a file]  
-i      interactive mode to specify files, etc.  
-k      will replace only "non-existing" files and will not overwrite existing files  
-I      Allows filenames to be translated into UTF-8  
-p      string [a, e, m, o, p ]  
-t      Resets access time to same time before server\_archive accessed files  
-J      Backs up, Restores, or Displays CIFS extended attributes [u w d]

**# info server\_archive** [for more complete detail of all switches]

**DATA MOVER RECORDS:**

Successful server\_archive operations, including NDMP tape operations which use the server\_archive function, records successful Full or Incremental Backups or Restores in the .etc directory of the DM: **./etc/BackupDates**

**\$ cat BackupDates |grep -i /fs00621/1/GRPF-HRS\_EnvelopeManagement**

|                                        |   |          |                     |
|----------------------------------------|---|----------|---------------------|
| /fs00621/1/GRPF-HRS_EnvelopeManagement | 0 | 3f2376f5 | 06:53:41 07/27/2003 |
| /fs00621/1/GRPF-HRS_EnvelopeManagement | 5 | 3f29fd6e | 05:41:02 08/01/2003 |

**II. NETWORK-BASED BACKUPS:**

--Generally speaking, NFS clients backup & restore Unix attributes, CIFS clients backup & restore CIFS attributes  
--tape devices typically attached to a Backup Server using standard backup products such as; EDM/Epoch, ADSM, Openvision, Cheyenne, Legato Networker, Veritas NetBackup, ARCServe  
--high network traffic load created using this method

--scheduling, cataloging, and TLU support provided  
--person performing backup must be member of Celerra's Backup Operator's Local Group  
--EDM involves backing up from Symm to DataMover and across network to EDM attached TLU  
  EMC Data Manager (EDM) 4.6/EDM 4.6 & EDM NT Client = NFS/CIFS backups, respectively

### **III. CELERRA BACKUP-to-DISK SOLUTIONS (LAN B2D or NDMP B2D):**

#### **CELERRA B2D:**

##### **Celerra offers two methods for backing up data to disk:**

NS700 LAN B2D → Requires configuration on Veritas or Legato Backup host to accomplish  
NDMP B2D → Requires configuration of VTLU, NAS 5.4, and NDMP Backups to disk-based storage  
Veritas NetBackup is LAN B2D qualified with v4.5+ and Celerra 5.4, set param cifs prealloc=6 for 512kb block writes  
Legato NetWorker is LAN B2D qualified with v7.0+

##### **FEATURES/RESTRICTIONS:**

VTLU configuration required for NDMP

Disks must be presented from Celerra

Server\_archive or server\_mt are not valid troubleshooting tools for VTLU configurations

VTLU requires dedicated file system

After backing up to disk with either LAN or NDMP B2D solution, data can be cloned to tape for offsite storage

##### **TROUBLESHOOTING:**

LAN B2D would require customer network investigation and traces

NDMP B2D would require configuration checks, file system layouts, etc.

### **IV. CELERRA NDMP PROTOCOL-BASED BACKUPS: NDMP=NAS 2.1.15.20 +**

##### **Intro:**

Network BackUp architecture based on a Client/Server model using NDMP protocol with backup software on NDMP Host Client, backing up using NDMP Server [Celerra]. NDMP Protocol is based on XDR encoded messages transmitted over TCP/IP. NDMP uses asynchronous XDR-encoded messages over bi-directional TCP/IP channels that are grouped together by NDMP Category or Interface (Such as SCSI, TAPE, DATA, etc). Actual Backup/Restore of Data is handled completely on the NDMP Server side, with Client Host Software providing control, etc

##### **BASIC NDMP BACKUP OPERATION:**

NDMP Client [NDMP Management SW] initiates Backups/Restores, indirectly accessing Tape devices via NDMP protocol interfaces. NDMP Client is not directly involved in any DATA movement--this is the NDMP Server's responsibility.

NDMP Client accesses tape via "pass through" commands.

NDMP Server does not require a special BackUp agent but uses the Media Agent provided by the NDMP Client instead and writes data to tape using "dump" or "tar" format.

**Note:** Celerra Data Movers serve as the "tape/media" Server, while NDMP Host serves as the "Console" providing Scheduling, Cataloging, and Tape Management functions.

##### **NDMP BackUp Flow:**

Data flows from Storage system to the DM to an attached Tape Library device, direct-attached, but not over network—only Backup SW control data for Scheduling, Cataloging, and TLU commands traverse network.

##### **CELERRA PAX SUPPORT:**

PAX is the Celerra subsystem that supports both NDMP and server\_archive services

PAX supports up to (4) concurrent archive streams

PAX code ensures that file names are the same during the RESTORE operation as in the original backup

**Note:** NAS 5.4.16.106 (see AR62002) will increase supported NDMP streams to 16 sessions.

##### **NDMP BEST PRACTICES:**

- Optimize file system layout when possible
- Use RAID-3 LUNs for large sequential IO for ATA drives
- Balance LUNs across SPs for file systems being backed up
- Limit IO from other applications while backing up or restoring file systems
- Ensure tape drives perform digital speed matching
- For DAR backups, ensure NMDP Client can handle history workload
- Use supported backup vendors and TLU solutions
- Enable CLARiiON read cache for prefetching
- Use jumbo Ethernet frames for 3-way backups

##### **ENVIRONMENTAL VARIABLES ASSOCIATED WITH NDMP & VENDOR SUPPORT:**

|                  |                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------|
| BASE_DATE        | →Clientside, works with dump_date, ignores LEVEL if set                                                   |
| DUMP_DATE        | →Serverside, works with base_date for incremental backups                                                 |
| DIRECT           | →Set to Yes for DAR                                                                                       |
| EMC_EDIR         | →use to exclude directories from backup, uses filter.numDirFilter (1-50)                                  |
| EMC_EFILE        | →use to exclude files or filetypes from backup, uses filter.numFileFilter (1-50)                          |
| EMC_OFFLINE_DATA | →Set to No by default to only backup offline attributes. Set to Y will backup attributes & data.          |
| FILESYSTEM       | →path to be backed up                                                                                     |
| HIST             | →Creates file history if set to y                                                                         |
| LEVEL            | →dump levels 0-10                                                                                         |
| OPTION           | →NT=NT attributes; LK=follow sym links; AT=preserve access times; MI/MC/MM=collision policy I18N restores |
| PREFIX           | →use in place of FILESYSTEM for backward compatibility                                                    |
| RECURSIVE        | →required for 5.5+, performs recursive restores when set to y                                             |
| SNAPSURE         | →uses SnapSure checkpoints for NDMP backups when set to y                                                 |
| TYPE             | →backup format tar, dump, or vbb                                                                          |
| VLC              | →Volume level copy to tape using RO file system; set to n by default                                      |

### **COMMENT ABOUT TLU (Tape Library Unit) SUPPORT:**

TLUs are not directly qualified by NAS, only Tape Drives are tested for support. However, the rule is that if the Backup Vendor software is listed in NSM as supported, if the Tape Drives and Bridges are listed as supported, and the TLU, Tape Drive, & Bridges are shown as supported by the Vendor software, then the entire configuration would be considered supported by NAS.

### **NAS 5.2 NDMP SUPPORT:**

#### **NASS:**

Thread that reads directories and file metadata and provides filenames to NASA thread via a Stat Buffer

#### **NASA:**

Archive thread that reads files and provides history information to NDMP Client

5.2 introduces multiple NASA threads for backups (not restores), see nThread parameter

5.3 introduces multiple nasA threads for Backups and for Restores

#### **NASW:**

Threads that write data to the tape unit

### **TROUBLESHOOTING NASW THREADS:**

#### **# .server\_config server\_2 -v "diag nasw"**

nasw00 No session found

nasw01 No session found

nasw02 No session found

nasw03 No session found

#### **# .server\_config server\_2 -v "diag tape"**

tape[0] No information found

tape[1] No information found

tape[2] No information found

tape[3] No information found

#### **USAGE STATEMENTS:**

#### **# .server\_config server\_2 -v "diag help"**

1138037924: PAX: 3: Usage: diag nasw

1138037924: PAX: 3: diag nasw=0..3

1138037924: PAX: 3: diag nasw=reset

1138037924: PAX: 3: diag tape

1138037924: PAX: 3: diag tape=0..3

1138037924: PAX: 3: diag tape=dev\_name blksz=kb(64) total=mb(1024) pattern=rand/(text)/zero

### **NDMP BACKUP PERFORMANCE CRITERIA/NDMP TROUBLESHOOTING:**

--File System layout is a consideration when evaluating NDMP performance throughput

--Raid Group structure is also important on Clariion systems (Raid5 4+1 & clar\_r5\_performance)

--If using (4) NDMP streams, overlapping file systems sharing same spindles would impact performance throughput

--Disk Read performance is paramount in importance and needs to be tuned for sequential access by backup applications [Using prefetch and more read cache are things that may help with Clariion systems]

--File names and metadata are often stored in separate locations, often affecting backups of many small files

--Use of DAR imposes more overhead on NDMP Clients and impede performance

--Use Server\_Archive dump when testing backup performance of Celerra

## \$ time server\_archive server\_2 -w -x emctar -J -b 60k -e /dev/cc32t0l0 /fs1

--PAX Backup performance statistics are available for tuning and troubleshooting

--MPD file systems yield higher performance throughputs

--Use TAR vs. DUMP file ordering whenever possible [default mode for Celerra]

--Using HIST with many very small files can cause performance overhead issues with job history archiving

--Typical Backup performance for NAS 5.2 would be 12MB/sec or higher [50-112GB/hour]

**Note:** Typical performance with NAS 5.6 is 40MB/sec

--Upgrade to NAS 5.3--new params and defaults are in place [clarion queue depth, FS traversing threads, etc]

## **NDMP PERFORMANCE COMPONENTS:**

Server, BackEnd, Client, TLU, Bridge, Drive, Switch, Cables

## **TROUBLESHOOTING 5.2 NDMP:**

### **\$server\_config server\_x -v “printstats pax full”**

**Note:** Outputs stats on NASA & NASW threads. NASA contains the backup/archive file reader threads whereas NASW concerns writing to tape. Get & Put Pools serve as buffers between NASA & NASW threads.

\*\*\*\*\* SUMMARY PAX STATS \*\*\*\*\*

#### ---- NASA STATS ----

cifs\_ea new count: 515079, delete count: 515077

Total nasa wait nass time: 2464059 msec

Total time since last reset: 2666 sec

Tape device name: /dev/c80t0l0

nasa01 isnot doing backup

nasa02 isnot doing backup

nasa03 isnot doing backup

#### ---- NASW STATS ----

nasw00 BACKUP (in progress)

Session Total Time: 00:44:26 (h:min:sec)

Session Idle Time: 00:37:17 (h:min:sec)

KB Tranferred: 15603588 Block Size: 64512 (63 KB)

Average Transfer Rate: 5 MB/Sec 20 GB/Hour

Average Burst Transfer: 35 MB/Sec 124 GB/Hour

Write Block Counters: 246225/1451 (List/Direct)

Point-in-Time (over the last 10 seconds):

Rate=2 MB/Sec Burst=55 MB/Sec Idle=948 msec/sec

Get Pool: 0 buffers Put Pool: 639 buffers

## **Get Pool:**

Buffer used for thread used to write data . Value >than 0 indicates that write thread has data available and is not waiting. 0 value indicates thread is waiting. Increase nThread value if this value is 0 and NASA wait counts are low.

## **nThread:**

Specifies number of backup threads used by NASA file reader for backup stream. Increasing value with small file sizes may enhance performance.

## **Put Pool:**

Buffer used for file reading threads. When this value is 0, tape unit is limiting the backup speed. Non-zero values indicate buffers available for reader threads.

**Note:** NDMP backups use a data buffer size of 60kb [Use server\_mt status command to verify tape buffer size]

## **paxStatBuff:**

Number of buffers available to the NASS thread. Increase this value if NASA wait counts or wait times are high.

## **nPrefetch:**

Number of buffers that NASA thread will prefetch

## **paxWriteBuff:**

Total number of buffers in GetPool and PutPool. Increase this value if GetPool buffers fall to zero. This buffer helps keep data streaming to tape.

## **TAPE DRIVE TIMEOUT PARAM:**

**param streamio timeout=180** →Used to increase read/write timeout value when a tape drive takes too long to respond to a single tape command. For NAS 5.5, default value hex 708, 1800 decimal, in secs. = ½ hour.

**NAS 5.5 PAX PARAMS:**

| Name                       | Current    | Default    |                                                |
|----------------------------|------------|------------|------------------------------------------------|
| PAX.allowVLCRestoreToUFS   | 0x00000000 | 0x00000000 |                                                |
| PAX.checkUtf8Filenames     | 0x00000001 | 0x00000001 |                                                |
| PAX.dump                   | 0x00000000 | 0x00000000 |                                                |
| PAX.filter.caseSensitive   | 0x00000001 | 0x00000001 |                                                |
| PAX.filter.dialect         | " "        |            | →Use when restoring ascii-mode tape to I18N DM |
| PAX.filter.numDirFilter    | 0x00000005 | 0x00000005 |                                                |
| PAX.filter.numFileFilter   | 0x00000005 | 0x00000005 |                                                |
| PAX.noFileStreams          | 0x00000000 | 0x00000000 |                                                |
| PAX.readWriteBlockSizeInKB | 0x00000040 | 0x00000040 |                                                |
| PAX.scanOnRestore          | 0x00000001 | 0x00000001 |                                                |
| PAX.writeToArch            | 0x00000001 | 0x00000001 |                                                |
| PAX.writeToTape            | 0x00000001 | 0x00000001 |                                                |

**param PAX.nFTSThreads** →hex & decimal 8; number of threads used for single backup job—increase to reduce NASA thread bottleneck

**param PAX.nPrefetch** →hex & decimal 8; amount data each backup thread prefetches from disk before finishing file read & writing to tape

**param PAX.nRestore** →hex & decimal 8; number restore threads per job. Increasing can help restore speed improve

**param PAX.nThread** →hex 040, decimal 64; number of backup threads used

**param PAX.paxReadBuff** →hex 040, decimal 64; →number of buffers between threads that read data from tape (NASA) & threads that restore to disk (NASW). Increasing can enhance tape streaming and restore speeds.

**param PAX.paxStatBuff** →hex 080, decimal 128; →number of buffers between threads that send & receive metadata (NASA) and read data from disk (NASS). Increasing can increase speed of metadata info.

**param PAX.paxWriteBuff** →hex 040, decimal 64; no. buffers between threads that read file data (NASA) & write data to tape (NASW)

**CELLERRA NDMP SUPPORT:**

--With NDMP Version 4, NDMP Client=Data Management Application, and NDMP Server=Data Service Provider

--Provides multi-protocol backups/restores [NT Attributes require use of HIST=Y and OPTIONS=NT

--Scheduling, cataloging, and TLU support for up to (8) Tape Drives, but only (4) streams at any given time

**Note:** Driver can see a maximum of 16 tape devices down any given FA port

--NDMP dump uses a control and backup data path

--Recommended that tar backup be used with Celerra vs. dump backup

--High Capacity--minimal network traffic

--Higher capacity with up to 4-simultaneous backup streams to each datamover

--Centralized control & media management, separation of Control and Data paths.

--Local backup using SCSI Tape Libraries and/or drives

--Support for NDMP Drive sharing through SANs only over Fibre

--NDMP does not support Archive Bit method, only Date/Time stamp method (i.e., only mtime is changed for backups)

--NDMP does not support use of wildcard characters, or exclude/include options

--3-Way Backups/Restores, but only with other Celerra DMs

--I18N support with default translation dialect of 8859-1

--DAR restores with HIST=Y and DIRECT=Y set

--NDMP Restores are not supposed to be intercepted by Virus Checking and scanned, however, AR45645 proves that this was happening, and causing customer issues. Set following param to disable VirusChecking on NDMP Restores:

**param pax scanOnRestore=0** [NAS 5.3, 5.1.26.x, 5.2.15.x]

**NAS 5.4:**

Celerra has capacity for (16) NDMP Jobs (still only 4 concurrent streams) if using (2) NDMP buffers per session, or (32) Jobs if using only a single NDMP buffer.

**HOMOGENEOUS 3-WAY NDMP BACKUP:**

--Data Server and Tape Server are on different Data Movers, with NDMP Host, and data is backed up over the Network

**HETEROGENEOUS 3-WAY NDMP BACKUP:**

--Data Server is on DM but Tape Server is on non-Celerra Server, with NDMP Host Server, and data backed up over Network

--Veritas NetBackup 4.5

**BASIC NDMP COMMUNICATION INTERFACES:**

**CONNECT:** Interface is responsible for establishing NDMP connection between Server & Client, authenticating Client, and negotiating version to use (Secure MD5 digest using special param file entry or clear-text). Uses NDMP well-known port #10000.  
**CONFIG:** Interface where Client discovers NDMP Server configuration and attributes (Tape Drives, Jukeboxes, File Systems, Database)

**SCSI:** This interface is used to pass SCSI CDB (Command Descriptor Blocks) commands to a SCSI device & receive status back. NDMP Client software interprets the status and data information received via SCSI commands. NDMP client uses SCSI to control locally-attached jukeboxes. Called a “Pass through” SCSI device driver.

**TAPE:** This interface supports control of Tape Devices, such as positioning of tape read/write operations for Backups/Restores, & header & trailer file writes. Backup software uses Interface to maintain Tape Labels, Tape Format, Tape positioning.

**DATA :** NDMP client initiates Backups/Restores with this interface. Generates Backup image & retrieves data from this image. Handles parameters and formatting. Performs the actual task of "streaming" NDMP data to and from Tape.

**MOVER:** This interface controls the reading/writing of data from or to a tape device. During Backups, this interface reads data from DATA Interface, buffers into tape records, and then writes data to tape device. During Restores, this interface reads data from Tape Device and writes data to DATA Interface.

## **NDMP CLIENT/SERVER MESSAGES:**

NOTIFY: Used by Server to obtain Client response

FILE HISTORY: File-by-file record during Backups

LOGGING: Informational & diagnostic data to a log file

## **3-WAY NDMP BACKUPS/RESTORES: NDMP v.2**

BackUp Server initiates backup job to datamover, which reads data from Symmetrix and streams data over the network to a datamover connected to the tape device, which then receives the data stream and writes to tape, all using NDMP. As opposed to direct-attached local backup, both File System & Control Data traverse the network.

**Note:** 3-Way NDMP Backups are only supported where the Celerra DM servers as NDMP Tape Server (direct-attached). Port 1000 is used for listening for NDMP requests, while ports 10001 – 1004 are used for 3-way Backups and Restores. Local Backups/Restores do not use these extra ports.

**Example:** An NDMP Sun “Client” serves as the Backup Station accessing the NDMP Server (DataMover), which pulls the filesystem data from the Symm and pushes to the Tape Device Station.

**Caution:** Ensure “params” are set properly for all Servers involved with NDMP Backups, not just ones attached to Tape Drives!

NDMPv1: Local Tape Backup

NDMPv2: Remote Data Stream Backup from one DM to another

## **NDMP SUPPORT:**

### **NDMP v4 SUPPORT:**

--Supported with NAS NAS 5.2

**param NDMP maxProtocol=4** [Default setting for 5.2. Set to 1, 2, or 3 if customer is using other NDMP Version]

**param NDMP.maxProtocolVersion** 0x00000004 0x00000004 [NAS 5.5 syntax change]

--NDMP to run as TCP sevice on DART, listening on port 10000

--NDMP Client and Dart to negotiate protocol version for each backup/restore

--PAX implementation to be changed in order to change File History handling to conform to version 4

### **NDMP V2 & V3:**

--Both NDMP & Server\_archive allows for simultaneous backup or restore of NT/Unix attributes due to Logical-level vs. Volume-level file backup

--Default DataMover port for NDMP=10000

--Shared tape drives only over a SAN environment [only Legato & IBM Tivoli offers this]

--Total of (4) Tape Drives per DM

--DM can host up to (4) simultaneous BackUp jobs

--Windows Backups require that User account be added to Celerra’s local “Backup Operator’s Group”

--NDMP uses Tar or Dump formats to write to tape

## **NAS 5.5 RESTORE ISSUE ON BACKUPS CREATED WITH PRE-NAS 5.5:** AR84993

In certain cases, the combination of the DMA settings and the pre-5.5 backups sets both environmental variables, Direct=N and Recursive=N, in which case the restore only restores the directory, and not the subdirectories and files. In order to circumvent this issue, turn on the following param on the DM to allow full recursive restore, new with NAS 5.5.25.1 +:

**param NDMP.forceRecursiveForNonDAR=1**

**DAR:** Direct Access Restore

**DDAR:** Directory Level DAR restore—Not yet supported by DART 5.3 or lower, though Legato NetWorker V7.1.1 and Dart 5.1.11.300 or higher will restore directory permissions successfully. Both DAR & DDAR are NetApp implementations. NAS 5.5 introduces DDAR support.

**DDS:** Dynamic Drive Sharing, supported NAS 5.1 and above. Set following param to 0 if using DDS with NDMP vendors.

### # server\_param server\_2 -facility NDMP -info scsiReserve

server\_2 :

```
name      = scsiReserve
facility_name = NDMP
default_value = 1
current_value = 1
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range     = (0,1)
description = Do scsi reserve for NDMP tape open
```

### # server\_param server\_2 -facility NDMP -modify scsiReserve -value 0

Note: With NAS 6.0, the scsiReserve parameter is set to 0 by default, i.e., do not do scsiReserve

## **NDMP VENDOR MATRIX:**

### **A TEMPO TIME NAVIGATOR (Quadratoc):**

Version 3.7 SP0 p946 3-way & DAR NAS 5.1; SP0 P1110 for NAS 5.2.10+

Version 3.7.0.3 SP1 p1270—NDMPv3 tar format, 3-Way & DAR—NAS 5.3 only

Version 3.7.0.4 SP2 p1929—NDMPv3, tar, 3-way, DAR—NAS 5.4.21.4

Version 4.0 SP2 p1929—NDMPv3, tar-3-way, DAR—NAS 5.4.21.4

Version 4.0.1—NDMPv4, tar, 3-way, DAR, NAS 5.5 for limited features only

Version 4.1—V4, tar, 3-way, DAR, no DDS, NAS 5.5 core, NDMP2D, Integrated Checkpoints

Version 4.2 SPO P3267--V4; dump/tar; 3-way; DAR; DDS; DDAR; NAS 5.6; NDMP2d; Filters; Int. Ckpts; NVB

### **BAK BONE NETVAULT 7.0/7.1:**

Version 7.1+ SPE or 7.1.1 NDMP APM v6.3 with PCHR8 or 6.301 NDMP v4, 3-way, DAR, DDS, NAS 5.3.14.2

Version 7.1.1, NDMP APM 6.302 NDMP v4 dump format, 3-way, DAR, DDS, NAS 5.4 only

Version 7.1.2, V4, dump, 3-way, DAR, DDS, NAS 5.5 Core, NDMP2D, DDAR, Integrated checkpoints

Version 7.4.2, V4, dump, 3-way, DAR, DDS, NAS 5.5 Core, NDMP2D, DDAR, Integrated checkpoints, & VBB

Note: Celerra supports NDMP v4 in NAS 5.2+

Version 7.4.5 APM 6.5, V4, Dump, 3-way, DAR, DDS, NAS 5.5

Version 8.0 NDMP APM 7.0.6—V4; dump; 3-way; DAR; DDS; NDMP2D; DDAR; Int. Ckpts; NVB

Version 8.2 NDMP APM 7.1.5—“

### **BRIDGEHEAD HYPERTAPE:**

Version v3.1.3 NMDP Agent (v)—NDMP v3 dump/tar format, 3-way, DAR, DDS, NAS 5.4.19.4 only

Version 3.1.5 NDMP Agent v, ay—V3; dump/tar; 3-way; DAR; DDS

### **CA BRIGHTSTOR ENTERPRISE BACKUP (BEB):** v10.5-b2290 patch QO44763 Win2k

Supports NDMP v3, 3-Way, & DAR on NAS 4.2 & 5.1

Brightstor Enterprise Backup V10.5-b2290 patch QO44763 W2K NDMP v3, 3-way & DAR, NAS 4.2 & 5.1

V10.5 SP1 patch QO53005 W2K NDMP v3, 3-way & DAR, NAS 5.2

V10.5 SP1 patch QO57428/QO54460 NDMP v3, dump format, 3-way & DAR, NAS 5.3 only

Brightstor ARCserve Backup V11.0/11.1 NDMP v3 dump format, 3-way & DAR, DDS (v11.1), NAS 5.1 (V11.0), 5.2, 5.3

Note: BEB not qualified for NAS 5.4. & is being obsoleted (BAB r.11.1 does work with 5.4.15.2)

### **CA BRIGHTSTOR ARCSERVE BACKUP (BAB):**

V11.0 NDMP v3 dump format 3-way & DAR; NAS 5.1-5.3

V11.1 includes DDS support; NAS 5.3 only

V11.1 patches QO63594, QO72174, QO72924, QO73743 NDMPv3 dump format, 3-way, DAR, DDS, NAS 5.4 only

V11.5 patch Q076318 V3, dump, 3-way, DAR, DDS—NAS 5.4.21.4 only

V11.5 SP2 patch Q084383 V4, dump, 3-way, DAR, DDS, Core, NDMP2D, DDAR, Filters, Integrated Checkpoints NAS 5.5 only

V11.5 SP4 patch RO02596, RO06497 (bb) V4, dump, 3-way, DAR, DDS, Core, NDMP2D, DDAR, Filters, Integrated Checkpoints

V12.0 SP2 with T31A531, same as above NAS 5.6

V12.5 RO07441, RO09048, T36A558, T31A530, same as above NAS 5.6

### **COMMVAULT GALAXY:**

Version 5.0 SP1 & 5.9, NDMP v4, 3-way & DAR, NAS 5.2 & 5.3

Version 5.9 SP1 NDMP v4 dump format, 3-way & DAR; NAS 5.4 only

V5.9 SP4 update 671, v4, dump, 3-way, DAR, DDS—NAS 5.5 for limited features only

V6.1 SP1, v4, dump, 3-way, DAR, DDS—NAS 5.5 for limited features only

V7.0, V4, dump, 3-way, DAR, DDS, NAS 5.5 core, NDMP2D, DDAR, Filters, Int.Checkpoints

Note: Disable SCSI-3 Reservations if in use with CommVault

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

V7.0 SP4a—V4; dump; 3-way; DAR; DDS; NAS 5.6; NDMP2D; DDAR; Filters; Int.Ckpts; NVB; Tape Silvering

V8.0 SP1 updates 11638, 11823—Same as V7.0 SP4a

### **EDM:**

EMC Data Manager 4.6.1/5.0: NDMP v2; 3-Way; no DAR; no DDS; Dump format

EDM 4.6.1 = NDMP v2 with 3-way only for NAS 4.1.12.1, 4.2.9.0, 5.0

EDM 5.0 = NAS 4.2.18.2, 5.0 & 5.1; MPFS NOT supported

EDM v5.1 NDMP v2 dump format 3-way only, NAS 4.1.12.1, 4.2.18.2, 5.0, 5.1, 5.2, 5.3, 5.5 with EDM patch 9--PE510\_09

### **FUJITSU SIEMENS NETWORKER:**

V7.0 patch NSx70A001 NDMP v3, 3-way & DAR NAS 5.1

V7.1A00 patch NSx71A001 NDMP v3 dump/tar format, 3-way & DAR NAS 5.2 & 5.3

### **HP OMNIBACK II/HP DATA PROTECTOR:**

Omniback II 4.1: No 3-way, has DAR, NAS 2.2.53.4; NAS 4.0, 4.1, 4.2, 5.0

OpenView Storage Data Protector 5.0/5.1, NDMPv3 dump format, No 3-way, DAR; NAS 4.1 – 5.1 are all qualified

Version A.05.50 NDMPv4, dump, DAR--NAS 5.2, 5.3, 5.4, & limited features in 5.5

OpenView Storage Data Protector 6.0, v4, dump, DAR,--NAS 5.4 & limited features in 5.5, Core, NDMP2D, Filters, Int. Checkpoints

Data Protector version 5.5 is in qual process (HP DP 5.1 is not supported with NAS 5.2 or 5.3)

### **IBM TIVOLI TSM:**

Version 5.2 NDMP v3 dump format with DAR & DDS; NAS 5.1.9.4 – 5.4; No 3-way backups

IBM Tivoli Storage Manager Version 5.3 v3, dump, DAR, DDS—NAS 5.3, 5.4, and limited 5.5 features

V5.4 V4, dump, DAR, DDS, NAS 5.5 Core, NDMP2D, Int. Checkpoints

V5.5—V4; dump; DAR; DDS; Core 5.6; NDMP2D; Int.Ckpts

V6.1; V4, dump, no 3-way, DAR, DDS, CORE, NDMP2D, Integrated Checkpoints NAS 5.6

### **EMC NETWORKER with NDMP (Legato):**

V7.0 NDMP v3 dump/tar NAS 4.1 to 5.1

V7.1/7.1.1 NDMP v4 dump or tar format, 3-way, DAR, DDS, NAS 4.1 to 5.4

V7.2 NDMPv4, dump/tar format, 3-way, DAR, DDS, NAS 5.1 to 5.4

V7.3 NDMPv4, dump/tar, 3-way, DAR, DDS, NAS 5.2 – 5.4, & most features in 5.5

V7.4 V4 dump/tar, 3-way, DAR, DDS, NAS 5.5 core, NDMP2D, Filters, Int.Checkpoints, VBB

V7.4.1, same as 7.4 plus DDAR

V7.5—V4; dump/tar; 3-way; DAR; DDS; NAS 5.6; NDMP2D; Filters; Int. Ckpts; NVB; Tape Silvering

EMC NETWORKER Fast Start with NDMP:

V7.4 SP3—v4; dump/tar; 3-way; DAR; DDS; Core 5.6; NDMP2D; Filters; Int.Ckpts; NVB; Tape Silvering

V7.5, V4, dump, 3-way, DAR, DDS, CORE, NDMP2D, DDAR, Filters, Int.Ckpts, VBB, Silvering NAS 5.6

### **NEC WEBSAM NetWorker:**

V7.2.1 V4, dump/tar, 3-way, DAR, NAS 5.5 Core, NDMP2D

V7.4.1 V4, dump/tar, 3-way, DAR, DDS, NAS 5.5 all features (DDAR, Chkpnts, VBB, etc)

V7.5—V4; dump/tar; 3-way; DAR; DDS; Core 5.6; NDMP2D; DDAR; Filters; Int.Ckpts; NVB; Tape Silvering

### **ORACLE SECURE BACKUP:**

V10.1.0.2 (aa), v4, dump, 3-way, DAR, DDS—NAS 5.4.28.4 only

V10.1.0.3 (aa,ak) V4, dump, 3-way, DAR, DDS, NAS 5.5 Core & NDMP2D [No 5.6 support]

### **SYMANTEC BACKUP EXEC:**

v11.0.7170 V4, dump, 3-way, DAR, NAS 5.5 core, NDMP2D, DDAR, Int. Checkpoints

v12.0 (an)—V4; dump; 3-way; DAR; Core 5.6; NDMP2D at 5.6.43; DDAR; Int.Ckpts

v12.5 (an)—V4; dump; 3-way; DAR; DDS; Core 5.6; NDMP2D at 5.6.43; DDAR; Int.Ckpts

### **SYNCSORT BACKUP EXPRESS:**

v2.1.4D patch I-1634 for Solaris NDMP v3, 3-way & DAR, NAS 4.2.18.2

v2.1.5D NDMP v3 3-way & DAR, NAS 5.1

v2.1.5D NDMP v3 3-way, DAR, DDS NAS 5.2

v2.2.1 NDMP v3 3-way, DAR, DDS, NAS 5.3

v2.3.1 NDMPv3 dump/tar, 3-way, DAR, DDS, NAS 5.4 only

v2.35.2, v4, dump/tar, 3-way, DAR, DDS—NAS 5.5 only and all features [No 5.6 support]

### **SYMANTEC VERITAS NETBACKUP:**

Version 3.2 JO820443 & SO820446 NDMP v2 dump/tar 3-way

Version 3.4 JO820443; NAS 4.1 only

Version 4.5 MP1 NDMP v3 dump/tar 3-way; NAS 4.2.9.0, 5.0, 5.1

Version 4.5 FP3 DAR, NAS 5.1 – 5.3

Version 5.0 MP1/v5.1 NDMPv4 dump/tar format, 3-way & DAR; NAS 5.1 – 5.4

Version 6.0 v4, dump/tar format, 3-way, DAR, DDS; NAS 5.2 – 5.4, and most features in 5.5

## **Supported Tape Devices/Drives:**

**SCSI Protocol over single Fibre or SCSI Cable HVD Only** [LVD is NOT supported]

### **QUANTUM:**

DLT 4000, 7000, 8000 SCSI or SCSI/FC Bridge for HVD—NAS 5.0 to 5.5

SDLT 220 SCSI or SCSI/FC LVD—NAS 5.0-5.5

SDLT 320 or 600--SCSI or SCSI/FC LVD—NAS 5.1-5.5

LTO-3—supported SCSI & Fibre NAS 5.1-5.6

### **EMC CDL:**

**Note:** See EMC Support Matrix for the latest information on EMC CLARiiON Disk Library solutions. Default emulation is ATL-P3000 with (4) DLT-7000 drives for pre-version 2.x systems. Post 2.x systems have expanded the emulation types.

Latest release CDL 4000 Series Rev 3.0 for DL310, 710, 720, & 740 with Flare 19 patch 040 minimum, NAS 5.4 & 5.5

### **EXABYTE SERIES:**

85xx series & Mammoth-2: SCSI & FCSW/FCAL or SCSI/FC HVD Bridge or Native NAS 4.0 – 5.5

### **HP:**

LTO-1; SCSI 5.1 – 5.4; SCSI/FC with LVD

LTO-2; SCSI 5.1 – 5.5; FCSW/FCAL 5.2 – 5.5; SCSI/FC Bridge with LVD or Native

LTO-3; NAS 5.1-5.5 for SCSI; NAS 5.1-5.5 for FCSW, or SCSI/FC with LVD

SDLT 320; SCSI 5.1-5.5, SCSI/FC LVD

SDLT 600 5.1 – 5.6 Fibre

### **IBM:**

MagStar 3590 SCSI or FCSW/FCAL or SCSI/FC Bridge with HVD or Native

3592-J1A FCSW/FCAL or SCSI/FC Native

Ultrium LTO-1 SCSI 5.0 – 5.5, FCSW/FCAL 5.0-5.5, or SCSI/FC Bridge with HVD or Native

Ultrium LTO-2 SCSI 5.1 – 5.5, FCSW/FCAL 5.1 – 5.5 or SCSI/FC Bridge with LVD or Native

IBM 3588 LTO-3 Ultrium SCSI for NAS 5.1-5.5, FC support for NAS 5.1 – 5.5 LVD or Native

LTO-4, 5.1 – 5.6 Fibre

### **SONY AIT:**

AIT-2 SCSI or SCSI/FC with LVD—NAS 5.0 to 5.5

AIT-3 SCSI NAS 5.1 – 5.5 or SCSI/FC with LVD

S-AIT FCSW/FCAL NAS 5.0-5.6 for FC only

AIT-4, 5.1-5.6, SCSI/FC LVD

### **STK:**

9840A or 9940A all SCSI or FCSW/FCAL NAS codes, or SCSI/FC with HVD or Native

9840B or 9940B FCSW/FCAL or SCSI/FC Bridge Native only

9840C FC only, NAS 5.0-5.6

10000A FC, NAS 5.0-5.6

## **FC-to-SCSI BRIDGES SUPPORT MATRIX:**

Chaparral 2620: NS Series LVD

CrossRoads 4200, 4150, 4250: NS Series HVD

CrossRoads 4450, 6000, 8000, 10000: NS or CNS Series LVD or HVD

HP M2402 NS or CNS Series LVD

HP e1200/e2400 LVD; HVD

Pathlight 3000 or 4000 ADIC NS Series LVD

Pathlight 5000 ADIC NS or CNS Series LVD

Quantum ATL FC 210 NS or CNS Series HVD

Quantum ATL FC 230 NS or CNS Series LVD

Quantum ATL FC 310, 420, 470 NS or CNS Series LVD

Quantum ATL FC 1202 NS & CNS

Spectra Logic G2 F-QIP: NS or CNS Series LVD

StorageTek SN3250, 3300, 3400 LVD & HVD [3250 not tested LVD]

**Purpose :** Convert FC Protocol to SCSI protocol. Sharing of FA ports between DMs & other hosts not supported!

**Note:** Quantum FC470 in arbitrated loop mode should have HARD ALPA port configured with range DC - EF

## **I/O VALUES FOR FIBRE TAPE DRIVES:**

**param streamio timeout=180**

**Note:** Celerra default timeout is 180 secs (3 minutes), 0xb4 hex. Increase this value for IBM LTO2 Fiber Ultrium drives to 30 minutes or 1800 seconds, as their timeout is 17 minutes. Caution, this param is only for fibre tape drives. NAS 5.1.25.0, 5.2.13.0, & 5.3.5.0 contain the new “param streamio” param, see AR57118. NAS 5.5 raises default to 708hex, or 1800 secs. in decimal.

### **NDMP TLU SUPPORT FOR CELERRA:** 3 Ways to Connect to TLU Robot

1. DataMover Fibre Channel or SCSI connectivity: NDMP Client routes commands to TLU via DataMover
2. IP LAN: NDMP Client controls TLU Robot directly over Network via commands
3. NDMP Client Direct Connection: NDMP Client directly connected to TLU [No LAN or DataMover communication]

### **NDMP INCREMENTAL BACKUPS:**

Performs backups based on file C-Time, not Archive bits

### **NDMP PARAMETERS FOR DART:**

**param NDMP bufsz=128**

**param PAX nbuf=8** [x \* 4 = y]

**Note:** **bufsz** is the max buffer size in kb for tape\_read and tape\_write operations from NDMP Client. When reading output of “param NDMP”, current value shows up as 20000 Hex, or 131072 bytes, which is 128KB.

#### **Typical Server Log Error When Exceeded:**

2002-10-12 19:55:36: NDMP: 3: Read count exceeds bufsz

**nbuf** is the preallocated buffer used by Celerra DART for backing up to tape or restoring from tape

**Note:** nbuf values must also be set the same on a 3-Way Server as for the Server directly-attached to tape! Nbuf memory buffers are allocated by DM during bootup, thus, changing values requires reboot to put into effect.

**param NDMP ntape=2** [ x \* 2 = y ]

**param NDMP md5=0** [purpose of this is to encrypt the NDMP passwd]

**param NDMP dialect=** [Default param value for I18N]

**Note:** NAS 5.3 and higher no longer contains the nbuf param--it is no longer applicable. The default ntape value is set to 4, sufficient to handle up to (4) attached tape drives, which is the Celerra limit for concurrent operations.

### **NAS 5.6.40.3:** MD5 Encryption

This NAS version enables MD5 encryption as the default, meaning that current backups and restores will fail unless an NDMP useraccount and password is setup on the Data Mover using server\_user.

**# server\_param server\_2 -facility NDMP -info md5**

server\_2 :

```
name          = md5
facility_name = NDMP
default_value = 1
current_value = 1
configured_value =
user_action    = none
change_effective = immediate
range         = (0,1)
description   = Turns on MD5 authentication for NDMP
```

**# /nas/sbin/server\_user server\_2 -add -md5 -passwd ndmp**

Creating new user ndmp

User ID: 505 →Select a UID

Group ID: 505 →Select a GID

Home directory:

Changing password for user ndmp

New passwd:

Sorry, password must be 6 characters or more

New passwd:

Retype new passwd:

**Note:** Used “ndmpndmp” as the new password since it had to be a minimum of 6 characters

**Adds line to Server ./etc/passwd file with encrypted password entry:**

ndmp:klvaFqcJuuRP.:505:505:HRb7QIpm2kdnpmndnqiIBLwaP0l::ndmp\_md5

### **DATA MOVER AUXILIARY FIBRE CHANNEL PORT SETTINGS NAS 5.6:**

## # server\_param server\_2 -facility fcTach -info linx\_speed\_aux0 -v

```
server_2 :
name      = linx_speed_aux0
facility_name = fcTach
default_value = 0x00008000
current_value = 0x00008000
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range      = (0x00001000,0x00008000)
description = Set the link speed for Fibre Channel tape port AUX0 (default auto-negotiate)
detailed_description
param fcTach linx_speed_aux0=0x8000 sets the tape backup port AUX0 to auto-negotiate the link speed. param fcTach
linx_speed_aux0=0x4000 sets the tape backup port AUX0 link speed to 1Gbps. param fcTach linx_speed_aux0=0x2000 sets the tape
backup port AUX0 link speed to 2Gbps. param fcTach linx_speed_aux0=0x1000 sets the tape backup port AUX0 link speed to
4Gbps. Note: This parameter applies only to the Celerra NS Systems.
```

**NAS 5.6.41:**

## # .server\_config server\_2 -v "param fcTach"

| Name                   | Location   | Current    | Default    |
|------------------------|------------|------------|------------|
| fcTach.linx_speed_aux0 | 0x02647b30 | 0x00008000 | 0x00008000 |
| fcTach.linx_speed_aux1 | 0x02647b34 | 0x00008000 | 0x00008000 |
| fcTach.linx_speed_be0  | 0x02647b28 | 0x00008000 | 0x00008000 |
| fcTach.linx_speed_be1  | 0x02647b2c | 0x00008000 | 0x00008000 |

→Aux ports default to Auto-sense, 0x8000

**AUX PORT LINK SPEED SETTINGS:**

**0x4000=1Gb (decimal 16384)**

**0x2000=2Gb (decimal 8192)**

**0x1000=4Gb (decimal 4096)**

**0x8000=auto (decimal 32768) →Code default since 5.3.15.3 & 5.4.12**

**CONFIGURING AUX FIBRE PORT SETTINGS ON NS DATA MOVERS (NAS 5.1-5.4):**

**Note:** Auxiliary port settings apply to NS Series Celerra--NS500, NS600, NS700, or X-Blade data movers. No aux ports on 510, 514 DM's, etc.

**param fcTach enable\_fabric\_aux0=0** →Indicates FC Arbitrated Loop, default Celerra setting for NAS 5.3 & 5.4

**param fcTach enable\_fabric\_aux0=1** →Set param value to 1 to hard-code support for FC-Switched Fabric

**fcTach.linx\_speed\_aux0 0x00008000** →Indicates auto-negotiate, default Celerra setting for NAS 5.3.15.3 & 5.4.12

**AUXILIARY PORT PARAMETERS FOR NAS 5.4.12:**

## # .server\_config server\_2 -v "param fcTach"

| Name                      | Location   | Current    | Default    |
|---------------------------|------------|------------|------------|
| fcTach.enable_fabric_aux0 | 0x017b98e4 | 0x00000000 | 0x00000000 |
| fcTach.linx_speed_aux0    | 0x017b98d0 | 0x00008000 | 0x00008000 |

**Note:** 5.4 removes references to aux1. Only aux0 link speed and topology can be specified, and defaults to auto-negotiate for speed & auto-sense for topology.

**AUXILIARY PORT PARAMETERS FOR NAS 5.5.79.0 (fabric is auto-sensed):**

| Name                   | Location   | Current    | Default    |
|------------------------|------------|------------|------------|
| fcTach.linx_speed_aux0 | 0x01fd4110 | 0x00008000 | 0x00008000 |
| fcTach.linx_speed_aux1 | 0x01fd4114 | 0x00008000 | 0x00008000 |

**AUX PORT INFO FOR NS500 SYSTEMS :**

The AUX port is an extension of the backend disk loop and can ONLY run at 2GB, not 1GB. AR61224 should address this issue in NAS 5.4. Port can be hard-coded to 2Gb/sec or left to auto-negotiate (0x8000).

**NAS 5.4 FCTACH PARAMS:**

## \$ server\_param server\_2 -f fcTach -i -all

```
server_2 :
name      = linx_speed_aux0
facility_name = fcTach
default_value = 0x00008000
current_value = 0x00008000
```

```

configured_value      =
user_action          = reboot DataMover
change_effective     = reboot DataMover
range                = (0x00002000,0x00008000)
description          = Set the link speed for AUX0 (default 1GBit)
name                 = enable_fabric_aux0
facility_name         = fcTach
default_value         = 0
current_value         = 0
configured_value     =
user_action          = reboot DataMover
change_effective     = reboot DataMover
range                = (0,1)
description          = Enables fabric support on port AUX0

```

**CHANGING PARAM SETTINGS USING SERVER PARAM :**

**\$ server\_param server\_2 -f fcTach -i -all**

```

server_2 :
name           = linx_speed_aux0
facility_name   = fcTach
default_value   = 0x00008000
current_value   = 0x00008000
configured_value =
name           = enable_fabric_aux0
facility_name   = fcTach
default_value   = 0
current_value   = 0
configured_value =

```

**\$ server\_param server\_2 -f fcTach -m enable\_fabric\_aux0 -v 1** →Example of change to FC Switched fabric

server\_2 : done

Warning 4126: server\_2 : You must reboot server\_2 for enable\_fabric\_aux0 changes  
to take effect.

**# server\_param server\_2 -f fcTach -m linx\_speed\_aux0 -v 0x4000** →Example of change to 2GB speed

server\_2 : done

**\$ server\_param server\_2 -f fcTach -i -all**

```

server_2 :
name           = linx_speed_aux0
facility_name   = fcTach
default_value   = 0x00008000
current_value   = 0x00008000
configured_value =
user_action     = reboot DataMover
change_effective = reboot DataMover
range          = (0x00002000,0x00008000)
description    = Set the link speed for AUX0 (default 1GBit)
name           = enable_fabric_aux0
facility_name   = fcTach
default_value   = 0
current_value   = 0
configured_value = 1
user_action     = reboot DataMover
change_effective = reboot DataMover
range          = (0,1)
description    = Enables fabric support on port AUX0

```

**PARAMS FOR I18N SUPPORT:**

**param NDMP convDialect=8859-1** [Default value; Change to convDialect=UTF8 to restore from non-ASCII backups]

**param NDMP dialect=UTF8** [Set this value when DM operates in I18N mode with UTF8 client backups/restores]

**Note:** Apply the above params in situations where UTF8 is being used and conversions are failing, as seen in the logs:

2005-07-03 21:06:36: NDMP: 6: NDMP client dialect is set (clientType=0xc4df4004) although NDMP.dialect is NOT

### **NDMP TUNING PARAMETERS (NAS 5.2 & 5.3+):**

**Example:** DM using two tape drives and buffer size of 128--recommended tuning settings

**param PAX paxStatBuff=1024** [Buffers between threads that send & receive metadata and Read data from disk]

**Defaults:** 128 for 507DM & 1024 for 510DM; Values range from 1-2048

**param PAX paxWriteBuff=640** [Buffers between threads that read file data and write data to tape]

**Defaults:** 64 for 507DM & 640 for 510DM; Values range from 1-2048

**param PAX nPrefetch=32** [Number blocks each backup thread prefetches from disk before finished file read and write to tape]

**Defaults:** 8 for 507DM & 32 for 510DM; Values range from 1-128

**param PAX nThread=64** [Number of backup threads]

**Defaults:** 16 threads for 507DM & 64 for 510; Values range from 1-256

**param PAX paxReadBuff** [Buffers between threads that read data from tape and restore to disk]

**Defaults:** 4 for 507DM & 16 for 510DM; Values ranges from 1-64

**Note:** Some PAX default values have been lowered from earlier NAS versions due to possibility to panic for out of memory

### **DETERMINING VALUES FOR 5.4 PARAMS USING SERVER PARAM:**

**\$ server\_param server\_2 -facility NDMP -info dialect -v** (with description)

server\_2 :

|                  |                            |
|------------------|----------------------------|
| name             | = dialect                  |
| facility_name    | = NDMP                     |
| default_value    | = "                        |
| current_value    | = "                        |
| configured_value | =                          |
| user_action      | = none                     |
| change_effective | = immediate                |
| range            | = '*'                      |
| description      | = Set the dialect for NDMP |

### **NAS 5.4 Values:**

|                          |            |            |            |                                                     |
|--------------------------|------------|------------|------------|-----------------------------------------------------|
| NDMP.bufsz               | 0x018f8d24 | 0x00000080 | 0x00000080 |                                                     |
| NDMP.convDialect         | 0x018f8ec4 | '8859-1'   | '8859-1'   | →Use when restoring ascii-mode tape to I18N DM      |
| NDMP.dialect             | 0x018f8ec0 | " "        | " "        | →Default “ “(null), or UTF8, use to match NDMP host |
| NDMP.maxProtocolVersion  | 0x00f06474 | 0x00000004 | 0x00000004 |                                                     |
| NDMP.md5                 | 0x018f8ec8 | 0x00000000 | 0x00000000 |                                                     |
| NDMP.scsiReserve         | 0x00f06478 | 0x00000001 | 0x00000001 |                                                     |
| NDMP.v4OldTapeCompatible | 0x00f0647c | 0x00000001 | 0x00000001 |                                                     |

### **SETTING NDMP VERSION:**

**param NDMP maxProtocolVersion=3** [Default version=4]

### **SETTING UP NDMP BACKUPS WITH LEGATO NETWORKER 7.2 WITH VTLUs:**

1. Create NDMP account

#/nas/sbin/server\_user server\_x –add –md5 –passwd ndmp

2. WebUI, create VTLU server using default values

3. Create Storage for VTLU: Rightclick new VTLU>properties>Storage Tab>New>Select VTLU file system created previously, Select number of tapes, use \*Slot for tape location, and LGTO for Barcode Prefix

4. VTLU properties>Drives: enter device names in Backup application

5. Create Auto-changer from Legato CLI:

C:\Program Files\Legato\lsrc\bin>jbconfig (Configure an Autodetected NDMP SCSI Jukebox)

**Note:** Enter Jukebox type 1, Tape Server IP address, User ndmp & password, Jukebox device name, NetWorker auto-cleaning, drive intended for NDMP--yes

6. Label Tapes Using Legato CLI: >nsrcjb –L –S <tape slot #>

7. Enter IP Address and Server name of DM in Windows>System32>drivers>etc>hosts file

8. Launch NetWorker: Programs>Legato NetWorker>NetWorker Administrator>NetWorker Groups>Manage Groups>rightclick groups Create>assign name

9. NetWorker Servers>rightclick on Windows system name>connect to this Server>Client Operations>Manage Clients>rightclick, Create>General Tab: Enter Server name, Save Set path to file system, Group name. Preferences Tab: Server name as alias, Storage

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
nodes, and Clone storage nodes, NDMP- Yes; Remote Tab: Remote access: “@”; Remote user: ndmp; Password: ndmpndmp; Backup command: nsrndump\_save –T tar; Application information: HIST=y, UPDATE=y, DIRECT=y

10. Create c:>bootstrap folder on Legato Windows Server
11. Create Boostrap from Legato GUI: Media Management>Devices>rightclick Create: Name: c:\bootstrap; Media type: file;
12. Rightclick Bootstrap device>Operations>Select Label
13. Perform manual backup: Networker Groups>Manage Groups>rightclick Group>Start  
→Click on Monitor tab to monitor progress  
→Rightclick Group>Details to see details of backup  
→Check Server Log

### **NDMP COMPATIBILITY ISSUE V3 vs. V4 ISSUE:**

Omniback 4.2 and Data Protector 5.0 have incompatibility between NDMP versions 3 & 4 in which restores of all appended backups will fail due to a tape positioning issue. Restores may complain about filemark problems:

“server\_archive: Cannot identify format. Searching...

ATTENTION! server\_archive archive volume change required...”

#### **NAS 4.2.18 + & 5.1.15 + Fix:**

1. Logon to CS
2. Add following to server param file: **param NDMP v4OldTapeCompatible=0**
3. Reboot

**Note:** Setting this param should allow restores of NDMP v3 Backups to work

#### **NAS 4.2.17.2 or 5.1.9.4 and Lower:**

1. Set following param in the “omnirc” file on the Omniback Client Host: **OB2NDMPFMV4=1**

**Note:** See NAS 5.1.15.3 Release Notes for more details. Also note that if you upgrade from 4.2.17.2/5.1.9.4, then this fix needs to be disabled and the previous fix applied

**TROUBLESHOOTING NDMP:** NDMP Messages categorized as SCSI, CONFIG, TAPE messages

### **INCREASING CELERRA NDMP LOGGING LEVELS FOR TROUBLESHOOTING:**

#### **TURNING NDMP LOGGING ON:**

**\$server\_config server\_2 “logsys set severity NDMP=LOG\_DBG2”**

**\$server\_config server\_2 “logsys set severity PAX=LOG\_DBG2”**

#### **TURNING NDMP LOGGING OFF:**

**\$server\_config server\_2 “logsys set severity NDMP=LOG\_PRINTF”**

**\$server\_config server\_2 “logsys set severity PAX=LOG\_PRINTF”**

**Note:** If implementing any 'DEBUG' levels of NDMP logging, it is highly recommended that you setup the following command to pipe the Server Log into a file so that all debug information is capture. Otherwise the Server Log wraps too quickly.

**\$nohup server\_log server\_3 -f -s > s3log.log & [\$jobs #fg %1 ctrl + c]**

**Server Log:** RPC, NDMP, SCSI/FC Errors [RPC=backup utility errors; NDMP=protocol errors; SCSI/FC=device errors]

**BackUp Software Logs:** [Depends on Platform being used for BackUps]

**Note:** NDMP only supports a single data stream!

NDMP does not require specific "client" software on DataMover--uses NDMP protocol

**\$server\_config server\_2 “printstats pax”**

**Note:** ‘getpool’ means waiting on backend while ‘putpool’ is waiting on tape drive

### **CREATING AN NDMP SERVER LOG CAPTURE SCRIPT:**

**1. # mkdir /nas/var/emc/ndmpleg**

**2. # vi ndmp\_capture.log and modify script to collect log from correct DM, chmod 755 to make executable:**

===== script template used to capture the server log. Pls modify as need=====

**#!/bin/sh**

**DM=server\_2**

**#**

**NAS\_DB=/nas**

**export NAS\_DB**

**STIME=`date '+%y%m%d%H%M'**

**\$NAS\_DB/bin/server\_log \$DM -s -a > /nas/var/emc/ndmpleg/log.\$DM.\$STIME**

**gzip /nas/var/emc/ndmpleg/log.\$DM.\$STIME**

**3. Create cronjob to run log capture script at 5 minute intervals:**

**#crontab -e**

**0-59/5 \* \* \* \* /nas/var/emc/ndmpleg/ndmp\_capture.log**

## **NDMP BACKUP LEVELS: LEVEL 0 and LEVELS 1-9**

### **LEGATO:**

Level 0 is a full backup of all files and directories into a “SaveSet” and is considered the lowest NDMP Backup level  
 Levels 1 – 9 are considered ‘differential’ and only backs up files that have changed since last lower level backup  
 i.e., Level 0 is taken, Level 1 will then backup all files that have changed since Level 0. Level 2 will backup files that have changed since Level 1, and so on.

## **NDMP INCREMENTAL BACKUPS/RESTORES:**

Supported Veritas 3.2/3.4 & Legato NetWorker 6.1 using BackUp Level 10

1. Verify NDMP Daemon is running on the Server: `$.server_config server_x -v "ndmp"`
2. Verify NDMP passwd account has been setup correctly: Test by FTP'ing to the DataMover [Resolved by NIS or local Passwd file]
3. Verify Devices seen by the DataMover [Tape & Jukebox]: Record device numbers for future reference  
`--server_devconfig server_x -p -s -n` [Probe verifies the SCSI devices on the bus]  
`--server_devconfig server_x -c -s -n`  
`--server_devconfig server_x -l -s -n`
4. Review NDMP Server Logs from either the NT or SUN Solaris Backup Server [Legato, Veritas, etc]

### **5. Review/Change Logging Levels on Celerra Server:**

`$server_config server_2 "logsys set severity NDMP=LOG_DEBUG"`

`$server_config server_2 "logsys set severity NDMP=LOG_DBG2"`

`$server_config server_2 "logsys set severity PAX=LOG_DBG2"`

[Higher logging level--use this]

[New logging parameter]

**Verify Logging On:** `$server_log server_2 -s -f ltail`

6. Conduct Testing/Operations to capture Verbose Server Logs

7. Turn off Celerra Server Verbose Logging:

`$server_config server_2 "logsys set severity NDMP=LOG_PRINTF"`

`$server_config server_2 "logsys set severity PAX=LOG_PRINTF"`

8. Verify NDMP & PAX Param Settings:

**Note:** Necessary to avoid Memory Fragmentation for NDMP/PAX Backup/Restores on DM's with Tape Drives Attached:

/nas/server/slot\_x/param

`param NDMP bufsz=128` [default: o.k. for most clients except Legato NetWorker!]

`param PAX nbuf=8 <number_for_pax>` [(2) tape drives \* 4 = 8]

`param NDMP ntape=2 <actual number of tape drives in use>`

**Warning:** *The above "params" are for NAS Code 2.2.46.0 and 3.1.3.0 and higher with (2) tape drives attached!*

**Note:** NAS 5.3 and higher no longer contains the nbuf param--it is no longer applicable. The default ntape value is set to 4, sufficient to handle up to (4) attached tape drives, which is the Celerra limit for concurrent operations.

## **NDMP/PAX PARAMS ON DATAMOVER:**

`# .server_config titanic -v "param NDMP"`

| <i>Name</i>   | <i>Location</i> | <i>Value</i>                                                            |
|---------------|-----------------|-------------------------------------------------------------------------|
| NDMP.dialect  |                 | 0x00b061f8 'latin1'                                                     |
| NDMP.ntdump   |                 | 0x00b061f0 0x00000001 / 1                                               |
| NDMP.md5      |                 | 0x0afe274 0x00000000 / 0                                                |
| NDMP.bufsz    |                 | 0x0afbe44 0x00020000 / 131072 [Actual value is 131,072 bytes, or 128kb] |
| NDMP.ntape    |                 | 0x01048a20 0x00000000 / 0                                               |
| NDMP.prefixNT |                 | 0x00afbcc8 '/.NT.'                                                      |

`# .server_config titanic -v "param PAX"`

| <i>Name</i> | <i>Location</i> | <i>Value</i>              |
|-------------|-----------------|---------------------------|
| PAX.nbuf    |                 | 0x01048558 0x00000000 / 0 |

## **DEFAULT PAX PARAMS NAS 5.2.x & 5.3:**

**param PAX paxStatBuff=1024**

**Note:** paxStatBuff specifies number of buffers between threads that send and receive metadata (NASA) and those that read data (NASS). Increasing this param value increases speed of metadata work. Values are 1-1024. Old default for 507 DM 128. 510 DM default is 1024 with latest 5.2 and new 5.3 code.

**param PAX paxWriteBuff=640**

**Note:** Number buffers between threads that read data (NASA) and write data to tape (NASW). Tape streaming can be enhanced with higher values. 507 Value=64. New 510 values=640.

**param PAX nPrefetch=32**

Note: Number blocks backup thread prefetches from disk before completing file read and write to tape. 507 value=8 510 value=32

**param PAX nThread=64**

Note: Number of backup threads. 507 value=16 510 value=64

**\$ server\_param server\_2 -f PAX -l**

server\_2 :

| name         | facility | default | current | configured |
|--------------|----------|---------|---------|------------|
| paxWriteBuff | PAX      | 64      | 64      |            |
| paxStatBuff  | PAX      | 128     | 128     |            |
| nFTSThreads  | PAX      | 8       | 8       |            |
| nThread      | PAX      | 64      | 64      |            |
| nPrefetch    | PAX      | 8       | 8       |            |
| nRestore     | PAX      | 16      | 16      |            |

Note: The higher default settings for PAX led to memory panics as buffers were gobbling up Server memory. New PAX defaults are reflected by NAS 5.3.12 output above

**# server\_pax server\_2 -s -v**

server\_2 :

**\$ .server\_config server\_2 -v "printstats pax full"**

### **5.3 ENHANCEMENTS:**

--multithreading restore process  
--multithreaded directory traversal, allows for better performance with small files and fragmented file systems  
--improves large file handling by allowing multiple NASA threads to work on the single file  
--NASA reads data and writes to file, uses larger data buffer pool  
--More threads and buffers will help on small file restores

**Note:** NAS 5.3 and higher no longer contains the nbuf param--it is no longer applicable. The default ntape value is set to 4, sufficient to handle up to (4) attached tape drives, which is the Celerra limit for concurrent operations.

NASA → Writes file header, reads file data, writes to buffers (paxStatBuff)

NASS → Traverses file system, provides metadata for each directory/file

NASW → Gets data from buffer pool (paxWriteBuff), writes them to tape, sends back to remote mover

**param PAX nRestore=16** [Default value for number of restore threads, with range from 1 – 256]

**param PAX paxReadBuff=64** [Default value for number of tape read-ahead buffers, with range from 1-512]

**param PAX nFTSThreads=8** [Default value for number of FTS threads, ranges from 1-256]

**\$server\_pax server\_x -stats -verbose** [PAX Statistics]

NASS Stats→stats on file system traversal, provides meta data for each directory/file

NASA Stats→reads file data and writes to buffer with NASW

NASW Stats→gets data from buffer pool with NASA and writes to tape or sends to remote mover

**\$server\_pax server\_x -stats -reset**

### **SETTING I18N PARAMETERS FOR NDMP:**

**Note:** Set following parameter when Data Mover has I18N enabled, for all NAS versions that support I18N. This will ensure that the DM will use UTF-8 translation instead of the default “Latin 1”

**param NDMP dialect=**

**param NDMP convDialect=8859-1** [Default value; Change to convDialect=UTF8 to restore from non-ASCII backups]

**param NDMP dialect=UTF8** [Set this value when DM operates in I18N mode with UTF8 client backups/restores]

### **INVALID UTF CHARACTERS MAY RESULT IN BACKUP/RESTORE FAILURE (NAS 4.2):**

#### **Legato NetWorker NDMP Service Log:**

server\_archive: Can't convert filename using the specified NDMP.dialect, or invalid utf8 filename:  
0x2f41302f6d6f6e746167652f68647574696c7334312f737461362f3fea3456789abcd4d45432e75736572.

#### **Resolution:**

**param NDMP.dialect=null**

**Note:** New default codepage with NAS 5.2 is null to address I18N issues.

### **SERVER LOG ERRORS REGARDING INVALID UTF8 NAMES DURING NDMP BACKUPS:**

2005-05-05 10:34:55: NDMP: 3: Can't convert filename using the specified NDMP.dialect, or invalid utf8 filename:  
0x2f766f6c302f706c69752f434354656d706c6174652f49432f496d61676520436166822063616e63656c6c6174696f6e5f72657175657  
3745f72656365697665645f6b6565705f646f6d61696e2e646f63.

2005-05-05 10:34:55: NDMP: 3: inode\_2137907 is using for filename

**Note:** Point of above example is that Celerra NDMP backups no longer fail when running into UTF8 names that cannot be translated. We log the error in the log, then instead of passing the file name history back to the NDMP Client, we pass the inode number of the file/folder.

### **OTHER NDMP PARAM VARIATIONS:**

**param NDMP dialect=<dialect string>**

**Note:** Dialect String is the dialect used by the NDMP Client. Celerra default without this param change is Latin1.

Restores From DM With ASCII Enabled:

**param NDMP convDialect=<dialect string>**

**Note:** Dialect string is the dialect used by the ASCII Mode DM. Default value is Latin1.

**param NDMP convDialect=null**

**Note:** ‘Dialect=null’ actually defaults to “cp437.txt” code page

### **RESTORING ASCII BACKUP TO UNICODE: NAS 5.0.11.4**

**param NDMP convDialect=null** [Restores in UTF-8 format]

**param NDMP convDialect=big5.txt** [Restores in alternate code page format]

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
**Note:** By default, Servers restore using Latin-1 (8859-1.txt). Changing to Dialect=null will stop translations from occurring.

### **I18N ISSUE WITH NDMP DIALECT SETTINGS:**

NDMP Service Log: server\_archive: Can't convert filename by the specified NDMP.dialect

NDMP Service Log: server\_archive: Backup continues with environment variable HIST disabled

**Comment:** Customer may see these errors if there is an NDMP dialect error or mismatch in the locale translations used by a Client and that configured for NDMP. In other words, a filename may contain a character that the default NDMP.dialect setting cannot translate properly.

### **NDMP BACKUPS WITH I18N USING TAR FORMAT:**

If files are found that cannot be translated, catalog information is not created, error logged, but backup continues. Mis-translated files can only be restored via Full Restore of a directory.

### **NDMP BACKUPS WITH I18N USING DUMP FORMAT:**

If files are found that cannot be translated, catalog information is not created for any files after that point, error logged, but backup continues. All data from point of first mis-translated file can only be Restored via full restore of directory.

### **INCREASE NDMP LOGGING IN SERVER LOG:**

**\$server\_config server\_x "logsys set severity NDMP=LOG\_DBG2"**

NDMP:5: HALT reason:NDMP\_DATA\_HALT\_SUCCESSFUL; <TAPE\_CLOSE>

--Keep NDMP Tape pools separate from Open Host formats!

--Must conduct restores to same host for NDMP--but can change the directory destination

--DataMovers support (4) datastreams [four separate tape drives using dual scsi cards--two drives handled per each SCSI channel].

But NDMP does not support multiple data stream backups yet!!!!

--"Cannot communicate with Server" --might mean that wrong NDMP passwd was used

**NDMP & I18N SUPPORT:** You cannot restore from tape from a system that was backed up as non-Unicode to a new file system created using Unicode [i.e., I18N is now turned on]--it will fail with this message in Server Log:

2002-06-01 12:34:11: NDMP: 3: Pattern Not Matched: /chainlink/ismp004 (not restored)

**Note:** New default codepage with NAS 5.2 is null to address I18N issues.

### **PATTERN NOT MATCHED:**

2003-05-28 15:39:13: NDMP: 3: Pattern Not Matched: /fs-dm2-data01/data01/Dept/Minimed/Public/ERP\_Imp/SECURITY PROFILES (not restored)

**Comment:** Generally see this error if the wrong Restore path was typed in or 'case' was not exact. Also see this error in 2.2 code for Veritas if a linked null file was backed up—the problem is that restore fails for a linked file that is null. Other probable causes for the "Pattern Not Matched" error are incorrect Restore path and 'case' sensitivity issues with the path defined for the Restore.

**DAR RESTORE ISSUE:** Also can lead to 'Pattern not matched' entry in 5.2. Single file DAR restores o.k. Memory leak and panic.

### **NDMP BACKUP or RESTORE ISSUE:**

NAS < 4.2.10.0 & 5.0.12.0

**Server Log Message: NDMP: 3: TAPE\_OPEN c0t110 fails with stat 16**

Celerra Bug that causes Tape Hang/Busy condition in Veritas and Legato

#### **Status 16 Error Defined:**

"stat 16" error returns are an EBUSY response which means another application has the device open

#### **Cause of Issue:**

The issue is a resource deadlock between two threads during an incremental backup which spans tape volumes and there are no more tapes available. PAX times out and begins to clean up resources. Buffer threads get into a deadlock situation.

#### **Workaround/Resolution:**

Reboot or failover/failback the data mover and make the new media available.

Issue resolved with NAS patch 4.2.20.0 & 5.1.17.0

#### **FULL RESTORES FAILED:**

NAS 5.2 full restores failed—fixed NAS 5.2.11 and higher

#### **NDMP RESTORE COMPLETES BUT NOT ALL FILES RESTORED:**

**Note:** For NDMP restores that encounter name collisions, the default policy is to NOT restore a file with a name collision

**MIGNORE:** Default, do not restore file when name collision exists [**OPTION=MI**]

**MDELETE:** Restore file upon name collision and delete existing file on target [**OPTION=MD**]

**MMANGLE:** When DOS names the same, will rename the restored file but leave original file alone [**OPTION=MM**]

## **DLm4080/DLm4020 (EMC Disk Library for mainframe) Version 1.2**

- Enterprise class tape-on-disk appliance solution for IBM mainframes, using virtual tape emulation (disk storage arrays replace tape libraries)
- A benefit of DLm is that it offloads the Tape Library function and processing from the Mainframe
- DLm connects to Mainframe using Escon or Ficon connections
- Uses SATA drives and RAID 6 protection (12+2)
- DLm4020 is a single rack system based on NS20 Integrated, with up to 47.5TB capacity (100TB compressed)
- DLm4080 can be from 1-7 racks, based on NS80 Integrated, with up to 570TB capacity using IDRC=Force option (1.5PB compressed)
- Can replicate between either solution
- Both NAS platforms ship with dual Control Stations and extra switch to connect to, but is in “cold standby”
- Reduce unknown CallHomes by configuring ConnectHome with following:  
**# /nas/sbin/nas\_connecthome –modify –site\_id “DLm4020”**

### **Components:**

- DLm Controller, or VTEC (Virtual Tape Emulation Controller) running version 2.0 (ACP hardware—DLm2-ACP)
- NAS front-end
- Storage back-end

### **DLm MODELS:**

- DLm4080 Version 1.0.0 NAS 5.5.33.2 Flare 26
- DLm4080 Version 1.1.0 NAS 5.6.37.6 & 5.6.38.2 Flare 26
- DLm4080 Version 1.2.0 NAS 5.6.40.3 Flare 26
- DLm4020 Version 1.2.0 NAS 5.6.40.3 Flare 26

### **DLm SUPPORT:**

MFSW supports VTE & Mainframe portion of the product, NAS the NS80/NS20

### **VTEC (Virtual Tape Emulation Controller) Components:**

- VTEC sits between IBM mainframe and EMC Storage array, providing IBM 3494 virtual tape library emulation for IBM 3480/3490/3590 tape drives, and connects using ESCON, FICON SM, or FICON MM
- Access Control Point (ACP) [provides configuration, management, & maintenance of VTE]
- Gigabit Ethernet switches [use two switches for path redundancy]
- LVD SCSI to HVD SCSI converter
- Virtual Tape Engines (VTE) emulate Tapes [IBM tape drive emulation, directs data to and from Celerra and its attached array]
- NS80 Integrateds or NS20 Integrated (NAS Support)

### **DLm120 Version 2.0:**

- Replaces NS20 configuration with NS-120
- Ships with (2) ACPS, (1-2) VTEs, FICON or ESCON Channel adapters, (2) GbE Ethernet switches, Modem, (2) NS-120 Blades with dual Control Stations (one CS is in ‘cold standby’, not cabled or powered on), CX4-120 array with dual SPS and (up to 5) DAEs, all SATA
- Support up to 47.5TB

### **DLm960 Version 2.0:**

- Replaces NS80 high-end with NS-960
- Ships with (2) ACPS, (1-6) VTEs, (2) 1GbE Ethernet & (2) 10GbE Ethernet switch, (2-6) NS-960 Blades, dual Control Stations cabled and ready, CX4-960 array, with up to (12) DAEs, all SATA except boot DAE, which uses (6) FC drives for vault
- Can ship with (2) NS-960's?
- NS-960 Blade configuration will consist of (1) Tomahawk FC card in slot\_0, Firestorm cards in slot\_1 & slot\_2, and Thunderbolt cards in slot\_4 and Annex slot\_5 [DLm960-DM-8C3 blade type]
- AUX configuration consists of (4) FC IO Modules
- Supports up to 1.2PB

## **DATA MIGRATION METHODS:**

EMCopy for NT; CPIO for Unix [cp -r; cp -pr; cpio; tar]

**Data Migration Considerations:** Using CPIO tools

Incremental if “live” systems v. static copy

Higher GID's than allowed would be a big problem

Having Negative UID/GID's a problem

Symbolic Links that go Across or Up are a problem

Deleted Files on Source are a problem—would be migrated over to target

Negative TimeStamps

Multiprotocol Environments [Permissions & ACL's; even tape Backups don't do it all]

Owners—Permissions—ACL's—LocalGroups—Share ACL's

CIFS—Robocopy/Scopy

**Possible Solution:** Use Lgdup, Sharedup, and EMCopy to migrate a File System.

## **PS MIGRATION TOOLS:**

CDMS, Rsync, EMCopy, Scopy, Robocopy, Secure Copy, Aelita, FastLane, NetIQ

Scopy--Migrate files between DC's; does not migrate "localgroups"

Robocopy--Migrates data & permissions; does not migrate "localgroups"

Secure Copy--GUI-based migration of data, shares, perms, ownership, and localgroups

Rsync--Useful for migration of NFS data from SOURCE to TARGET IP4700 using "rsh" & "ssh" communications. Rsync 2.5.6 is a fast incremental file transfer utility. Note that if copying sparse files, must use the -S flag or else the migration will convert files to dense.

Aelita: Consolidation Wizard 5.63--comprehensive migration tool

XfrPerms: Windows tool backing up SD of files/directories and can reapply to same or migrated directory tree

XfrShares: Windows tool backing up shares and perms. Do not need source up to apply to target system

rmtshare: MS tool to remotely manage Shares from command prompt [ \\server\\sharename=drive:path]

MapSID: tool to find and manage orphaned SIDs

## **QUEST FASTLANE CONSOLIDATOR:** Version 4.1

Win2k SP3, IE 5.5, PIII 400Mhz, 512MB RAM; 350MG space

Migration tool that can preserve cross-domain file, folder, share, & local groups; Maintains file ownership, last access date, W2K inheritance, File filters, migration reports, User Profiles, Storage analysis prior to migration

Best Practices for using Consolidator with Celerra: [www.quest.com/fastlane/consolidator](http://www.quest.com/fastlane/consolidator)

## **MIGRATING TO CELERRA USING ROBOCOPY XP010 WINDOWS 2003 VERSION:**

1. Use LGDUP to migrate local groups from Source to Target
2. Run initial migration: c:>`robocopy.exe \\source \\destination /NP /V /B /MIR /FFT /COPY:DAT /LOG:logname`
3. Repeat step 2 for incremental copies. Stop access to Source and run a final time to complete data migration.
4. Run following to copy security, ownership, and auditing information:  
c:>`robocopy.exe \\source \\destination /NP /V /B /MIR /IS /FFT /COPY:SOU /LOG :logname`

**Note :** User account for migration should have Backup Operator privileges

## **HOW TO COPY FILESYSTEM VIA NFS STREAM AND THEN COPY OVER NT ATTRIBUTES:**

Step 1. From Remote Unix Host, mount to Celerra NFS Exports:

FS\_A = Source filesystem

FS\_B = Destination filesystem

Step 2. From UNIX host, cd to the mounted directory of FS\_A & run following command:

**`tar cf - . | (cd <<full path of directory mounted of FS_B>>; tar xfBp -)`**

[this will stream the data from FS\_A to filesystem FS\_B & retain all UNIX rwx and sticky bit permissions]

Step 3. When NFS Stream operation is complete, conduct following from an NT Server:

--Map the two filesystems as CIFS shares from the NT server

--Run following from NT Server command prompt:

**`c:>emcopy <<FS_A dir full path>> <<FS_B dir full path>> *.* /s /sefix`**

[this will copy the NT permissions from the directory on FS\_A to the same named files on FS\_B]

## **ROBOCOPY NTRESKIT TOOL:** Robust File Copy for Windows NT v.1.96

**Intro:** Robocopy is an NT Resource Kit tool similar to "xcopy" or "scopy", only better. For basic copying of data from an NT Server to the Celerra, this requires very little preparation. The only caveat is that without running another tool such as EMCopy's "LGDUP", "robocopy" does not copy "ownership" information over for Celerra:

**`C:>robocopy.exe \\win2kbde\ robocopy \\celerra\migrate /E /SEC /SECFIX >robo.txt`**

### **Robocopy Switches:**

/mir [combination of /E to copy directories and /Purge to purge files on Source after copying

/SEC [copy security information—requires volumes be NTFS]

/SECFIX [fixes security information on files & directories]

/mir [mirrors Data & NTFS attributes from Source to Target]

/S : copy Subdirectories, but not empty ones

/E : copy subdirectories, including Empty ones

/NP : No Progress - don't display % copied

/XO : eXclude | Older files

/R:n : number of Retries on failed copies: default is 1

/W:n : Wait time between retries: default is 30 seconds

/Z : copy files in restartable mode

**ROBOCOPY XP010:** Windows 2003 Resource Kit

## **CELERRA CDMS VERSION 2 (CDMSV2): CIFS & NFS**

**Note:** CDMS v1 was first version and introduced with NFS support only in NAS 2.2

Introduces CIFS support using 4.2.10+, 5.0.11+, 507DM+, running on NT or WIN2K Platforms; Adds NFSv2 support (keeps NFSv3 support) with both UDP & TCP support; Map source file system root to a 'directory'; Intended to fully support NT/Windows 2000 Domains; Does not require port mapper to support migration; Uses standard RPC client generated by "drpcgen"; Can now consolidate multiple source file system types into one local file system; Migrates all CIFS file attributes

**Note: NAS 5.1M introduces support that allows Customers to conduct their own CDMS migrations**

### **CDMS MIGRATION EVALUATION TOOLS FOR CIFS/NFS:**

dircount.pl /mntpoint → Script to verify tree structure depth and number of dirs & files

diskUsage.pl -m → Script to validate amount of space needed on target for the migration

### **CDMS CONNECTION THREADS:**

→NAS 5.2 only supports a single connection thread for the migration process

→NAS 5.3 supports multiple connection threads to different connection paths

**Note:** Important to know that even when errors are seen in the migration process, the MGFS Threads do not stop, even if the WebUI says that they have failed. This is one of the main reasons for not kicking off a verify until you know that the MGFS thread is completed.

### **CDMS MIGRATION PROCESS:**

CIFS CDMS migration does not impact Users and is done synchronously for directories [entire directory migrated & offline inodes created] and asynchronously for files [data is pulled over per Client requests on reads—when whole file is read, the offline inode is brought online]. A key point of our target “mgfs” filesystem on the Celerra is that we have added a new inode type [offline inode] to support this type of migration. Another important point is that inodes are read block-by-block, not individually. Cross-domain CDFS migrations are possible but are very complicated and should engage EMC PS support.

### **HOW DO MIGRATION DIRECTORIES AND FILES GO ONLINE?**

When running the CDMS migration from Source to Target, the root directory on the Target is the first to be brought “online”, then the parent directories, but each directory is done linearly across and recursively down the entire subdirectory structure before moving to the next parent-level directory. In other words, the directory itself is marked online immediately, though until the process completes, many of the sub-directories are not yet online. Files themselves are migrated piecemeal as Clients request to read various portions of the file—if the last byte of the file is read by a Client, then a 2<sup>nd</sup> CDMS thread ensures that any other parts of the file are read, then migrates and marks the file header as “online”. Files might not be properly migrated if they contain incompatible special characters or linkages that the CDMS process cannot resolve—this is why the use of the dirprivW.pl tool is important and is run on the Source file system prior to migration—files should be identified and corrected prior to the migration. The term “offline inodes” refers to the state of directories and files that are in the migration process.

### **POST-MIGRATION RULES & THINGS TO CHECK PRIOR TO CONVERTING FROM MGFS:**

Rule 1: Do not convert from mgfs file system before reviewing AND correcting any CDMS migration log errors!

Rule 2: Do not run the verify command before reviewing AND correcting any CDMS migration log errors!

**Note:** If you run the verify command and I/O is still occurring for the migration process, the verify will stop and restart from the beginning of the file system—essentially, you will bog down the Server CPU and never get anywhere. For blocks that were successfully checked by the verify, if the process has to start from the beginning again, it will cover the checked blocks very quickly—however, it DOES have to start from the beginning each time.

Rule 3: Check Server Log for evidence of offline inodes and other errors

### **WHAT TO DO AFTER A MIGRATION:**

#### **I. ALWAYS CHECK & RESOLVE ERRORS FROM MIGERR LOG:**

→Temp files, such as .xls, .tmp, may be recorded in migErr log, but these are normal and will have been migrated by the User, even if the migration thread did not read

→Certain system files & process can lock files, preventing migration—in many cases this will be normal and they can be deleted on the Celerra, but customer should make these decisions

→Other files or directories may be listed in migErr log, but when checking for the files on the Celerra, if the files are no longer present, it generally means that the files have been deleted since the migration thread was run—as in reading a file, the act of deleting files also puts the inode “online”, so this is normal and expected & no further action required

→Remaining files or directories in migErr log are seen on the Celerra—try to read the contents of the files to see if the files are good—if so and there are many such files, run the migration thread again

→If there are files that cannot be read on the Celerra (and are referenced as errors in the migErr log), it’s possible that the source files are corrupt, or there could be access problems on the source, or the ‘Backup Operator’ rights were not properly assigned to the migration user account

→As a last step, try reading files from the Source server—if they cannot be read then they can be safely deleted. If they can be read, then try migrating via another method, such as EMCopy or Robocopy

→Network problems can cause files to be dropped or skipped during the migration [process can only ‘pause’ for a finite time before continuing], resulting in offline inodes

→Only run the ‘getOnline’ procedure as a last resort and only after all the above measures have been taken, as the ‘getOnline’ procedure does not ‘fix’ problem inodes. For example, if there is a directory with only partially migrated files, the rest of the files will not be migrated and will be missing. Make sure that all ‘offline’ inodes are understood before running this:

**#/nas/tools/cdms/specialCmd getOnline server\_2 /fs01**

## **II. RUN VERIFY AFTER ENSURING MIGRATION IS COMPLETED & MIGERRs CHECKED:**

**#server\_cdms server\_2 –verify fs01**

### **TACTICS FOR RESOLVING OFFLINE INODES:**

1. Determine if the offline inode can be seen on the Celerra file system. If you cannot see the offline inode on the Celerra, then there is a good chance that it was deleted on the Source side during the migration.

**Note:** Deleted inodes are actually placed “online” before they are deleted for CDMS

2. If cannot be seen on Celerra, check to see if it can be seen on the Source and handle accordingly. Determine if file is corrupt on the Source side, which could prevent migration.

→In most cases, the first step after reviewing the Logs would be to start the MGFS threads again to force the migration to bring inodes online

**#server\_cdms server\_2 –start mgfs -path /conn -log /path/subpath -Force**

**Note:** For CIFS CDMS migrations, use the –Force flag only for “restarting” a CIFS thread for the migration, or else the CDMS thread will think that a directory marked ‘online’ does not need checking for its subdirectories and files! This command does not alter inodes. NFS migrations do not experience this limitation. Deleting an offline inode could also be an option at customer discretion. This command is documented in NAS 5.4.

3. Running the /nas/tools/cdms/specialCmd can be used to bring an offline inode online—specify the complete path to the inode  
4. Cat the offline inode file directly to /dev/null and this should also place the inode online

### **SERVER CDMS COMMAND OPTIONS:**

**\$ server\_cdms**

```
-connect <mgfs> -type {nfsv2|nfsv3} -path <localpath> -source <srcName>:<srcPath> [-option <options>]
-connect <mgfs> -type cifs -path <localpath> -netbios <netbios> -source \\<srcServer>[.<domain>]\<srcShare>[\<srcPath>]
-disconnect <mgfs> {-path <localpath>|-path <cid>|-all}
-verify <mgfs> [-path <localpath>|-cid>]
-Convert <mgfs> [Caution—use this command only as a last resort and after all else has been checked]
-start <mgfs> -path <localpath> -log <logpath> [-include <include_path>] [-exclude <exclude_path>]
-halt <mgfs> -path <localpath>
-info [<mgfs>] [-state {START|STOP|ON_GOING|ERROR|SUCCEED|FAIL}]
```

### **OFFLINE INODE PROBLEM WITH CDMS MIGRATION:**

#### **PROBLEM INDICATORS:**

**# server\_cdms server\_2 -i fs01**

```
server_2 :
fs01:
path  = /temppath
cid   = 0
type  = cifs
source = \\source1.rcb.ford.com\u1$ netbios= RCB9010201.NA1.FORD.COM
admin  = na1.ford.com\$kcardwel
threads:
path  = /temppath
state = FAIL
log   = /cdms_logs
```

#### **SERVER LOG:**

**2004-12-30 14:54:14: MGFS: 3: node 547058 is offline, abort**

2004-12-30 18:35:58: MGFS: 3: node 171621 is offline, abort

1. Use calculator to convert offline inode number from Server Log to true inode number if using /nasmcd/quota/slot\_2 to locate and fix the offline inode. If you nfs mount the file system from the Control Station, then the inode to find and fix is the same number as listed in the Server Log:

-->Open calc, enter inode number, 547058, then xOR file system id, 28, and result is 547070. This will be the inode number to use when conducting find and fix to the offline inode.

2. Locate file on file system:

**\$ find /fs01 -inum 547070**

547070 -rw-r--r-- 1 1000943 3000002 553 Aug 4 08:24 img\_presentation.gif

3. Check Migration logs to identify problems

4. Run MGFS Thread against file system path or subdirectory path to try and convert again

5. Optionally, bring inode online by running cat offline\_file /dev/null from NFS, or use following script tool:

**#/nas/tools/cdms/specialCmd getOnline server\_2 /fs01/path/specific\_file**

6. Run Verify to Check Status only after verifying that MGFS Threads are completed and no I/O is occurring:

**# server\_cdms server\_x –verify fs01**

**# server\_cdms server\_2 -i fs01**

**# Server\_log server\_2**

## **CDMS MIGRATION NOTES:**

--“mgfs” file system creates “offline migration inodes” which contains the actual data during the migration

--An “mgfs” file system can be extended during the Migration--will not to restart the ./migrate.pl script

--“migrate.pl” script should be started during periods of low I/O--works by reading last byte of each file in File System

--File System may be larger after migration due to our 8k block size requirement

**Note:** After the script is run to “read” contents of every file that has been migrated, the offline inodes are marked “online” and the data is written to disk.

--recommendation would be to export Source File System to Celerra as “root=” so that there will be no problems migrating files that are owned by Root

--If using 32-bit GIDs for file systems, set param on DM prior to migration [param ufs gid32=1]

--CDMS does not support sparse files during migrations, will result in dense files

## **CDMS FOR NFS V2:**

### **SUPPORT:**

--I18N supported, but must configure prior to migration

--NFS V2 & V3 supported, for UDP & TCP protocols

--Can combine multiple source filesystems into single UxFS filesystem

--Export aliasing permits consolidated filesystems to be reexported under original names

--Simultaneous migration of multiple filesystems

--Migrates Inode Information: Size, Access & Modification Times, UID, GID, Privilege & Mode bits, Link count

--Migrate from NT 4.0 Domain or Windows 2000 Domain, but not both at same time

--migration supported without using Portmapper

--Symbolic and Hard links are migrated and preserved

### **LIMITATIONS/REQUIREMENTS:**

--100MB Network, with recommended limit of (3) migration streams in parallel

--Files that cannot be opened by NFS cannot be migrated

--Filesystem Quota information is not migrated

--Timestamps with attribute changes are not migrated [chmod attributes, etc]

--NFS V2 supports max. 2GB Filesizes

--Compressed files migrated uncompressed

--When migrating from NetApp Source using Network Appliance Snapshot, must use additional software on Celerra side

--local mountpoints can cause dircount.pl script to fail

**Cautionary Note:** Files that cannot be opened by the migrating Data Mover (for instance, files in use by the system or other locks), will not be migrated!

## **CDMS V2 FOR CIFS SUPPORT:**

--Migration of CIFS attributes: ACLs, DOS attributes, Audit bits

## **CDMS V2 CIFS LIMITATIONS:**

- ADS named streams are not supported for migration
- I18N must be configured on the Target Celerra Server in order for CIFS CDMS migration to work, as Unicode is used in process!
- Migration of DOS 8.3 names not guaranteed due to name mangling differences between Windows and Celerra
- No cross-domain migrations allowed (NT → WIN2K & not vice versa—however, in order to migrate from an NT Domain to a Windows 2000 Domain, must have the normal Trust prerequisites in place and have run ADMT migration with SID History)
- Migration of Quotas Information is not supported—recreate Quotas after the migration
- Sparse Files are not supported—migrated sparse files will become dense files
- Compressed data will be migrated uncompressed
- Single Domain Migrations only
- Does not support EFS (Encrypted File System) migrations for Windows 2000—decrypt files first. Nas 4.2 & 5.0 will allow these files to be migrated, but they will be useless. Nas 5.1 will not allow the migration of encrypted files.
- Migrations are done for NFS or CIFS attributes, but cannot migrate over both attributes at one time!
- DFS is not supported for CDMS as there is no WIN32API built in to support this yet
- Windows has a directory path length limitation of 255 characters [Identify these problem paths first, then run separate migrations at different levels to accomplish complete migration of all data from the Source]
- Source file server should be set to RO once share migration begins
- XP systems cannot be a migration Source
- Source NT Server only supported for migrations within an NT 4.0 security domain, not W2K or W2K3
- Local Groups and CIFS Shares cannot be migrated by CDMS alone [use lgdup and sharedup utilities]
- Local Users can be migrated if the Local Users feature is configured on the CIFS Server, and running NAS 5.4 or higher

**Note:** Previously, Local User account ACLs were dropped during migration. Invalid owner or primary group SIDs were replaced by SID of account used in migration

## **CIFS CLIENT TIMEOUT VALUE:**

# server\_param server\_2 -facility cifs -info cifsclient.timeout -v

```
server_2 :  
name      = cifsclient.timeout  
facility_name = cifs  
default_value = 20000  
current_value = 20000  
configured_value =  
user_action = none  
change_effective = immediate  
range      = (0,4294967295)  
description = CIFS client timeout used in CDMS (default:20000)  
detailed_description
```

Specifies the amount of time in milliseconds that is required for a response to a cifs client request from one Data Mover to another cifs server (other DM, regular MS server or other cifs server). Mainly used by CDMS. Value is defined in milliseconds.

## **CDMSv2 SUPPORT:**

- Timefinder/fS
- HighRoad MPFS
- NT/Windows 2000
- SRDF
- MGFS filesystem can be extended during a migration
- Migrating up to 1024 filesystems into one can be done [but migrate only 4-5 at a time]

**Note:** What this really means is that you can have up to 1024 concurrent connections to the Source Server's local directory structure, implying that you can migrate multiple filesystems, directories, etc.

## **BASIC METHODOLOGY FOR CIFS CDMS MIGRATIONS:**

1. LGDUP from Source to Target Server to copy over local group database
2. Setup, mount, and export the MGFS file system & log file system on the Target
3. Create the CDMS connection, which then copies over the inode structure of Source fs to Target fs
4. Conduct Sharedup to copy over Share information
5. Start the actual CDMS migration thread(s)
6. Monitor migration using nas\_fs -s
7. Inspect logs after completion to verify migration of fs
8. Convert file system to MGFS

## **CONDUCTING CIFS CDMS MIGRATION:**

### **1. Migrate LocalGroups database using lgdup, from Source to Target systems**

### **2. Create MGFS File System on Destination using GUI or CLI:**

2005-12-12 12:04:16.692 db:201:29385:S: nas\_fs -name speced -type mgfs -create size=30720M pool=clar\_r5\_performance storage=SINGLE -option slice=y,mover=server\_2

### **3. Mount MGFS file system Read/Write:**

2005-12-12 12:04:28.641 server\_2:201:29485:S: server\_mountpoint server\_2 -create /speced

2005-12-12 12:04:31.789 server\_2:201:29543:S: server\_mount server\_2 -option rw speced /speced

### **4. Start CDMS Service on Destination CIFS Server:**

**\$server\_setup server\_2 -P cdms -o start** (default 32 threads)

### **5. Create CIFS CDMS Connection between Source and Target (always run from Target Side):**

2005-12-12 12:06:43.703 server\_2:0:30570:S: server\_cdms server\_2 -connect speced -type CIFS -path /speced -netbios dpsnas01 -source \\dpsnas01\_t.dpsk12.org\c\$\speced -admin dpsk12.org\cdms

**Note:** From CLI, actual syntax requires the use of ‘ ‘ for UNC and Admin paths, as well as password

**# server\_cdms server\_2 -connect speced -type cifs -path /speced -netbios dpsnas01 -source**

**'\\dpsnas01\_t.dpsk12.org\c\$\speced' -admin 'dpsk12.org\cdms'**

server\_2 : Enter Password:\*\*\*\*\*

### **6. Create Share on Destination Server for MGFS file system called “speced”**

### **7. Start CDMS Migration Thread:**

2005-12-12 12:10:26.945 server\_2:0:32238:S: server\_cdms server\_2 -start speced -path /speced -log /mgfslog

### **8. Verify Migration Progress:**

**# server\_cdms server\_2**

server\_2 :

CDMS enabled with 32 threads.

speced:

path = /speced  
cid = 0  
type = CIFS  
source = \\dpsnas01\_t.dpsk12.org\c\$\speced  
netbios= DPSNAS01.DPSK12.ORG  
admin = dpsk12.org\cdms

threads:

path = /speced  
state = ON\_GOING  
log = /mgfslog  
cid = NONE  
recall = FALSE

**# nas\_fs -i speced**

id = 32  
name = speced  
acl = 0  
in\_use = True  
type = mgfs  
worm = off  
volume = v118  
pool = clar\_r5\_performance  
member\_of = root\_avm\_fs\_group\_3  
rw\_servers= server\_2  
ro\_servers=  
rw\_vdms =  
ro\_vdms =  
status =

|           | Total KBytes | Used KBytes | Total inodes | Used inodes |

**# nas\_fs -s speced**

```
total = 30251 avail = 11527 used = 18723 ( 61% ) (sizes in MB) ( blockcount = 62914560 )
```

```
volume: total = 30720 (sizes in MB) ( blockcount = 62914560 )
```

**# .server\_config server\_2 -v "mgfs action=query fsid=32"**

```
1134416714: MGFS: 4: Total KBytes Used KBytes Total inodes Used inodes
1134416714: MGFS: 4: Dart cid: 30977264 9590128 3778558 62495
1134416715: MGFS: 4: -----
1134416715: MGFS: 4: remote 0: 1978496 184624 0 0
1134416715: MGFS: 4: type=CIFS path=speced cifs=\dpsnas01_t.dpsk12.org\c$\speced localServer=DPSNAS01.DPSK12.ORG
account=dpsk12.org\cdms passwd=*
1134416715: MGFS: 4: -----
1134416715: ADMIN: 4: Command succeeded: mgfs action=query fsid=32
# server_export server_2 |grep -i speced
share "vol2" "/speced/speced/vol2" netbios=DPSNAS01 maxusr=4294967295 umask=22 comment="Student Services Share"
# cat /nas/server/slot_3/param
param mgfs logPathPrefix=/mgfslog/mgfs
# cat /nas/server/slot_3/netd
migThreadPool action=startPool
```

**NEW SERVER CDMS COMMANDS USED WITH NAS 5.2:**

**CREATING MGFS FILE SYSTEM:**

```
#nas_volume -n vol_mgfs1 -c d30
#nas_fs -n mgfs1 -t mgfs -c vol_mgfs1
```

**MOUNTING & EXPORTING MGFS FILE SYSTEM:**

```
#server_mountpoint server_x -c /mgfs1
#server_mount server_x mgfs1 /mgfs1
```

```
#share -F nfs -o ro,root=10.241.169.20/0 /fs1 [Exporting Source for DM with root access privileges]
```

**SETTING UP CDMS SERVER THREAD POOL:**

```
#server_setup server_x -P cdms -o start=50
```

**CONNECTING TO CDMS EXPORT FOR NFS:**

```
#server_cdms server_x -connect mgfs1 -type nfsv3 -path /cdmsexport -source
10.241.169.30:/cdmsexport -o useRootCred=true proto=TCP
```

**Note:** The ‘useRootCred’ option ensures that data reads on source are UID=0, GID=1, instead of file owner’s UID/GID, especially in environments with mixed permissions on files and directories. Also export Source file system to Data Mover as root.

**CONNECTING TO CDMS SHARE FOR CIFS:**

```
#server_cdms server_x -connect mgfs1 -type cifs -path /cdmsshare -netbios cdmsserver -source
\\source.domain\cdmsshare -admin Administrator
```

**EXAMPLE CIFS CONNECT COMMAND:**

```
# server_cdms server_2 -connect fs303 -type cifs -path /Groups -source "\\\xbwsdata1\groups" -netbios
bwssdata1 -admin ex88889
```

```
server_2 : Enter Password:*****
```

```
done
```

**Note:** When specifying the path “/Groups”, this is the path and share that actually exists on the Source side and does not exist on the Target side by foldername or sharename—there should be no CIFS shares in use when conducting the migration to the Data Mover. Furthermore, the CDMS ‘connection’ and ‘migration start’ commands can be run from CLI or WebUI GUI.

**VERIFYING CDMS CONNECTION:**

```
# server_cdms server_x -verify mgfs1 -path /cdmsshare
```

**VERIFYING DATA MOVER CDMS CONNECTION TABLE:**

```
$ .server_config server_5 -v "queryCid fsid=547 cid=0 range=20"
```

```
1124861497: MGFS: 4: ----- cid information -----
```

```
1124861497: MGFS: 4: cid=0 fsid=547 type=CIFS path=/studappdata1 cifs=\studentspc8.students.intranet.epfl.ch\AppData\
localServer=STUDENTSPC6.STUDENTS.INTRANET.EPFL.CH account=students.intranet.epfl.ch\rootb wins=128.178.50.44
passwd=*
```

```
1124861497: MGFS: 4: ----- end cid information -----
```

1124861497: ADMIN: 4: Command succeeded: queryCid fsid=547 cid=0 range=20

### **VERIFYING DM CREDENTIALS TO REMOTE HOST:**

**#.server\_config server\_5 -v "mgfs action=query fsid=547"**

```
1124860820: MGFS: 4:          Total KBytes  Used KBytes  Total inodes  Used inodes
1124860820: MGFS: 4:  Dart  cid:  206515184    6104288    25190398    208377
1124860820: KERBEROS: 7: send_as_request
1124860820: KERBEROS: 7: _krb5_use_dns: use dns = yes
1124860820: KERBEROS: 7: krb5_locate_srv_dns: for service _kerberos at realm STUDENTS.INTRANET.EPFL.CH, # KDC: 2
1124860820: KERBEROS: 7: krb5_locate_srv_dns: name studentsdc1.students.intranet.epfl.ch
1124860820: KERBEROS: 7: krb5_locate_srv_dns: prior. 0
1124860820: KERBEROS: 7: krb5_locate_srv_dns: port 88
1124860820: KERBEROS: 7: krb5_locate_srv_dns: IP @ 128.178.50.116
```

### **IN MEMORY CID MAP vs. ONDISK MAP:**

**\$ .server\_config server\_2 -v "queryCid action=onDiskCidQuery fsid=1503"**

```
1263504004: MGFS: 6: ----- cid information -----
1263504004: MGFS: 6: ----- end cid information -----
```

1263504004: ADMIN: 6: Command succeeded: queryCid action=onDiskCidQuery fsid=1503

**\$ .server\_config server\_2 -v "queryCid action=incoreCidQuery fsid=1503"**

```
1263504032: MGFS: 6: ----- cid information -----
1263504032: MGFS: 6: Last Cid Available is 1022
1263504032: MGFS: 6: cidMap: (0) state=2 rpolicy=15 wpolicy=1 http=http://tlsm389a.cw01.contiwan.com cgi=
1263504032: MGFS: 6: cidMap: (1023) dart://RDE
1263504032: MGFS: 6: ----- end cid information -----
1263504032: ADMIN: 6: Command succeeded: queryCid action=incoreCidQuery fsid=1503
```

### **VERIFYING DATA MOVER CLIENT CONNECTIONS TO SOURCE:**

**\$ .server\_config server\_2 -v "cifsclient audit"**

```
1134574620: SMB: 4:
Server:CLUSFS001NASTST.us.cly (10.55.9.92) Client:CLUSFS001NASTST.US.CLY (10.55.9.92)
1134574620: SMB: 4: NativeOS: EMC-SNAS:T5.3.20.1
1134574620: SMB: 4: NativeLanman: NT1
1134574620: SMB: 4: Status: Connected
1134574620: SMB: 4: Auth mode: kerberos
1134574620: SMB: 4: Capabilities: 8000e3fd
1134574620: SMB: 4: Encrypted password: Yes
1134574620: SMB: 4: Protocol: NT LM 0.12
1134574620: SMB: 4: Refcount: 3
1134574620: SMB: 4: List of sessions:
1134574620: SMB: 4: * Name: us.cly\hsadmin
1134574620: SMB: 4: uid: 3f
1134574620: SMB: 4: Vc: 0
1134574620: SMB: 4: RefCount: 3
1134574620: SMB: 4: List of connections::
1134574620: SMB: 4: * Name:zummy_archive
1134574620: SMB: 4: tid:: 3f
1134574620: SMB: 4: RefCount: 2
1134574620: SMB: 4: Service: (NULL)
1134574620: SMB: 4: Mounted by: us.cly\hsadmin
```

### **DISCONNECTING FROM CDMS SHARE:**

**# server\_cdms server\_x –disconnect mgfs1–path /cdmsshare**

**Note:** Do not issue this command unless absolutely required as the entire migration will have to be done over. Rebooting Data Mover should allow a halted migration to continue.

### **STARTING CDMS MIGRATION:**

**# server\_cdms server\_x –start mgfs1 –path /cdmsexport –log /mgfs1/logs.txt**

### **EXAMPLE STARTING CDMS CIFS MIGRATION:**

**2004-06-26 12:37:59.954 server\_2:201:28663:S: server\_cdms server\_2 -start fs303**

### **-path /Groups -log /fs00**

**Note:** Do not have to use a special param to create a log file, simply point to a file system mountpoint and the default log name is as follows: **/fs00 → migLog\_fs303\_Groups**

### **HALTING CDMS MIGRATION:**

**# server\_cdms server\_x –halt mgfs1 –path /cdmsexport**

### **OBSERVING CONNECTION AND THREAD STATUS OF CDMS MIGRATION:**

**# server\_cdms server\_x –info | mgfs1 | -info –state failed | -info –option format=parseable | format=raw**

**Note:** -state switch displays threads for state info requested. Parseable is in comma-separated fields, raw is human readable form.

### **PROBLEM WITH ALL CDMS THREADS IN USE:**

#### **Server Log:**

2007-04-07 22:14:01: MGFS: 4: migThread: All migration threads are in use

2007-04-07 22:14:01: ADMIN: 3: Command failed: migThread action=start fsid=107 migpath=/h/fs01\_ns80g logpath=/miglog1 recall=FALSE

→For a variety of reasons (deleting MGFS filesystem with thread in use; forced converts then threads are hung or incomplete, connection is broken while threads are active, etc.), there are situations where all CDMS migration threads can show up as in use, preventing further migrations. Perform the following steps to remove the “stuck” CDMS threads:

- 1.) Halt all running migration threads (if any) using “server\_cdms server\_2 –halt”, but leave the CDMS connections as is
- 2.) Run “server\_setup server\_2 -P cdms -o delete” to clean out the “stuck” CDMS threads, but not to remove the CDMS data table, or affect the CDMS connections—cleans out the state and data information in the table used to track threads, but not the table itself
- 3.) Restart the migration threads per the normal method

### **MIGRATION STATES:**

start → thread has started stop →thread has been stopped by user

ongoing →thread is running without errors

error →thread is running with errors—check migration log and server log for error messages

succeed →thread is completed with user-specified directory migration

fail →thread is completed but with errors

### **FORCING MGFS FS TO UXFS TO COMPLETE MIGRATION:**

**# server\_cdms server\_x –Convert mgfs1**

**Caution:** This should never be used except as a last resort—ensure integrity of migrated filesystem before using this

### **EXAMPLE OF CDMS SERVER OUTPUT:**

**# server\_cdms server\_5**

```
server_5 :  
CDMS enabled with 50 threads.
```

```
test2:  
path = /test5  
cid = 1  
type = nfs  
source = 10.64.133.11:/export/spare/toby/TEST3  
options= useRootCred=True
```

### **EXAMPLE OF MIGRATION STATUS WITH ERROR CONDITION:**

**# server\_cdms server\_2 -info fs303**

```
server_2 :  
fs303:  
path = /Groups  
cid = 0  
type = cifs  
source = \\brwsdata1.PHARMA.AVENTIS.COM\groups\  
netbios= BRWSDATA1.PHARMA.AVENTIS.COM  
admin = ex88889  
threads:  
    path = /Groups  
    state = ERROR  
    log = /fs00
```

**Note:** Corrective action for a migration that has stopped would be to restart migration using –start command

### **MIGRATION STATE ON GOING=ACTIVE:**

**# server\_cdms server\_2 -i fs303**

```
server_2 :  
fs303:  
path = /Groups  
cid = 0  
type = cifs
```

```
source = \\xbrwsdata1.PHARMA.AVENTIS.COM\groups\  
netbios= BRWSDATA1.PHARMA.AVENTIS.COM  
admin = ex88889  
threads:  
path   = /Groups  
state  = ON_GOING  
log    = /fs00
```

## **VERIFYING CDMS MIGRATION STATUS/PROGRESS:**

# **server\_cdms server\_2 -i fs303**

# **nas\_fs -s fs303**

total = 1008374 avail = 684787 used = 323587 ( 32% ) (sizes in MB)

volume: total = 1024000 (sizes in MB)

## **LISTING OFFLINE INODES:**

# **.server\_config server\_2 -v "param mgfs listAllOfflineInodes"**

## **CDMS TOOLS: APPS & TOOLS CD**

### **NFS:**

ch\_group.pl—change GID numbers on a tree against GID template, used for consolidating file systems with duplicate GIDs

dircount.pl—tool to size the directory tree

dirprivU.pl—verifies file privileges & access and what files can be read so migration will work

diskUsage.pl—estimates storage space required on Target Celerra FS

migrateU.pl—script for Unix donor systems

**Note:** Recommendation is to use Perl 5.6 or 5.8

### **CIFS:**

migrateW.pl—Windows migration script

dirprivW.pl—checks that files can be Read by Windows for successful migration (checks privileges & access)

dircount.pl—use this tool to traverse directory tree & output map of filesystem into CSV file, import to Excel to sort by size, etc.

diskusage.pl—use this tool to determine how much space will be required on the Target filesystem—takes Shadow file into account

connBuilder.pl—Pre-migration tool, output from sharedup.exe to map top level shares for connection cmd's, builds exclude file list

backupWrapper.exe—Gives Backup Operator privileges to running process so scripts can read exclusively owned files for CIFS migrations

Pototype.PM—perl module required by Windows for running all scripts, used in CIFS migrations only

### **LOGFILES:**

/mgfs1.migLog\_mgfs1 and migErr\_mgfs1

## **NATIVE TOOLS ON CELERRA: /nas/tools/cdms**

disconnect.pl—script to remove unwanted connections

setParam.pl—

snapshotHandler.pl—marks inodes online, used especially for NetApps systems that use ‘snap shot’ feature

#specialCmd getOnline server\_x fsid cid [brings offline directories online; CID=Common Identifier]

#./specialCmd disconnect server\_2 27 <cid> [removes connection without migrating data]

## **DOS 8.3 NAME MANGLING:**

Celerra handles 8.3 names exactly as does Windows. Whenever large numbers of like-named files are copied, Windows or Celerra will not retain exact 8.3 shortened name but will dynamically assign new 8.3 names based on the order of the copy operation.

## **SUPPORTED CDMS V2 NFS PLATFORMS:**

|                                       |                    |
|---------------------------------------|--------------------|
| NetApp Data ONTAP 5.3.4, 5.3.6, 6.1.1 | NFS v2/v3; 4.2.x + |
| AUSPEX 1.9.2                          | NFS v2/v3; 4.2.x + |
| Sun Solaris 2.6/2.7/2.8               | NFS v2/v3; 4.2.x + |
| IP4700 R2.0, R2.1                     | NFS v2/v3; 4.2.x + |
| Celerra 1.2.57, 2.2, 4.1              | NFS v2/v3; 4.2.x + |

| AIX 4.3.3                             | NFS v2/v3; 4.2.x + |

## **SUMMARY OF MIGRATION STEPS:**

1. Create MGFS File System on Celerra
2. Mount MGFS File System
3. Connect to Source File System
4. Export the MGFS File System
5. Query, Verify, Convert MGFS File System after migration, permanently unmount and remount from Celerra

## **CDMS V.2 CIFS MIGRATION:**

- Scenario:** Migrating FileSystem from NT 4.0 Server to CIFS NT 4.0 Data Mover  
--Not recommended for WAN connections  
--Not recommended for many very large files  
--Does not support migration from NT to Win2k domains [Just NT to NT or Win2k to Win2k]  
--Biggest benefit of CDMS is that it allows for migration online with less downtime  
--Multiple sources can now be migrated to a single filesystem

### **1. Create Migration User Account on NT DC:**

- Create User called “cdms\_migrator”, add to Domain Admins and BackUp Operators Global Groups  
--Set Primary Group membership to Domain Admins  
--Remove cdms\_migrator account from Domain Users Group  
--Add User to Target & Source Servers Administrators and BackUp Operators local groups  
--Grant User the Generate Security Audits & Manage Auditing & Security Logs rights on Source & Target Servers  
**Note:** During migration, assign “Deny Access to this computer from the Network” to Domain Users group & grant “Access to this computer from the Network” for the migration User account.

### **2. Conduct complete Tape Backup of Source Server’s Data:**

### **3. Setting Up NT Server With CDMS Migration Tools:**

- Download and install Perl 5.6.1 or later from [www.activestate.com](http://www.activestate.com)  
--Download and install special Win32 API Library for Perl from [www.roth.net/perl/packages](http://www.roth.net/perl/packages)  
c:>ppm  
PPM>install Win32 – API – Prototype

### **4. Copy CDMS Tools from CD-ROM to NT Server [c:\Copy Tools CD\CDMS\cifs>]**

### **5. Run LGDUP Tool to migrate Local Groups from Source to Target Servers:**

c:>lgdup -l logfile.log \\nt1 \\ntdm3

### **6. Run following CDMS Perlscript Tools to Verify & Validate FileSystem to be Migrated:**

**>backupWrapper.exe dirprivW.pl**

This script attempts to read one byte from every file, ensures that directory path names are less than 256 characters, and determines access rights to Share based on the User Account you are logged in with. Script also checks to see if encrypted bits are set on files for Windows 2000 Servers—cannot migrate these files.

**>backupWrapper.exe dircount.pl j:\\**

This script also traverses directory tree path and determines number of path levels deep and number of names involved, and is capable of outputting information into CSV file, which can be imported into Excel, then sorted for path lengths, file sizes, etc.

**>backupWrapper.exe diskusage.pl -m -h**

Script that looks at Source disk usage and translates into Celerra’s 8k block size requirement to estimate Target disk usage

### **7. CREATE LOG FILESYSTEM:**

```
#nas_slice -n disk3 -c d3 11000 1
#nas_volume -n log_vol -c disk3
#nas_fs -n log -c log_vol
#server_mountpoint server_2 -c /mgfslog
#server_mount server_2 /mgfslog
#vi /nas/server/slot_2/param
param mgfs logpathprefix=/mgfslog/mgfs
#server_export server_2 -o anon=0 /mgfslog
Map or Mount to log file system to view logs
```

### **8. Create MGFS FileSystem:**

```
#nas_volume -name str1 -create -Stripe 32768 d3,d4,d5,d6
#nas_volume -name -mtv1 -create -Meta str1
#nas_fs -name mgfs1 -t mgfs -create mtv1 -o mover=server_3
#nas_fs -i mgfs1 [Verify that filesystem is mgfs]
```

**Note:** NAS Versions prior to 5.1 require CDMS license and invokes CallHome

### **9. Mount MGFS FileSystem:** [Front End Mount]

```
#server_mountpoint server_3 -c /mgfs1
#server_mount server_3 mgfs1 /mgfs1
#nas_fs -i mgfs1 [Note change after mounting the filesystem]
```

### **10. Create CDMS Connection to Source:**

```
#server_mount server_3 -o connect,type=CIFS,path=/f$,cifs=\\\\nt1.cdmstn\\f$\\,netbios=ntdm3.cdmstn,account=cdmsnt\\cdmsntb
mgfs1
```

Password: \*\*\*\*\*

**Note:** path=/f\$ is Sharepoint on Source NT Server; \\nt1.cdmsnt\\ f\$\\ is Source NT Server Netbios & Domain name; netbios=ntdm3.cdmsnt is Netbios name for Target Server\_3 & NT Domain name; account=cdmsnt\\ is NT Domain Name; cdmsntb is User Account used in migration—must be a member of Domain Admins and BackUp Operators Groups.

## **11. Create CIFS Share for the MGFS FileSystem:**

```
#server_export server_3 -P cifs -n mgfs1 /mgfs1
```

## **12. Migrate Shares from Source to Target Servers:**

```
c:>sharedup \\nt1 \\ntdm3 f: /SD /P:server_3\mgfs1 /LOG:mgfs1.log
```

## **13. Map Drive From Source NT Server to Target DataMover Sharepoint:**

```
Start>Run: net use * \\ntdm3\mgfs1
```

**Note:** In this example, the drive mapping created drive J: on the NT Server, against which the Migration script will be run

## **14. Start the Migration Script:**

```
c:\Copy Tools CD\CDMS\cifs>backupWrapper.exe migrateW.pl J:\
```

## **15. Observe Progress of Migration:**

```
$server_log server_3 -s -f
```

```
$nas_fs -i mgfs1
```

**Note:** Touch data on folders in migration path for f\$ to help migration along

## **16. Run Verify Command at end of Migration:**

```
#server_mount server_3 -o verify mgfs1
```

**Note:** This will run through entire filesystem to verify the migration & output results to screen

## **17. Convert MGFS FileSystem to UXFS:**

```
#server_mount server_3 -o convert mgfs1
```

```
#nas_fs -rename mgfs1 uxfs1
```

```
#server_umount server_3 -p /mgfs1
```

```
#server_mount server_3 uxfs1 /mgfs1
```

## **RESOLVING INODE ISSUES DISCOVERED WITH VERIFY COMMAND:**

**Note:** CDMS migration cannot complete without the resolution of all unknown inodes. Verify command will indicate which inodes are a problem.

1. \$server\_export server\_x -o anon=0 /mgfs1

2. #mount 192.10.3.32:/mgfs1 /mnt1

3. #find /mgfs1 -inum 187 -print or \$ls -ailR /mgfs1 |grep 187 #find . -inum 14 -print [Prints out path & file for inode]

**Resolution:** Delete inode or force online using specialCmd getOnline server\_x /mgfs1

## **#/nas/tools/cdms/specialCmd getOnline server\_2 /path/file**

**Note:** Use \* for each space if there are spaces within names in the path and enclose entire path in quotations “ “

**[specialCmd getOnline server\\_2 '/fs05/01/Data/Warehouseusers/!!20050120\\_SE\\_EC\\_MIGRATION\W534MGR3/Tony\'s'](#)**

**Note:** Example of various escape slashes and single quotes required to make command execute with \$ & ‘ marks in path

4. Verify effect of command in Server Log

## **TWO METHODS FOR MIGRATING CIFS DATA FROM SOURCE:**

**PREREQUISITES:** sharedup.exe operation & connbuilder.pl utility

## **CONNECTION BUILDER UTILITY:**

Connbuilder.pl utility's purpose is to migrate only those directories of a Source Server that had Shares that you wanted. In otherwords, any folders [such as Program Files, applications, etc] that you did not want to migrate over, you would not have Shared.

Step 1. Use sharedup.exe tool with the /FO switch to obtain a share map of the Source filesystem and output to a file

Step 2. Use connbuilder.pl [must be using a system with Excel & Word programs] to run against sharedup.exe file output to produce template files to support either an Administrative or Top-Level Share migration.

## **ADMINISTRATIVE SHARE METHOD:**

Everything below the Administrative mountpoint is migrated. Data not needed can be ‘excluded’ using exclude parameters in the migrateW.pl, but resulting filesystem “structure” still exists.

## **TOP LEVEL SHARE METHOD:**

Everything underneath the “toplevel” share is migrated, but nothing above.

## **CDMS V.1 MIGRATION:**

|                     |             |                    |
|---------------------|-------------|--------------------|
| Source: Unix System | 192.1.4.250 | Netapps NFS Server |
|---------------------|-------------|--------------------|

|                  |            |                    |
|------------------|------------|--------------------|
| Target: Server_3 | 192.1.4.21 | Celerra NFS Server |
|------------------|------------|--------------------|

|                      |             |                                                                          |
|----------------------|-------------|--------------------------------------------------------------------------|
| Client: Unix Solaris | 192.1.4.200 | [Requires Perl 5.0+ to run migrate.pl script, diskusage.pl script, etc.] |
|----------------------|-------------|--------------------------------------------------------------------------|

**CDMS NFS MIGRATION STEPS:**

**Note:** Target Server requires “root” access to everything on Source because migration requires the Reading of every file!

Step 1. Sun Solaris Client: Must have Perl 5.005\_3+ installed. Load "migrate.pl" & "diskUsage.pl" scripts to Client.

**Note:** Ensure perl is located in correct path! [#which perl]

Step 2. Mount Source NFS Server's File System to SUN Solaris Client:

**#mount 192.1.4.250:/vol/test /mnt2**

a. Determine Disk Usage Requirements for Migration: **./diskUsage.pl -m | 1 | /mnt2 | 8 | no**

Step 3. Create MGFS File System on Target Celerra NFS Server:

a. **\$nas\_volume -n mv\_mgfs1 -M -c d11** [creates metavolume for mgfs fs]

b. Run **#nas\_license -I** to obtain Password Key: 3a8dedc0

b. **#nas\_fs -n mgfs1 -t mgfs -c mv\_mgfs1** [Creates mgfs File System]

**Note:** During creation of MGFS FS, will prompt for password key obtained above

c. Create mountpoint for MGFS File System on Celerra:

**\$server\_mountpoint server\_3 -c /mgfs1**

d. Mount MGFS FileSystem on Server\_3:

**\$server\_mount server\_3 mgfs1 /mgfs1**

Step 4. Create MGFS Logging File System on Target Celerra:

a. Create standard ufs file system for MGFS Logging:

**\$nas\_fs -n mgfs1log -c mtvmgfs1log**

b. Create mountpoint for Log File System:

**\$server\_mountpoint server\_3 -c /mgfs1log**

c. Mount MGFS Log FS:

**\$server\_mount server\_3 mgfs1log /mgfs1log**

d. Edit Param File on DataMover so as to log to this new File System:

**\$vi /nas/server/slot\_3/param**

**param mgfs logPathPrefix=/mgfs1log/mgfs1** [MGFS FS/Log Path]

e. Reboot DataMover

f. Export Log File System on DataMover:

**\$server\_export server\_3 /mgfs1log**

g. Mount to Target File System from Source Server:

**\$server\_mount server\_3 -o connect,type=NFSV3,path=/source,nfs=10.100.50.14:/mgfs1**

Step 5. Unmount Source NFS FileSystem and remount as "RO" for Host Access during Migration

Step 6. Mount Source NFS File System to Server\_3's "MGFS" File System as ReadWrite:

**\$server\_mount server\_3 -p -o nfs=192.1.4.250:/vol/test rw mgfs1 /mgfs1**

Step 7. Export Source NFS File System on Server\_3's MGFS Mountpoint:

**\$server\_export server\_3 -o anon=0 /mgfs1**

**\$server\_export server\_3 -P nfs -n mgfs1 -o anon=0 /mgfs1**

Step 8. From Sun Client remote mount Server\_3's MGFS File System:

**#mount 192.1.4.21:/mgfs1 /server\_3**

Step 9. From Sun Client, begin data migration from Source Server to Target Celerra Server\_3:

a. Have Users mount "mgfs1"on Server\_3 and access data--this will "pull" data over automatically

b. Use Migration Tool Script:

**#export/home/user2/migrate.pl -m /server\_3** [Use of -m switch recommended]

**./migrateU.pl /remote\_mnt**

c. Monitor Migration Status from Celerra: **#nas\_fs -i mgfs1** [From Client: #df -k]

**\$server\_mount server\_3 -o verify mgfs1**

Step 10. After Migration, convert MGFS File System to "UXFS":

**\$server\_mount server\_3 -F -o convert mgfs1 /mgfs1**

Step 11. Permanently unmount "mgfs1" from Server\_3, rename if desired, and remount on Server\_3

**SERVER LOG ENTRIES DURING MIGRATION:**

MGFS: 4: in-processing: fsid=23 40% done

**MONITORING CIFS MIGRATION:**

**\$nas\_fs -i mgfs1**

**\$server\_mount server\_3 -o verify mgfs1**

[Monitor completion of migration via ‘Used Kbytes’ value]

```
$server_mount server_3 -o convert mgfs1      [Converting MGFS1 to UxFS]
$server_config server_3 "mgfs getOnline=/mgfsMountPoint/parentDir1/parentDir2/offlineDir"
```

## **TROUBLESHOOTING CDMS:**

### **NFS Data Migration Summary: Auspex machine to a Celerra**

Step 1. Run disk\_usage.awk & verify that no existing user links remain

Step 2. Copy data from one File System to another and then compare results [using what copy command/tools?]

### **NFS Post Migration Process:**

Step 1. Mount Target & Destination FileSystems from Client [/source /target]

Step 2. #cd source #(date ; find . -print -depth | cpio -pdmv /target/. ; date) > /tmp/move/log.original

Step 3. #cd destination #find . -print -depth > /tmp/move/log.target

Step 4. Vi Original Log: #vi /tmp/log.source

Step 5. Check File System Consistency: #diff /tmp/move/log.source /tmp/move/log.target

Step 6. #df -g /source /target

Step 7. Run disk\_usage.awk on new Celerra to confirm Files & Directories identical

## **KNOWN CDMS MIGRATION ISSUE:**

Primus emc65794 indicates potential for file corruption during migration if >than 4GB in size. Contact TS2 for patch.

## **USING CELERRA EMCOPY MIGRATION TOOLS:**

**Note:** Tools are not publicly posted and are available from the Apps & Tools CD

### **Migrating From NT Server to Celerra:**

**Introduction:** Main objective is to migrate "data" and "NT Attributes" from an existing NT Server to the CIFS Server, while retaining as many original ACL and ACE Directory/File Entries, including file "ownership" permissions, as possible.

**Note:** EMCopy does not transfer files like a 'backup'--that is, as a data "stream", though recent versions of EMCopy are supposed to be equivalent to a 'robocopy' in speed. Therefore, there is a lot of overhead as each file has a Start & Received signal associated with it--up to 20ms delay for each file copied. A better solution for large transfers might be to use a full Tape Backup, and Incrementals, to do the bulk of the migration & then run EMCopy to cleanup. Unlike robocopy, Emcopy does not list and sort directory files first before copying, so there is a slight risk that any Long Filenames that are named with DOS 8.3 names (filename~1.txt) could be overwritten by a file name with an 8.3 name that is the same.

**Caution:** In order to properly copy over NT User Rights, Ownership, & Permissions, the Celerra must have complete UID/GID-mapping information, or Usrmapper running, in order to copy over files & directories completely.

## **BASIC EMCOPY METHODOLOGY:**

### **Source Windows System to Target Celerra CIFS Server**

- I. Select User Account for EMCOPY migration with Domain Admin Privileges
- II. Assign User to 'Localgroups' called 'Administrators' on SOURCE & TARGET Servers
- I. Assign User Rights to this User on both the SOURCE & TARGET Servers
- II. Use LGDUP.EXE to Mirror the "Localgroups" attributes from SOURCE to TARGET
- III. Use EMCOPY.EXE to Mirror both the "Data" & "NT Attributes" from SOURCE to TARGET
- IV. Use SHAREDUP.EXE to replicate NT Shares/Share ACL's from SOURCE to TARGET

### **I. USE A USER ACCOUNT WITH DOMAIN ADMIN PRIVILEGES FOR EMCOPY:**

**Note:** To run any EMCopy Tools, you must select a User Account to be used to conduct the "migration" that has Domain Admins privileges. In the following example, User "newby" is a member of Domain Admins.

### **II. ASSIGN USER ACCOUNT TO LOCAL GROUPS "ADMINISTRATORS" ON SOURCE NT & TARGET CELERRA SERVERS:**

- a.) As Administrator, open "User Manager for Domains" >User>Select Domain> \\SOURCENTSERVER
- b.) Doubleclick on "localgroups" called "Administrators" and add User "newby"
- c.) Repeat step (a) for Celerra: "User Manager for Domains" >User>Select Domain> \\TARGETCELERRA
- d.) Doubleclick on "localgroups" called "Administrators" and add User "newby"

### **Note: If multiple NT Domains are used, add following Global Groups from each Domain:**

"Domain Admins" from each accessing Domain to Celerra's Local Group—"Administrators"

"Domain Users" from each accessing Domain to Celerra's Local Group—"Users"

### **III. ASSIGN USER RIGHTS TO USER ACCOUNT ON SOURCE & TARGET SERVERS:**

#### **SETTING USER RIGHTS FOR NT SERVER & CIFS NT 4.0 DM:**

a.) As Administrator, open "User Manager for Domains" >User>Select Domain> [\\\$SOURCENSERVER](#)

b.) Select Policies>User Rights>Show Advanced User Rights>

c.) For each of the following "rights", highlight the "right" and then "Add" the User "newby":

**Summary of User Rights Required:**

"[Backup Files & Directories](#)"

"[Generate Security Audits](#)"

"[Manage Auditing & Security Logs](#)"

"[Restore Files & Directories](#)"

d.) Repeat Steps (a) thru (c) on [\\\$TARGETCELLERRA](#)

e.) Stop and Start the CIFS Service on the Target Celerra Server [if allowed to do so]

f.) Log Off your NT System and then Log On as the User "newby"

**SETTING USER RIGHTS FOR CIFS 2000 TARGET DM:**

a.) Grant following privileges or rights to the "migration\_user" account on the Data Mover using Celerra Management snapin:

b.) Start>Programs>Administrative Tools>Celerra Management>EMC Celerra Management>Data Mover Management>

c.) Rightclick and select 'Connect to Data Mover'

d.) Add the appropriate compname from the dropdown box

e.) Expand 'Data Mover Security Settings'>User Rights Assignment: Add following rights to "migration\_user"

[→Backup Files & Directories](#)

[→Restore Files & Directories](#)

[→Generate Security Audits](#)

[→Manage Auditing and Security Log](#)

**SETTING RIGHTS ON WINDOWS 2000 SOURCE SERVER:**

Start>Programs>Administrative Tools>Domain Controller Security Policy

Expand "Security Settings">Local Policies>User Rights Assignment

"[Backup Files and directories](#)" >Add>User and group names>select User>Add>o.k., o.k. & repeat for other rights

"[Generate Security Audits](#)"

"[Manage Auditing & Security Logs](#)"

"[Restore Files & Directories](#)"

**IV. RUN LGDUP.EXE: Current Version 1.0.10 (NAS 5.4.19.4)**

**PURPOSE:**

Replicates "Local Groups" database information from SOURCE to TARGET SERVERS. Also replicates User and Group privileges to DataMover. Without this, DataMover would not be able to access Domain-based local Groups.

**PREREQUISITES:**

--Member of either 'Administrators' or 'Account Operators' Local Groups on Source & Target Servers

--Member must have "Generate Security Audits" & "Manage Auditing & Security Log" Privileges within the NT Domain(s)

**LGDUP LIMITATIONS:**

--LGDUP does not migrate "Unknown Accounts" or Local User Accounts such as "local" Administrator account.

**LGDUP SWITCHES:**

**Note:** By default, LGDUP will merge the SOURCE to TARGET localgroups database

**-r** --Use the "-r" switch if you would rather "replace" the TARGET localgroups database with the SOURCE

**Caution:** Versions prior to 1.0.6 "erased" the localgroups database on TARGET!!

**-p** --Use "-p" switch if you are copying localgroups databases from multiple SOURCE servers & want to maintain each SOURCE Server's privileges on the TARGET—adds SOURCE Server name prefix to TARGET database

**-v** --Use "-v" switch for Verbose logging details and redirect output into a text file

**-s** --Use "-s" switch if you do not wish to set or add any member of localgroups on first resolve error—LGDUP will stop

**-l** --Use "-s" switch to redirect output to a new log file

**-l + logfile.name** --Use this switch to append output to existing log file

**-nopriv** --Use "nopriv" switch if you do not wish to duplicate local groups privilege settings

**-u** --Allows for migration of local users (5.4 code)

**Note:** Encoding status of 0 means LGDUP operation was successful

**EXAMPLE OF LGDUP COMMAND PROMPT SYNTAX:**

**FROM SOURCE NT SERVER → TO TARGET CELERRA**

**C:\emctools>lgdup.exe -v \\ntwk1dom1 \\suncor > suncorlgdup.txt**

**C:>lgdup.exe -r -p -v \\source \\target**

**TROUBLESHOOTING:**

--Redirect LGDUP output to file. Check for errors after running to verify results. If following error obtained, User probably does not have appropriate Administrative membership or User Rights to conduct the "migration"

**Error: you do not have the "Generate security audits" privilege on this server.**

*Please set the required privilege(s).*

*You must logon again to get the new privilege(s).*

## **V. RUN EMCOPY.EXE: Current Version 03.01 (NAS 5.6.38.2)**

### **PURPOSE:**

Duplicates Directory Tree from SOURCE to TARGET Servers, preserving Windows NTFS/Ownership ACL's & ACE's on TARGET. Copies both "Data", Windows Ownership/DACL?SACL information, and time stamps.

### **EMCOPY SLOWER THAN ROBOCOPY?**

Robocopy and Emcopy are similar tools used to copy data and NT attributes from a Source to a Target Server. Robocopy, however, caches the target directory & filesystem handle information in a local cache file while performing the copy operation, whereas EMCopy has to open each file and do a GetFileInformationByHandle request across the network to the target side. Next version of EMCopy will cache directory and file attributes so that it more closely emulates Robocopy behavior and will therefore be much faster.

### **PREREQUISITES:**

- Member must have "Backup files and directories" on Source and "Restore files and directories" privileges on Source/Target
- Member of either the 'Administrators' or 'Account Operators' Local Group on Source & Target

**Note:** Must use the Celerra Data Mover Security Management Console for Windows 2000, when setting Celerra User Rights

--Must run "LGDUP.EXE" first or Security attributes will not copy over correctly

--Use following params if Invalid or Orphaned SIDs exist on the Source Server

**param cifs acl.mappingErrorAction=3** [Save ACE & SID if resolved during 1<sup>st</sup> lookup, but don't try again if fails]

**param cifs acl.retryAuthSid=600**

**param cifs acl.FailOnSDRestoreError=0**

### **EMCOPY SWITCHES:**

**/nosec** Disables the copying of NT Security properties for Files/Directories [Takes priority over /o /a /lg /i switches]

**Note:** By default, DACL's are replicated on TARGET—this switch disables copying of DACLs

**/o** Copies ownership information of files & directories--otherwise defaults to account used in Migration, when original owner SID cannot be copied over

**/a** Enables copying of auditing info but "Manage Auditing" privilege must be granted to User account doing copy (SACL)

**Note:** User account requires "Manage audits and security log" Privilege

**/secfix** Forces update to NT security on destination folders & files when they already exist (i.e., updates security)

**Note:** If switch not used, NT Security will only be copied to newly created files & folders during the copy operation

**/lg** Copies local groups security entries—[Use LGDUP first]—local group entries are ignored without this switch

**/lu** Copy local user security entries—ignored without this switch [Added in version 2.17]

**Note:** If SOURCE & TARGET localgroups are not identical, then EMCOPY will stop

**/i** Ignores security entries with local users & suppresses errors

**/create** Create 0 file length rather than copy data

**/s** Copies all subdirectories and files in the tree

**/lev:n** Sets depth of copy operation for scanned subdirectories

n=1 Copies only files in specified source directory

n=2 Copies first level of subdirectories with files

n=3 Copies 2<sup>nd</sup> level of subdirectories with files, [n=4, etc.]

**/d** Copies only those files where LAST modification timestamp is newer than those on the TARGET

[Use this switch if you were running the EMCopy a 2<sup>nd</sup> time, like an incremental copy]

**/sd** Preserves security of Source files--does not copy file if there are Security Descriptor errors, erases Target files with errors

**/l** Evaluates the number of files to copy without conducting any copying [Use with /secfix switch to test security]

**Note:** When used with /secfix switch, will compare NT Security on Source & Target files

**/c** Allows process to continue after retries, otherwise will stop

**/z** Restarts from point of failure

**/r:n** Sets the number of retries that EMCopy will resume after encountering failures—default=100 retries

**/w:n** Set the number of seconds between retries—default=30 secs

**/log:d:\logpath** Creates new file & redirects console messages to the file

**/log+:d:\logfile** Appends new messages to existing logfile, as in incremental migrations

**/purge** Removes files & directories from Destination tree which no longer exist on the Source

**Note:** The 'purge' switch in 2.0.9 removes all contents at Target, acting not as an incremental but a full copy again

**/stream** Switch added version 2.22 to copy ADS (alternate data streams) for files and directories—not copied if switch not used

**/q** Disables file printing as standard output—added version 2.05

**/f** Prints path of SOURCE & DESTINATION files [default is to print only Source Path—version 2.05]

**/u** Switch that forces logfile to be written in Unicode characters (version 2.30)

**/nocase** Creates all files & directories in lower case—added to emcopy 2.06

**/nd:domain\_name** Allows translation of SD using new domain name instead of original domain name

**/preserveSIDh** Preserves SIDs from previous domain [Default is to replace obsolete SIDs with current domain SIDs—version 2.11]

**/xd dir <dir...>** Exclude directories with specified names, paths, or wildcards [Added emcopy 2.16]

**/xf file <file...>** Exclude files with specified names, paths, or wildcards

**/backupsd** Backup security properties without copying file contents—extra files are removed at TARGET as in /purge switch

**Note:** Takes precedence over /nosec; /o; /lg; /i; /create; /purge; /l; /nocase; /d switches

**/restoresd** Restores security properties without copying data

**Note:** When using either backupsd or restoresd switches, must have param set on DM if you wish to have security information restored even if errors are encountered. The /restoresd & /backupsd was introduced with EMCopy 2.07 to allow for the backing up of all Security Descriptors from a Source tree without copying any data. EMCopy creates 0 length files and duplicates the SD without localgroup SID translations and local SID suppression. Restore switch allows SD's (Security Descriptors) to be restored to a destination tree.

**/preserverSIDh** Forces preservation of historical SID info during SD translation

**param cifs acl.FailOnSDRestoreError=0**

## EMCOPY SYNTAX EXAMPLE:

**FROM SOURCE NT SERVER → TO TARGET CELERRA**

**C:\migration>emcopy.exe c:\migration \\suncor\users\ /o /a /lg /s /secfix /d > emcopy.txt**

**Note:** Above command copies the contents of "c:\migration" from the SOURCE NT Server "NTWK1DOM1" to the TARGET CELERRA Server "SUNCOR". File Ownership and ACL properties are mirrored from the Source to the Target.

## EMCOPY SECURITY DESCRIPTOR BACKUPS[ACL Backups]:

### SAMPLE COMMAND SET:

**C:\emcopy x:\ c:\acl /s /lg /o /backupsd**

**Note:** Above command backs up Security attributes on a share called "dave\_test", as represented by the drive mapping letter "x" from the Windows system, and backs up to local "c:\acl" folder on the Windows system. Look at Readme.txt file for other syntaxes available and logging options for debugging.

**C:\emcopy c:\acl x:\ /s /lg /o /secfix /restoresd**

**Note:** Above command will restore Security attributes to the mapped "x" drive for a share called "dave\_test". Also note that in order to run EMCOPY, you will need to configure the following (4) User rights on both the Windows system (Computer Management) and the Celerra (Celerra CIFS Management tool>Security>User Rights Assignment), for the Domain Admin User account being used. You may also need to add this User account explicitly to the Compname's localgroup called Administrators on both systems.

"Backup Files & Directories"

"Generate Security Audits"

"Manage Auditing & Security Logs"

"Restore Files & Directories"

## TROUBLESHOOTING EMCOPY:

### Error When Local Groups Not Migrated Properly or Wrong EMCopy Version Used:

\hsbc\hsbcshare\: Security Descriptor error: Unable to set SD: Error 1337: The security ID structure is invalid.

An ERROR occurred on \hsbc\hsbcshare\

### Error (1359): An internal error occurred

→Above error occurs with Win2k3 migrations where user account names contain illegal characters:

### ILLEGAL WINDOWS USERNAME CHARACTERS:

/ \ “ [ ] : | < > + = ; ? \* , [Nor can names end with period]

**Server Log:** lsa.acct ==\UNIX GID=0x1 (Unsupported character in account name)

User names limited to 20 characters while Group names limited to 256 characters

**Fix:** Use emcopy switch /preservesidh option

### Encoding Status Error Codes:

|   |                                                                                   |
|---|-----------------------------------------------------------------------------------|
| 0 | No error                                                                          |
| 1 | Mismatch error—directory not created because file with same name exists on TARGET |
| 2 | Security error—one or more SD's not applied                                       |
| 4 | Data Copy error—one or more files not duplicated                                  |
| 8 | Critical error—no files or directories copied                                     |

**SHARE LEVEL SECURITY:** Must use /nosec option for Share-Level Security on Celerra

## **VI. SHAREDUP.EXE: Current Version 01.09 (NAS 5.4.14)**

### **PURPOSE:**

Replicating NT “Shares” & “Share ACL’s” from SOURCE to TARGET; replicates only data shares, not admin shares

### **PREREQUISITES:**

--Member of Administrators Local Group on Source & Target [No special privileges or User Rights required]

--Target folder path & directories must already exist

### **SHAREDUP.EXE SWITCHES:**

**ALL** New ‘ALL’ value allows all Source Shares to be migrated over to the Target

**/P** Target Server rootpath, followed by mountpoint to CIFS file system [physical path]: \mnt39 represents File System Mount Point—Unix FileSystem name is “FS39”, Shared as “Suncor”, and Mountpoint is “/mnt39”]

**/r** Replaces target shares if they already exist

**/sd** Duplicates Security Descriptors on all Shares. All "localgroups" on SOURCE must match TARGET Celerra--this is why "LGDUP" is run first when conducting an EMCOPY or SHAREDUP migration

**/lu** Enables copying of local user security entries, else local user info is ignored

**/nd:domain\_name** SIDs translated to new domain based on user/group name from source

**/PREFIX** Adds prefix to shares on Target Server with Source Server’s name

**/FO:shareoutput** Creates list of shares to duplicate on Target Server

**/FO+:shareoutput** Concatenates several drive letters for SOURCE server to TARGET server

**/FI:inputfile** Uses specified file as list of Shares to create on Target

**/LOG:path** Creates log file

**/LOG:+path** Appends to log file

### **EXAMPLE OF SHAREDUP COMMAND PROMPT SYNTAX:**

**FROM SOURCE NT SERVER → TO TARGET CELERRA**

**C:\emctools>sharedup.exe \\ntwk1dom1 \\suncor c: /P /mnt39 /PREFIX /r /sd**

### **Exit Codes:**

- |   |                                            |
|---|--------------------------------------------|
| 0 | No error                                   |
| 1 | Syntax error                               |
| 2 | Server name error or Server Not Responding |
| 3 | Duplication error                          |

### **ALTERNATE NTRESKIT TOOL: PERMCOPY.EXE**

## **VII. EMCACL: Current Version 01.08 (NAS 5.4.14.3)**

### **PURPOSE:**

Used to display or edit ACLs or to change Ownership of files or directories

### **PREREQUISITES:**

--Assign account used to run EMCACL the Backup Files and Directories and Restore Files and Directories privilege

--Member of Domain Users

--Enclose User/Group Account names in Quotations if there are spaces within the names [“Domain Admins\account”]

--Can use wildcards to specify more than one file or directory

--Can combine Access Rights

### **EMCACL.EXE SWITCHES:**

**/T** When used by itself, will scan a directory’s ACLs and display without changing [c:\>emcacl stuff /T]

**Caution:** If used with /O; /G; /R; /P; /D switches, will change ACLs

**/E** Used to Edit an existing ACL without replacing—adds ACEs to the ACL list without deleting

**/C** Continue if errors encountered

**/O** Changes owner to specified User

**/G user;perm F; T spec P** Grants specified Access Rights to Users

**Note:** “perm” applies to files—if “spec” is not included, will also apply to directories; “spec” option will apply only to directories [Values for “spec” & “perm” are the same]

R=Read (equiv. E+X); C=Change (write); F=FC (R+C+P+O+D)

P=Change Perms; O=Take Ownership; X=Execute; E=Read; W=Write; D=Delete (all are Special Access rights)

T Flag will apply if used before the “spec” option. If T used after “;T”, then ACE inheritance is disabled. If T Flag is present, new files will not inherit User privileges of directory itself. If T flag is omitted, new files will inherit ACEs of parent Directory.

**/R** Revokes specified User’s right

**/P user:perm F; T spec** Replaces specified User's access rights—perm is same as /G

**/D user** Denies specified User access rights

**/Y** Replaces User's Access rights without confirmation

**/Q** Prints only Errors & Summary

**EXAMPLE OF EMCACL COMMAND PROMPT SYNTAX:**

**C:\>emcacl.exe \\wkdom4\stuff\\*.\* /T**

**Note:** Will display ACL's for mountpoint

**PRINTING ACLs FOR GIVEN PATH (Not the Sharename):**

**C:\>emcacl.exe \\wkdom4\stuff\\*.\* /T**

**PRINTING ACLs for GIVEN MAPPED DRIVE :**

**C:\emcacl>emcacl.exe z:\\*.\* /T**

**CHANGING OWNERSHIP RECURSIVELY TO ADMINISTRATOR :**

**C:\emcacl>emcacl.exe z:\emcacl /E /O administrator /G administrator:F /Y**

**Exit Codes:**

0 No error

1 Syntax Error

2 Given path not found

3 ACL change failure

OI: Object Inherit ACE (file creation)

CI: Container Inherit ACE (directory creation)

NP: No Propagate Inherit ACE

IO: Inherit Only ACE (used only for inheritance, not access checking)

IA: Inherited ACE

**FSTOOLBOX.EXE:** Version 01.02 NAS 5.5

Tool to remove or change ownership on files or directories for a specific owner, as well as managing Quotas; needs to be run as local administrator—specify User name or SID

**C:>fstoolbox.exe z: info |list |enumallfiles |removeallfiles |removequota |removefilesandquota |changeowner |moveusertree**

Info→Print quota setup of a file system

List→lists all user quotas or specific User if specified

Enumallfiles→list all files/dirs owned by particular user

Removeallfiles →remove all files owned by Username or SID

Removequota →remove quota entry for particular User

Removefilesandquota →remove files & directories of the User and then removes quota entry

Changeowner →change file/dir owner

Moveusertree →move files owned by User in a tree structure

**EMCABE:**

Used to manage access-based enumeration feature for Shares, version 1.00 NAS 5.5

/e →Enables ABE on specified shares

/d →Disables ABE on specified shares

/g →Gets ABE state of share/shares on target server

/t →Target server name

/a →run cmd against all Shares on Target server

/s →specify name of share to run command

**Note:** Must be run against mapped drive letter

**XCACLS:** Command Line Reskit Tool to view and modify NT Access Control Lists that are accessible from Windows Explorer

/E Edit ACL instead of replacing

/G Grants access to User/Group specified

/P Replaces access rights for User or Group specified

**USING EMCACLS UTILITY TO REPERMISSION COMPLETE FILE SYSTEM:**

1. Start with clean slate by running “cifs update /mnt resetacl” to make all files & folders Everyone FC

2. Run recursive #chown -rv administrators to make Administrator owner of all files & folders

3. Run emcacls command to grant Domain Admins, System, Administrator FC permission

4. Run emcacls again to remove Everyone FC group and to assign other permissions as required

## **CELERRA NETWORKING:**

**Intro:** When troubleshooting Celerra Networking issues, aside from the usual customer variables, key areas will be:

1). Ethernet IP configuration, Broadcast Address, subnet mask , gateway address--for both Control Stations and DataMovers.

**Example:** Celerra will not be accessible from NT in a Windows environment unless a valid Subnet Mask and Broadcast Address are used [for Netbios Name Resolution & communication]

2). Verify both Physical-layer and Application-layer connectivity to Celerra using Ping, FTP, TRACERT, etc.

3). Verify Switch/Router setup, such as Duplexing and Speed settings.

4). Verify Name Resolution, WINS, Hosts files are setup, etc.

5). Verify appropriate Celerra services are configured and running—such as CIFS, etc.

## **ETHERNET FRAMES:**

802.3 Frames are always less than 1500 bytes

### **PHYSICAL LAYER 1:**

Wiring & devices used to connect Hosts to a network to transmit and receive data; ability to detect signaling errors on cable

**MEDIA:** Layer 1 physical medium on wire sends data in Bits

**DATALINK:** Layer 2 Protocol using MAC Addresses to deliver Frames; min. frame size 60 bytes, max 1514 bytes

**IP:** NetworkLayer 3 Protocol using IP Addresses delivering Packets

IP is connectionless datagram service designed to interconnect packet-switched networks [Each packet handled as individual entity]

Due to size of UDP segments, IP must fragment for delivery and reassembles UDP Datagrams on receiving end via ID & Offset

UDP is limited to maximum datagram size of 64k

TTL of IP = 255

**MTU = Max. Transmission Unit** = 1500 bytes for Ethernet [Obtain true MTU setting on Interface from server\_ifconfig -a]

**Note:** Windows clients use PMTU Discovery method (Path Maximum Transmission Unit Discovery)

**MSS = Max. Segment Size** = MTU – IP & TCP Header sizes = 1460 bytes [maximum size of data within a TCP segment as negotiated during SYN—largest segment that TCP will send to other end]. Default T\_maxseg for Celerra is 536 bytes.

**UDP:** Layer 4 User Datagram Protocol that provides connectionless delivery of datagrams using IP. Any retransmissions required are generated at Application Layer and must resend the whole datagram.

**TCP:** Layer 4 Transport Protocol using Ports & Sockets delivering segments in both directions in a virtual full duplexing circuit. TCP uses timers when sending data and waiting for Acknowledgements and uses Receiver Flow Control to maintain the optimal data stream. For missing or dropped packets, TCP performs retransmission of only the missing data.

## **TCP/IP 3-WAY HANDSHAKE—“SESSION SETUP”:**

1. SYN seq=x to Server

2. SYN ACK=x+1 Seq=y from Server

3. ACK Seq=y+1 from Client completes session setup

## **CLOSING TCP SESSIONS:**

1. Client sends FIN seq=x to Server

2. Server ACKs with seq=x+1

3. Server performs ‘half-close’ FIN seq=y

4. Client ACKs with seq=y+1 to perform “complete close”

**Purpose:** TCP is a Byte-stream protocol that requires Byte-Stream synchronization of sequence numbers for each host

## **Options Field:**

Negotiated during SYN

--In event of multiple segments lost in a single Window, SACK allows for Sender to specify packets needed to be retransmitted

--Advertised Receive Window also negotiated here

## **TCP FLAGS:** URG, ACK, PSH, RST, SYN,FIN

**Note:** PSH is the “pushbit” and is set by Sender to indicate that no more data remains in its buffer—requires immediate ACK

SYN—synchronize sequence numbers

FIN—sender is finished sending data

RST—reset the connection when segment arrives that appears incorrect for the socket connection in place

PSH—push data to receiving process immediately

-- --no flag is set

## **LISTEN STATE:**

A TCP endpoint that Server uses when new connection requests are received

## **ESTABLISHED STATE:**

TCP module of kernel creates new end points after accepting an incoming connection requests→from LISTEN to ESTABLISHED

**2MSL WAIT STATE (TIME\_WAIT state):**

Max. segment lifetime (MSL) that any segment can exist on the wire before expiring. Common implementations are that upon a TCP close, the TIME\_WAIT status of a connection must remain open for twice the MSL, while not allowing the socket connection to be reused.

**FIN\_WAIT\_2 STATE:**

Time while waiting for other end to acknowledge our FIN, or half-close.

**ACK:**

Acks are typically triggered for every other full sized frame sent

Acks are also triggered when Receiving end gets a frame out of order

**DEFAULT MTU SETTINGS:**

Gigabit Ethernet: 1500 bytes

Fast Ethernet: 1500 bytes

FDDI: 4500 bytes

ATM: 1500 bytes

**SETTING LARGE PACKET 9000MTU SUPPORT ON GIGE:**

**\$server\_ifconfig server\_2 ace0 lcge0 | fxg0 mtu=9000**

**MAXIMUM TRANSMISSION UNIT—MTU:**

Each media type has a maximum frame size that can be transmitted, but in turn, each NIC Interface may have a different MTU value. Link Layer protocol discovers what the common MTU denominator is for TCP for each TCP session between two hosts. The MTU is negotiated during the 3-Way Handshake in setting up a TCP session between two hosts and is negotiated in the SYN packet. Every “route” used typically will have a unique MTU. Most modern switches & routers support 1500 byte frames without fragmenting.

**FIGURING OUT TRUE MTU SETTING FOR NETWORK DEVICES:**

**# server\_netstat server\_2 -i**

| Name           | Mtu  | Ibytes     | Ierror | Obytes    | Oerror           | PhysAddr         |
|----------------|------|------------|--------|-----------|------------------|------------------|
| mge0           | 1500 | 25621621   | 0      | 139978212 | 0                | 0:60:16:f:df:55  |
| mge1           | 1500 | 1112423355 | 0      | 196511688 | 0                | 0:60:16:f:df:57  |
| ---abridged--- |      |            |        |           |                  |                  |
| cge-3-0        | 9000 | 2784149    | 0      | 975247    | 0                | 0:60:48:1b:58:b2 |
| ---abridged--- |      |            |        |           |                  |                  |
| fxg-1-0        | 9000 | 0          | 0      | 0         | 0:60:16:1d:d5:14 |                  |
| fxg-2-0        | 9000 | 0          | 0      | 0         | 0:60:16:1d:d5:17 |                  |

**Note:** The Server Netstat command displays the default physical NIC MTU values (Ethernet Layer), and most Celerra production NICs default to 9000 MTU support—internal NICs use 1500 MTU.

**# server\_ifconfig server\_2 -a**

```
server_2 :
fxg1 protocol=IP device=fxg-1-0
    inet=192.1.4.3 netmask=255.255.255.0 broadcast=192.1.4.255
        UP, ethernet, mtu=1500, vlan=0, macaddr=0:60:16:1d:d5:14
192-1-4-1 protocol=IP device=cge-3-0
    inet=192.1.4.1 netmask=255.255.255.0 broadcast=192.1.4.255
        UP, ethernet, mtu=1500, vlan=0, macaddr=0:60:48:1b:58:b2
```

**Note:** Server Ifconfig displays the MTU setting at the IP level, which is where we generally control the MTU values. Since we default to 1500 MTU, we manually change the device to 9000 MTU Large Packet support.

**# server\_ifconfig server\_2 fxg1 mtu=9000**

server\_2 : done

**CELLERRA TCP ADVERTISED WINDOW SIZE:**

**Definition:** TCP Window Size is the number of data packets that the Sender is allowed to have outstanding with having received an ack from the Receiver. TCP uses a ‘sliding window’ to adjust this Window Size value dynamically during the Session.

Parameter for Windows Clients that determines size of TCP ‘receive’ window, which is the number of bytes that can be received before the Sender must acknowledge. Sender advertises its “receive” buffer size window with every segment of data sent. Sender cannot send more data once full number of bytes is sent that represents the “Receive Window”.

**Default TCP Window Size for Celerra is 65kbytes, max 256kbytes [“param tcp”=tcp.doRFC1323=1]**

**Note:** This option is related to what is called “Windows Scaling” and allows for the Celerra to supply Clients that request “Receive Window” sizes > than 65kb with the larger data window.

→Advertised Window is flow control imposed by Receiver

## **CONGESTION WINDOW & SLOW START:**

Segments are incrementally injected into the network, up to the Window Size advertised by receiver. However, with more complex networks with multiple routers and slower links, there is a need to have a “slow start” mechanism that calculates how quickly to add segments to the network based on the rate of acknowledgments received. This is achieved by using a “Congestion Window” whereby after each ACK, the cwnd is increased by one segment.

→Congestion Window is flow control imposed by Sender

## **HOW THE TCP ADVERTISED WINDOW WORKS:**

--Sender must wait for ACK once full the number of bytes sent equals the Receive Window & cannot send more until ACK

--Normally, TCP ACKs occur for every other full sized segment sent

--Missing frames also automatically cause ACKs for each subsequent frame until the system is back to a normal state

## **KeepAliveTime:**

Determines how often TCP verifies idle connections to determine whether to maintain or breakdown. Keep Alive is not enabled by default. A KeepAlive packet is sent to host connections and if acknowledged, will keep connection alive.

## **TCP IP STACK (NAS 5.4 Enhancements):**

SACK—Selective Acknowledgement—param tcp do\_sack

FACK—Forward Acknowledgement

NEWRENO—param tcp do\_newreno (New Reno algorithm)

**Note:** 3 Algorithms designed to help recovery from lost TCP segment traffic

## **MAC OS (Apple) McIntosh Performance Issues with NAS 5.4:**

Macs do not handle the delayedACK feature well with CIFS and this can cause bursts in traffic followed by long pauses, and overall performance degradation.

### **Solutions:**

**param tcp.maxburst=0** (turn off maxburst from default value of 4—NAS 5.4.17.0 will have this disabled by default)

**# /sbin/sysctl -w net.inet.tcp.delayed\_ack=0** (turn off delayed ack on Mac Client)—to make change persistent, edit the /etc/sysctl.conf and add the string “net.inet.tcp.delayed\_ack = 0” to the end of the file as a new line.

## **CHANGING DM MTU SETTINGS:**

**#server\_ifconfig server\_2 ana0 mtu=1500**

## **Celerra CIFS Interface Rules:**

--multiple NT Domains can be supported by one DataMover, but is not recommended

--Can have multiple Netbios names for a NIC if IP's or Domains are different

--Multiple NIC Ports can have the same name, however, only if different IP's are used within same Domain

--Different NIC Ports can have different Netbios names on Same or Different Domain with different IP's

--All Shares go out over all Interfaces and Domains by default when exported from CLI, to specific Comname when using MMC

**SUPPORTED CELERRA INTERFACES:** ana0=Ethernet fpa0=FDDI fa20=ATM ace0=Gigabit Ethernet

**Maximum of 32 Interface Configurations per DataMover** [2 for Internal network; 1 for loopback; 29 for IP configurations]

## **INTERNAL IP ADDRESSES FOR LINUX CONTROL STATION:** NAS 2.2.34.5

**emcnas\_i0 192.168.1.100**

**emcnas\_i1 192.168.2.100**

## **STOPPING & STARTING INTERNAL CONTROL STATION INTERFACES:**

**# /sbin/ifconfig down eth0**

**# /sbin/ifconfig up eth0**

## **INTERFACE CONFIGURATIONS:** \$server\_ifconfig server\_2 ana0 | ace0 | fsn0

--Shows IP, Mask, Broadcast, whether device is UP or DOWN, MTU Size, and VLAN info

**Caution:** Interface variable is the “name” of the device in lefthand column of server\_ifconfig -a command, not the logical name!

## **CHECKING INTERFACE SETTINGS/STATS using “.server\_config”:**

**\$server\_config server\_x -v “ace ana0 clearstat”** [Use this to clear the server\_netstat -i Statistics counters]

```
$server_config server_2 -v "ana ana0 stat"
$server_config server_2 -v "ace ace0 stat"
$server_config server_2 -v "fsn fsn0 stat"
$server_config server_x -v "bcm cgeX stat" |showmac |intrstat |timerstat [Stats for Broadcom NIC]
$ .server_config server_2 -v "bcm"
```

Usage: bcm <device> <command> [parameters]

commands and parameters are:

- up | start - Enable interface
- down | stop - Disable interface
- clearstat|clearstats - Clear all statistics counters
- showmac - prints current and native mac addresses
- setnative|mac - set current mac addr to native mac addr
- stat - prints default statistics
- ifstat - prints interface statistics (MIB-II[8,9])
- intrstat - interrupt statistics
- timerstat - Timer statistics

```
# .server_config server_2 -v "bcm cge0 showmac"
```

Current Mac Address -> 8:0:1b:42:48:65

Native Mac Address -> 8:0:1b:42:48:65

1074543292: ADMIN: 4: Command succeeded: bcm cge0 showmac

```
$ .server_config server_X -v "bcm cge0 stats"
$ .server_config server_X -v "bcm cge0 macstat"
$ .server_config server_X -v "bcm cge0 intrstat"
$ .server_config server_X -v "tcp stat"
$ .server_config server_X -v "ip allstat"
$ .server_config server_X -v "trunk trk0 stats"
```

## **TRUNKED OR FSN CONFIGURATIONS PRESENT SINGLE MAC ADDRESS BASED ON ACE0:**

```
# server_ifconfig server_3 -a
```

server\_3 :

```
fsn protocol=IP device=fsn0
    inet=10.73.3.24 netmask=255.255.255.0 broadcast=10.73.3.255
        UP, ethernet, mtu=1500, vlan=0, macaddr=0:60:cf:20:26:71
```

```
# .server_config server_3 -v "ace ace0 showmac"
```

Current Mac Address -> 0:60:cf:20:26:71

1112965793: DRIVERS: 4: ace0: Using Local MAC address 0:60:cf:20:26:71

Native Mac Address -> 0:60:cf:20:26:71

1112965793: ADMIN: 4: Command succeeded: ace ace0 showmac

    mtu=32768, dmtu=65536, vhid=0, mac=0:0:0:0:0:0 dmac=0:0:0:0:0:0
```

**Note:** This command also is useful for determining whether the Server is negotiating Full, Auto, or Half Duplex, Speed, etc!

**10/100 Interface:** Tells whether Auto/Manual, Speed and Duplex Settings [Half, Full, 10/100Mb/s]

**Gigabit Interface:** Tells you whether interface “LINK is UP, NIC is STARTED”

**Virtual Interface:** Tells you whether Virtual Interface is UP, and which NIC Port is ACTIVE--Also lists NIC's configured.

### **DETERMINING DM SPEED & DUPLEX SETTINGS:**

```
$server_config server_2 -v "ana ana0 stat" [Shows status of link]
$server_log server_2 > slog2 [Negotiation status reflected after a BootUp too]
```

### **SPEED & DUPLEX SETTINGS ON GOLDEN EAGLE:**

```
# .server_config server_2 -v "ians cge0 ifstat"
```

Intel Gigabit Controller

| IfType   | IfMTU  | IfSpeed   | IfOper    |        |
|----------|--------|-----------|-----------|--------|
| ethernet | 9018   | 1 Gb/s    | Up        |        |
| AutoNeg  | Duplex | RXFlowCtl | TXFlowCtl | Media  |
| disabled | full   | disabled  | disabled  | Copper |

**Note:** Above output indicates speed and duplex as FULL DUPLEX.

### **SERVER LOG WILL ALSO SHOW SPEED SETTINGS:**

```
# server_log server_3 -s |grep -i speed
```

```
2005-02-26 14:19:25: DRIVERS: 4: cge4 : Link Status : UP, Speed : 1000, Duplex: FULL
2005-02-26 14:19:25: DRIVERS: 4: cge0 : Link Status : UP, Speed : 1000, Duplex: FULL
```

### **TROUBLESHOOTING COMMANDS:**

```
$server_config server_2 -v "printstats rpc" [RPC Statistics]
```

**\$server\_config server\_2 -v "ace ace0 stat"** [Gigabit Interface]

**\$server\_config server\_2 -v "ace ace0 updown"** [Gigabit Interface]

**\$server\_config server\_2 -v "logsys set severity IP=LOG\_DEBUG"** [Debug cmd for IP]

### **CLEARING STATISTICAL COUNTERS ON INTERFACES FOR IP, TCP, ICMP, UDP:**

**\$server\_config server\_2 -v "printstats tcpcstat reset"**

**\$server\_config server\_2 -v "printstats ipstat reset"**

**\$server\_config server\_2 -v "printstats udpstat reset"**

**\$server\_config server\_2 -v "printstats icmpstat reset"**

### **TUNABLE UDP/TCP TIME-TO-LIVE PARAMETERS:**

Default udp.ttl and tcp.ttl values are 0x40, while MAXTTL value is 255

**\$server\_config server\_x -v "param udp ttl=0x80"**

**\$server\_config server\_x -v "param tcp ttl=0x80"**

**# .server\_config server\_3 -v "param fulldescription udp ttl"** [add'tl syntax required to output param info NAS 5.5]

udp.ttl 0x01b74710 0x00000040 0x00000040

### **PLACING INTERFACE UP or DOWN/DELETING:**

**\$server\_ifconfig server\_4 ana0 up [down|trk0,fsn0]**

**\$server\_ifconfig server\_2 -d ana0**

**Note:** This also is the way to make changes to the Interface effective, rather than rebooting the whole server!

### **FAST ETHERNET SETTINGS:**

1. Setting IP/Mask/Broadcast:

**\$server\_ifconfig server\_2 -c -D ana0 -n ana0 -p IP 193.1.21.172 255.255.255.0 193.1.21.255**

2. Setting Speed and Duplex Settings:

**\$server\_sysconfig server\_2 -pci ana0 -o speed=10|100|auto,duplex=half|full|auto**

**# server\_sysconfig server\_2 -pci cge0 -o speed=auto,duplex=full**

server\_2 : done

**# server\_sysconfig server\_2 -pci cge0**

server\_2 :

On Board:

Broadcom Gigabit Ethernet Controller

0: cge0 IRQ: 23

speed=1000 duplex=full txflowctrl=disable rxflowctrl=disable

### **VERIFY DM SPEED/DUPLEX/LOAD BALANCING SETTINGS (MAC, IP, TCP):**

1. Server Log contains correct speed/duplex condition

**2. \$ server\_ifconfig server\_2 ana3**

server\_2 :

ana3 protocol=IP device=ana3

inet=10.64.25.72 netmask=255.255.255.0 broadcast=10.64.25.255

UP, ethernet, mtu=1500, vlan=0, macaddr=0:0:d1:20:50:4c

**3. \$ server\_sysconfig server\_2 -v -i fsn01**

server\_2 :

\*\*\* FSN fsn01: Link is Up \*\*\*

active=trunk01 standby=trunk01 trunk02

**\$ server\_sysconfig server\_2 -v -i trunk02**

server\_2 :

\*\*\* Trunk trunk02: Link is Up \*\*\*

**\*\*\* Trunk trunk02: Statistical Load Balancing is IP \*\*\***

Device Link Duplex Speed

---

ana4 Up Full 100 Mbs

ana5 Up Full 100 Mbs

**Note:** Output from these commands may be incorrect—see Server Log!

**\$ server\_sysconfig server\_2 -v -i trk001**

server\_2 :

\*\*\* Trunk trk001: Link is Up \*\*\*

\*\*\* Trunk trk001: Statistical Load Balancing is TCP \*\*\*

**4. \$ .server\_config server\_2 -v "ana ana2 stat"**

```

**FAST ETHERNET QUAD CARD PERFORMANCE CHARACTERISTICS:** Adaptec Quad FE for 507 DM**Theoretical maximum output is 100Mbps=12.5MB/second****Actual Performance:** READ TRANSFER RATES = 7MB/second [Adaptec Hardware limitation]

WRITE TRANSFER RATES = 11.7MB/second

**Typical Performance:** 5MB/sec**CASE STUDY: COPYING DATA FROM ONE DIR TO ANOTHER ON SAME FILESYSTEM:**

**Situation:** Slow performance while performing copy of data from one subdirectory to another on the same Celerra file system. Customer calculates throughput of 4.375MB/sec while copying 500GB from one part of the filesystem tree to another when using Windows 2000 Client Explorer interface [rightclick copy, rightclick paste]. Network Traces show that DM SRT [Server Response Time] is very good--1.5ms, while Windows 2000 Client CDT [Packet Data Unit] and CNRT [Client time to next Read request] times of 5.1ms & 6ms, respectively, were poor.

In actuality, throughput operation on the Data Mover had a combined "read" and "write" rate of 8MB/sec. The limiting factor in this scenario was the Windows 2000 client, which [as designed] conducts non-overlapping synchronous 64k Reads from and Writes to, the DM. The overall effect is somewhat analogous to half-duplexing and limits the theoretical throughput to a maximum of 12.5MB/sec. If the Windows 2000 client used overlapping asynchronous IO operations, then the combined theoretical maximum rate would be closer to 25MB/sec.

The combined throughput of 8MB/sec, out of a total theoretical maximum of 12.5MB/sec, reflects a healthy and normal copy operation rate on the Data Mover. While using a more powerful Windows 2000 Client would increase the actual overall read/write operation throughput, a better solution for the customer would be to perform a "cut & paste" operation, which does not have to copy actual data, just changes the metadata pointers to reflect the change in directory location of the data.

**OPTIMAL ETHERNET SETTING FOR CELERRA FE:**

Hard-code the Link Partner settings to 100 Full for Celerra Interface and Switch Port.

**FAST ETHERNET SPECS:**

**100BASE-T** →Original Fast Ethernet spec 100Mbits/sec based on old Ethernet standard (IEEE 802.3 ) using CSMA/CD (Carrier Sense Multiple Access/Collision Detection), IEEE 802.3u is the updated spec for 100Mbits/s

**100BASE-TX** →2 prs of cat5 wire, performs at 100Mbits/s half-duplex mode or 200Mbits/s Full Duplex, distance 100 Meters 4 bits/transmission sent at 25MHz clock speed to yield 100Mbits/s

**100BASE-T4** →4 prs twisted pair wire, purpose to link two 100 meter segments together on the LAN

**100BASE-FX** →100Mbits/s Fast Ethernet over Fibre Optic cables half-duplex (400meters) or Full Duplex mode (2km), two multi-mode optical fiber strands for receive and transmit

**Changing Ethernet Max Received Packets-Processed:** Change when more packet processing per interrupt is required

**param ana rxburst=512** [Default value=hex 100, decimal 256]

## **FAST ETHERNET PORT LIGHTS:**

Righthand light for each ana port: Green Light indicates network link and running at FULL DUPLEX 100TX SPEED  
Amber Light indicates network link but running at HALF DUPLEX 10BASE-T SPEED

Lefthand light for each ana port: Amber light indicates network traffic [port is passing data]

## **DM ETHERNET INITIALIZATION:**

When links are being brought up, link pulses are suspended to ensure that links are severed.

When link pulses are restarted, Switch senses and initiates link from its end.

DM then broadcasts ARP request for itself in order to update MAC forwarding tables of Switches

## **DISABLING/ENABLING RIP PROTOCOL ON DM:**

**\$server\_rip server\_2 noripin ana0 | ripin ana0**

**\$server\_rip server\_2** [Displays RIP Status]

**Note:** Introduced with NAS 4.0.12.1

## **USING TRACEROUTE ON CS:**

**# /usr/sbin/traceroute**

## **USING TRACERT ON DATA MOVER (NAS 5.6):**

**\$ .server\_config server\_2 -v "tracert ip=128.222.121.1"**

\$ server\_log server\_2 -a -s ltail

HOP:1, DST:128.222.121.1, Router:10.8.126.1

HOP:2, DST:128.222.121.1, Router:10.5.191.202

HOP:3, DST:128.222.121.1, Router:57.225.20.57

HOP:4, DST:128.222.121.1, Router:57.215.105.188

HOP:5, DST:128.222.121.1, Router:57.215.105.182

HOP:6, DST:128.222.121.1, Router:10.6.193.233

## **SWITCH BASICS:**

--Celerra should work with all switches [FE or GbE] that are IEEE compliant

--Switches should guarantee that packets from single TCP connection always go through same link in each direction if using Celerra Trunking [link aggregation]

--Celerra understands ARP, RIP, 802.3ad, 802.1q

--Each port on a switch is its own Collision Domain [Dedicated vs. Shared Network that Hubs offer]

--Switches operate in Full Duplex mode

--switches are multiport ‘bridges’ that make use of ‘learn & forward’ tables

## **SPEED & DUPLEX MISMATCHES: [Settings of Host and Switch Port are key]**

### **DUPLEX MISMATCH SYMPTOMS:**

--On side with Full Duplex set, may see Runt, Alignment errors, CRC errors, but no collisions

--On half-duplex side will see High Collisions & Errors

**Note:** Netstat command can help in determining collisions. Most important concept in Duplex mismatches is that the “link partners” must be set the same [Host interface to Switch interface]. Settings between Connection Partners is not as meaningful.
