**HUBS:** Hubs always check for Collision Detection since by definition they are always half-duplex. Hubs can never negotiate with a switch—it does not have the intelligence built-in. Since Hubs cannot autonegotiate with the switch, if the Switch cannot set itself to half duplex by default, then the link may never come up. Newer Cisco switches tend to default to 100 Full.

**Note:** You can still change the switch setting manually to half-duplex.

### **LINK PARTNERS:**

Physical NIC connection between Host and Switch—this is where Duplexing matters, between the Host and the Switch, not between one Host and another Host on the other side of a switch. Link pulses, or link light comes on when each Interface is linking together.

### **CONNECTION PARTNERS:**

Logical connection between two Host systems on different networks [more along TCP Socket connection]

### **BRIDGES:**

- Bridges bring two different Broadcast Domains together
- Uses table of MAC Addresses
- bridges forward Broadcasts to all ports if it hasn't learned the specific MAC Address [Learn & Forward]
- Spanning Tree attempts to detect Broadcast loops

### **Route Table:** Celerra uses "rip" protocol by default

Temporarily Flushing Route Table: \$server\_route server\_2 -f [good until next reboot]

Permanently Flushing Route Table: \$server\_route server\_2 -DeleteAll

Removing an Entry from Table: \$server\_route server\_2 -d guppy 192.10.2.34

**Note:** server\_route -list can only output 64 lines. Use “amgr showroute” to output all entries.

### **CELERRA GIGABIT ETHERNET:** Stnd SC Cables: FDDI 62.5 micron or FC-AL 50 micron

**Alteon 1000Base-SX Gigabit Ethernet Rules:** (2) ports/Datamover. + (1) Quad Eth. Or FDDI card. Jumbo Frames, mtu=9000bytes 505DM+

1. **\$ server\_ifconfig server\_4 -c -D ace0 -n ace0 -p IP 193.1.21.122 255.255.255.0 193.1.21.255**
2. **# server\_sysconfig server\_2 -pci ace0 -o linkneg=disable** [disables autonegotiation]

### **COPPER ETHERNET vs. FIBER ETHERNET:**

Copper Ethernet usually configures Port Negotiation for Catalyst Cisco Switches as part of the port speed settings:

speed:auto | duplex:auto

speed:1000 | duplex:full

For Cisco versions of CatOS, Fiber Ethernet (1000BaseX) still uses Speed & Duplex settings, but Port Negotiation is handled via separate protocol and configuration. If Port or Gigabit Negotiation is Enabled (#show port negotiation), Celerra ACE ports will not work unless Linkneg is Disabled.

For Cisco versions of Native IOS or CatIOS, Port Negotiation would be enabled or disabled when configuring port speeds. If speed is hard-coded, i.e. Full, then Port Negotiation is Disabled. Again, Celerra ACE ports would not work correctly unless Linkneg were Disabled. If port speed is Auto, Port Negotiation is Enabled, and Celerra default is also Linkneg Enabled.

**# show port**

**# show port negotiation**

**# set port negotiation**

**# show tech**

**# show etherchannel load-balance** [Port load balancing scheme in use]

### **CELERRA GbE SETTINGS & LINK NEGOTIATION:**

**Note:** Following case example is based on Alteon 1000Base-SX Interface on Celerra, and the Cisco 6509 GbE Switch. Newer GbE switches that use fibre ports vs. copper will have different criteria.

#### **CISCO 6509 & ALTEON 1000Base-SX NIC:**

Speed settings are automatic and are set to Full Duplex by Default. In some cases, you may need to change Celerra “linkneg”, or autonegotiation, to “disable” and set the Switch accordingly, per the following example:

Step 1. Disable Gigabit AutoNegotiation: **\$ server\_sysconfig server\_2 -pci ace0 -o linkneg=disable**

Step 2. Catalyst 6509 GB Switch:

- a. Set port flowcontrol 9/3 send off
- b. Set port negotiation 9/3 disable
- c. Set spantree portfast 9/3 enable

**Explanation:** Problem can be that the NIC & Switch will have trouble negotiating the link because of conflicting flowcontrol settings. Setting the flowcontrol on the switch to off, then disabling negotiation on both sides, “hard-codes” a mutually acceptable link configuration on each side. Also, use the “portfast” command on Switch if the server is an end node, as it is desirable to bypass the

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
full spanning-tree calculations on ports connected to end nodes. DO NOT use this command on ports connected to other network devices, because that can create a bridging loop, which can degrade an Ethernet network.

## **CELERRA & GIGABIT SWITCH RULES:**

Always Full Duplex with effective bandwidth of 2GBPS on each Switch port

Port Negotiation—all Ports on switch enabled by Default

Duplex-----Full Duplex by default [CANNOT be changed for Gigabit] {two stations Tx and Rx simultaneously}

Flow Control-----Set to Off for Rx and Desired for Tx

Jumbo Frames-----Disabled by default

### **Enabling Jumbo Frames on a Port:**

#set port jumbo 2/1 enable [disable]

#show port jumbo

**Switch Management:** Telnet or SNMP or SSH using the In-Band sc0 Interface or Out-of-Band s10 Interface

In-Band sc0 Interface: Connected to switch fabric and used with STP, CDP, VLAN's—tool normally used

    Switch IP Routing Table: Used to forward traffic originating on the switch, not for forwarding traffic sent by devices  
    Connected to the switch

Out-of-Band s10 Interface [Serial Line Internet Protocol—SLIP]: Not connected to switch fabric

### **Setting Switch VLAN, IP address, and MASK:**

#set interface sc0 5 172.20.52.124/255.255.255.248

#set interface sc0 up [down]

**Note:** IP Address and Subnet Mask required. Broadcast address optional. Gateway needed for inter-networking.

## **TROUBLESHOOTING GB SWITCH PORTS:**

|                                                     |                                                            |
|-----------------------------------------------------|------------------------------------------------------------|
| #ping -s 12.20.5.3 800 5                            | [ping host with packet size of 800 bytes with (5) packets] |
| #traceroute 12.20.5.3                               | [Layer 3 IP Trace between network Hosts]                   |

| #show interfaces trunk                              | #show mac-address-table                                    |

## **BASIC INFORMATION WHEN WORKING ISSUE INVOLVING CELERRA GbE PORTS :**

→Are Celerra interface ports built into Trunks, FSNs, or both ? [Relevant for all Ethernet 10/100/1000 Ethernet ports]

→Is network backbone built on Copper or Fiber GbE ?

→What is the link negotiation on the Switch ports that Celerra is connected to ?

→What is the Switch Port Speed Settings & Duplexing for ports connected to Celerra ? [Relevant for all Ethernet issues]

→If EtherChannel port aggregation is used, are Switch Ports enabled for EtherChannel (Cisco) ? [Relevant for all Ethernet]

→If Trunking is in use, verify type of Statistical Load Balancing in use—NAS 5.4 provides new default based on IP [MAC, IP, TCP]

→Is Flow Control Enabled or Disabled on Switch ports and data mover interfaces ?

→CatIOS or CatOS Version of the Switch that we are connected to ? [Relevant for all Ethernet issues]

→Network Topology would be ideal (though frequently not available) [Relevant for all Ethernet issues]

→Switch chassis model & switch module model numbers for ports to which DM is connected to [Relevant for all Ethernet issues]

→If LACP aggregation is configured on the DM, are the switch ports also configured ? [Relevant for all Ethernet issues]

→Switch port state and port error statistics on the ports to which the DM are connected to [Relevant for all Ethernet issues]

→Switch error log (if available) [Relevant for all Ethernet issues]

→Switch port VLAN configuration ?

## **GBIC [Gigabit Interface Converter] MODULES :**

I/O device that plugs into GB Ethernet Switch port supporting UTP Copper or Fibre Optic media. A GBIC is a transceiver that converts serial electrical current to optical and optical to digital electrical current.

**GIGABIT PORT NEGOTIATION:**

- Not used for negotiating port speeds
- Used for flow-control parameters and duplex information
- Port negotiation set to Enable by default for all ports
- Ports on both ends of a link must have same setting!!!! {Link may NOT come up if both ends are set differently}

**AutoNegotiation States and Resulting Link Status Table:**

| <i>Local Port Neg. State</i> | <i>Remote Port Neg. State</i> | <i>Local Link Status</i> | <i>Remote Link Status</i> |
|------------------------------|-------------------------------|--------------------------|---------------------------|
| Off                          | Off                           | Up                       | Up                        |
| On                           | On                            | Up                       | Up                        |
| Off                          | On                            | Up                       | Down                      |
| On                           | Off                           | Down                     | Up                        |

**ENABLING/DISABLING SWITCH PORT NEGOTIATION:**

# set port negotiation 2/1 enable [disable]

# show port negotiation 2/1

**GIGABIT FLOW-CONTROL:** Flow-control for a Gigabit port is implemented when the port's "receive" buffer becomes full. The port transmits a "pause" to remote ports in order to delay inbound traffic for Xamount of time.

**Flow Control Table:**

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| Receive on      | Port uses flow-control if dictated by neighboring ports           |
| Receive desired | Port uses flow-control if neighbor ports uses, otherwise does not |
| Receive off     | Does not use flow-control at all                                  |
| Send on         | Port sends flow-control frames to neighboring ports               |
| Send desired    | Port sends flow-control fames to neighbor ports only if requested |
| Send off        | Port does not use flow-control to send to neighboring ports       |

**SETTING SWITCH FLOW CONTROL:**

# set port flowcontrol 2/1 send on [receive on, etc.]

# show port flowcontrol [To verify settings]

**SPANNING TREE PROTOCOL:**

**Purpose:** Since there should only ever be (1) active path between (2) nodes on an Ethernet network, the Spanning Tree Protocol {STP} is used to prevent loops in multi-path configurations by automatically calculating the best path. Also used for path redundancy. A problem with Spanning Tree is that new connections are blocked for 45 sec. while deciding if the connection will cause a bridge loop. Fast Access is an option that will prevent this Spanning Tree Blocking.

**Basic Operation:** STP Works at each Port by Blocking>Listening>Learning>Forwarding>Disabled

**SPANNING TREE PROTOCOL: Port Transition States**

- I. Initialization to Blocking
- II. Blocking to Listening
- III. Listening to Learning [or Disabled] [This state not active if port uses Frame Forwarding for PortFast]
- IV. Learning to Forwarding [or Disabled]
- V. Forwarding to Disabled

**Note:** Use "PortFast" mode only on Ports that are directly connected to workstations so as to go directly to the "Forwarding" state, which bypasses the "Listening" & "Learning" states. The use of PortFast helps to overcome the problem where new connections are blocked for 45 secs. by the STP.

**ENABLING PORTFAST FOR SPANNING TREE PROTOCOL:**

# set spantree portfast 2/1 enable [disable]

# show spantree portfast 2/1

**Troubleshooting Switches:**

- |                         |                               |                                             |
|-------------------------|-------------------------------|---------------------------------------------|
| --switch configuration  | --switch blades configuration | --are there VLANs configured                |
| --Jumbo packets set?    | --Flow Control on?            | --Is there a diagram available?             |
| --switch software/patch | --switch model number         | --Network traces--port spanning of switches |

**SETTING PAUSE FRAME FLOW CONTROL ON CELERRA GbE INTERFACES:**

With NAS 4.2 and higher, gigabit interfaces can now be enabled for "Pause Frame Flow Control"

**Example:** Switch buffers can overflow, resulting in dropped packets to or from Celerra using GbE

**Cause:** While not generally likely in modern switches, some switches may be susceptible to having their buffers fill, overflow, and drop packets due to traffic bursts from the Celerra using Gigabit Ethernet.

**Fix:** Celerra can be configured to conform to 802.3 GbE Standard in which a feature called "Pause Frame Flow Control [RxTx]" can be enabled on the DM GbE interface. Implementing the following settings means that a capable switch can stop traffic flow from a Host if its buffers are getting full, then allow a resumption of traffic [similar to an X-on, X-off operation]:

### **SETTING PAUSE FRAME FLOW CONTROL ON CELERRA GbE INTERFACES:**

**1. \$server\_sysconfig server\_7 -pci ace0 -o txflowctl=enable | disable**

**2. \$server\_sysconfig server\_7 -pci ace0 -o rxflowctl=enable | disable**

### **PAUSE FRAME FLOW CONTROL:**

NAS 4.2 adds this feature where the switch can stop the flow of data if its buffers are full, and restart client when ready [X-on -off]

#### **Celerra Pause Frame Flow Control works under the following conditions:**

1. Autonegotiation is turned on: linkneg=enable
2. Pause Flow Control Set using Sysconfig: txflctl=desired; rxflctl=desired
3. Switch port also set to autonegotiate
4. Only supported on full duplex GbE links

### **WHEN WOULD PAUSE FRAME FLOW CONTROL BE USED FOR DM?:**

If inbound packets are being received and dropped by DM. Prior to implementing, check outbound flow control RingFull Errors on DM: \$.server\_config server\_x v “ace ace0 stat”. If autonegotiation is turned off on the DM & Switch port, pause frame send and receive can be enabled via the “txflowctl” & “rxflowctl” parameters.

**Note:** Pause Frame Flow Control support was added for Copper Gigabit interfaces on the DM with NAS 5.2.10.0.

### **RINGFULL ERRORS ON DM ETHERNET CARDS:**

RingFull errors result when outbound frames are being dropped from the DM interface, often due to oversubscribed hardware buffers during heavy load conditions or during GETTATTR storms from Solaris clients. Engineering has provided a software buffer to help handle these conditions, but the patch is not yet developed for BCM Copper Gigabit devices yet:

**param maxsecringsize=4000**

### **INTEL (ians) & BROADCOM (bcm) COPPER GbE INTERFACES:**

Both devices can experience a problem with ringfull errors on their transmit rings. We added secondary transmit ring for BCM devices—this is also being reviewed for IANS.

### **GIGABIT ETHERNET & AUTONEGOTIATION:**

**Term “autonegotiate” means that a device will detect Speed and then try to find out what the Duplex setting is at the other end**

1. Duplexing—usually always set to Full
2. Pause Frame Flow Control [RxTx]
3. Remote Fault—ability of link partner to signal status even if its receive link is not operational

### **CELERRA BEST PRACTICE WITH GIGE AND AUTONEGOTIATION:**

Celerra performs autonegotiation by default if Switch is enabled—in otherwords, if Switch supports Auto, then set Celerra to Auto  
If autonegotiation is not supported on the Switch, then it must be disabled [-o linkneg=disable]

**\$ server\_sysconfig server\_2 -pci ace0 -o linkneg=disable | enable** [flow control is also on]

### **GIGABIT ETHERNET NEGOTIATION RULE FOR CELERRA:**

→GbE on Celerra should never have a setting that is different from the corresponding Switch Port. Also, potential performance issues if Clientside is not set correctly from Interface to Switch:

**Full—Full or Auto—Auto**

### **GIGABIT INTERFACE TROUBLESHOOTING/KNOWN ISSUES:**

Symptom: Gigabit interface loses connectivity

**\$server\_config server\_x -v “ace ace0 clearstat”** [Clears the stats—server\_netstat server\_x -i]

**\$server\_config server\_x -v “ace ace0 stat”**

**\$server\_config server\_x -v “ace ace0 ringstat”**

Resolution: Delete Gigabit interface and rebuild using server\_ifconfig command

### **XBLADE 65 TEMPEST MODULE NETERION XFRAME 10GbE OPTICAL NIC:**

**\$ .server\_config server\_x -v “xena fxg0 stat”** [Viewing port statistics on the 10GbE interface]

**\$ .server\_config server\_x -v “xena fxg0 macstats”**  
**\$ .server\_config server\_x -v “xena fxg-1-0 stop”**  
**\$ .server\_config server\_x -v “xena fxg-1-0 start”**

### **10GbE NETERION FAILOVER ISSUES (Trunking, LACP, 10GbE to 1GbE, etc) AR152623:**

→A recent issue in 5.6.44 & 5.6.45 code exists when using Jumbo frames with 10GbE

#### **Suggested Workarounds:**

1. Set the following param

**param xena maxRxJumboRefill=192**

**\$ .server\_config server\_2 “xena fxg0 maxjumborefill 192”**

2. Or, if the customer is not using Jumbo Frames, then remove the following param from the /nas/site/slot\_param file

**param xena maxsdu=9000**

### **CELERRA MULTIHOMEING CHARACTERISTICS:**

- I. Multihome V1.0: Ability to have multiple interfaces in different subnets, but each interface supports only one subnet
- II. Multihome V1.1: Multiple interfaces on same subnet
- III. Multihome V1.2: Multiple NIC ports on one DM
- IV. Multihome V2.1: Trunking device; Single IP for multiple interfaces; Bandwidth aggregation; statistical load balancing; Link Failover; Supports Fast and Gigabit Ethernet.

### **CELERRA 10GbE ETHERNET NETWORKING:**

Single port Neterion 10GbE Ethernet module: NS80, NSX, NS-960 (Firestorm), NS-G8

Dual port Neterion 10GbE Ethernet module, + dual port Copper 1GbE: NX4, NS-G2, NS-120, NS-480 (Mojito)

#### **Media Specification for 10Gbps Ethernet:**

→Based on the IEEE 802.3ae standard, which allows for 10Gbps Ethernet transmission over short wavelength Multi-mode fiber (MMF), using core diameters of 50 or 62.5 microns

→10GBASE-SR/SW 10G Ethernet topology (SR=short range; SW=short wavelength)

→Full duplex and optical fiber only

→Firestorm and Mojito 10GbE cards use Finisar SFP+ Transceivers, FTLX8571D3BCL-E5, EMC Part # 019-078-041, which is a Class 1 VCSEL Laser Product (Vertical Cavity Surface Emitting Laser—low cost & power) that is RoHS-6 compliant, lead-free, and operates at 850nm wavelength as a 10Gb/s Datacom SFP+ Transceiver, delivering serialized data over multi-mode fiber (MMF) single wavelength @10.3125Gbit/s, modal bandwidths from 160MHz/km – 2000MHz/km, and distances from 26meters to 300meters, and is specifically designed for use in 10GBASE-SR/SW networks

→The SFP+ uses a duplex LC fiber optic connector (1.25mm), basically a miniature version of the SC connector (2.5mm)

#### **OM2 Shortware Optical Cable Media:**

8Gbps 50 meters

4 Gbps 100 meters

2 Gbps 300 meters

1 Gbps 500 meters

#### **OM3 Shortware Optical Cable Media:**

8Gbps 150 meters

4 Gbps 380 meters

2 Gbps 500 meters

1 Gbps 860 meters

### **CELERRA HIGH AVAILABILITY: (Ethernet Channels; Link Aggregation; FailSafe Networking)**

#### **CELERRA TRUNKING vs. CISCO:**

→Celerra trunking is considered link or port aggregation

→Cisco trunking is more along the line of VLAN tagging or multiplexing on a single logical port

→Celerra trunking consists of 2 or more ports logically trunked (aggregated for load distribution & statistical load balancing) so that the primary interface (ace0, cge0, etc) presents a single MAC address to the Switch, regardless of which actual physical interface the traffic may have left on. All traffic for individual TCP conversations (or IP or MAC, if designated), will travel from the same physical link.

→EtherChannel is called “port-channel” with Cisco’s CatIOS

#### **CELERRA NETWORK FAULT-TOLERANCE DEFINED:**

Both Ethernet Channels and Link Aggregation are methods for logically grouping physical ports together into fault-tolerant connections. Data Mover would have (2) or more ports connected to a switch configured for either Ethernet Channels or Link

Aggregation (trunking). Failure of (1) physical port in the group means that the Switch would automatically failover and route all traffic over remaining ports in configuration—this is not FSN, but normal switch failover from one port to another in an ethernet channel configuration. Failure of the entire ethernet channel or link aggregation channel would entail failing over to the next available connection.

### **BASIC TRUNKING/FSN RULES:**

#### **CELERRA PRESENTS SINGLE MAC ADDRESS FOR FSNs & TRUNKs FROM ACE0/CGE0:**

- For Trunking (EtherChannel), Switch ports must be enabled for EtherChannel. For Celerra, the act of creating a trunk between 2 or more interfaces invokes Trunking protocol and the MAC address of the primary NIC port (ace0/cge0) is presented to the switch.
- For Trunking, by definition, a set of Trunk interfaces must be plugged into the same Switch—cannot be split to 2 switches
- Trunking protocol must be enabled both on DART & the Switch Ports plugged into
- For FSNs, one port must be plugged into one switch while the other is plugged into a different, redundant path switch
- FSN feature is governed by DART, failing over from one FSN to another when the Active FSN fails

**Comments:** ‘MAC Address flapping’ occurs when a switch continually has to re-learn the same MAC address as it arrives on different ports (as would occur from a set of trunked DM interfaces), when the switch ports themselves are not configured for trunking. Some switch model types disable ports periodically when ‘mac address flapping’ occurs.

### **CELERRA FAILSAFE NETWORKS DEFINED:**

FSN's are fully redundant network connections consisting of (2) or more sets of connections—(1) connection is Active and the Other is in Standby, taking over if the Active segment fails. This type of network redundancy is monitored by the DataMover and upon failure, the DM will failover to next available connection in the FSN group. This feature is monitored and managed solely by DART and not the Switch. Each Link Aggregation or Ethernet Channel is considered a single logical connection & only one is active at a time. If implementing Ethernet Channels/Trunking and Link Aggregation with FSN, be aware that FSN failover would only occur if all devices failed in the Channel or Aggregation—therefore performance could degrade. In otherwords, implement FSN independent of Channel or Link Aggregation.

If using FSN's with a Primary & Secondary connection, the DM will automatically failover to secondary upon loss of primary, and then fail back to Primary if the latter is available. Best practices state that FSN's should not be configured with a primary so that the DM will switch to the next available connection and continue to use the connection until it too fails.

**# server\_netstat server\_3 -i**

| Name  | Mtu  | Ibytes     | Ierror | Obytes     | Oerror | PhysAddr        |

**Note:** Above example shows pure FSN setup only, where primary interface for each of the (4) fsn's is handling the traffic, while the standby interface is only showing inbound bytes due to network broadcasts, etc., and no outbound bytes.

### **I. CELERRA ETHERCHANNEL (PORT AGGREGATION, aka CISCO ETHERCHANNEL):**

**Supported in NAS 2.1 +**

**Purpose:** Provides High Availability by using multiple physical links or ‘channels’.

- All Ports in the Ethernet Channel share the same IP and MAC addresses and are connected to the same switch
- EtherChannel can combine 2, 4, or 8 ports (8 links/channel) and can use comb. of Fast Ethernet and/or Gigabit, i.e., different speeds
- Provides for statistically based data distribution, not load balancing

**Note:** Inbound trunk traffic is distributed across receiving MAC addresses based on an algorithm called “statistical multiplexing”, which is done using the last two-four bits of the MAC address. In juxtaposition, ‘Etherchannel’ provides for Bandwidth aggregation, Statistical load balancing, and Link failover. Ethernet Channels group multiple physical ports into a single logical port. Network Switches are responsible for distributing traffic across ports in the Channel and for redirecting traffic to remaining ports upon a port failure (failover). Ethernet Channels can consist of 2, 4, or 8 ports and is similar to Link Aggregation.

**Note:** Statistical data distribution may increase combined throughput, but not single client throughput. We no longer refer to “Ethernet Channel or Trunking” for Celerra—EtherChannel.

**CELERRA ETHERCHANNEL DEFINED:** Mode used on Cisco switches to support EMC “trunking” [uses ISL protocol]. ‘EtherChannel’ is a proprietary Cisco protocol that allows multiple physical interfaces to be combined into a single logical channel, a single MAC address, and one or more IP Addresses. Celerra’s implementation of EtherChannel will use the MAC Address of the first interface specified in the Trunk Group. EtherChannel provides for more physical ‘links’ for clients to access the DM,

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
thereby allowing better throughput as well as higher link availability [However, the caution is always given that this is not “Link Aggregation” of throughput, as is real “EtherChannel Trunking”].

**ETHERCHANNEL AVAILABILITY:** Both ethernet channel "link failover" and Statistical Data Distribution are handled by the "switch", not datamover. In otherwords, on the DM itself, all EtherChannel ports are active and potentially in use.

**I. Link Failover:** If an active ‘link’ or ethernet port fails on DM, switch reroutes traffic to remaining “links” in channel.

**II. Statistical Data Distribution:** Switch controls distribution of packets based on source-destination MAC addresses and XOR bits.

**Note:** If a router were used, the MAC address of router will be used & will be same link [No Statistical distribution]

## **ETHERCHANNEL SUPPORT:**

--Celerra supports both Fast Ethernet and GbE interfaces at the same time

--Celerra uses 802.1Q VLAN Trunking protocol

**10/100 Fast Ethernet Support:** **2 or 4 ports on Cisco 5000; 2, 4, or 8 ports on Cisco 6000**

**Gigabit Ethernet Support:** **2 ports only**

**Key Concept:** Switches will transfer traffic to specific NIC ports in a channel based on XOR of predefined number of bits in MAC address of client and MAC address of Celerra channel [1,2,3 XOR bits for 2 NICs, 4 NICs, 8 NICs respectively]

**Celerra EtherChannel Trunking v. “Ethernet Trunking”:** True Ethernet Trunking uses the 802.1Q protocol and is known as “aggregate trunking”—it can combine multiple Ethernet Ports, such as four 100MB Ethernet Ports, to create an aggregated output of 400MB. While overall throughput may increase for Celerra Trunking, we DO NOT support it—we employ this mainly to provide “link” redundancy.

## **ETHERCHANNEL DEFINITIONS:**

--Ties multiple physical interfaces into logical channels that use a single MAC address to (1) or more IP Addresses

--Uses the MAC address of the first interface in the Celerra Trunk Group

--EtherChannel trunks are setup manually on Celerra

--Can combine 10/100/1000 Ethernet interfaces

--IP4700 uses PagP (Port Aggregation Protocol)

--A (2) Trunk Port sends data down one or the other pipe based on the last bit of the originating MAC

--4-Trunk Ports use the last 2 bits to determine path & 8 Trunk Ports uses 3 bits

Ethernet trunking is a point-to-point link between one or more switch{es} ports.

Trunks carry traffic for multiple VLANs over a single link, with the purpose of extending VLAN’s across the network.

**Multiple Ethernet Ports share a single IP address through one switch.** These port devices are combined into “Virtual Devices” that appear as a single “link.” Celerra Trunking can combine 2, 4, or 8 NIC ports on a DataMover into a single Channel—these ports would all “share” the same IP & MAC addresses. All “links” in a channel connect to the same switch

**Link:** A “link” is synonymous with an ethernet Port on the DataMover. I.e., all 2, 4, or 8 port combinations are “links” that combine under a single IP address known as a single “channel”.

**Channel:** A “channel” is synonymous with a single DataMover trunk. A channel is a virtual device that combines multiple physical devices into a single link.

**Rules:** NIC Ports all must be the same type!

Switch determines both Definition and Utilization of Ports.

Can configure 2, 4, or 8 NIC Ports on a Single DataMover [Sharing a single IP & MAC Address through one switch]

Over a Single Switch only.

## **FACTSHEET ON CELERRA ETHERCHANNEL:**

1. If switch supports Trunking, will conduct **statistical load balancing** based on hashing MAC addresses of Client--Server

2. If one port fails, other port will assume load, providing **High Availability—Link Failover**

3. **Single IP Address over multiple network devices** [i.e., ports share a Single address through one switch—virtual devices]

**Note:** Does not provide any increase in throughput for single clients but may for multiple clients

4. Compatible with Cisco “EtherChannel”

5. Can Trunk 2, 4, or 8 ports using mixed Duplexing and Speeds

6. 2 or 4 Ports on Celerra 10/100 Ethernet supported for Cisco 5000 or Bay Networks 450

7. 8 Ports on Celerra 10/100 Ethernet supported for Cisco 6000

8. 2 Ports for Gigabit ethernet on Alteon

9. A “trk” represents a ‘channel’ device [default=trk0]. Devices in a channel can be of different speeds! [not so with FSN]

10. Maximum of (8) Fast Ethernet ports can be trunked [ana0 – ana7]

11. Maximum of (2) Gigabit Ethernet ports can be trunked [ace0 – ace1]

12. Only one NIC port can be a Standby for another

13. Only one Port can be active at a time

14. Channel link on DM and Switch must be set the same

15. Spanning Tree must be enabled on switch in order to prevent bridge loop multicast/broadcast storms

## **SETTING UP CELERRA ETHERCHANNEL:**

1. Create Trunk Device: **\$server\_sysconfig server\_4 -v -n trk0 -c trk -o "device=ace0,ace1"**  
8-Port Trunk Device: **\$server\_sysconfig server\_4 -v -n trk2 -c trk -o "device=ana0,ana1,ana2,ana3,ana4,ana5,ana6,ana7"**
2. Set Trunk IP: **\$server\_ifconfig server\_4 -c -D trk0 -n trk0 -p IP 193.1.21.124 255.255.255.0 193.1.21.255**  
8-Port Trunk IP: **\$server\_ifconfig server\_4 -c -D trk1 -n trk1 -p IP 193.1.21.125 255.255.255.0 193.1.21.255**

**Note:** You can trunk 2, 4, or 8 ports across single or multiple Network Interfaces

## **TROUBLESHOOTING ETHERCHANNEL:**

1. Determine which devices are assigned to the Virtual Trunk: **\$server\_sysconfig server\_x -v**
2. Verify Duplex & Speed Settings: **\$server\_sysconfig server\_x -pci**
3. Check for Connectivity/Activity: **\$server\_netstat server\_x -i | -a | -s | -r**
4. Check ARP Table to verify Networking: **\$server\_arp server\_x -a**
5. Check Routing Table to verify Gateway, Routes, etc: **\$server\_route server\_x -l**
6. Verify IP, Mask, and Broadcast are Correct: **\$server\_ifconfig server\_x -a**
7. Check server logs—if Link goes Up and Down = bad port: **\$server\_log server\_x legrep trk**
8. Use Ping to verify/troubleshoot physical layer connectivity: **\$server\_ping server-x -send xxxx.xxxx.xxxx.xxxx**

**Note:** Windows systems, use c:>ping -n 20000 -l 65500 -w 0 10.241.169.24 [Max buffer size is 64k, 65500]

**Linux CS, use #ping -c 20000 -f -q -s 65507 10.241.169.25** [IP address of CS]. Use server\_ping -s command to hostname to see how fast the network is performing & whether there are timeouts.

9. Determine which method of ‘Statistical Load Balancing’ is in use [MAC Address, TCP, IP] and then make sure that the Switch ports are also configured to support the same thing

**\$ server\_sysconfig server\_2 -v -i trk001**

server\_2 :

\*\*\* Trunk trk001: Link is Up \*\*\*

\*\*\* Trunk trk001: **Statistical Load Balancing is TCP** \*\*\*

## **REMOVING AN ETHERCHANNEL GROUP FROM CELERRA:**

1. Delete IP Configuration of Trunk Group first using **\$server\_ifconfig server\_x -d trk0**
2. Delete the Virtual Interface using **\$server\_sysconfig server\_x -v -d trk0**

## **TROUBLESHOOTING NETWORKS USING .SERVER CONFIG COMMANDS:**

**\$server\_config server\_x -v "amgr showarp"**

**\$server\_config server\_x -v "amgr showroute"** → Outputs complete Routing Table

**# .server\_config server\_2 -v "amgr stat"**

UseHash is 0

### **CELLERRA ETHERCHANNEL STATISTICS:** Use “nfsstat” for traffic statistics

Use \$server\_netstat server\_x -i to view which interfaces are active for In and Out Bytes

### **CELLERRA LINK AGGREGATION CONTROL PROTOCOL: LACP**

**New with NAS 5.0:** 802.3ad Link Aggregation Control Protocol. Tested with Cisco and Foundry switches, but Foundry's implementation does not work well.

#### **PURPOSE:**

Similar to Ethernet Channels (Trunking) in that groups of physical ports are combined into a single logical interface to provide for enhanced performance or enhanced availability. Link Aggregation works with Switches that support IEEE 802.3ad Link Aggregation standards for two or more ports. A major difference from Ethernet Channels is that all ports in the Channel must have same Speed & Duplex settings & have the same type of NIC cards. Switch is responsible for failing over traffic to all unaffected ports. Similar to Cisco's PAgP EtherChannel protocol.

#### **LINK AGGREGATION ATTRIBUTES:**

- Combines multiple Ethernet Links or Ports into a single Virtual Device trunk, and does not need to be in multiples of two [could be 2, 3, 4, 5, 6, 7, etc. links combined]
- Number of links per trunk are not limited
- Unlike EtherChannel, however, LACP does not support different speeds among the devices in the Trunk
- Provides for Higher Availability [One link goes down, others still active—may result in loss of bandwidth, but not loss of service]
- Port Distribution: Links are determined by Source & Destination MAC Addresses
- Provides for better Link Control between DM and Switch
  - [LACPDU Frames are transmitted over each link in the Trunk to monitor]
- DM Ethernet devices must be set to FULL Duplex as Links operate at FULL Duplex
- No ATM or FDDI with LACP
- All Ports should be set at the same Speed, Full Duplex, and of same NIC type
- Maximum of (12) physical Ethernet devices can be combined into a single LACP Trunk [Only Physical Ports can be used]
- LACP protocol can automatically identify links operating correctly and take improperly configured links offline
- Link aggregations provide more overall bandwidth, but any single client only communicates through one port and is limited to the bandwidth of that port

#### **SETTING UP AN LACP TRUNK:** Very similar to EtherChannel Trunking Setup

Step 1. Create Virtual LACP Trunk:

**\$ server\_sysconfig server\_6 -v -n trk0 -c trk -o “device=ana2,ana1,ana0,ana3 protocol=lACP”**

Step 2. Add IP to Device: **\$server\_ifconfig server\_6 -c -D trk0 -n trk0 -p IP 192.10.3.28 255.255.255.0 192.10.3.255**

#### **DELETING AN LACP TRUNK DEVICE:**

**\$ server\_sysconfig server\_6 -v -d -Force trk0** [Deletes both IP & Trunk]

#### **CREATING LACP TRUNKS WITH FSN NETWORKS:**

1. **\$ server\_sysconfig server\_6 -v -n trk0 -c trk -o “device=ana0,ana1,ana2,ana3 protocol=lACP”**

2. **\$ server\_sysconfig server\_6 -v -n trk1 -c trk -o "device=ana4,ana5,ana6,ana7 protocol=lacp"**
3. **\$ server\_sysconfig server\_6 -v -n fsn0 -c fsn -o "device=trk0,trk1"**
4. **\$ server\_ifconfig server\_6 -c -D fsn0 -n fsn0 -p IP 192.10.3.28 255.255.255.0 192.10.3.255**

### **VERIFYING LACP VIRTUAL DEVICES:**

```
$ server_sysconfig server_6 -v  
$ server_netstat server_6 -i  
$ .server_config server_6 -v "fsn fsn0 ifstat"  
$ .server_config server_6 -v "fsn fsn0 stat"  
$ .server_config server_6 -v "fsn fsn0 clearstat"
```

**FROM CISCO SWITCH:** Only Supported on Catalyst OS Version 7.1 and above

```
# show port lacp-channel [LACP Statistics]  
# show lacp-channel traffic
```

### **CISCO CATALYST 6000 SWITCH:**

```
#set channelprotocol lacp 9  
#show channelprotocol  
#set port lacp-channel 3/3-16 [Sets Ports to an Admin Key]  
#set port lacp-channel 3/3-16 mode active  
#show port lacp-channel
```

### **LACP LIMITATIONS:**

--Only supports full duplex Ethernet Links  
--All links must be same speed setting

### **ENHANCING LACP AND TRUNKING STATISTICAL LOAD BALANCING:**

**param trunk LoadBalance=tcp**

**param trunk LoadBalance=ip**

**param trunk LoadBalance=mac**

**Note:** Default is statistical load balancing based on source IPv4 and Destination IP addresses—binds to IP of NIC card (ip). MAC value binds to mac address of NIC cards connecting to Clients, useful if large number of NICs with sequential MAC values, not similar values, where load is distributed based on ranges of MAC values. TCP filtering is similar to IP but also takes ‘port’ into account.

**\$ .server\_config server\_2 -v "param trunk"**

| Name              | Location   | Current | Default |
|-------------------|------------|---------|---------|
| trunk.LoadBalance | 0x01356f20 | 'tcp'   | "       |

**\$ server\_sysconfig server\_2 -v -i trk001**

server\_2 :

\*\*\* Trunk trk001: Link is Up \*\*\*

\*\*\* Trunk trk001: Statistical Load Balancing is TCP \*\*\*

Device Link Duplex Speed

**Note:** Prior to NAS 5.4, which now uses IP as the default value for statistical load balancing, mac address was used

### **LACP TROUBLESHOOTING COMMANDS:**

**# server\_sysconfig server\_3 -v -info trk0**

**# .server\_config server\_3 -v "trunk trk0 lacpinfo"**

**# .server\_config server\_3 -v "trunk trk0 lacpstats"**

**# .server\_config server\_3 -v "trunk trk0 showcfg"**

## **II. CELERRA FAILSAFE NETWORKING [FSN]: Failover is DataMover dependent!**

FSN = 2.2.6+ NAS code

### **Purpose:**

FailSafe Networks are redundant network connections that failover from an Active to a Standby. FSNs are monitored and failed over by the Data Mover alone, and not the Switch. FSNs can consist of a group of Ports, Ethernet Channels, or Link Aggregation connections—Data Mover supports up to 2-8 “connections”. FSNs typically retain full bandwidth performance after failover. All connections in the FSN device share a single MAC address and a set of common IP Addresses. Additionally, the underlying Ethernet devices can be of different speeds. By default, failover is automatic, but fallback is manual.

**Note:** Unlike trunking, where all ports are still “active”, FSN has only a single active port at a time, with one in standby

## **FSN ATTRIBUTES:**

- Composed of multiple NIC ports on same DataMover as a Virtual Device using one IP and MAC Address
- Fails over to a Standby device if the primary Failsafe network device fails
- Fails over if the Switch fails on the Failsafe Network Device
- Each 'channel' must be identical in an FSN group!
- Can use FSN in Multiple Switch, VLAN, or Trunking configurations
- Can use a combination of NIC Ports together--e.g., Fast Ethernet or Gigabit Ethernet
- Only one port in an fsn network is active at a time

## **Typical FSN Configurations:**

Datamover NIC ports connected to different physical switches in support of Failsafe Switch Failover  
NIC ports combined as a virtual primary device, failing over to Standby device when necessary

## **Typical FSN Failover:**

- Primary port fails--the operational Standby port will take over
- When active communications link between Switch & DM fails--will failover to an available link within the fsn group
- If primary device is recovered, the communications link is restored automatically
- If no 'primary' device was specified in an fsn setup, then the original device does not restore automatically

## **IMPORTANT NOTE:**

**FSN Failover is monitored and conducted by DART, not the network switch! We failover from an fsn on one switch to a different fsn on an alternate switch.**

### **Restores:**

- If Primary device is restored, will take over from Standby port

### **FailOver Between Different IP Channels in a Switch for the same DataMover:**

"Automounter" feature can be used so that a timeout value will force failover to another IP channel if the first one becomes too busy.

## **TESTING GIGABIT FAILOVER BETWEEN PRIMARY [ace0] & STANDBY [ace1]:**

Step 1. Testing "FSN" failover: Remove sc connector from "ace0"--assumption is that it is the "primary" interface

Step 2. Standby port [ace1] will take over immediately with no noticeable pause in activity

Step 3. When getting ready to plug "ace0" back in, insert the top "TX" connection first, wait 5 seconds to allow time for the switch to bring that port back up, then insert the "RX" connector--this should allow for a seamless failback. Otherwise, there could be a 3-4 second delay as the switch reactivates the port

## **RESULTS OF MISMATCHED INTERFACES ON DM FAILOVER:**

**Configuration:** DMs have FSNO configured (Active Port=ACE0 Stndby=ACE1); Primary DMs have linkneg=disabled and corresponding Switch ports disabled for autonegotiation. Standby Server has switch ports set for autonegotiation.  
Failover of Primary to Standby Server is this situation will not allow ACE0 to come up due to switch port mismatch—instead, ACE1 will come up.

## **LAYER 3 FAILOVER [NAS 5.6]:**

- IP Addresses are assigned to Virtual devices and not to physical devices
- Data Mover uses Routing Tables to determine proper return route
- IPReflect feature must be disabled if using Layer 3 failover
- Data Mover uses RIPv2 to advertise to Routers for all interfaces configured to a Virtual device
- Available RPQ only, requires Eng. Key to enable

### **Example of how Layer 3 failover is used for High Availability:**

Data Mover A in one location uses 192.168.50.10 IP on a virtual device with RIP cost of 0

Data Mover B in other location uses 192.168.50.10 IP on a virtual device with RIP cost of 15

Scenario→Data Mover A goes down, Routers update tables and send packets to Data Mover B

### **# server\_param server\_2 -facility vdevice -list**

```
server_2 :  
param_name           facility default   current   configured  
key                 vdevice    'none'   'none'
```

### **ENABLING LAYER 3 FAILOVER:**

```
# server_param server_2 -facility vdevice -modify key -value <eng_key>  
# server_param server_2 -facility ip -modify reflect -value 0  
# server_sysconfig server_2 -virtual -name ha_vdevice -create ha [failover device]  
# server_ifconfig server_2 -create -Device ha_vdevice -name ha_interface -p IP 192.168.50.10 [failover interface]
```

# server\_rip server\_2 –modify ha\_out\_enabled y [Enable RIP advertisement on DM]

# server\_rip server\_2 –append ha\_out cge1 [Globally accessible gateway interface]

### DELETING LAYER 3 FAILOVER:

# server\_ifconfig server\_2 –delete ha\_interface

# server\_sysconfig server\_2 –virtual –delete ha\_vdevice

### STOPPING RIP ADVERTISEMENTS:

# server\_rip server\_2 –remove –ha\_out cge1

# server\_rip server\_2 –modify –ha\_out\_enabled n

### LISTING VIRTUAL TRUNK/FSN DEVICES:

# server\_sysconfig server\_2 -v

server\_2 :

Virtual devices:

fsn1 active=cge3 primary=cge3 standby=cge4

fsn0 active=cge0 primary=cge0 standby=cge1

fsn failsafe nic devices : fsn0 fsn1

### Verifying IP Configuration for Virtual Devices: \$server\_ifconfig server\_2 fsn0

Shows IP, Mask, Broadcast, whether device is UP or DOWN, MTU Size, and VLAN info

Caution: fsn0 represents the “name” of the virtual interface, as given in lefthand column of server\_ifconfig –a command

### CONFIGURING FAILSAFE NETWORKING: [FSN]

1. Create Failsafe Configuration:

\$server\_sysconfig server\_4 -v -n fsn0 -c fsn -o “primary=ana0 device=ana1”

2. Create IP Configuration:

\$server\_ifconfig server\_4 -c -D fsn0 -n fsn0 -p IP 193.1.21.126 255.255.255.0 193.1.21.255

Note: Must use quotations around the “primary=” & “device=” statements!!

Specifying Primary & Failover FSN Device: -o “primary=ana0”litrk0|fsn0 “device=ana1”litrk1|fsn1” [device=failover Standby]

Specifying Failover List of FSN Devices: -o “device=trk0,trk1” [trk1 represents failover device for trk0]

### CONFIGURING TRUNKING WITH FAILSAFE NETWORK:

1. Trunk Group: \$server\_sysconfig server\_4 -v -n trk0 -c trk -o “device=ana0,ana1”

2. FailSafe Group: \$server\_sysconfig server\_4 -v -n fsn1 -c fsn -o “primary=trk0 device=ana2,ana3”

3. IP Configuration: \$server\_ifconfig server\_4 -c -D fsn1 -n fsn1 -p IP 193.1.21.127 255.255.255.0 193.1.21.255

### CONFIGURING MULTIPLE TRUNKS WITH FAILSAFE NETWORKS:

1. Trunk Group One: \$server\_sysconfig server\_4 -v -n trk0 -c trk -o device=ana0,ana1,ana4,ana5

2. Trunk Group Two: \$server\_sysconfig server\_4 -v -n trk1 -c trk -o device=ana2,ana3,ana6,ana7

3. FailSafe Group: \$server\_sysconfig server\_4 -v -n fsn2 -c fsn -o device=trk0,trk1

4. Reboot server!

Configuration Output: fsn2 active=trk0 standby=trk1  
trk0 devices=ana0,ana1,ana4,ana5

trk1 devices=ana2,ana3,ana6,ana7  
Fsn failsafe device: fsn2 Trk trunking device: trk0 trk1

--VLANs are best used for routing a single logical network over a single VLAN—however, with caution, multiple logical networks can be configured over the same VLAN

--Data Movers will not allow two different physical interfaces to be on the same subnet if the VLAN ID is different

**VLAN TRUNKING:** Celerra uses “VLAN Trunking”, which consists of a grouping of Ports on a switch. VLAN Trunking is better defined as a point-to-point link between two switches that can pass unique VLAN numbers over a single or multiple links. We support “trunking” in a VLAN environment without reference to a specific “protocol”. The two basic VLAN Trunking protocols are 802.1Q (Celerra) and Cisco’s proprietary ISL protocol.

**Note:** All ports in a trunk are “active” & capable of passing traffic

**Trunking Protocols:** ISL and 802.1Q

Inter-Switch Link [ISL]—Cisco trunking encapsulation protocol [Catalyst 5000+ switches]

IEEE 802.1Q—industry standard trunking encapsulation protocol [Catalyst 4000+ switches]

**UNSUPPORTED:**

*Nortel Switches do not support Celerra EtherChannel Trunking*

## **USING VLANS WITH DATA MOVERS:**

Customer might want to multi-home the DM so that clients can access from different logical networks without having to go through a Router. Would do this by setting up a Virtual Interface with different IP addresses, one for each logical network.

## **TWO WAYS TO IMPLEMENT VLANS FOR CELERRA:**

1.) Configure VLAN on switch port with VLAN identifier and connect Server to the port.

**Note:** Typical client configuration. File Server is not aware that it is part of the VLAN, and no special configuration required. The VLAN ID is set to 0.

2.) Configure Switch ports for VLAN tags and configure DM to process VLAN tags on packets. This enables DM to connect to multiple VLANs through a single physical interface, also useful when configuring Standby DMs for failover if the failover server is on a different VLAN. Using this method, both Switch Ports and Celerra Servers are configured to used VLAN tags on packets.

## **ADVANTAGES OF VLANS:**

--ease of Administration

--Reduces Broadcast traffic by creating separate VLANs or Broadcast Domains

--Better than Routing by reducing Broadcast traffic & enabling better efficiency in network traffic

### **Disadvantages:**

--Fewer standards: LANE; 802.10; 802.1q; 802.1p

### **Misc:**

--Setup VLAN trunks between switches to allow traffic to pass between VLAN groups

--Use a router to route traffic between VLANs

--VLANS share ports on multiple switches using trunking

--Grouping ports under one IP Address

--Ports in a VLAN share Broadcast traffic

--DM can have multiple VLANs per port or single VLAN, spanning multiple IPs and Subnets

--Support for up to 14 DataMover's per VLAN

--Requires Layer 3 Switches

## **VARIOUS TYPES OF VLAN IMPLEMENTATIONS:**

**PORT-BASED VLANS:** Easy setup; only (1) virtual LAN per port; Static assignments

**MAC-BASED VLANS:** Difficult setup; Easy to maintain

**LAYER-3 VLANS:** Based on IP Subnets

**PROTOCOL-BASED VLANS:** Protocol type of frames determine membership

**MISC VLANS:** Policy-Based; Multicast; Authenticated Users

## **CISCO VLAN:**

IOS Virtual LAN Services

IEEE 802.1Q

IEEE 802.10 Interoperable LAN/MAN Security Standard (SILS)

--allows LAN traffic to carry a VLAN identified

--MAC layer frame with 802.10 header, called PDU using SDE (Security Data Exchange)

## **SOME CISCO DEFINITIONS OF VLAN:**

→VLAN is a shared broadcast domain within a switched network that is logically segmented into distinct groups of users

→End stations may be in separate physical LANs, but grouped together in a VLAN segment

- VLAN ports can be grouped on a single switch or across multiple switches per VLAN group
- Communication between (1) VLAN and another is done across a Router
- VLANs are normally numbered from 2-1000 (1 is reserved for the Management VLAN)
- Configuring VLAN on single switch is easy, just configure
- Configuring VLAN across multiple switches requires VLAN Trunking Protocol (VTP), and requires certain Trunk mode and Trunk encapsulation mode match (the manner in which frames are tagged for the trunk)
- Frames travelling over a trunk are tagged to identify which VLAN the frames belong to

### **FOUR TYPES OF TRUNKING ENCAPSULATIONS:**

- 1) Inter-Switch Link Protocol (ISL) -- Cisco proprietary trunking protocol.
- 2) IEEE 802.1Q (dot1q) -- Industry standard trunking protocol.
- 3) LAN Emulation (LANE) -- Used for trunking VLANs over ATM links.
- 4) IEEE 802.10 (dot10q) -- Cisco proprietary method for transporting VLAN information inside standard FDDI frames.

### **CONFIGURING VLAN ON SINGLE CISCO IOS SWITCH:**

```
SwitchA# vlan database
SwitchA(vlan)# vlan 2 name vlan2
SwitchA(vlan)# exit
SwitchA# configure terminal
SwitchA(config)# interface fastethernet 0/1
SwitchA(config-if)# switchport mode access
SwitchA(config-if)# switchport access vlan 2
SwitchA(config-if)# end
```

### **SETTING UP TRUNKING BETWEEN TWO CISCO IOS SWITCHES:**

1. SwitchA(config)# interface fastethernet 0/1  
SwitchA(config-if)# switchport mode trunk  
SwitchA(config-if)# switchport trunk encapsulation dot1q
2. Repeat commands on SwitchB.

**Note:** Sets up fast Ethernet interface 0/1 to be a trunk port using dot1q encapsulation. It is important to note that once you change one side of a connection to trunk mode, communication between the two switches will be lost until the other side is configured for the same mode/encapsulation. If you are trying to set up trunking remotely, always change the far side of a connection first. The port is currently passing information for all VLANs (1-1005).

3. To limit which VLANs will be allowed to pass information on the port:

```
SwitchA(config)# interface fastethernet 0/1
SwitchA(config-if)# switchport trunk allowed vlan remove 1-1005
SwitchA(config-if)# switchport trunk allowed vlan add 1-3
```

4. Repeat commands on SwitchB.

5. This removes the default of all VLANs, and adds back support for VLANs 1-3.

### **VLAN SWITCH/ROUTER TROUBLESHOOTING:**

1. Ports assigned to wrong VLAN—i.e., same IP Address each VLAN  
**Note:** VLANs are setup on the SWITCH
2. Running wrong protocol, as set on the “Router”—ISL v. dot1Q {802.1Q}—must be all .1Q or ISL.
3. Check to see if VLAN trunk is “active”
4. Cross Connection Issue: To route between VLAN’s, must be on a different subnet and must use a Router  
**Note:** (5) Modes of Trunking for Fast Ethernet/Gigabit—default mode is AUTO [on—off—desirable--auto—nonegotiate]  
Commands: sh config; sh vlan; sh port; sh trunk [commands to verify VLAN setup on a Switch]

### **CELLERRA VLAN TAGGING:**

--VLAN Tagging can be implemented over a single “link” or multiple “links” such as in EtherChannel.

--Feature using 802.1Q protocol over GigabitEthernet to support VLAN tagging of packets.

--Supported with NAS 4.2

--VLAN Tagging for network devices is only supported for GbE ace and cge ports using 802.1Q

--‘Frame Tagging’ using 802.1Q; 22-byte VLAN ID in header of every packet

--Another IEEE standard is 802.3q for VLAN frame Tagging

--802.1Q only supported with Gigabit Ethernet

--VLAN Tagging is useful in situations where you have multiple VLANs

--VLAN Tagging is controlled on the Switch

**Note:** NS600 changes this with NAS 5.1 code—supports 10/100/1000

### **VLAN TAGGING & NIC DEVICE DRIVER SUPPORT:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
VLAN Tagging support is a function of device drivers, not speed. Hence, both Alteon (ACE) & Broadcom (CGE) can support VLAN Tagging for 10/100/1000 Base T, while LSI (ANA) drivers do not.

## **CONFIGURING VLAN TAGGING:**

Step 1. Create Gigabit Interface:

```
$server_ifconfig server_2 -c -D ace0 -n Group1 -p IP 192.50.13.24 255.255.255.0 192.50.13.255
```

Step 2. Set Interface to Use VLAN: \$server\_ifconfig server\_2 Group1 vlan=100 [Value can be between 1-4095]

```
Deleting VLAN: $server_ifconfig server_2 Group1 vlan=0 [Vlan=0 means no VLAN ID set]
```

Step 3. Verifying VLAN on an Interface: \$server\_ifconfig server\_2 Group1

**Note:** Do not use “vlan=1” as an ID, as many switches reserve this for their native VLAN

## **CREATE MULTIPLE VLANs USING SINGLE PHYSICAL INTERFACE & 802.1Q TAGGING:**

Step 1. Create Virtual Interfaces:

```
$server_ifconfig server_6 -c -D ace0 -n acev1 -p IP 192.10.4.28 255.255.255.0 192.10.4.254
```

```
$server_ifconfig server_6 -c -D ace0 -n acev2 -p IP 192.10.4.29 255.255.255.0 192.10.4.254
```

Step 2. Assign VLANs:

```
$server_ifconfig server_6 acev1 vlan=acev1
```

```
$server_ifconfig server_6 acev2 vlan=acev2
```

## **CONFIGURING FSN WITH 802.1Q TAGGING:**

Step 1. Create Virtual FSN:

```
$server_sysconfig server_6 -v -n fsn0 -c fsn -o device=ace,ace1
```

```
$server_ifconfig server_6 -c -D fsn0 -n acev1 -p IP 192.10.4.29 255.255.255.0 192.10.4.254
```

```
$server_ifconfig server_6 acev1 vlan=10
```

## **CONFIGURING TRUNK WITH 802.1Q TAGGING:**

Step 1. Create Trunk:

```
$server_sysconfig server_6 -v -n trk0 -c trk -o device=ace0,ace1
```

```
$server_ifconfig server_6 -c -D trk0 -n acev1 -p IP 192.10.4.28 255.255.255.0 192.10.4.255
```

```
$server_ifconfig server_6 acev1 vlan=10
```

```
$server_ifconfig server_6 acev1
```

## **CONFIGURING VLAN TAGGING ON CISCO SWITCHES: 802.1Q, Cisco 4000, 5000, 6000**

1. #set vlan 100 3/10 [Assigns switch port to the VLAN]
2. #show vlan 100 or #show port 3/10 [Use to verify VLAN membership, speed, & duplex settings]
3. #set trunk 2/8 on dot1q [Setting the Trunk on the switch]
4. #show trunk 2/8 [Verify trunk configuration]
5. #set vlan mapping dot1q 100 [Set valid VLAN range for 802.1Q: 1-4095 value; For isl\_vlan, values are 1-1005]
6. #show vlan mapping [Verify mapping]

## **ISSUE WITH OUT OF SEQUENCE VLAN PACKETS AND TOE DRIVERS:**

# .server\_config server\_2 -v "param ip vlanFilter"

ip.vlanFilter INT 0x0136b2f8 1 1 (0,4294967295) FALSE REBOOT 'NA'

**Note:** VlanFilter is set by default to drop packets that are received with unexpected VLAN id. Disabling this param does not affect DM id tagging of outbound VLAN packets

## **TROUBLESHOOTING TCP:**

### **Max Number Client TCP Connections to the DataMover:**

Max number of connections/concurrent sessions per Datamover using 2.2.35.4+: 20,000/3000

Max number of concurrent TCP connections prior to 2.2.35.4: 2000

## **TCP PROTOCOL:**

- Connection-oriented byte-stream service using IP network layer.
- Applications generate data into segments, which are transmitted by TCP
- TCP keeps track of segments with timers and acknowledgements to ensure delivery
- TCP segments are also transmitted as IP segments
- TCP is full duplex to the Application layer

## **I. CELERRA TCP/UDP RETRANSMISSIONS (NFS or CIFS):**

Layer 4 retransmissions at the TCP layer. Basic rule of thumb is to have .01% or lower retransmit rates.

**\$ .server\_config server\_2 -v “tcp stat”** [Includes TCP retransmits & retransmit timeouts--RTOs]

**\$ server\_netstat server\_2 -s -p tcp** [Does not contain the RTO information]

**\$ .server\_config server\_2 -v “printstats tcpstat reset”**

#### **FAST RETRANSMISSIONS(fastRTO):**

Fast retranmissions are triggered whenever (4) consecutive duplicate acknowledgements are received. The sending host retransmits data after the 3<sup>rd</sup> duplicate ACK. i.e., whenever the Server receives (3) or more consecutive ACKS that are out of order, it will request a retransmission. Thereafter, will ACK every segment received for a period of time. Fast retranmissions generally occur when a single packet is missing from the Receiver's advertised TCP window & have a minimal impact on performance. FastRTO = 1 slow clock tick, 500ms. FastRTO is a TCP parameter that would apply to CIFS, NFS, TCP, or IP Replication activities.

#### **RETRANSMISSION TIMEOUTS (RTO's):**

RTO's occur when there is multiple packet loss within Receiver's TCP window, occurring when sending hosts retransmission timer expires. Celerra RTO is (3) slow clock ticks, or (1.5) seconds [most NT clients wait much less, say 200ms]. RTO's have a very negative impact on performance. NAS 5.4 will reduce RTO's with implementation of NewReno and SACK RFC's.

**Comment:** TCP runs on a slow and fast clock. Problem can occur on networks where because of the slow RTO mechanism, the Celerra will seem to take a long time before retransmitting because of lost packets. Usually, this all happens on dirty networks.

Microsoft's implementation of RTO is to resend the missing packets without waiting for RTO Timer to expire. Usually, the Server should wait for 3 consecutive out of order packets before doing a retransmit: Microsoft can adjust this to between 1-3 consecutive packets.

--Celerra's Slow Clock is based on a retransmission timer (RTO) of 500ms (by default the retransmission timer is set to (3) slow clock ticks, or 1.5ms total)

--Celerra's Fast Clock is based on a retransmission timer of (1) slow clock tick, or 500ms (Windows' Hosts=200ms)

#### **Celerra Fast Retransit Mechanism: NAS 2.2.53.5 +**

/nas/site/slot\_param [Changing this value will trigger fast RTO whenever 3 or more consecutive ACKs received out of order & changes slow retansmit clock to 200ms]

**param tcp fastRTO=1**

**Note:** Setting this parameter may have the effect of increasing response times for the Celerra when experiencing network packet loss--however, it serves to mask network problems and may actually degrade the overall network with increased retransmission traffic. Celerra doesn't yet use SACK (Selective Acknowledgements).

#### **CELLERRA RPC RETRANSMISSIONS (NFS over UDP):**

Layer 5 retranmissions at the RPC layer using NFS over UDP. Typical Linux RPC timeouts are now 35ms. Goal is to have no greater than .01% retranmissions. Entire Request or Reply is retransmitted. If Client performing Reads, client must retransmit Request and DM must retransmit the Reply data. If Client performing Writes, client must retransmit Request data write and DM must retransmit the Reply.

**# server\_nfsstat server\_2 -rpc**

server\_2 :

Server rpc:

| ncalls     | nBadRpcData | nDuplicates | nResends | nBadAuths |
|------------|-------------|-------------|----------|-----------|
| 3762239871 | 0           | 27447775    | 149909   | 0         |

nResends indicate number of duplicate RPC requests (XIDs) to the DM and retransmitted responses (i.e., RPC retranmissions)

nDuplicates indicates number of duplicate client retransmission requests while DM still working on request—could indicate slow responses or locking problem

**# nfsstat -c** [Use this on the Client to examine RPC retranmissions]

retrans

6

#### **CELLERRA PACKET LOSS:**

**# server\_netstat server\_2 -i**

Ierror or Oerror columns could indicate packet loss due to corruption

#### **Windows Client:**

C:\>netstat -e

Look at Discards & Errors for Client packet loss corruption

#### **Unix Client:**

# netstat -i

Look for RX-ERR and TX-ERR for evidence of packet loss due to corruption

**Note:** Causes of packet loss can be Duplex mismatch (10/100Mb), Faulty cable, Faulty switch port, Faulty DM or Client NIC

#### **Cisco Switch:**

#sh tech

Look at Duplex settings, for Runts, Giants, and Collisions

### **CELERRA PACKET LOSS DUE TO CONGESTION:**

1. Look for ringfull errors on the DM NIC (output ring buffer overflows and packets are dropped)

```
$ .server_config server_2 -v "ians cge0 stat"
```

```
$ .server_config server_2 -v "bcm cge0 stat"
```

-----Secondary Send Ring-----

DescCnt MaxDescCnt SecRingSize **OutDrops** →This is the key field to examine for ringfull issues

```
0x00000 0x00000000 0x000000800 0x0022bf71
```

2. For excessive DM retransmissions, look at output buffers on Client's switch port

3. For excessive Client retransmissions, look for packet drops in receive buffer of client's switch port or send buffer of DM's switch port

#### **Corrective Actions:**

Upgrade to NAS 5.4 to take advantage of SACK, NewReno, and FACK to reduce RTO's

Mount NFS over TCP vs. UDP

Escalate OutDrops ringfull errors to EE

#### **Try setting following param if DM is retransmitting:**

```
param tcp fastRTO=1
```

Lower “rsize” by 4k decrements on mount option for NFS Clients if DM is retransmitting until retransmits are reduced

For TCP Windows Size for Windows clients, and DM is retransmitting, set Windows size to 32k, then lower in decrements of 4k

#### **Client retransmitting with NFS:**

Reduce mount option wsizze by decrements of 4k. Check using netstat –s for TCP and nfsstat –c for UDP.

## **II. TCP ACKNOWLEDGMENTS & WINDOWS 98/95 CLIENTS:**

Celerra no longer sends an immediate acknowledgment [TCP ACK] for frames received with TCP Push Bit set, causing a 150ms delay before ACK's are returned. By default, this TCP Push Bit was set for previous versions of NAS [2.1 & 2.2]. With introduction of NAS 4.x, Celerra no longer has this feature set by default and must be enabled in the /nas/site/slot\_param file:

**param tcp ackpush=1**

**Note:** Setting this bit should increase copy performance when using Windows 95/98 Clients to Celerra Shares

#### **DEFINITION OF TCP PUSHBIT: [PSH flag]**

When Client sets this Flag [PSH], the Server will respond with an ACK immediately. The Push Bit Flag is usually set whenever the Client has sent all data in his buffer out onto the wire. Push Bit is an efficiency measure by which the Sender is telling Receiver not to wait for anymore data and to offload data up the protocol stack. Sun Solaris has an old bug that if the Server does not immediately reply with an ACK after sending data with PSH Flag set to 1, then it will wait a long time before sending again, by which time the Celerra may timeout. Setting the Push Bit (by Sender) may indicate that its system is running slow due to load.

## **III. INCREASING TCP STREAMS/PCB CACHE VALUES FOR MORE CONCURRENT TCP CONNECTIONS:**

Some Customer sites have very high numbers of Users, which can overwhelm the default "tcp maxStreams" and "tcp pcbCacheSize" values. This can create a situation where Users may begin to have problems connecting to the Celerra, and/or being able to effectively use the connection once established.

**Tcp maxStreams:** Default is now 64k concurrent TCP dialogues taking place at once [Reads/Writes/Logons].

**Tcp pcbCacheSize:** Default buffer size 401 [Other values: 5077; 8209; 9973]

### **HOW TO OBSERVE OPEN TCP STREAMS ON A DATAMOVER:**

Method 1:      \$server\_netstat server\_2 | wc -l                [Outputs number of active connections]

Method 2:      \$.server\_config server\_2 -v "tcp stat"        [Subtract 'Connections Closed' from 'Connections Established']

Method 3:      \$.server\_config server\_2 -v "param tcp"        [Viewing Open TCP Streams on a DataMover—"tcp.maxStreams"]

### **OBSERVING PROTOCOL STATISTICS ON DATA MOVER (retransmissions, etc.):**

**\$ server\_netstat server\_2 -s** [Use to verify DM TCP retransmission rate]

ip:

\*\*\*

```
219026 total packets received-----abridged
```

icmp:

\*\*\*\*

```
echo reply: 174-----abridged
```

tcp:

\*\*\*\*

```
298483227 packets sent
```

**1402 data packets retransmitted** →TCP retransmits

0 resets  
273079526 packets received  
108 connection requests  
36 connections lingered  
udp:  
\*\*\*\*  
0 incomplete headers  
32211 bad ports  
56722904 input packets delivered  
56679958 packets sent

### **PARAMETER TWEAKING:**

**Example:** Changing parameters to allow for increased "fs" memory caching for users pertaining to the "NFS" parameter called "openfiles". Allowing for 16,000 simultaneous User TCP connections and increased "openfiles" capability at two files each:

#### **TCP Protocol Parameters for Celerra:**

##### **/nas/site/slot\_param**

param tcp maxStreams=16384 [Add this value to slot\_param]

#### **VALUES FOR MAXSTREAMS AND OTHER PARAMS—TO BE SET CONCURRENTLY:**

**param tcppcbCacheSize=16993** Hex Value=0x00004261 Decimal Value=16993 (param no longer used)

**param tcppcbMaxCacheSize=39839** Hex Value= 0x00009b9f Decimal Value=39839 (param no longer used)

**param tcp.maxStreams=16384** Hex Value=0x00004000 Decimal Value=16384 (Default now 65535)

#### **NFS Protocol Parameters for Celerra:**

##### **/nas/server/slot\_x/netd**

nfs start openfiles=15360 nfsd=96 [default Celerra values]

#### **UFS/CIFS File System Parameters for Celerra:**

##### **/nas/server/slot\_x/file**

**file initialize nodes=65536 dnlc=262144** [default Celerra values; Change to nodes=49152 in this example]

### **DATAMOVER SPEED/DUPLEX SETTINGS:**

**#server\_sysconfig server\_2 -pci ana0 -o speed=100** {10|100|auto}

**Note:** Eventhough Celerra autonegotiates speed settings, it is recommended that the settings be manually set!

**Deleting Speed & Duplexing Manually:** vi /nas/server/slot\_x/sysconfig {sysconfigtab} Delete speed & duplexing entries

**CHANGING DATAMOVER DUPLEX/SPEED:** Orange Light on NIC = Half Duplex [10MB]; Green Light = Full Duplex [100MB]

**#server\_sysconfig server\_2 -pci ana0 -o duplex=half {full|half|auto}**

Or, directly edit /nas/server/slot\_2/sysconfig and sysconfigtab files [Remove references to Speed and Duplexing]

**Note:** Eventhough Celerra autonegotiates duplex settings, it is recommended that the settings be hard-coded

### **AUTO NEGOTIATION AND ETHERNET:**

Autonegotiation is a system that takes control of the cable when NIC devices are being initialized, and uses 16-bit word FLP (Fast Link Pulse) to detect modes of other devices on the other end of the wire (Link Partner), while advertising its own capabilities. What this does is allow devices to detect and choose the best connection type to use between nodes. Control of cable is relinquished after the negotiation is completed.

#### **APPLICABLE ETHERNET TYPES:**

10-BaseT; 10BaseT Full Duplex; 100BaseTX; 100BaseTX Full Duplex; 100BaseT4

#### **AUTO SENSE:**

Older technology that is passive only, and devices do not send FLP to detect or communicate with Link Partners

**CELERRA PACKET REFLECT (aka IP Reflect):** Enabled by default with 4.0.12.1 [Supported with Linux 2.2 NAS]

→Packet Reflect operates at TCP layer and ensures that inbound traffic to a specific port is replied to from the same port

→Packet Reflect does not allow routing of packets across interfaces (Routing Tables are not used when Packet Reflect is enabled)

→Packet Reflect is on by default

→Incoming & Outgoing ports are always the same

→When disabled, outgoing traffic will be determined by IP Routing Tables

→Routing Tables are used for all data mover initiated outbound traffic, such as DNS resolution requests, etc.

**Note:** In most cases, Network packets will go out via the same NIC port that they were received on because the Source & Destination MAC Addresses and VLAN ID are saved and passed up the protocol stack to the application layer. In the case of TCP, MAC Addresses of every packet are passed up to TCP, saved, and then sent back down to the same MAC address. See exception below.

#### **DISABLING IP REFLECT:**

\$server\_config server\_x -v “param ip” [Verify current settings]

**param ip reflect=0**

\$vi /nas/site/slot\_param **param ip reflect=0**

#### **BENEFITS OF USING PACKET REFLECT:**

--supports PVLANS on Celerra [replies will go out same VLAN as received if VLAN Tagged]

--Better network security

--speeds up router failover, example HSRP environments

--Especially useful in environments where Customers want multiple Routes defined and want to turn RIP off on the DMs—used in place of multiple default Routes

--Yields better performance by cutting down on number of Route & ARP lookups

--Works with Clients having single IP Address and Multiple MACs

#### **How IP Reflect Works:**

UDP→Source & Target MAC Address & VLAN ID are passed up to Application Layer. Application Layer saves and sends back down for transmission out original port [good example of application would be NFS].

TCP→Source & Target MAC Addresses & VLAN ID are saved in TCP connection data structure [which is then used when sending packets back out from the same TCP connection]

#### **USING PACKET REFLECT:**

/nas/server/slot\_2/param param ip reflect=0 [disables packet reflect]

**/nas/server/slot\_2/param param ip reflect=1** [default value and enables packet reflect feature]

ip.reflect 0x00fd6184 0x00000001 0x00000001

#### **PACKET REFLECT & NIC TEAMING:**

In general, the use of the IP Reflect feature & NIC Teaming at the same time is not encouraged and may lead to inconsistent communication on the Data Mover, especially if being used on AD or DNS Servers. What can happen when IP Reflect is configured is that the Data Mover will not use local ARP tables and will instead transmit to the NIC-teamed server using the underlying physical MAC addresses and not the virtual MAC address for the team. Disabling IP Reflect takes care of this issue.

In general, the use of NIC Teaming on network Servers where the Data Mover co-exists will work, but in certain cases NIC Teaming could be incompatible with the use of IP Reflect, and IP Reflect would have to be disabled. There is no bug here, it's just an interop issue between two different feature sets. On the Microsoft side, they pretty much say that NIC Teaming is a function of the various hardware components involved: Servers, NICs, Switches

If MS is engaged for a case that involves NIC Teaming, their pat requirement would be to disable the teaming to see if this resolved the issue. If it did resolve the issue, they would say go talk to the hardware vendors involved, etc. In general MS recommends that you only use NIC Teaming for externally presented NICs that do not transmit traffic to private intranets, go through firewalls, or are routed to NAT devices. In otherwords, NIC Teams should be used for a single network presentation.

For the Celerra, NIC Teaming is something that we have been doing for a long time now, more commonly known as EtherChannel or Link Aggregation. From my understanding, NIC Teaming can provide for Fault Tolerance (High Availability), and maybe Load Balancing, depending on the vendor implementation.

#### **SITUATION WHERE IP REFLECT WILL NOT ALWAYS BE SENT OUT SAME “PHSYICAL” PORT AS RECEIVED:**

With Celerra EtherChannel and Packet Reflect, if the DM is using two ana ports configured in an EtherChannel “Trk0” where both interfaces share a common IP address, in certain situations, packets received via a switch will enter the “logical” network on “TRK0” via either ana0 or ana4. In this situation, Packet Reflect only knows how to reply via the “logical” port TRK0. An algorithm on the data mover determines which “physical port” to send reply out, meaning that it could go out either ana0 or ana4 for any given received packet. All that IP Reflect can do in this instance is to ensure that the packet goes out the same logical “network”, which in this example is TRK0. So, IP Reflect cannot guarantee reply via same physical port, just logical port.

**Note:** Both ports in an EtherChannel configuration are active

**Rule:** IP Reflect can only reply using the “logically” defined trunk, TRK0 in the above example, not physical port.

#### **TROUBLESHOOTING TCP/IP CHECKLIST:**

1. ARP [ARP IP address to MAC address resolution at physical layer]
2. Hostnames [nodenames]
3. Ipconfig [Windows IP configuration, WINS, DNS, DHCP information]
4. Nbtstat -c [shows contents of netbios cache] -n [shows locally registered names] -S [Netbios sessions]

5. Netdiag /fix [diagnose network problems and DNS issues] /v /l /DCAccountEnum
6. Netstat -a -s -p -r [Network protocol statistics & TCP connections]
7. NSLookup [Useful in verifying DNS name resolution on a network & Win2k DNS SRV resource records]
8. PathPing [combination Ping & Tracert tool]
9. Ping/Route/Tracert [default ICMP echo request TTL is 32 hops]

### **PDUs/SDUs—Protocol Data Units & Service Data Units:**

Protocol Data Units operate at each Layer in the OSI model, and are used to encapsulate data and protocol headers for transmission to the next layer. So, PDUs from one Layer become SDU's when received at the next layer, and so on throughout the process.

### **DATA ENCAPSULATION DOWN THE OSI LAYERS:**

→TCP receives SDU's from upper layer protocols, adds its headers to encapsulate and create Layer 4 PDU's called "segments" that are passed down to the IP Layer, which receives the segments as SDUs, which in turn are encapsulated into Layer 3 PDUs called IP packets or IP Datagrams, and passed to Layer 2 Ethernet, which receives Datagrams as SDUs, and in turn are encapsulated into Layer 2 PDUs called "Ethernet frames", which are passed to Layer 1 for transmission as electronic bits over the physical media.

### **DATA ENCAPSULATION UP THE OSI STACK:**

→Basically, the process of encapsulation is reversed. The Ethernet device inspects the Layer 2 PDU Ethernet frames, removes the Layer 2 SDU IP Datagram, and passes to IP as Layer 3 PDU. IP Layer 3 removes the Layer 3 SDU TCP Segment and passes to TCP Layer 4 as a Layer 4 PDU. TCP continues to process up the protocol stack.

### **APPLICATION LAYER—Layer 5:**

Protocols such as NFS, FTP, DNS, SNMP, Telnet communicate with Layer 4 through use of Port numbers  
Data Containers in this layer are called 'messages'

### **TRANSPORT LAYER—Layer 4:**

TCP & UDP protocols—data containers in this layer are referred to as "datagrams" or "segments"

→TCP is connection-oriented, full duplex, contains error checking, sequencing of packets, uses flow control and acknowledgements, and contains packet recovery services for retransmission of lost packets

→UDP is connectionless, unreliable, non-guaranteed transport, used especially in broadcast or multicast deliveries

→TCP encapsulates data from higher-level protocols into "segments", which are then passed down as TCP PDU's (Protocol Data Units), and passed to the IP protocol, Layer 3.

### **TROUBLESHOOTING UDP TRANSPORT PROTOCOL:**

#### **UDP PROTOCOL:**

Protocols that use UDP are TFTP, SNMP, NFS, DNS

NFS→RPC→UDP→IP

--UDP is a datagram transport protocol that outputs a single UDP datagram per transmission, as received from Applications via the IP Layer. Depending on MTU, etc., IP datagrams may need to be fragmented into separate packets. This allows for the out of order delivery of fragments—problem arises when one of the fragments is lost, the whole datagram must then be retransmitted. UDP header is always 64 bits.

--RPC Calls on behalf of NFS use Transaction IDs (XID) and is registered with Portmapper process on Server

--Much different than TCP—UDP has no concept of lost packets and retransmissions

--Applications enforce lost packets, and when this happens UDP must retransmit the whole datagram, which could be many IP Packets, unlike TCP which performs timeout and retransmissions of individual packets

--NFS typically uses UDP to mount remote filesystems

--RPC (NFS) keeps track of timeout values and if they expire, will require that UDP retransmit

**Note:** Unlike TCP, which uses ACKs to indicate packet loss, UDP uses silence

#### **UDP REASSEMBLY QUEUE:**

UDP uses unique IDs and Offset values to reassemble inbound IP fragments from its 'reassembly queues'—by default, the Queue is set to expire after 60 secs, meaning that an IP Datagram would have to be completely retransmitted.

#### **TIPS WHEN USING UDP:**

**Comment:** On clean networks, UDP has the potential to deliver more payload with less overhead than TCP. However, from experience, any dropped 'packets' on the network can significantly slowdown delivery of data when using UDP since the complete "datagram" must be retransmitted if any single "packet" is dropped or lost. TCP, on the otherhand, only needs to re-transmit a single lost "packet" and can therefore handle dirty networks by providing better overall throughput.

--Because of the above statement, it is usually always recommended to "mount" NFS File Systems for TCP rather than UDP.

--But, if NFS over UDP is required, it may be better to set an rsize/wsize of 8k or lower for the NFS mounts

### **IP NETWORK LAYER 3→IP PROTOCOL:**

- IP protocol receives PDU's from TCP, and encapsulates them as Layer 3 SDU's (Service Data Units) called “packets or datagrams”
- IP provides routing of interconnected packet-switched networks
- IP provides for unreliable, connectionless datagram delivery service
- IP provides for data transfer via datagrams, addressing via 32-bit IP Addresses, routing, & fragmentation of datagrams into packets
- All IP fragments carry same ID as original packet
- ICMP, ARP, DHCP also work at this layer
- IP uses protocol field to determine which application protocol to route datagrams to [e.g., 6=TCP; 17=UDP, etc]
- IP datagrams are used for both TCP and UDP

#### **CHARACTERISTICS OF IP PROTOCOL:**

- Packets are treated independently between sender and receiver
- Packet delivery is not guaranteed
- Lost or corrupted packets are not recovered, except by other layers

#### **ICMP PROTOCOL:**

Announces network errors, network congestion, assists in network troubleshooting with ping echo, announces timeouts

### **DATALINK ETHERNET LAYER 2:**

Data containers at this layer encapsulate packets into “Ethernet frames”, turned into bit streams at the physical layer

### **PHYSICAL LAYER 1:**

Receives Ethernet Frames from Layer 2 and converts into bits for transmission on the wire

#### **NFS NETWORK LAYERS:**

NFS v2 or v3 uses RPC Client-Server calls over TCP/UDP, IP, Ethernet

#### **CIFS NETWORK LAYERS:**

RPC, Pipe Protocol, SMB, NetBIOS, TCP, IP, Ethernet

#### **NETWORK LAYERS:**

|                  |     |                                                                                                                                                                           |
|------------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Layer 7 NFS      | PID | Application Layer [Unix NFS, Mount, NIS; Windows WINS, Login, SMB]                                                                                                        |
| Layer 6          |     | Presentation Layer [XDR for NFS—External Data Representation Standard]                                                                                                    |
| Layer 5 RPC      | XID | [Client & Server requests are tied together by unique transaction XID numbers]                                                                                            |
| Layer 4 TCP      |     | Transport Layer--Port Sequence Numbers and Acknowledgments                                                                                                                |
| Layer 3 IP       |     | Network Layer--IP Addresses—IP protocol ‘interconnects’ packet-switched networks                                                                                          |
| Layer 2 DLC      |     | Data Link Layer--MAC Addresses & Frames—Ethernet transmits & receives data packets, decodes packets; detects errors; method behind physical delivery of packets to a Host |
| Layer 1 Physical |     | Media & bits [This is where bad cables & mismatched duplexing manifest themselves]<br>NICs use MDI pinout scheme, while Switches & Routers use MDIX pinouts               |

### **ROUTERS, SWITCHES, HUBS:**

**Hubs:** By definition Hubs run at Half-Duplex—if you have a Hub involved with Celerra, must force the DM's to talk Half Duplex. Why? Because a switch will automatically negotiate at Full Duplex to the Hub and pass along to Celerra at Full Duplex—over time, the switch buffers will overflow and cause poor performance, possibly failure. Half-duplex interfaces transmit on a transmit pair while listening to receive traffic on a receive pair. Receive pair is where Collision Detection and Avoidance takes place. Full Duplex does not need to do this.

**Switches:** Layer 2 device that builds tables based on MAC addresses and port received from [Configure VLAN's on switches]

- show config: Displays switch configuration
- show vlan: Displays VLAN assignments—confirm that switch ports 3/1-16 are in correct vlans
- show port: Verify Port connection status; Duplex negotiation; speed negotiation
- show trunk: Displays trunking info; a)Mode set to On b)Encapsulation c)verify vlans memberships in trunk

**Basic Troubleshooting:** Check Port Light Negotiation and VLAN configurations

**Cisco 2900 Layer 3 Switch:** >enable [type “enable” at prompt to log into Privileged mode on a switch or router]

**Looking at settings:** sh config; sh int fast6

Run from Privileged Mode: Config t>interface fast6>speed auto [duplex auto] or speed full [duplex full] ctrl + Z to end session

#### **DART & SWITCH PROTOCOLS:**

DART understands only (3) Switch protocols; Ethernet Trunking; ARP; RIP

### **FULL/HALF DUPLEXING; AUTOSENSING/AUTONEGOTIATION:** #server\_sysconfig server\_2

Rule: Celerra must match settings of Switches!! [Celerra to Switch; Switch to Host; Switch to Switch—ALL must be same!!]

Switch              DataMover

|                 |                 |
|-----------------|-----------------|
| Auto            | Auto            |
| Fixed 10/100    | Fixed 10/100    |
| Fixed Half/Full | Fixed Half/Full |

**Performance Issues Related to Hubs, Switches, Celerras:** Speed and Duplex settings; or an Overloaded device

### **CISCO SWITCH COMMANDS:**

|                                                                    |                                                                                      |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| #set port channel 5/17 mode on                                     | [Sets EtherChannel Mode On for the Switch]                                           |
| #show port capabilities 5/17                                       | [Shows capabilities of the port indicated on the switch]                             |
| #show port channel                                                 | Channel Mode On=Cisco Etherchannel=Celerra “trunking” ADMIN GROUP 12 Channel ID 777] |
| <b>Note:</b> This is our basic Celerra Trunking mode of operation! |                                                                                      |
| #show port 5/17                                                    | [VLAN 2 and other information displayed]                                             |

### **QUALIFIED SWITCHES FOR USE WITH CELERRA:** Others can be used with Product Qualifier Statement

**Ethernet 10/100 Base T:** RJ45 connectors and manual configuration of Speed and Duplexing recommended

Cisco Catalyst 5000/5500/6500; Alantec; FORE Powerhub 7000; Cabletron MMAC; SMC TigerSwitch 100; Bay Networks Baystack Hub; 3COM Linkswitch 3000; LANPlex 2500; Linkbuilder FMS100

**Gigabit Ethernet:** SC Connectors 62.5 or 50 micron cables with Jumbo Packet support

Alteon; Cisco 6500; Foundry BigIron 4000; HP ProCurve 9304

**FDDI Switches:** Uses SC connectors and is Half Duplex

DEC GIGAswitch FDDI; DECconcentrator 900/500MX; Synoptics 2914; Cableton MMAC Plus; 3COM Fiber Concentrator; Xylan Omniswitch; Cisco 5000/5500; Fibronics GigaHub

**ATM Switches:** SC connectors with LANE V1.0 emulation

Fore Systems ASX200/1000; Cisco LightStream 1010; Bay Network Centillion 100

### **CLIENT OPERATING SYSTEM SUPPORT:**

Compaq Digital UNIX Tru64; HP-UX; IBM AIX; LINUX; Silicon Graphics IRIX; SUN Solaris; Windows NT/2000

### **Routers:**

Layer 3 device designed to deliver packets from Layer 3 to Layer 2 MAC Addresses

RIP Protocol=Distance Vector      OPSF Protocol=Link State      Hybrid Protocol=IGRP [Cisco]

Router Access Lists: Standard, Extended, Deny, and Filters—all based on Protocols, Port Numbers, and/or IP Addresses.

**#show run** → Verify Encapsulation; Vlan assignments; IP Address & Mask; Access-Group assignments; That no IP redirects or Shutdowns listed

**#show route** → Confirm destination network has a defined route

**#show access-list 101** → Examine access-lists as necessary

**#show ip route; show init; show encaps** → Trunking protocol in use]; show config; show port 4;

**Note:** Trunking Protocols are set up on Routers, not Switches! VLANS are set up on Switches, not Routers!

**Basic Troubleshooting:** Check Access Lists; Routing Tables; Encapsulation protocol

**Blackhole Router:** Troubleshoot with ping command: #ping -f -i 50 [MTU size—vary size until no reply]

**Cisco 5500:** >enable>set port speed 4/1 auto    >set port duplex 4/1 full

### **TROUBLESHOOTING CELERRA NETWORKING:**

**Server\_route Command:** Routing Table entries. -f to flush entries -l to list -d to delete a route -D to delete all entries -a to add \$server\_route server\_4 -flush      \$server\_route server\_4 -list      \$server\_route server\_4 -add 193.1.21.200 193.1.21.254

**Adding DataMover Default Gateway Command:**

**#server\_route server\_2 -add default 10.127.15.238**

**Viewing a Routing Table:** #server\_route server\_2 -l

### **CELERRA ROUTING TABLES/DEFAULT GATEWAY:**

Ifconfig command adds IP entry for interface and takes the assigned IP address and netmask assigned to determine the Destination Network address seen in the Route Table

Default Routes can be assigned as Static entries and are always checked last in the Route Table before routing a packet  
packets are delivered in Ethernet network via MAC hardware addresses

### **Dynamic Routing:**

RIP Protocol runs by default on the Celerra

Disable RIP in order to build Static Routing Tables using the “server\_route -add” command

### **ICMP REDIRECTS:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
If RIP is disabled on DM, & Routing Tables are Static, ICMP Redirects have the capability of changing Routing Tables on the Receiving end & causing problems.

## **VERIFYING DM ICMP STATISTICS & ROUTE REDIRECTS:**

**\$server\_config server\_x -v “icmp stat”**

```
Source quench      0/0  
Redirect route     0/0  
Echo request      143654/0
```

-----abridged-----

**SERVER NETSTAT UTILITY:** Network Statistics for IP, ICMP, TCP, UDP [also, use to verify NIC transmitting!]

-a lists TCP & UDP sockets      -i state of interfaces      -r Routing Table      -s Protocol stats      -p tcpludplip

**Note:** Input errors could indicate network cabling problems, bad CRC checksum errors from failing NIC's, etc.

Output errors may indicate host problem or flooded network. Sustained Errors >than 5% would indicate a problem.

```
$server_netstat server_4 -a          [active TCP/UDP connections]      $server_netstat server_4 -s [stats for all protocols]
```

```
$server_netstat server_4 -s -p tcp    [udp/ip protocol stats]      $server_netstat server_4 -i [interface info]
```

```
$server_netstat server_4 -r          [routing table statistics]
```

## **DISPLAYING NETWORK STATISTICS FOR IPv4:**

**# server\_netstat server\_2 -A inet -a**

```
Proto Local Address                    Foreign Address        (state)  
*****  
tcp 128.221.252.2.mac            128.221.252.100.990 ESTABLISHED  
tcp *.portmapper                    *.*                    LISTEN  
tcp *.mount                        *.*                    LISTEN  
tcp *.nfs                         *.*                    LISTEN  
tcp *.Network-Block-Service        *.*                    LISTEN  
tcp *.Replication-Services        *.*                    LISTEN  
tcp *.Replication-Services        *.*                    LISTEN  
tcp *.Replication-Services        *.*                    LISTEN  
tcp *.5085                        *.*                    LISTEN  
tcp *.7777                        *.*                    LISTEN  
tcp *.RCP                        *.*                    LISTEN  
tcp *.NDMP                        *.*                    LISTEN  
tcp *.usermapper                 *.*                    LISTEN  
tcp *.xattrp                      *.*                    LISTEN  
tcp *.rquotad                    *.*                    LISTEN  
tcp *.statd                      *.*                    LISTEN  
tcp *.lockd                      *.*                    LISTEN  
tcp *.SNMP                        *.*                    LISTEN

*****  
udp *.SNMP  
udp *.Routing-Information-Protocol  
udp *.4646  
udp *.lockd-forward  
udp *.pax  
udp *.RFA  
udp *.mac  
udp *.56790
```

## **ANALYZING NETSTAT OUTPUT:**

**Network Collision Rate:** Divide Number of Output Collisions by Number of Output Packets [greater than 10% is a problem]

**Input Packet Error Rate:** Divide Number of Input Errors by Number of Input Packets [> than 25% could indicate host problem]

**Statistic Commands:** #server\_netstat server\_2 -a -i -r -s [tcp/udp/lip stats] #server\_netstat server\_2 -s [stats on all protocols]  
#server\_nfsstat ALL -rpc -nfs #server\_sysstat ALL {Key stats on DataMover activity} #server\_nfsstat ALL -z -n

**Netstat:** Should have less than 10% errors on a NIC or else could indicate a problem!

**Netstat -e** command will show network statistics, especially if there are a lot of collisions [packet loss]

### Linux Interface Statistics: #netstat -i

### OBSERVING PORTS AND SERVICES CONNECTED ON CONTROL STATION:

\$ netstat -alp

### ADDRESS RESOLUTION PROTOCOL—ARP:

**Purpose:** To resolve a node's Layer 3 IP Address to its Layer 2 Data Link MAC, hardware, or Network Interface Address.

--ARP sends ARP Request message to request MAC address for a forwarding IP address via MAC-level broadcast

--Receives ARP Reply

--Default ARP Cache TTL for Windows 2000 is 2 minutes, with a max lifetime of 10 minutes

**Gratuitous ARP:** Method for detecting duplicate IP addresses. Node sends an ARP Request for own IP address—if no ARP reply is received, then assumption is made that its IP address is o.k.

**Note:** If another Host shares same IP address, then ARP cache might have MAC address of other computer, or vice versa, leading to ARP resolution problems.

**Proxy ARP:** Answering ARP Requests on behalf of another node, commonly used in Routing & Remote Access services.

### CELLERRA ARP ISSUE:

NAS 5.1.15.3 fixes gratuitous ARP issue by providing for a new ARP engine that will issue gratuitous arps every 10 seconds for up to 2 minutes. Purpose is to allow time for multiple switches to be properly updated with new ARP information from Celerra.

### ARP PARAMETERS:

**param ip ifAdvertiseDuration=119** [Defines how long DART sends advertisements for ARP--default is 119 secs in length.  
If set to 0, DART sends only a single ARP message when the Interface is started—previous code behavior]

**param ip ifAdvertiseFrequency=10** [Defines how frequently advertisements are sent—default=10 secs. Gratuitous arp is advertised every 1-10 secs for the 2 minute window]

**ARP TABLES:** #server\_arp; arp -a; arp -d 10.127.15.229; arp -s 10.127.15.227 macaddress or arp -d\* [delete all]  
Arp maps layer 3 IP addresses to Layer 2 MAC addresses [Reverse ARP maps Hostname to IP Address]

**Default ARP Cache Value:** 10 minutes most systems, 5 minutes for DM

\$server\_arp server\_4 193.1.21.210 [Arp cache from IP Address] \$server\_arp server\_4 -a [Arp cache locally]

\$server\_arp server\_4 -s 193.1.21.210 macaddress [adding entry to ARP] \$server\_arp server\_4 -d 193.1.21.210 [deleting entry]

**Server arp Command:** -a Displays ARP tables {IP to MAC address resolution} -d delete entry -s set static entry

**Note:** Default ARP Cache timeout = 5 minutes. View ARP Cache to see entries for other systems.

# server\_arp server\_13 -all

server\_13 :

192.168.2.100 at 0:4:76:30:c:6a

192.168.1.100 at 0:1:2:ee:74:1f

10.10.28.254 at 0:0:c:7:ac:1c

### DUPLICATE IP ADDRESS ISSUE:

**Symptom:** Customer adds new network interface to Celerra and receives “Network path not found” error

**Cause:** Duplicate IP Address

### Troubleshooting Duplicate IP for Celerra:

→Ping from Client to DM IP

→Do arp server\_x and note MAC address of DM

→Do server\_ifconfig on DM and compare MAC addresses [If different, then there is a duplicate IP address on network]

**Network Commands:** #server\_arp #server\_dns #server\_ifconfig #server\_nis #server\_ping #server\_route ALL -l [lists out the DM routing table] #server\_snmp Network Connections, Info, & Ports Listening: #server\_netstat server\_x -a [-i]

#server\_ifconfig server\_2 ana0 [parameters for specific interface] #server\_ifconfig server\_2 ana0 up [enable/disable interface]

#server\_netstat server\_2 -i [interface info] #server\_netstat server\_2 -r [server routing tables]

### Server Sysconfig Command: Displays Interface Information about DataMovers

Device name, slot, port, IRQ, Processor, RAM, Motherbd, Bus speed, etc

-pci : Display or configure NIC's for duplex speed -o {speed=10|100 default} duplex=full|half default

/nas/bin/server\_sysconfig ALL -P [shows server configurations]

## **DISABLING RIP PROTOCOL ON DM:**

#vi /nas/server/slot\_2/netd [comment out #routed]

## **NETWORK ANALYZERS:**

Solaris Snoop Program; NT Network Monitor; Network Associates SnifferPro 3.5; Ethereal Program

**Sniffer Placement on Network:** Consideration needs to be given as to where the desired traffic capture should be—between Client & Switch; Data Mover and Switch, etc. Consideration also needs to be given as to taking the trace by spanning switch ports or doing the trace in-line.

## **CONFIGURING A SWITCH TO SPAN A PORT:**

1. #set span 1/1 1/3 [All traffic from port 1/1 will be sent to 1/3]

## **NETWORK BROADCASTS:**

Two Types: Layer 2 and Layer 3

LAYER 2 BROADCASTS: Conducted by applications such as ARP and system discover

LAYER 3 BROADCASTS: Conducted by NetBIOS, etc. [Most common]

Most networks should have no more than 50-100 Broadcast packets per second to be healthy

## **IPv4 CLASSES:** 32-bit values, up to 4 billion addresses, Layer 3 in OSI model

→interfaces with Layer 4 [TCP & UDP] via the Protocol ID field in the packet header

→Autoconfiguration through use of DHCP

→Handles fragmentation

→QOS and Security functions not really useful or used

→Use of broadcasts [ARP, RIP, etc.]

→ICMPv4 ping for Error and Informational messaging

## **IPv4 Enhancements:**

→Classless addressing [CIDR—Classless Interdomain Routing]

**Note:** Network ID indicated by leftmost high order bits, usually written like /24, /30, etc., requires use of subnetting

→NAT

## **RFC 1918 Establishes Private Network Addresses:**

10.0.0.0 – 10.255.255.255

172.16.0.0 – 172.31.255.255

192.168.0.0 – 192.168.255.255

**Note:** These private address spaces are NOT maintained by Internet Routers—hence “private”

| Class | Default Mask  | Network Range     | # Host Bits | #Network Bits        | #Networks | #Hosts per Network |
|-------|---------------|-------------------|-------------|----------------------|-----------|--------------------|
| A     | 255.0.0.0     | 1-126.255.255     | 24 bits     | 8 bits               | 126       | 16,777,214         |
| B     | 255.255.0.0   | 128.0-191.255.255 | 16 bits     | 16 bits              | 65,000    | 65,534             |
| C     | 255.255.255.0 | 192.0-223.255.255 | 8 bits      | 24 bits              | 2,097,152 | 254                |
| D     |               | 225.0-239         |             | [Multicast networks] |           |                    |

## **IP Subnetting Refresher:**

n<sup>n</sup> - 2

### **I. How to Find Subnet Mask Value for a Given Number of Required Subnets**

Example: 172.20.30.40 Given IP Address Problem: Need to support 6 subnets

Class B: 255.255.0.0

**Note:** To provision a Class B network for 6 subnets, requires (3) bits from the Host octet because you count the Value from l-to-r; 2    4    8    16    32    64    128 ....to obtain (8), the minimum number of bits required for (6) subnets.

Subnet Mask= 11111111.11111111.11100000.00000000

Or 128 + 64 + 32 for the (3) bits = 255.255.224.0

### **II. How to Calculate Broadcast Address: Subnet Mask: 11111111.11111111.11100000.00000000**

Note: Take value of 3<sup>rd</sup> bit, which is (32), and that becomes your network boundaries;

172.20.0.0 – 172.20.31.255                      Broadcast Address = 172.20.31.255

172.20.32.0 – 172.20.63.255                      Broadcast Address = 172.20.63.255

172.20.64.0 – 172.20.95.255, etc.                Broadcast Address = 172.20.95.255, etc.

## **Internal IP Address Ranges:**

\* 10.0.0.0 - 10.255.255.255  
\* 172.16.0.0 - 172.31.255.255  
\* 192.168.0.0 - 192.168.255.255

## **IPv6 STANDARD:**

### **IPv6 NETWORKING FEATURES/BENEFITS:**

- Larger public & private address space
- Automatic addressing easier
- Support improved for extensions and options
- Uses QOS in header for Traffic Class and Flow Label [New, allows for prioritization & filtering of traffic using RSVP—Resource Reservation Protocol]  
**Note:** Flow Labeling is one-way directional data transfer and is identified using Source & Destination addresses, and Flow Label. Flow Labeling is really just a special handling indicator for Routers. DiffServ for internal network priority schemes [DSCP—Differentiated Services Code Point]. DiffServ is class-based approach, while IntServ is flow-based approach to QOS
- Authentication & Privacy capabilities
- No more broadcasts as in IPv4—instead, uses multicasting and anycast addressing [1:1:many]
- Security built-in with IPSEC
- Use of scopes based on topology or geography for communications [Link local, subnets, Global]
- Subnetting is done using CIDR rules [Classless Inter-Domain Registration] with network prefix notation, NOT subnet masks
- IPv6 supports Stateful DHCP and Stateless (no DHCP) address configuration

**Note:** With Stateless configuration, Hosts auto configure IP addresses on local link and globally unique prefixes advertised by local routers

## **IPv6 HEADER:**

- (8) fields fixed at 40 bytes, using Version (4-bits), Traffic Class (8-bits), Flow Label (20-bits), Payload Length (16-bits), Next Header (8-bits), Hop Limit (8-bits), Source Address (128-bits), Destination Address (128-bits)
- Note:** Traffic Class of 0 means best-effort. Anything else means routers treat with preference. Next Header identifies the next header after the IPv6 header—replaces Protocol field. Hop Limit max. is 255 and packets discarded if decremented to zero—replaces TTL

## **IPv6 PACKET TERMINOLOGY:**

Frame consists of Layer 2 (Ethernet), Layer 3 (IPv6), Layer 4 (TCP/UDP), Layer 7 (Applications), and Data fields

Packet/Datagram consists only of Layer 3 – Data fields

Segment consists of Layer 4 – Data fields

Link MTU is Maximum Transmission Unit, packet size in octets, that can be conveyed over a link

Path MTU is the minimum MTU to all links between Source & Destination systems

## **IPv6 EXTENSION HEADERS:**

Optional Layer 3 headers placed between IPv6 and Upper Layer headers in a packet, multiples of (8) octets (bytes)

Packets can contain multiple extension headers

Extension Headers are used for Hop-by-Hop, Routing, Fragment, Destination, Mobility, Authentication, & ESP options

### **Hop-by-hop Extension Header:**

Option used to inform Routers of special QOS processing or MLD messages, or Jumbo payload attached

Indicated to Router by Next Header=0 flag in IPv6 Header

Immediately follows the IPv6 Header, and is examined by all Routers

### **Routing Extension Header:**

Indicated by value of 43 in Next Header of preceding header

Used as Loose Source Route option when one or more intermediate nodes are desired for routing

Lists addresses to be visited

### **Fragment Extension Header:**

IPv6 Routers are not allowed to fragment packets, and IPv6 Header cannot be fragmented

Source system can fragment large packets using the Fragment Header option, multiples of (8) bytes

Receiving system reassembles fragments in correct order at Layer 3

### **Destination Extension Header:**

Processed on destination system at upper-layer, though each Router along the way inspects

## **IPv4 HEADER:**

- Could be variable in length, 20-60 bytes, using (14) fields: Version, IHL, TOS, Total Length, ID, O, DF, MF, Fragment Offset, TTL, Protocol, Hdr Checksum, Source Address, Destination Address

## **CONFIGURING IPv6 ON WINDOWS CLIENTS:**

XP requires use of CLI utility called netsh c:>netsh interface ipv6 install [Installs the IPv6 stack]

Vista offers a GUI for configuration

## **IPv6 ADDRESS:** 128 bits in length

→ An IPv6 Address is 128 bits, represented by 16 octets (aka, hex pairs) totaling 32 hex characters [see RFC 2460]. Visually, the address is segmented into (8) fields of 4 Hex characters separated by colons, and shortened per accepted abbreviations.

→ Colons are used to separate groups of 16 bits, totaling (8) sections

**2001:030b:0000:0000:0004:6c2a:008d**

**2001:30b::4:6c2a:8d** → Example of acceptable abbreviation

### **IPv6 Addressing Abbreviation Rules:**

\* Successive fields of all zeroes can be indicated by double colon ::, which can be used at beginning, middle, or end of address, but only used once within the address

\*\* Beginning zeroes of any field can be dropped—they are implicitly known

\*\*\* Never drop trailing zeroes from any field

→ IPv6 addresses are based on Interfaces, not Nodes

→ All IPv6 addresses have a specific scope built-in, such as Link-local, Enterprise, and Global, based on topology or geography

→ IPv6 addresses are written in Hex, with each hex character representing 4-bits

### **CONFIGURING IPv6 NODES:**

#### **Stateless:**

→ autoconfig with Router providing the network prefix & subnet via ICMPv6 Router Advertisements, with host creating Host ID from MAC address

→ Router might also reply to use DHCP for other configuration information (such as DNS, Domain Name, etc.)

→ Hosts use ICMPv6 Router Solicitation messages to talk to Routers [sends to FF02::2, hop limit of 255]

→ Routers use ICMPv6 Router Advertisement messages to talk to Hosts

#### **Stateful:**

→ Autoconfig with DHCP Server providing the network prefix for hosts & other required information

**Manual** configuration also possible

→ IPv6 Header has been simplified in the PDU packet [Protocol Data Unit] and now fixed at 40 bytes vs. variable length

**Note 1:** IPv4 header fields IHL, Identification, Fragment offset, Header checksum, Options, all removed

**Note 2:** TTL is now Hop Limit, TOS is Traffic Class, Total Length is Payload Length, Protocol is Next Header

→ IPv6 uses Extension Headers instead of Header Options, which are dynamic, used as needed, processed as needed

### **INTERFACE IDENTIFIERS:**

→ Minimum of two Interface IDs are configured with this method:

1. EUI-64 ID 2. Temporary interface ID, which is a hash of the EUI-64 ID

**Note:** EUI 64-bit Interface ID is created from the interface MAC address, and substitutes a “02” hex as the Universal/Local bit at the beginning of the identifier, followed by Vendor ID in 4 hex numbers, pads the middle with a standard FF-FE, and ends with last 6 hex numbers.

#### **EXAMPLE:**

48-bit MAC Address: 00-03-47-28-45-8F

Converted to EUI 64-bit Identifier: 02-03-47-FF-FE-28-45-8F

→ All interfaces have at least one Link-local unicast address, and usually other addresses as well

### **STANDARD NET PREFIX AND COMPOSITION OF AN IPv6 ADDRESS:**

2000::/3

#### **FULL IPv6 ADDRESS as assigned to ISPs:**

2001:0DB8:0000:0000:0000:0000:0000/48

#### **First 48 High Order Bits Represent Network Prefix:**

2001:db8::/48

#### **Next 16 Bits Represent Subnet ID:**

0000

#### **Last 64 Bits Represent Interface ID:**

0000:0000:0000:0000

### **IPv6 ADDRESS CLASSES:**

Unicast 1:1 → Unique IPv6 interface node

Multicast 1:many → Group of IPv6 interfaces, members of a multicast group

Anycast 1:1 of many → Address assigned to multiple interfaces; Packet sent to anycast address usually goes to nearest interface

### **MANAGING MULTICAST ADDRESSES:**

→ Routers use Multicast Listener Discovery (MLD) to add, advertise, and prune entries

→ MLD replaces the IPv4 functionality of IGMP

→ Uses ICMPv6 as the transport protocol

→ Routers can query a link to see who's present using FF02::1 [Closest thing to IPv4 Broadcast 255.255.255.255]

→ Host Listeners can register with Router

→ Host Listeners should inform Router when leaving the group [FF02::2]

→ Solicited node multicast used in Neighbor Discovery process when only a single Host discovery is desired

## **ICMPv6:**

Used to return Error messages—represented by bits 0-127

Used to return Informational messages—represented by bits 128-255 in Echo Request and Echo Reply messages

Neighbor Discovery protocol replaces IPv4 ARP

An 8-bit ICMPv6 Header is indicated by 58 (0x3A), and follows the IPv6 Header [0-127; 128-255 values]

DAD (Duplicate Address Detection) uses Neighbor Solicitation to ensure that node address is not duplicated

## **DEFINED ICMPv6 ERROR MESSAGE TYPES:**

Destination Unreachable, Type 1 Code 1-6

Packet too big, Type 2 Code 0 [Used as part of the Path MTU discovery process between Interfaces]

Time exceeded, Type 3 Code 0 [Hop Limit Exceeded] or 1 [Packet reassembly time exceeded, from Host]

Parameter problem, Type 4 Code 0-2

## **NEIGHBOR DISCOVERY PROTOCOL:**

→ ND uses ICMPv6 with values 133-137

→ ND is used by IPv6 nodes (hosts & routers) to discover each other's Link-layer addresses of neighbors using multicast

→ ND used by Hosts to locate Routers

→ Used by Hosts to track reachable and non-reachable neighbors, and changed link-layer addresses

Type 133 Router Solicitation

Type 134 Router Advertisement → default timer 200secs

Type 135 Neighbor Solicitation → FF02:0:0:0:0:1:FF00::/104

Type 136 Neighbor Advertisement

Type 137 Redirect [from Router]

## **ND CACHE TYPES:**

### **Destination Cache:**

→ Entries regarding recent destination interfaces

→ Stored on Source hosts as cache maps of destination IP addresses, along with next-hop neighbor

→ Updated by Router Redirect messages

→ Stores Path MTU information for destination addresses

→ Stores link-local addresses of destinations

### **Neighbor Cache:**

→ Entries regarding neighbors, with flag to indicate Router or Host

→ Stores on-link unicast IP addresses and link-layer information (MAC)

→ Information on reachability

# show ipv6 neighbors

c:\>netsh interface ipv6 show destinationcache | neighbors | route

## **IPv6 ADDRESS TYPES:**

### **UNICAST:**

→ Global Unicast Addresses are manually set, and are the addresses used to route over the Internet. 64bits define the Network portion of the address, while 64bits define the Interface portion of the network. Currently, ISPs are only using prefix 2000::/3 addressing for Internet routing

→ A single Unicast Global address identifies only a single Interface

→ A single Interface can have multiple Unicast Global addresses

→ Global scope addresses are internet routable whereas Link-local scope addresses are IDs for the local link/network only

→ Global Unicast addresses usually consist of a Temporary address with same /64 prefix, with a default life of 24hrs, and an Interface ID that is hashed (i.e., unique) from the EUI-64 portion of the MAC address

→ Global unicast addresses are equivalent to public IPv4 addresses

→ Unicast is an identifier for a single interface and is point-to-point

→ Usually, an interface will have multiple unicast addresses (Global & Local unicast, and multicast addresses)

→ Local Unicast addresses (aka, private addresses inside a firewall) are unique, use a prefix of FD00::/8, and are not used for routing over the Internet

→ Link Local addresses are automatically configured by DART when using a Global Unicast or Unique local Unicast address

→ Link Local addresses only apply to the local Ethernet broadcast domain

→ Link-local Unicast addresses should never be used as a Source address if the Destination is a Global Unicast address

→ Link local interfaces are used for Neighbor Discovery, Router Discovery, and Duplicate Address Detection (DAD)

→ Link local addresses always begin with FE80::/10 or 64

### **MULTICAST:** Multicast---FF00::/8

→ Identifier for a set of different interfaces that are combined into a multicast group

→ Packets sent to multicast are delivered to all interfaces that are members of the address [FF02::2 all Routers on this link]

→ Multicast groups can be local, enterprise wide, or Internet

→ Many scopes possible

→Multicast addresses should not be used as a Source address

→Multicast addresses identified by first 8-bits, FF's, in network prefix portion of address, followed by 8-bits to define flags and scope

#### **4-bit Scope Field for Multicast Addresses:**

| Binary | Hex | Scope              |                  |
|--------|-----|--------------------|------------------|
| 0001   | 1   | Interface-local    | [FF01::1]        |
| 0010   | 2   | Link-local         | [FF02::1]        |
| 0100   | 4   | Admin-local        |                  |
| 0101   | 5   | Site-local         | [FF05::2, et al] |
| 1000   | 8   | Organization-local |                  |
| 1110   | E   | Global scope       |                  |

#### **ANYCAST:**

→Identifier for set of interfaces

→Packet is sent to only one interface in a group of different address nodes/interfaces

→Can be Global or Link-local scope addresses

→Address created from 64-bit network prefix and 57-bits of host ID portion, with 7-bits of host ID reserved for anycast ID

#### **IPv6 ADDRESS TYPES:**

**Link-local Unicast—FE80::/10** [1111111010 is the leftmost 10 bits]

**Link-local Multicast—FF02::/16**

**Note:** By definition, Link-local addresses are used only on local link and are not Routable

Local Unicast—Private internal networks—FD00::/8

Dual-stack Unicast--::FFFF:a.b.c.d [IPv4 over IPv6 for dual-stacked systems]

Site-local Unicast—FEC0::/10

**Multicast---FF00::/8** [All 1's for leftmost 8 bits, 4-bits for flags, 4-bits for scope]

FF02::2 →Link-local all-routers multicast [1<sup>st</sup> 8-bits indicate multicast, next 4-bits=flags, next 4-bits=Link-local]

**Global Unicast—2000::/3** (001) [2001::/16]

**Loopback---1/128** [all zeroes and a single bit on far right]

**Unspecified---1/128** [all zeroes]

#### **USING IPv6 ADDRESS WITH BROWSER:**

**Note:** Key is to enclose the IPv6 address within brackets [ ]

http://[2001:0db8:0:cd30:0200:abff:fe2e:2345]:8080/page.html

#### **MIGRATION/CO-EXISTENCE STRATEGIES FOR IPv6 & IPv4 NETWORKS:**

Creating Dual stacks on Hosts and Routers is one way to allow both IPv4 & IPv6 to co-exist (requires RIPng or OSPFv2/v3)

--Applications must support dual-stack

--IPv6 DNS Resolver call is getaddrinfo() vs. IPv4 gethostbyname()

Using Static or Automatic Tunneling methods is another way to bridge IPv6 networks that span IPv4

#### **MANUAL IPv6 TUNNELING (Point-to-Point):**

→point-to-point and unidirectional

→IPv6 packets are encapsulated and carried over the IPv4 network

→ideal for connecting two IPv6 networks together over the IPv4 internet

→Border Routers are dual-stacked

→Uses OSPFv3, RIPng (RIP for IPv6 distance vector routing protocol), or EIGRPv6 protocols for Routers

→Requires default IPv4 gateway on Hosts

#### **6to4 AUTOMATIC TUNNELING:**

→point-to-multipoint

→Automatic and dynamic tunneling of IPv6 packets over IPv4 networks, using 6to4 or ISATAP addresses

→most common technique is to use 6to4 tunnels [Net prefix 2002::/16]

→Hosts must be dual-stacked and have global IPv4 address to use 6to4 tunnel

→tunnels automatically created

#### **Example 6to4 Address:**

2002:AE13:4AOC:4:0:0:0:C7 (Dest. Router IPv4 address embedded: 174.19.74.12)

**Note:** Number of other tunneling protocols: GRE, ISATAP, IPv6IP, NAT, TEREDO, etc. NAT servers cannot handle IPv6.

#### **OSPFv3 (Open Shortest Path First) ROUTING PROTOCOL:**

→Updated version of OSPF that supports IPv6

→Protocol used in large or small networks based on link state algorithms, fast convergence, uses metrics to establish least-cost path

→Enabled on an interface-by-interface basis

#### **Enabling OSPFv3 on Router:**

```
# config t
```

```
# interface fastethernet 0/1
```

```
# ipv6 ospf 1 area 0
```

## **OTHER FACETS OF IPv6:**

### **DHCPv6 Servers:**

→Supplies all configuration parameters to Nodes except network prefixes for STATELESS configuration, requires Router [O flag set in Router Advertisement]

→Supplies all configuration parameters for STATEFUL, does not require use of a Router [M flag set in Router Advertisement]

### **DNS:**

IPv6 entries are stored as AAAA records using an IPv6 compliant BIND

Linux adds /etc/named.conf entry:

```
listen-on-v6 {any};
```

### **MOBILE IPV6:**

Supports an internet connection for mobile users when transiting from one IPv6 network to another

Router supports through use of MN entries (Mobile Node) onto foreign networks when traveling

Home Agent refers to mobile user when on the Home network

## **WINDOWS XP IPv6 NETWORK SHELL UTILITY:** netsh.exe

### **Configuring IPv6 on XP:**

```
C:\>netsh interface ipv6 install  
C:\>netsh interface ipv6 show interface  
C:\>netsh interface ipv6 show address  
C:\>ping <router_ipv4_addr>  
C:\>ping <router_ipv6_addr>  
C:\>ping ::1 (loopback) | ff02::1 (all hosts) | ff02::2 (all routers)  
C:\>nets hint ipv6 add dns "P-IV Laptop LAN #1" 2001:abcd:0:1001::6 [adding host IPv6 ID to DNS]
```

## **CISCO ROUTER COMMANDS IPv6:**

### **Enabling IPv6 on Router, then Interfaces:**

```
# ipv6 unicast-routing  
# interface fastethernet 0/0  
# ipv6 enable  
#ctrl z  
# show ipv6 interface [to verify—creates several multicast group addresses and a link-local address]  
# write memory [saves to startup config]
```

Configuring an IPv6 Network on the Router:

```
# config terminal  
# interface fastethernet 0/0  
# ipv6 address 2001:abcd:0:6::/64 eui-64  
# ctrl z  
# write mem  
# show ipv6 interface fastethernet 0/0
```

### **Configuring Manual Tunnel between IPv6 Sites:**

```
# config t  
# ipv6 unicast-routing  
# interface fastethernet 0/1  
# no shutdown  
# ip address 10.1.6.254 255.255.0.0  
# ipv6 address 2001:abcd:0:1001::6/64  
# ipv6 enable  
# ipv6 nd dad attempts 2  
# ctrl z  
# show run # write mem  
# config t  
# router rip [enabling RIP]  
# network 192.168.6.0 # network 10.0.0.0 # exit  
# interface fa0/0  
# ipv6 rip process1 enable [Enabling RIPng]  
# interface fa0/1  
# ipv6 rip process1 enable  
# ctrl z # write mem # show run  
# config t  
# interface tunnel 100  
# ipv6 address 2001:abcd:0:106::1 [Tunnel endpoint on one side] # ipv6 enable # ipv6 rip process1 enable  
# ipv6 address 2001:abcd:0:106::2 [Tunnel endpoint on other side] # ipv6 enable # ipv6 rip process1 enable
```

```
# tunnel source 10.1.6.254 # tunnel destination 10.2.16.254 [Configuring endpoints & associating with tunnel]
```

```
# tunnel mode ipv6ip # ctrl z #write mem # show run # show ip route # show interface tunnel100
```

## **CELERRA COMMANDS:**

```
# .server_config server_2 -v "ifconfig showall"
```

-----output abridged-----

Interfaces:(1)

loop6 on loop address= ::1/128 DNIF UP

```
mtu=32768, dmtu=32768, vlid=0, mac=0:0:0:0:0:0 dmac=0:0:0:0:0:0 if_index=4
```

## **CELERRA NAME SERVICES [HOSTS, NETGROUPS, NIS, DNS, WINS]:**

### **NIS SERVICE:**

**Intro:** NIS is usually used when using UNIX Security & User-Level Authentication [NT Domain Controllers are not used]. NIS is a network lookup service that provides for hostname-to-IP translation or IP-to-hostname, netgroup memberships, etc.

However, NIS is sometimes configured in “mixed” environments where NT Security is also used. In these cases, an NT client accesses the Celerra via Netbios name [as registered by WINS], which in turn interrogates the Domain Controller with the Security Access Token information of the User for validation and access rights. When using NIS, the DataMover points to the NIS service, which must have the NT User Names and Domain listed in its Map files—this information can be maintained on the NIS service by using NT Migrate [or manually by adding the proper entries whenever new NT Users are added to the Domain], or pushed out to the DataMover for better reliability and redundancy in case the NIS server becomes unavailable.

**Caution:** NIS+ is not supported by Celerra!

**Note:** When using following param entry, Usernames will be resolved to first matching name in NIS passwd file without regard to NT Domain extension—in otherwords, it would no longer be required to add the “username.domain” syntax.

```
/nas/server/slot_x/param
```

```
param cifs resolver=1
```

**NIS LIMITATION:** CIFS User Migration Tool, UNIX User Management Tool, & UNIX Users & Groups property pages might not be able to return Users or Groups with names longer than (17) characters

### **NIS SERVICE CONFIGURATION FILES: Network Information Service [NIS]**

--Functions as the Unix Nameserver & Security Server; files are located in **/var/yp** directory [ypserv ypbind]

--Master copy of **Hosts**, **Passwd**, **Group**, and **Netgroup** files

--Ypserv—Server daemon servicing client requests: client lookups; map maintenance; internal NIS calls

--Ypbind—Client daemon making requests and server uses to reply to clients.

**CELERRA NETGROUPS (NIS):** A netgroup file is a NIS database map file that is used for creating sets of Users and Hosts that help administratively define access to specific Hosts or NIS Domains. A netgroup file’s format consists of a set of triples or three ‘fields’ within ( ): setname (hostname, username, domainname). If an entry within the ( ) is left blank, that field becomes a wildcard. If an entry contains a dash (-), then the field has no value. One suggested method for building netgroup files is to use a netgroup to define “users” and a netgroup to define “hosts”:

#### **EXAMPLE 1:**

gate-users: ( ,isaac, ), ( ,moby, ), etc..... [Defines Users for Netgroup “gate-users”]

gate-hosts: (taco, ,), (bell, ,), etc..... [Defines Hosts for Netgroup “gate-hosts”]

#### **EXAMPLE 2:**

```
/etc/netgroup
```

root-users (,user1,), (,user2,), (,user3,)

trusted-machines (machine1,,), (machine2,,),

**Purpose:** When exporting NFS filesystems, customer may want to use NetGroup files to control access. Default Celerra behavior is to allow any unix client to mount a directory. You could restrict this behavior by using NetGroup files to restrict Users or Hosts.

Netgroups can be defined by local Datamover **/.etc/netgroup** files, or using NIS.

1. Defined in the **/.etc/netgroup** file on the DataMover

2. Or defined using NIS

**Note:** Recommended that 'Hosts' not be members of more than (1) netgroup!

--Netgroups only works when NIS is implemented, and combines password & host files to control User access via password file or Host access to NFS filesystems via host file.

--You can use Netgroups in the Passwd file by adding following at end of /etc/passwd: +@root-users

--Workaround for NIS+; Push the Netgroup Tables from NIS+ Server to NIS Host. Then use Cron job to send to Control Station, then put out onto the **/.etc** directory

--Netgroup line length limitation is 16,383, see AR37564 [5.1.20.2 & 5.2.6.0]—previous limitation was 1024 characters per line

## **NFS EXPORT RESOLUTION PRECEDENCE:**

- Subnet entries take more precedence than netgroup entries and overrule
- Host entries take precedence over Subnet entries

## **NETGROUP EXAMPLE FOR NFS:**

**\$server\_export server\_2 -Protocol nfs -ignore -option root=test\_test1 /fs12**

**Note:** If using DNS with FQDN, then netgroups must also use the FQDN

## **CONFIGURING THE NETGROUPS FILE:**

--Each line of Netgroup File consists of a Groupname followed by (3) fields that define:

**groupname (hostname, username, domainname)**

## **EXAMPLE:**

jupiter (, , galaxy) →Represents the group called “Jupiter” in the NIS domain called “Galaxy” that includes all Hosts and Users  
planets (-, ,galaxy) →Represents the group called “Planets” in NIS domain called “Galaxy’ that includes all Users but no Hosts

**Note:** Celerra does not support netgroup queries in NIS+ compatibility mode—must use local netgroup file on DM.

## **ORDER OF CELERRA HOST NAME RESOLUTION:**

→ Celerra searches its ./etc/hosts, then ./etc/netgroup files first, then NIS, then DNS until a match is obtained

**Note:** Configure local ./etc/hosts file with IP Addresses and Host names; Configure ./etc/netgroups file; Configure DM to run NIS & DNS Services

### **Example of Hostname resolution from ./etc/hosts file:**

**# .server\_config server\_2 -v "gethostbyname loner"**

1211898331: LIB: 7: Querying LOCAL host file by name.

1211898331: LIB: 6:

1211898331: LIB: 6: Name: loner

1211898331: LIB: 6:

1211898331: LIB: 6: Aliases:

1211898331: LIB: 6: No aliases

1211898331: LIB: 6: IPv4 Address(es):

1211898331: LIB: 6: 192.1.4.222

1211898331: LIB: 6:

1211898331: LIB: 6: IPv4/IPv6 Socket(s):

1211898331: LIB: 6: ::ffff:192.1.4.222 AF\_INET

**Note:** NAS 5.5 only returns a single IP address for a given Hostname, whereas NAS 5.6 correctly displays all known IP addresses for a given Host. See AR117706 for more details—NAS 5.5.33 and higher contains the fix.

## **CONFIGURING NIS CLIENT ON LINUX CONTROL STATION:**

Step 1. #linuxconf [provide NIS Domainname & server IP address]

Step 2. #/sbin/chkconfig ypbndt on [sets up ypbndt to start on next reboot of CS]

Step 3. #/sbin/chkconfig --list ypbndt [verifies your ypbndt setup]

Step 4. Reboot Control Station #reboot

## **CONFIGURING DATA MOVER AS NIS CLIENT:**

Step 1. Copy Control Station Hosts file to DataMover: \$server\_file server\_2 -p hosts hosts

Step 2. Configure DataMover to use NIS: **\$server\_nis server\_2 nsgprod 172.24.80.100,172.24.80.101** [NIS IP Addresses]

**Note:** Be aware that data mover uses names when mappings are made using NIS or local passwd/group files, not SIDs. Also know that all NIS entries must be in lowercase as Celerra forces all Windows names to lowercase before making NIS ‘yp match’ call.

## **EXAMPLE OF PROBLEM NAME:**

**\$server\_config server\_2 -v "yp match nas-nis 13434 group.bygid"**

1121950202: NETLIB: 4: Research=20Admins.umc-users:x:13434:

## **NIS SERVICE LIMITATIONS:**

Only a single NIS domain can be used, with up to 10 NIS Servers specified

## **WINDOWS SERVICES FOR UNIX 3.0:**

Be aware that NIS can be run as a service on Windows 2000/2003 systems—Celerra Servers can be NIS clients

## **NIS COMMANDS:**

**\$server\_nis server\_2 nsgprod 172.24.80.100,172.24.80.101** [IP Addresses of NIS servers]

```
$server_nis server_2 135.112.5.11,135.112.5.12 [Configures DataMover to use NIS]
$server_nis server_x      [Displays NIS configuration]
$server_nis server_x -d   [deletes NIS Services]
$server_nis server_x hostname | ip      [queries NIS for Hostname or IP Address]
$server_nis server_x -status           [Displays status of NIS Servers]
# ypwhich
# ypmatch reduced2@mouse.com.mouse passwd [Using Linux CS to conduct lookup of User in NIS]
reduced2@mouse.com.mouse::52007:110:S-1-5-15-42f831d9-66417ccd-28a68b82-4ca:/usr/S-1-5-15-42f831d9-66417ccd-28a68b82-4ca:/bin/sh
# ypmatch admins.mouse group          [Using Linux CS to conduct lookup of Group in NIS]
admins.mouse:*:2000:S-1-5-15-42f831d9-66417ccd-28a68b82-200:
# ypcat hosts
```

### **USING YP MATCH TO RESOLVE USERS, GROUPS, HOSTS BY DART:**

**Note:** You can use YP calls from data mover to query NIS status, to find users by name, groups by gid, and hosts by name

#### **Typical map names are:**

```
group.byname
group.bygid
passwd.byname
passwd.byuid
hosts.byname
hosts.byaddr
netgroup
netgroup.byhost
netgroup.byuser
```

```
# .server_config server_2 -v "yp status"
```

```
1103244764: NETLIB: 4: NIS default domain: atd.gmeds.com
1103244764: NETLIB: 4: NIS server 143.242.8.152
1103244764: NETLIB: 4: NIS server 143.242.8.153
```

```
# .server_config server_2 -v "yp match atd.gmeds.com tzn2y3 passwdbyname"
```

```
1103244796: NETLIB: 4: tzn2y3:RDxsnL1a4.ymk:35176:5000:Rusk, Clinton (NO ALIAS):/home/tzn2y3:/bin/csh
```

```
$ .server_config server_2 -v "yp match mynisdomain 5003 group.bygid"
```

```
1103173920: NETLIB: 4: managers::5003:
```

```
1103173920: ADMIN: 4: Command succeeded: yp match mynisdomain 5003 group.bygid
```

```
$ .server_config server_2 -v "yp match mynisdomain corp002 hostsbyname"
```

```
1103174936: NETLIB: 4: 10.16.10.13 CORP002 corp002
```

```
1103174936: ADMIN: 4: Command succeeded: yp match mynisdomain corp002 hostsbyname
```

```
# .server_config server_2 -v "yp match 171dc domain=20admins.eng groupbyname"
```

```
1129229947: NETLIB: 4: domain=20admins.eng: *:25001:
```

**Note:** Must use fully qualified groupname when resolving groups by name if CIFS resolver=0 is set, including the “=20” for a space between names

#### **DO NOT USE UPPERCASE CHARACTERS IN NIS MAPS:**

**Note:** Celerra forces all Windows names to lowercase before making NIS call, meaning that any uppercase names would fail because NIS is case sensitive and would not be able to provide a match. Also know when to use the cifs resolver param. For NIS entries that contain name.fqdn, you would keep default cifs resolver=0 param.

```
$ .server_config server_2 -v "yp match nas-nis 13434 group.bygid"
```

```
1121950202: NETLIB: 4: Research=20Admins.umc-users:x:13434:
```

```
$ .server_config server_2 -v "lsarpc user='research admins'"
```

```
1121950720: SMB: 5: Unix group 'research=20admins' unknown
```

```
1121950720: SMB: 5: dom='UMC-USERS' (2d8e3ce4)
```

```
1121950720: SMB: 5: ExtractSIDs:Usr='UMC-USERS\research admins' RID=347a U=4 D=0 UID=65534 T=3 (4)
```

```
1121950720: SMB: 5: MsError sendLookupNames=6 NTStatus=0
```

Finding User SID from Name=0

Interface 'elv0' Address=128.206.8.41

UserName0='UMC-USERS\research admins' (0) use=4 nameType=0

S-1-5-15-bfc2566-26bd6a90-49c7643a-347a research admins

UNIX ID=65534 Type=3

**Note:** Lsarp call does retrieve SID from DC but fails to map, so assigns the default ‘Nobody’ group gid or 65534

## **CONFIGURING/VERIFYING DNS/NIS ON DM:**

```
#ypwhich [NIS setup on CS] #more /etc/resolv.conf [Nameservers for client] #more /nas/server/slot_x/misc [DM DNS info]
#/usr/sbin/nslookup hostname {IP Address} #server_dns ALL #server_nis ALL #server_arp ALL -a
```

## **SETTING UP NIS ON 7.2 LINUX CONTROL STATION: NAS 4.1 and above**

Edit the following file to allow the Control Station to resolve NIS Hostnames:

1. **#vi /etc/nsswitch.conf**

hosts: files nisplus dns

2. **Change above line to read:**

hosts: files nis dns

## **SETTING UP LINUX AS NIS CLIENT WITH AUTOMOUNTER & PAM SECURITY:**

1. Define NIS Domain and Server in /etc/sysconfig/network file
2. Define NIS Domain and Server in /etc/yp.conf
3. Uncomment “nis or yp” line in /etc/nsswitch.conf
4. Run #authconfig to configure system as NIS client, specifying NIS Domain and NIS Server IP
5. #/sbin/service sshd restart [Restart Sshd so as to use NIS]
6. Configure AutoMounter so as to define NIS Users’ Home Directory on NIS Server:  
#vi /etc/auto.master → /home/guests /etc/auto.guests --timeout=60  
#vi /etc/auto.guests → \* -rw,soft,intr 192.168.1.20 :/home/guests/&  
#chkconfig autofs –runlevel 345 on #/sbin/service autofs restart

## **TROUBLESHOOTING NIS:**

### **Example of NIS Service on DataMover:**

\$ server\_nis server\_2

**server\_2 : yp domain=peoplesoft.com server=216.131.193.79**

### **Using YPWHICH Command to Resolve NIS Server Name:**

**\$ ypwhich 216.131.193.79**

it-sun66

### **Test for NIS Resolution of the DataMover and ‘Client’:**

1. Success would show test1 as resolving with the NIS server—[or use IP address]
2. Failure might indicate that the DataMover’s Unix name is not listed in the NIS Server’s /etc/hosts file

## **MORE NIS TROUBLESHOOTING:**

1. Ping by Hostname from DataMover
2. Gather output from NIS Server: #ypcat -k hosts #ypcat -k netgroup
3. If ‘automounter’ is used, can we see it?
4. Obtain Snoop traces between NFS Client and DataMover; between NIS Server and DataMover
5. For multiple NIS Servers, do map files update properly? /var/yp/domainname /etc/nsswitch.conf
6. \$more /nas/server/slot\_2/misc [Obtain NIS & DNS configuration on DataMover]
7. Check ARP tables

**Note:** NIS runs in Broadcast Mode by default—be careful when going across subnets!

## **USING NIS TO RESOLVE NT USERS FOR ACCESS TO CIFS SHARES ON DATAMOVER:**

**Note:** Common in environments that are predominantly Unix in nature, but require some CIFS User access

### **REQUIREMENTS:**

#### **1. NT DOMAINS REQUIRE GID MAPPING ENTRY IN GROUP FILE ON DM’s:**

\$ more group

**na01:\*:11992:** [NT Domain called “na01” with GID of 11992]

nj7460rd01:\*:11993:

domain=20admins.nj7460rd01:\*:2001:

domain=20users.nj7460RD01:\*:2002:

domain=20users.na01:\*:2003:

#### **2. NIS PASSWORD FILE ON NIS SERVER [or locally on Datamover]:**

kola:x:35012:4000:Ojebuoboh,Kolapo=kola:/home/kola:/bin/ksh

**kola.na01:x:35012:11992:Ojebuoboh,Kolapo=kola::**

**Note:** This is correct entry for NT User “kola.na01”

### **3. DM AS NIS CLIENT:**

**\$ server\_nis server\_4**

server\_4 : yp domain=wayne\_manor server=135.17.47.100

**\$ server\_nis server\_4 135.17.47.100**

server\_4 :

joker-cc = 135.17.47.100

### **4. ADD PARAM & REBOOT DM's:**

**param cifs useUnixGid=1**

**Note:** For Windows User access, will apply the GID from the local passwd file or NIS database as the default Windows group to be used, instead of the default Windows group, “Domain Users”

**YP Domain:** wayne\_manor 135.17.47.100 [Server name is ‘Joker’]

**NIS Password File Location:** /var/yp/etc/passwd

Kola:x:35012:4000:Objebuoboh:,Kolapo:/home/kola:/bin/ksh

Kola.na01:x:35012:11992:Objebuoboh,Kolapo=kola::

**Comment:** Second password entry for User “Kola” defines the NT Domain entry for the User whereas the first line defines Unix

**NIS Netgroup File:** /var/yp/netgroup [view netgroup: allft2k—itself contains a list of Users & machines]

## **ADDING USER TO LOCALGROUPS DB WITHOUT CORRESPONDING NIS PASSWORD ENTRY:**

**“A new member could not be added to a local group because the member has the wrong account type”**

**Note:** This would be equivalent to not having a password UID/GID match to the User Name

## **TROUBLESHOOTING CELERRA NAME SERVICES:**

--#more /nas/server/slot\_x/misc --Contains DNS/NIS/NTP info for DM's

--#more /etc/resolv.conf --Shows the DNS server info if DNS is configured on the CS.

--Use “traceroute” tool & “ping” to examine routes and responses

--Use “nslookup” on Control Station to verify DNS resolution

--Use “dig” to query nameservers

--Use “host” command to resolve hostnames or IP Addresses in DNS

--#dnsdomainname --shows DNS Domain

--#ypdomainname --shows NIS Domain

--#ypwhich --shows NIS Server

--#ypcat --shows NIS database

## **TROUBLESHOOTING DNS CONFIGURATION FILES:**

/etc/resolv.conf [File used to setup DNS client on Control Station]

/etc/host.conf [File used to indicate the order of resolution for DNS, NIS, Hosts file, etc]

/etc/nsswitch.conf [hosts: files nisplus dns →Order of resolution is Hosts File, NIS, then DNS]

/usr/bin/host 172.24.80.10 [Command to see if DNS will resolve Host by IP or machinename, etc.]

## **WINDOWS 2000 DNS SERVICES:**

--Integrated with Active Directory

--Uses Secure Dynamic updates

--Aging & scavenging feature

--Unicode character support for UTF-8

--Commandline tool: dnscmd.exe

## **DNS UPDATES WITH CIFS:**

→Prior to NAS 5.6 code, DNS updates were performed via the default interface

→With NAS 5.6, DNS updates are performed on the interface configured for the CIFS server

**param dns.bindUpdInterface**

**Note:** The above param added with NAS 5.6.46 to support NAS 5.5 DNS bind method (AR137299). Problem happens when a CIFS server is on a different physical network, and cannot reach the DNS server with the CIFS interface because the route to the DNS is defined on a different interface via the default route. New param is set to 0 by default and will now allow Dynamic DNS updates to occur via the default route interface on the Data Mover, as opposed to the CIFS comppname interface, which may be on a different network.

## **CONFIGURING DNS CLIENT ON DM:**

**#server\_dns server\_2 -p tcp {udp} domain\_name 192.1.2.7** [IP Address DNS server]

## **TEXTBOOK WAY TO UPDATE DNS CLIENT CONFIGURATION ON DM:**

- 1. \$ server\_dns server\_2 -o stop**
- 2. \$ server\_dns server\_2 -o flush**
- 3. \$ server\_dns server\_2 -p tcp win2kemc.com 10.62.25.115,10.64.25.114**
- 4. \$ server\_dns server\_2 -o start**

**Note:** The abbreviated method would be just to issue Step 3 and then verify that DNS is still updating o.k. DNS starts with UDP protocol by default, use “-p tcp” to define TCP protocol.

**Server dns Command:** Display & setup DNS for client DataMover \$server\_dns server\_4 -p tcp comics 193.1.21.200

-p tcpludp {default} start DNS client using tcp or udp protocol Domain\_name -d delete client from DNS

**Verify DNS Settings:** \$more /etc/resolv.conf \$more /nas/server/slot\_4/misc \$/usr/sbin/nslookup

## **Configuring a Sun Machine as a DNS Client:**

Step 1 #cd /etc and vi nsswitch.conf [add the following to the Hosts Line: “Hosts: files [NOTFOUND=continue] dns”]

Step 2 #vi resolv.conf file and add following: “domain <dns domain name>” “nameserver <IP of nameserver>”

Step 3 #ps -ef |grep inetd [record PID number and #kill -HUP 407]

**Comment on NIS and DNS:** Up to (10) NIS servers can be defined [1 Primary, 9 Slaves] for a single NIS domain, and (3) DNS servers per Domain [1 Primary and 2 Secondaries]—no limit to DNS Domains that can be defined.

**NIS+ NOT supported for Celerra!!** Local Netgroup file is supported by NIS.

## **MICROSOFT WINS:** Windows Internet Name Service

**Purpose:** Distributed database for registering and querying netbios computer names-to-IP addresses

## **CONFIGURING WINS CLIENT ON DM:**

**# server\_cifs server\_2 -a wins=10.127.15.252**

Netbios name is limited to 15 characters.

## **Default Celerra Name Resolution Process:**

1.) Local Hosts File      2.) NIS server, if used [DataMover client]    3.) DNS Server, if used [DataMover client]

## **NETBIOS NAME RESOLUTION:**

Uses UNC paths or Browsing

Resolves via: Cache/WINS/Broadcast/LMHosts/Hosts/DNS

## **BROWSE ISSUES ON MS NETWORKS:**

--Netmask incorrect

--Broadcast address incorrect

--Ensure that NT Server is setup as Browse Master: HKLM>CurrentControlSet>Services>Browser>Parameters>MaintainServerList

## **NTRESKIT TOOLS:**

--browstat.exe [CLI program]

--browmon.exe [GUI Program]

## **NBTSTAT UTILITY:**

**Purpose:** Useful for determining NetBIOS Name Table Information on both Local & Remote Hosts

nbtstat -n [Local Host NetBIOS registrations]

nbtstat -a [Remote Host NetBIOS Name Table by Hostname]

nbtstat -A [Remote Host NetBIOS Name Table by IP]

nbtstat -r [Name statistics resolved by Broadcast & WINS locally]

nbtstat -c [Netbios cache on local or remote system]

nbtstat -S [Sessions by IP]

nbtstat -s [Sessions by Name]

nbtstat -RR [Sends name release to WINS and Refreshes]

nbtstat -R [Purges & reloads remote cache table]

**EXAMPLE:** c:>nbtstat -a corpusdc1 [-A 128.221.13.132]

NetBIOS Remote Machine Name Table

| Name         | Type        | Status     |
|--------------|-------------|------------|
| CORPUSDC1    | <00> UNIQUE | Registered |
| CORP         | <00> GROUP  | Registered |
| CORP         | <1C> GROUP  | Registered |
| CORPUSDC1    | <20> UNIQUE | Registered |
| CORP         | <1E> GROUP  | Registered |
| CORPUSDC1    | <03> UNIQUE | Registered |
| CORP         | <1D> UNIQUE | Registered |
| .._MSBROWSE_ | <01> GROUP  | Registered |
| CORP         | <1B> UNIQUE | Registered |

MAC Address = 00-B0-D0-B0-93-5E

**WINS-Enabled Client LookUps:** Once IP address obtained, client communicates directly with ‘other’ computer

- 1.) Client checks cache
- 2.) Client directs query to WINS server (h-node mode, if configured with WINS IP address)
- 3.) Client b-node Broadcasts query on local subnet—if target on same subnet, will return its IP address
- 4.) Local LMHosts file checked

**Note:** If “Enable DNS for Windows Resolution” is configured on client, additional steps are used to resolve:

- 5.) Hosts file checked
- 6.) DNS Server queried

**Non-WINS Client LookUps:**

- 1.) b-node broadcast name query on local subnet—if target on same subnet, will return its IP address
- 2.) Local LMHosts file checked

**Host Name Resolution:** DNS & NIS

Used for Internet names; Unix Hosts, TCP protocols such as Ping, Telnet, FTP

**Note:** Ping & FTP use Hosts file by default

**USING NSLOOKUP TO TROUBLESHOOT DNS ISSUES:**

**\$ /usr/sbin/nslookup**

**Note:** NSLOOKUP uses UDP queries by default, but will use TCP if necessary

**START OF AUTHORITY:**

>set type=soa [Start of Authority]  
>t2dom2.local [Returns information about the dns domain]

**NAME SERVERS:**

**>set type=ns** [querying for Name Servers]  
>t2dom2.local [Name Servers for specific domain]  
>server win2dom2.t2dom2.local [Changing DNS lookup to a specific Name Server]  
>ls -t t2dom2.local [lists out subdomains in a domain]

**QUERYING A RECORDS:**

**>set type=a**

>cpc1223 [queries for “A” Address Record for Host name-to-ip address resolution]  
\$/usr/sbin/nslookup cssc1223 [Returns Address Record for Host “cssc1223”]

**QUERYING PTR RECORDS:**

**>set type=ptr**

>192.10.3.2 [Queries for “PTR” Pointer Record for Host ip-to-name resolution]  
\$/usr/sbin/nslookup 192.10.3.2 [Returns address record for cssc1223.us.dg.com]

**Note:** Querying by IP automatically checks Host Name against PTR Record

**QUERYING REMOTE HOST NAME:**

\$/usr/sbin/nslookup [ftp.emc.com](http://ftp.emc.com) [If resolution returned, means that your DNS server is querying DNS Root servers]

**Comment:** Together, querying for A, PTR, and Remote Host names will validate whether local DNS System is functioning

**Aliases:** Additional names beyond the A Record name [CNAME or canonical name]

**Example:** Multi-homed systems might want to have (1) Alias name to point to all addresses

**(3) Default Zones for Every DNS Server that are SOA:**

0.in-addr.arpa 127.in-addr.arpa 255.in-addr.arpa

**CELLERRA & SYMMETRIX: Bin Files & Volume Management**

**Symmetrix IntegratedCachedDiskArray [ICDA]:** ICDA is the “Technical” name for the Symmetrix

Data Volumes for Storage [SA Ports]; BCV's for EMC Timefinder/FS;

**Max. 240 Target & LUN Addresses used on a Symm:** All vol.'s addressed by SCSI Target ID [0 – F except 7] and LUN [0 – 7]

Maximum Number of Logical Volumes seen by a single SA or FA: 554

Largest Single MetaVolume Size: 3.825TB

**Note:** SCSI ID 7 is reserved for the DataMover controller

**Gatekeeper Devices:** Normally, one configured per Symm-Celerra, as an AS400 Gatekeeper device, located on the last logical volume, 7 cylinders in size [3.5MB] and addressed as FF. The Celerra Gatekeeper interfaces with Symm API calls using SCSI commands for applications such as Timefinder, SRDF, or Celerra Monitor. Without a GateKeeper device, NAS will not install on Celerra! Additionally, a 2<sup>nd</sup> GateKeeper would need to be configured for the “Volume Logix” [VCM] application [16 cyl.]

**Max. Number SA/FA Ports for Celerra:** SA's=32 SCSI ports      FA's=14 ports

**Note:** If using multiple Symmetrixes with Celerra [Outside of an SRDF configuration], then only (1) of the Symmetrixes can have the (6) Celerra Hyper Volumes configured. I.E, only one Symm can host a Celerra's Boot Devices. First two Symmetrix Volumes, d1, d2, are reserved for the Symm O/S and Logs

## **CYLINDER SIZES FOR CELERRA CONTROL LUNS:**

### **PRE-DMX3:**

LUN 0 & 1 = 24788 cylinders for 11GB LUNs

LUNs 2-4 = 4432

Gatekeeper = 6, set to AS400

### **DMX3/DMX4 (Pre 5.6):**

LUN 0 & 1 = 12394

LUNs 2-4 = 2216

Gatekeeper = 2

### **POST 5.6:**

LUNs 0 & 1 = 12394

LUNs 2-4 = 2216

LUN 5 varies: 2GB=2216; 32GB=34956; 64GB=2@34956

## **SYMMETRIX STORAGE SYSTEMS:**

### **DMX SERIES—Symmetrix Direct Matrix**

**DMX800, DMX1000, DMX2000 (aka Symm 6), replaces Symm 8000 series**

→Enginuity microcode

→RAID 0, 1, or 10 software RAID

→Direct Matrix architecture, using up to 128 direct dedicated data paths

→2Gb/s FC backend speeds

### **DMX800:** Jan 2003

→8-120 2Gb/s drives, 4-64GB memory, raw capacity of 58 TB, high-end entry point (73, 146, 300GB drives)

→Rack-mountable version of Symm 6.0

### **DMX1000:**

→DMX1000 is a single-bay system from 64-144 drives, raw capacity of 59TB & 128GB memory, 16-48 Host FC ports or ESCON, and up to 24 FICON, GbE, or iSCSI Host connections

→Up to 12 director/cache slots

→Symm 6 technology

### **DMX2000:**

→Dual bay version of the DMX1000, 24 director/cache slots

### **DMX3000:** Sep 2003

→Enginuity v5670, 3-bay system, up to 576 drives total, 84TB

→Really an extension of the DMX2000 platform by adding a bay

### **DMX-2 SERIES:** Feb 2004, both DMX-1 & DMX-2 run Enginuity 5671

→Extends capabilities of DMX platform for iSCSI, faster processors, etc. for DMX1000/2000/3000 series, Enginuity 5670

### **DMX-3 SERIES:** DMX3500/4500 GA 31 Aug 2005 Enginuity 5771

→24-card slot for channel, disk directors, cache & XCM boards

→Enginuity 5772 released March 2007 for enhanced security, cache partitioning, workload controls, 4Gb/s FC connectivity, RAID 6 support, and up to 128 RDF groups per array

→OpenHosts supported via iSCSI & FC, with mainframe hosts supported via FICON (GbE & ESCON later release)

→Front-end directors are not compatible with DMX-2 Series

→Each Bay will support 240 drives, with a max system of 960 drives

→Max total of 2400 disk drives, 12 Channel directors, 8 disk directors, FC, iSCSI, GbE, FICON, ESCON host connectivity, 256GB memory

→Cache bandwidth 32GB/sec and new 1.3GHz Power PC processors for Disk & Channel directors

→128 hosts per Fibre port; 256 hosts per iSCSI port

→Jan 2006, support for 1024TB, (1) Petabyte, up to 2400 drives, LC-FC (low cost) drives; Native GigE support

**DMX-3 950:** Oct 2006, extension of the DMX-3 series, Enginuity 5771

→Runs Enginuity 5771 code, replacement for DMX800 for OpenSystems hosts

→Latest high-end Symmetrix platform with central bay of 120 disks, with one additional bay of 240 disks, up to 1PB data

→Up to 64 FC hosts or 48 FICON/GbE or iSCSI Host connections

→64GB memory, 32-360 disks total

→Bandwidth twice that of DMX-2 Series, at 128GB/s

→12 Channel directors & 8 Disk directors

→73GB or 146GB 15k RPM FC drives, 146GB or 300GB 10k RPM FC drives, 500GB 7200RPM FC drives

**DMX-4 1500-4500:** Highend Symmetrix family July 2007 GA, Enginuity 5772

→System bay & up to (8) storage bays, 2-8 DAs, up to 12 Channel Directors [total 16 combined], 2, 4, 6, or 8 global memory directors

→Supports from 96 to 1920 disk drives with total capacity of nearly 1 PB

→(4) dual 1.3GHz PowerPC processors per director

→Enginuity 5772 software, which provides most of the performance gains

→4Gbps end-to-end architecture

→Supports data protection methods:

RAID 1, 10, 5, 6, SRDF, Dynamic & Permanent sparing

→Supports disk drives:

73, 146, 300, & 500GB FC drives; 750GB SATA (Serial Advanced Technology Attachment) II drives

**Logical Volume Structure:**

Each logical volume has n cylinders

Each cylinder consists of (15) tracks/heads

Each track contains 128 blocks of 512bytes each

To calculate volume size: n \* 15 \* 128 \* 512

**DMX-4 950:** August 2007

→Touts itself as first high-end array to support 4Gbps fibre speed, 750GB capacity SATA II disk drives

**Note:** Serial Advanced Technology Attachment Drives (SATA II) have a number of improvements, the biggest being a doubling in speed from 1.5 to 3Gbps

→Total of 180TB capacity, 6-slot, supporting 2-4 DA directors, with up to 360 drives when daisy-chained to additional Storage Bays

**SYMMETRIX TIGON (V-MAX):**

GA April 2009, new virtual matrix storage platform using Enginuity 5874, 96-2400 drives up to 2PB, system can have up to 1TB memory, supports 128 FC ports, 64 GbE ports, or 64 iSCSI connections. Drive options include SATA, FC, and EFD.

Celerra tolerance for V-MAX with 5.6.45. With Solutions Enabler 7.0 and VMax, device masking is done using ACLX, for Auto-Provisioning volumes from storage pools, Enginuity 5874 and later, and using SMC or ECC. You would need to set the ACLX flag on front-end Director ports to support auto provisioning of Symmetrix devices. You do not need to manually address the ALCX db volume with the OE address.

**TOTAL NUMBER SUPPORTED DEVICES PER FA/SA PROCESSOR PORT:**

904 for SymmWin 5266/5267

2048 for SymmWin 5566/5567/5568/5669/5670

4096 for SymmWin 5771

**OLDER SYMM MODELS**

**Symmetrix Product Family Nomenclature:**

3xxx = Open Systems Hosts      3300/5300 = Half Bay

5xxx = Mainframe Hosts      3400/5400 = Full Bay

8xxx = Symm 5      3700/5700 = 3-Bay

Symm 4

Symm 4.8

Symm 5

Symm 8230 & 8000 Series (Uses Enginuity O/S and Mosaic hardware architecture)

**CELERRA FA PORT SHARING:**

FA Port Sharing is supported by Celerra with Symm 8000 & DMX series—see E-Lab Navigator and EMC Support Matrix

ARB director flag still required for all Celerra FA ports to prevent host reset being propagated back to DM & for FC connectivity

**Different Types of Symmetrix “Contention”:**

1. Disk Adapter Contention
2. SCSI Contention
3. Physical Disk Contention
4. RAID-S Contention

**QUERYING FOR SYMM SERIAL #, MICROCODE LEVEL, SYSTEM & DISK INFORMATION:**

**\$/nas/bin/nas\_symm -l** [Outputs ID and NAME of Symmetrix]

```
id          acl      name
000283600226 0      000283600226
```

**\$/nas/bin/nas\_symm -i -all**

**nas\_symm -i Output:**

**Note:** Use of nas\_symm -i across Multiple Symmetrixes is a good way to test whether the Gatekeeper devices are properly setup. That is, you will not receive output for a Symm if the Gatekeeper is not in place or addressed correctly to a DataMover

**\$/nas/bin/nas\_symm -i 000283600226** [Outputs specifics on Symm Hardware, Software, Celerra Configuration, etc.]

```

**Note:** Provides Director Status, WWN, & Flags set on each Director

**#/nas/symcli/bin/symstat -i 5 -c 9996 -type PORT -dir ALL**

**Note:** Use command to obtain I/O stats on SCSI or Fibre Directors. I/O/sec of 3000 is extremely busy.

## SETTING UP RDF LINKS:

**#/nas/sbin/nas\_rdf -init** [Run on R1 side, then R2 side]

**\$nas\_server -a -i** [verify datamover relationships]

## SYMMETRIX APPLICATIONS:

**#/nas/symcli/bin/symcfg list -applications**

Wed Sep 7 16:20:26 CDT 2005

**#/nas/symcli/bin/symcfg list -lock**

**#/nas/symcli/bin/symcfg list -meta**

## **USING SOLUTION ENABLER v6.0.3 to PRESENT SYMM DEVICES (LUN Masking) FOR WINDOWS OR CELERRA HOSTS:**

**Note:** Solution Enabler uses the symmask API to perform the work

1. Load Symmetrix BIN file for the new configuration & set FA bits: PP/UWN/EAN/C; SC-3 for heterogeneous; ARB for Celerra
2. Use Solution Enabler v6.0.3 to run symmask command

### **For Windows Hosts:**

```
symmask -sid 0178 -wwn 10000000C928CACF -dir 04b -p 0 add devs 005CA:005D1
symmask -sid 0178 -wwn 10000000C926D762 -dir 13b -p 0 add devs 005CA:005D1
```

### **For Celerra Hosts:**

```
symmask -sid 0178 -wwn 5006016039a004f5 -dir 04b -p 0 add devs 0005:00F7,05B9:05BA -celerra
```

3. Host Action after performing LUN Masking:

### **For Windows Hosts:**

Reboot Windows system

### **For Celerra Hosts:**

Perform NAS install

## **VERIFYING CELERRA HBA LOGINS TO SYMMETRIX FA's:**

**\$ .server\_config server\_2 -v "fcp bind show"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 5006048acc193b58 HBA 0 FA-09da

**Note:** Run “fcp show” to see which DM WWN’s are associated with each FA

**\$ ./symmask list logins -sid 941 -dir 9d -p 0** (FA-09da = 9d –port 0)

Symmetrix ID : 000187720941

Director Identification : FA-9D

Director Port : 0

| Identifier       | Type  | Node Name        | User-generated Logged On |        |     | Fabric |

-----output abridged-----

**SYMMETRIX INLINE COMMANDS:**

Logging In brings you to the Default Director [e.g., DA-15a\* = Default Director for INLINES]

\$ sign commands are “global” commands , Used to indicate the end of a command

|                  |                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------|
| <b>\$RS</b>      | [Returns you to Default Director]; \$Rx [Enables you to change Director—e.g., \$R2A]                             |
| <b>E0,</b>       | [Online/Offline director status—Displays status of all Dir’s {0A/0B v. 00}, Memory Cards, Cables connected {X} ] |
| E7,              | [DA Host&Disk subsystems—Listing of all Primary and Secondary devices controlled by the DA logged into]          |
| T#               | are SCSI target numbers for that Director                                                                        |
| ‘Shadow devices’ | are listed as grayed-out secondary devices for its partner DA                                                    |
| D2,tt            | [tt=T# number of device]—Physical disk info of the logical device                                                |
| <b>9B,A</b>      | [Displays Error & Event Codes logged at each Director—errors logged on all Directors]                            |
| 99,A             | [Displays Error Codes logged at each Director]                                                                   |
| E1,,E,A          | [Fatal errors on all Directors]                                                                                  |
| E6               | [Provides errors logged by the indicated Director]                                                               |
| <b>A7,D</b>      | [Location of all Drives, Directors, and SCSI—Information on all Logical Devices configured on the SYMM]          |
| A7,              | [Displays all devices with anything irregular in status--Not Ready; Write Disabled; Write Pending, Invalids]     |
| A4,              | [Write Pending in Cache]                                                                                         |
| A7,FE            | [Physical device information such as SCSI code & Splits]                                                         |
| A7,’LGND’        | [Legend of Abbreviations used in the various output columns]                                                     |
| A7,’EMUL’        | [Displays Emulation & Cylinder Size for each SYMM Volume; 3390, FBA, etc]                                        |
| <b>A7,C</b>      | [Status of logical vol., Invalid Tracks, Not Ready, Write Disabled, Write & Format Pending, etc—all Directors]   |
| A7,DC            | [BCV status]                                                                                                     |
| E7,D,A           | [EEPROM & IMPL revision levels for all directors—Verifying running code on System]                               |

A7,AAAA [Listing of A7 Inlines commands]  
 E7,AAAA [Listing of E7 Inlines commands]  
 A7,FD [device table as defined by IMPL file]  
 E1,,AB,AB [memory config]  
 A7,B [all SA's & assoc.devices]  
 A7,'GRUP' [RAID-S Groups—3 data & 1 parity per group]  
 A1,B [Target & LUN addresses]  
 A2,BA,ADD [I/O on all SCSI Channel Directors]  
 A2,CA [Host activity & I/O on Channel Directors]  
 E7,CF [Basic SYMMETRIX Configuration Information]  
 A7,DC [Shows the Standard Volumes and the corresponding BCV volumes]  
 8D,,,,'GDAT' [Shows history of BCV establishes and splits]  
**FD,CE** [FAST IML of a Single Director]  
**\$F0,CE,0** [Bringing single director back online after Fast IML]  
 How to Stop a Running Script? Esc key and/or Menu>Sympl>Halt script

#### **INLINES to Run Whenever First Logging Into a Symmetrix and Before Logging Out:** ‘Symmetrix Keys to Success’

9B,A Look for new Errors & Events by Director & Time [eg, 0472=Environmental RealTime errors]  
 E0, Verify that all Directors are alive and all Memory available. Verify cable connections.  
 A7,C Verify Ready status of drives. Check for Invalids on valid mirrors.  
 A3 Verify Cache slots are o.k.—look for Errors listed in RED  
 A4 Verify that ‘Invalid Cache Flags Count’ is 0  
 E1,,AB,AB Look for fragmented memory in Error column  
 E1,,DB Determine if any Memory is disabled—look for values ‘other than 0’ in “mem enable table”  
     Each ‘ADDR SLOT MAP’ horizontal location = 256MB of RAM  
 E1,,E,A Look for “Director Fatal Errors” in the “EXCEPTION\_COUNTERS” section  
 9B,A Verify that there are no Director errors  
 E7,D,A Verifies Microcode on each Director’s “Control Store” [RUNNING CODE], to EEPROM, giving “CODE OK!” msg  
     [Code is first loaded on Service Processor, then on each Director using Procedures>Code Load Procedures]  
 A1,DA/A1,CA/ A1,F3 Look for any RED Values indicating errors  
 E7, Run from RA director--verify that SRDF Flags are set properly [S column, red NR=link down]  
 \$A0, Clears all Test parameters that may have been used

#### **LINUX-CELERRA VOLUMES—OLD STYLE:**

##### **[6 regular volumes, 1 GateKeeper 7cyl. volume]: 1-6=4430 Cylinders or 2GB:**

|                                                      |                                                                                                                                                         |
|------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Volume 00=Hyper1 CS0 only; Target 0/LUN 0            | 4430 Cylinders; 2 GB; SCO O/S; CS0 Boot partition                                                                                                       |
| Volume 01=Hyper2 CS1 only; Target 0/LUN 0            | 4430 Cylinders; 2 GB; SCO O/S; CS1 Boot partition                                                                                                       |
| Volume 02=Hyper3 CS0&1 as Target 0/LUN 1; DM's T0/L0 | Shared NAS Work Partition—DOS & DART; DM boot & rootfs; Dump; map areas--CS's Read & Write;<br>CS Logs. Sys. DB Partition: Celerra Config. & Swap files |
| Volume 03=Hyper4 CS0&1 as Target 0/LUN 2             | All DataMovers [File System Transactions UxFS]                                                                                                          |
| Volume 04=Hyper5 DM's as Target 0/LUN 1              | Additional logs for Panics, Event Logging, etc.                                                                                                         |
| Volume 05=Hyper6 CS0&1, Target 0/LUN 3               | 7Cylinders; TID FF; AS/400; SRDF, TimeFinder, C.Monitor                                                                                                 |
| Volume 07=optional Gatekeeper Volume; TID FF         |                                                                                                                                                         |

**Note:** All (7) Volumes are usually created on one physical drive

#### **LINUX CELERRA VOLUMES—OLD STYLE:**

Device 00 Linux CS0 Mapped to SCSI Port 16A, Processor A, Port A; Target 0, LUN 0  
 Device 01 DOS Boot Volume for DataMovers Mapped to SCSI Port 16A, Processor A, Port A; CS0=01; DataMovers=00  
 Device 02 Linux Log Files for Failover Mapped to 16A, Processor A, Port A; CS0 02  
 Device 01 DOS Boot Volume for DataMovers Mapped to SCSI Port 15A, Processor A, Port A; CS1=01; DataMovers=00  
 Device 02 Linux Log Files for Failover Mapped to SCSI Port 15A, Processor A, Port A; CS0=02  
 Device 03 Linux CS1 Mapped to SCSI Port 15A, Processor A, Port A; CS1=00  
 Device 04 Data Mover Log Files Mapped to all SCSI Ports except 15A& 16 A, Processor A, Port A; DataMovers=01  
 Device 05 TBD Mapped to SCSI 15a & 16A, Processor A, Port A; CS0 & CS1=03  
 Device 06 DataVolumes Mapped to all SCSI Ports except 15A & 16A, Proc. A, Port A; DataMovers=10 and up numerically

#### **CELERRA BIN FILES--After NAS 2.2.25.5+:**

VCM GateKeeper TID = OE for all ports

**Note:** This is a change—CS now sees all volumes that DM sees

Regular GateKeeper TID = OF for all ports

Data Volumes should be addressed as TID 10+ for all ports

Control Volumes for DM & CS: Two Volumes--8860 cyl, TID 00 & 01

Volume 00 & 01: All DM's and CS's. 8860 cylinders. TID 00 & 01

Volume 02, 03, 04, 05. 4430 cylinders. TID 02 – 05.

## **HOW TO DETERMINE IF AS400 BIT IS SET/ON FOR CELERRA GATEKEEPERS:**

BIN File>Configuration>Edit Volumes>vol "02E">Go to Heading: "Flags 2. As400 Gate Keeper"

Gate Keeper bit is "ON" if "GK" is capitalized but is off if "gk" is lowercase

### **GateKeeper Device [AS400 Volume]:**

*Looking at the System Impl Volumes Map: configuration>VolumesMap>Channel Addresses tab*

| Volume | Emulation | Size | SA,5A | SA,5B | SA,12A | SA,12B |    |
|--------|-----------|------|-------|-------|--------|--------|----|
| 000    | FBA       | 4430 | 00    | --    | --     | --     | -- |
| 001    | FBA       | 4430 | --    | --    | --     | --     | -- |
| 002    | FBA       | 4430 | 01    | --    | 00     | 00     | -- |
| 003    | FBA       | 4430 | 02    | --    | --     | --     | -- |
| 004    | FBA       | 4430 | 03    | --    | --     | --     | -- |
| 005    | FBA       | 4430 | --    | --    | 01     | --     | 01 |

**Purpose of GateKeeper Devices:** Allows Celerra to execute SCSI commands in support of TimeFinder & Celerra Monitor.

## **CELERRA TIMEFINDER/FS [Snapshot]:**

Symm 4.0+ and 5265+ code; 5266 code introduces "InstantSplit"

New min. microcode levels for Timefinder & SRDF is 5567.24.13.S

**Chronological TimeFinder Process:** Establish, Synchronize, Freeze, Split, Thaw

### **TIMEFINDER PURPOSE:**

→Creating point-in-time copy (snapshot) of Celerra file system onto dedicated BCV devices from R1 devices

**Note:** i.e., fs\_timefinder creates copy of fs or fs group that can be mirrored with original pfs

→Timefinder/FS copies are used for Backups, Replication of data for live testing, mirrored file system updating

**Note:** Copies can be mounted and made accessible over the network

### **TIMEFINDER/FS REQUIREMENTS:**

--Use only one filesystem per STD volume for Timefinder/FS

--Requires symm backend and STD volumes (R1 or R2 devices)

--Do not use nas\_slice command when creating file systems

--Snapshots occur only with FileSystems from STD to BCV which contain Metas

--Only a single Snapshot can take place at a time

--Can only restore to a single FileSystem

--Avoid slicing when using AVM by specifying slice=n when creating file systems

--BCV's are used as mirror devices for STD device

--BCV volumes must be the same size as the volumes used by the production file system

--Whenever changing device type from BCV to STD, delete using nas\_disk -d -p, then vtoc volume, then readd using devconfig -c

**NAS 2.1 & 2.2 Commands:** nas\_fs -S; nas\_fs -M on {off}; nas\_fs -R [NAS 2.1.x; 2.2.x]

**NAS 4.0.12.1 Commands:** fs\_timefinder -S; fs\_timefinder -M on | off |refresh; fs\_timefinder -R | fs\_group\_name

**Note:** NAS 4.0.12.1 introduces support for grouping of multiple filesystems for TimeFinder/FS operations

### **DEVICE REPLACEMENT FOR FAILED BCV DRIVES:**

--Replace disk for failed BCV device

--PSE Lab needs to do full establish for that hyper only (clear GDAT tables)

--Other BCVs associated with failed device will also need to be established and split using fs\_timefinder --refresh, which recreates diskmark on the replaced device

### **TIMEFINDER/FS OPERATIONS:**

--automatically "splits" after the snapshot copy is complete (fs\_timefinder -S)

--Incremental copies are made using --mirror on or refresh switches

--Split by using the --mirror off command

--the --restore command will copy the BCV to STD device (no fs restore, just entire volume, which should only consist of one fs)

--BCV's are automatically selected when --Snap is run, but can manually create BCV volumes on same structure as STD

--Snapshot is synonymous with a ‘full establish’ (fs mirrored) and split (fs becomes ufs again)  
--With the mirror on command, the BCV becomes “mirrors” type (fs01\_snap2 -M on)  
--With the mirror off, the BCV becomes “ufs” type (use #fs\_timefinder -i fs01\_snap1 to query state of volume)  
--Later NAS codes do not lock the GK during the entire refresh or establish operation (only at start & end of sequence)  
--When using the –Restore –Force command, the BCV must be ufs and “unmounted” (cannot be in mirrored on state)  
--When fs\_timefinder operations are in progress, the STD & BCV devices are added to a “device group” which becomes part of the symapi\_db.bin, and then deleted from the symapi\_db.bin after the devices are mirrored off or split (1REG are normal BCV devices & 1R1\_1 are where BCV’s are group as RDF BCV devices)  
--#/nas/symcli/bin/symmir –g 1REG or 1R1\_1 query shows BCVs as fs type=1 when split, or fs type=6 when mirrored  
--#/nas/symcli/bin/symdev show <device> will show the state of the STD==>BCV pair, with “synchronized” meaning “mirrored”  
--#/nas/symcli/bin/symdev –bcv list will show NR for ‘Not Ready’ for hosts, meaning it is in an “established” state (also, symbcv dev list)  
--After a mirror on establish, the BCV device will move into the M3 position on the paired STD device  
--After a split mirror off, the BCV M3 position will be deleted from the paired STD  
--SDDF tables keep track of changes between STD & BCVs  
**Note:** Please note that at the end of each refresh operation, when the BCV device is being split from the standard device, it will have its former diskmark replayed from the Camdisk file and reassigned to itself. A diskerr:mismatch:tid error can be seen in a Server devconfig –probe if the diskmarks have not been correctly replayed—See AR69029  
tid/lun= 0/12 type= disk sz= 172631 val= 75 info= 56705532F560 diskerr= mismatch:tid  
1128101311: STORAGE: 3: IsMarkerValid(): BadDiskMark vname:54 disk\_id:54 marker:6  
1128101311: STORAGE: 3: 1: Error: Path:c32t4l3 for volume:54 not validated (Path/DiskMark inconsistent)

## **FS TIMEFINDER TROUBLESHOOTING:**

[/nas/log/symapi.log](#) is a good place to see Incremental\_Establish, pairings, Succeeded, SPLIT operations, etc.

Other important logs: [cmd\\_log](#), [cmd\\_log.err](#), [nas\\_log.al.trace](#)

**# export SYMAPI\_DEBUG=-1;export SYMAPI\_DEBUG\_FILENAME=debug\_sep05.log** (debug logging)

## **NAS UPGRADES:**

--All BCVs must be split prior to upgrades, otherwise the devices will not be visible to Celerra for the setup\_slot discovery

**Note:** BCVs can only be seen via probe when “mirrored off” or “ufs”. Look for any volumes in the filesys file as type 6

**# grep ^6 /nas/volume/filesys**

## **GROUPING FILESYSTEMS TOGETHER FOR TIMEFINDER OPERATIONS: NAS 4.0.12.1**

### **CREATING GROUP FILE SYSTEMS:**

**\$ fs\_group -n grp1 -c fs1 fs2 fs3**

**Results:** grp1 [Type 100 FileSystem]

### **SNAPPING GROUP FS:**

**\$ fs\_timefinder grp1 -S**

**Results:** grp1\_snap1

### **RESTORING GROUP FS:**

**\$ /nas/sbin/rootfs\_timefinder grp1\_snap1 -Restore -Force**

### **REFRESHING GROUP FS:**

\$nas\_fs grp1\_snap1 -Mirror refresh

**\$ fs\_timefinder grp1\_snap1 -Mirror refresh** [alternative command]

**Verify:** \$fs\_group -i grp1\_snap1

### **OTHER COMMANDS:**

fs\_group -shrink; fs\_group -xtend; fs\_group -delete; fs\_group -l; fs\_group -i

## **COMMAND OUTPUT EXAMPLES:**

**# fs\_group -l**

```
id    name      acl in_use type member_of fs_set
24   KF2_nggf_all 0  n   100      18,19,20,21,22,23
```

**# fs\_group -i KF2\_nggf\_all**

```
id      = 24
name    = KF2_nggf_all
acl     = 0
in_use  = False
type    = group
```

**fs\_set = nggf\_fs01,nggf\_fs02,nggf\_fs03,nggf\_fs04,nggf\_fs05,nggf\_fs06**

rw\_servers=

ro\_servers=

symm\_devs = 000183700172-00E,000183700172-013,000183700172-018,000183700172-01D,

## **GROUPING FILESYSTEMS TOGETHER FOR TIMEFINDER OPERATIONS: NAS 4.2**

--One filesystem or fs\_group can belong to multiple fs\_groups

--Can add new FS to fs\_group and then conduct Snap Refresh to update snap volume

## **TIMEFINDER/FS METAS NEED TO BE IDENTICAL ON BOTH STD & BCV VOLUMES:**

**Problem:** Timefinder/FS fails to complete Snap with screen error: Error 2231: Ecap1\_fs02 : invalid duplicate [Ecap1\_fs02 = BCV Meta Volume]. The problem is that all production filesystems were built from regular metas, such as d11, d12, etc., except the filesystem in this case, which was built from stripe volumes and then a meta. Since the corresponding BCV Meta was not built on the same stripe volume layout, the TimeFinder/FS command failed with the "invalid duplicate" message.

**Solution:** Deleted the BCV Meta & recreated using the same Striping scheme as used to build the PFS that was being snapped.

## **RDF CHAND PROCESS:**

1. Verifying Process: #ps -ef |grep chan [Should be running on R1 & R2 side]

2. Starting Process: #/nas/sbin/rdf\_chand -c rdf\_channel

**Note:** RDF\_Chand process is required for TimeFinder functions, not nas\_rdf init, activate, or restore commands

## **SRDF TIMEFINDER/FS FARCOPY & NEARCOPY SUPPORT: NAS 2.2.49.2/4.0.12.1 [Uses diff. commands]**

**SRDF FARCOPY ++:** GA with 2.2, 4.1, 4.2

## **CREATING A FILE SYSTEM COPY USING TIMEFINDER (4.0):**

Step 1. For CIFS File Systems, it is recommended that you first update the production File System CIFS attributes

**\$server\_cifs server\_2 -update /home mindirsize=0**

Step 2. Create the File System Copy: **\$fs\_timefinder fs01 -S**

**Note:** Once a timefinder command is issued, do not stop the process! The default BCV volumes are used unless otherwise specified, such as in this example: \$fs\_timefinder fs01 -S -volume mtv1

## **MIRRORING A FILE SYSTEM USING TIMEFINDER(4.0): Synchronizing orig. file system with timefinder copy**

Step 1. Creating the Mirror: **\$fs\_timefinder fs01 -M on | off | refresh** [automatically conducts mirror on, mirror off]

**Note:** Normally, the mirrored file system copy should be "unmounted", but use the following command if this cannot be done:

**\$fs\_timefinder fs01 -M on -Force**

In case of mirroring problems, contact Symmetrix PSE Lab to complete the establish/split operation manually. Basically, PSE can conduct a complete Establish to sync up all volumes, then we can Split the mirrorfs using our commands.

## **PROBLEM WHERE DISK DRIVE FAILS & HOT SPARE IS INVOKED:**

1. Problem may manifest itself with "smbcv" list showing invalids for bcv meta heads used to make up bcv's of file system (s)

2. Replace disk drive

3. Establish file systems

4. Split bcv's from production file systems

## **RESTORING A FILE SYSTEM FROM A TIMEFINDER COPY:**

**\$fs\_timefinder fs01 -Restore -Force**

## **REFRESHING A FILE SYSTEM COPY(4.0):**

**\$fs\_timefinder fs01 -M refresh**

## **RUNNING REFRESH ON R2 SIDE R2BCVs:**

**\$fs\_timefinder fs01 -M refresh -o protect=no**

## **RUNNING REFRESH ON R1 SIDE:**

**\$fs\_timefinder fs01 -M refresh -o**

## **REMOTE TIMEFINDER/FS--NEAR COPY & FAR COPY:**

Purpose is to provide remote copies of data for Backups, Application Testing, Data Warehousing

## **REMOTE TIMEFINDER/FS (FARCOPY):**

Far Copy uses R1BCV devices on local Active Celerra, snaps a copy of the local file system onto one of these R1BCV's [command must specify the R1BCV's as opposed to regular BCV's or this whole process will not work!], then uses the RDF link to Import the snapped File System across the link to the Remote Celerra's R2BCV's. From there, the file system can be snapped onto a local R2 Celerra BCV Volume and exported for use in a RO or RW mode. This snapped filesystem can then be routinely "refreshed" or synchronized with the original file system on the R1 side, and restored from Remote to Local side.

## **FAR COPY/EXTENDED DISTANCE REMOTE TIMEFINDER/FS/R-2COPY: 2.2/4.x**

### **Farcopy:**

- Requires SRDF adaptive copy write-pending mode (extended distance) configuration between local and remote symmetrix
- Local R1 side may have local BCVs and R1BCVs
- FS snapped from local STD to Local R1BCV's
- FS imported from R1BCV to R2BCV on Destination side
- Imported FS is snapped to local STD volumes on Destination side
- ACTIVE/PASSIVE ASYNCHRONOUS MODE
- NOT A DISASTER RECOVERY SOLUTION
- Supports Semi-Synchronous (Journal1) mode—1<sup>st</sup> write to local client acknowledged, but 2<sup>nd</sup> write not acknowledged until Symm replies to 1<sup>st</sup> write
- Supports Adaptive Copy mode—writes acknowledged to local client & cached until written to Symm storage

## **SETTING UP FARCOPY & ESTABLISHING REMOTE FILE SYSTEMs (NAS 5.5):**

1. Have BIN files applied to each Symmetrix to create local R1BCV's on Active Side & R2BCV's on Passive Side
2. Establish RDF Link between Symms & IP Data Network between Control Stations
3. Initialize Remote Celerra from Local side:

**# /nas/sbin/nas\_rdf –init Celerra\_remote 10.241.169.51**

**Note:** Create “rdfadmin” account and give same password as name. Select passphrase when prompted. Verify visibility of the Remote Celerra using nas\_cel –list. Should see Local and Remote Celerras listed.

4. Initialize Local Celerra from Remote side:

**# /nas/sbin/nas\_rdf –init Celerra\_local 10.241.169.50**

**Note:** Create “rdfadmin” account and passphrase, using same passwords are in step 3. Run # nas\_cel –list—should see both systems in the output.

5. Create local snapshot of production file system:

**\$ fs\_timefinder fs1 –Snapshot –option disktype=R1BCV**

**Note:** This automatically creates the mirrored relationship between R1BCVs and R2BCVs—note that FarCopy requires snapping to local R1BCVs and not local BCVs.

6. Refresh the R2BCV with changes from R1BCV & to resume communication between device pairs over RDF:

**\$ fs\_timefinder fs1\_snap1 –Mirror refresh**

7. Import the refreshed snapshot of the production file system to the destination R2BCVs from the Remote Celerra:

**\$ cel\_fs Celerra\_local –Import fs1\_snap1**

**Note:** Use \$ nas\_disk -l to see devices that have been imported to Remote Celerra as “R2BCV rootdxxx”, etc

8. Create a local snapshot of the imported file system on the Remote Celerra:

**\$ fs\_timefinder fs1\_snap1 -Snapshot**

**Note:** This will snap a copy of the file system located on the R2BCVs to the local STD devices

9. Mount and export the file system as needed

**Note:** File system will be mounted RO by default, but you can specify to mount RW

10. Refreshing changes to original Source file system and importing changes to Remote Celerra:

**\$ fs\_timefinder fs1\_snap1 –Mirror refresh**

**\$ fs\_rdf fs1\_snap1 –Mirror refresh** (imports updates from Source R1BCVs to Destination R2BCVs)

11. Update the Destination File System (located on STD volumes) from R2BCVs:

**\$ fs\_timefinder fs1\_snap1 –Mirror refresh**

**Note:** At this point, the updated changes in the source file system snap are transferred to the destination snap filesystem

## **RESTORING FROM REMOTE SNAPSHOT TO LOCAL R1BCV SNAPSHOT:**

Unmount and unexport remote snapshot file system

**\$ /nas/sbin/rootfs\_timefinder fs1\_snap1 –Restore** (Restoring Remote R2BCV from snapshot file system)

**\$ /nas/sbin/rootfs\_rdf fs1\_snap1 –Restore** (Restoring remot R2BCV copy to local R1BCV)

**FAR COPY BIN FILE ARRANGEMENT:****R1 ACTIVE SOURCE SYMMETRIX:**

Data Volumes are seen as R1BCV's locally and on R2 Side: 00c0→2DF (RA Group A)

R1Control Volumes are Mirrored: 015E→14E (RA Group A)

R2Control Volumes are Mirrored: 043F→423 (RA Group B)

**TROUBLESHOOTING FARCOPY OPERATIONS:**

**Note:** Lun0 should be in synchronous mode for rdf\_chand process

1. Conduct nas\_fs -l to see if any filesystems are in a status 6, which is mirrored, when they should be split

**id inuse type acl volume name server**

**27 n 6 0 186 uslist22\_BCV\_ftp**

2. Run **nas\_fs -i uslist22\_BCV\_ftp**

**# /nas/bin/nas\_fs -i uslist22\_BCV\_ftp**

id = 27

name = uslist22\_BCV\_ftp

acl = 0

in\_use = False

**type = mirrorfs [Means filesystem is mirrored and not split]**

volume = uslist22\_mtv01\_BCV

rw\_servers=

ro\_servers=

backup\_of = fs01 Thu May 15 05:32:49 CDT 2003

remainder = NOT ACCESSIBLE

symm\_devs = 000185700111-02F8,000185700111-02F9,000185700111-02FA,000185700111-0

3. Run List of BCV Devices:

**# /nas/symcli/bin/symbcv list**

|                    |                      |                      |             |                       |
|--------------------|----------------------|----------------------|-------------|-----------------------|
| <b>Not Visible</b> | <b>0314 R1 (M) -</b> | <b>1 Not Visible</b> | <b>02FC</b> | <b>0 Invalid</b>      |
| <b>Not Visible</b> | <b>0315 R1 (m)</b>   | <b>- Not Visible</b> | <b>02FD</b> | <b>- Synchronized</b> |
| <b>Not Visible</b> | <b>0316 R1 (m)</b>   | <b>- Not Visible</b> | <b>02FE</b> | <b>- Synchronized</b> |
| <b>Not Visible</b> | <b>0317 R1 (m)</b>   | <b>- Not Visible</b> | <b>02FF</b> | <b>- Split</b>        |

4. Try to mirror off the offending filesystem:

**# /nas/bin/nas\_fs -M off uslist22\_BCV\_ftp**

operation in progress (not interruptable)...Error 2201: unable to acquire lock(s), try later

5. Look for Devices that are Locked—status “9”:

**# /nas/symcli/bin/symdev -lock list**

Symmetrix ID: 000185700188

S Y M M E T R I X D E V I C E L O C K S

Device Name Device

| Sym  | Physical    | Lock Number | Lock Holder ID | Seconds Held | Device Flags | Attribute   |
|------|-------------|-------------|----------------|--------------|--------------|-------------|
| 02FC | Not Visible | 9           | 0x0E0236EB     | 1362759      | None         | Grp'd (M)   |
| 02FD | Not Visible | 9           | 0x0E0236EB     | 1362759      | None         | N/Grp'd (m) |
| 02FE | Not Visible | 9           | 0x0E0236EB     | 1362759      | None         | N/Grp'd (m) |
| 02FF | Not Visible | 9           | 0x0E0236EB     | 1362759      | None         | N/Grp'd (m) |

6. Release the locks on STD & BCV volumes by using the following:

**# /nas/symcli/bin/symdev -sid 0188 -lock 9 -RANGE 1<sup>st</sup>#:2<sup>nd</sup># -noprompt release**

[Alternatively, release one volume at a time: #/nas/symcli/bin/symdev -sid 1118 -lock 9 release ]

7. Contact PSE Lab to establish all devices in same Meta groups making up filesystems

8. Once synchronized, /symbcv list should show all devices for PFS and Snap filesystems in synchronized state

9. Snap Volume should now mirror off:

**# nas\_fs -M off uslist22\_BCV\_ftp**

**Verifying RDF Chand Process is Running on Both Sides:**

**# ps -ef |grep rdf\_chand**

root 1296 1124 0 Mar16 ? 01:42:02 /nas/sbin/rdf\_chand -c rdf\_chann

**EXAMPLE OF REGULAR & R2BCV'S ON R2 SIDE:**

```
133 n 13943 000185700967-35F BCV rootd133 1,2,3,4,5
134 n 13943 000185700967-360 BCV rootd134 1,2,3,4,5
139 y 13943 000185700967-2DF R2BCV rootd39
140 y 13943 000185700967-2E0 R2BCV rootd40
```

**LISTING OF RDF GROUPS & ASSOCIATED SYMMS:****\$ /nas/symcli/bin/symdg list****DEVICE GROUPS**

## **REMOTE TIMEFINDER/FS--NEARCOPY CAMPUS MODE (60km limit):**

- NearCopy Supports Campus Mode (Writes are acknowledged to Client only after remote Symm acknowledges as written to disk)
- Active/Passive SRDF/S with Synchronous operation for DR purposes
- Bin files same as for regular Active/Passive SRDF

### **Basic Operation:**

- Step 1. R1 Celerra, discover SRDF-linked Celerras: \$nas\_cel -list
  - Step 2. From R2 Celerra, choose the R1 File System to be imported: \$cel\_fs R1Celerra -list [choose fs01\_orig]
  - Step 3. R2 Celerra, Import File System from R1 Celerra to R2STDs: \$cel\_fs R1Celerra -Import fs01\_orig
  - Step 4. Create Local TimeFinder File System Copy to BCVs: \$fs\_timefinder fs01\_orig -S
  - Step 5. Mount and export the Remote Copy on the R2 Celerra
- Note:** By default timefinder copies are mounted as "Read Only"--use -F switch to force RW mount

## **SETTING UP NEARCOPY & ESTABLISHING REMOTE FILE SYSTEMs (NAS 5.5):**

1. Setup SRDF/S in Synchronous Mode Campus configuration for DR
2. Initialize Active/Passive Celerra configuration from Source:

### **\$ /nas/sbin/nas\_rdf -init**

**Note:** At prompt, create the RDF standby Servers from the Remote side that will be used for failover

3. Run RDF Initialization again to establish RDF relationship between Source & Remote Celerras:

### **\$ /nas/sbin/nas\_rdf -init Celerra\_remote 10.241.169.51**

**Note:** At prompt, create "rdfadmin" account & password, and Passphrase (this step not used with NAS 5.3)

4. Initialize Remote Celerra:

### **\$ /nas/sbin/nas\_rdf -init**

**Note:** At prompt, create "rdfadmin" account & Passphrase as in previous step, and create rdf\_standby relationships

5. Verify configuration by running \$ nas\_cel -list on both sides (both sides should see two Celerras) & symdg list:

|           |         |     |           |                                     |
|-----------|---------|-----|-----------|-------------------------------------|
| 1R1_1     | RDF1    | Yes | <symm_ID> | →Represents R1 volumes on Remote CS |
| 1REG      | Regular |     |           | →Local non-SRDF volumes             |
| 1CS_500   | RDF2    |     |           | →Source CS R2 volumes               |
| 1R2_500_1 | RDF2    |     |           | →R2 data volumes on Remote CS       |

**Note:** Remote side nasadmin account should not be able to see or manage the RDF standby servers

6. List SRDF-linked Celerras from Remote side

### **\$ nas\_cel -list**

7. List Source Celerra file systems from Remote side:

### **\$ cel\_fs Celerra\_local -list**

8. List & Identify Remote file system in order to Import Production File System from Source:

### **\$ nas\_fs -list**

9. Import PFS from Source to Remote Celerra & Verify:

**Note:** Imports to R2STD devices on Remote Celerra

### **\$ cel\_fs Celerra\_local -Import fs1**

### **\$ nas\_fs -list**

### **\$ nas\_fs -info fs1**

10. Create Snapshot of imported file system onto BCVs:

### **\$ fs\_timefinder fs1 -Snapshot**

11. Refresh the newly created BCV Snapshot:

### **\$ fs\_timefinder fs1\_snap1 -Mirror refresh**

12. Mount and export snap file system on Remote Celerra

## **RESTORING NEARCOPY SNAP FILE SYSTEM TO R2STD & THEN PFS:**

Unexport and unmount snap file system

### **\$ /nas/sbin/rootfs\_timefinder fs1\_snap1 -Restore**

**Note:** SRDF R1 & R2 device pairs are automatically suspended after conducting a Restore. Verify using the following commands:

### **\$ /nas/symcli/bin/symdg list**

|           |      |     |          |    |   |    |   |
|-----------|------|-----|----------|----|---|----|---|
| 1R2_500_1 | RDF2 | Yes | <sym_ID> | 55 | 0 | 64 | 0 |
|-----------|------|-----|----------|----|---|----|---|

**\$ /nas/symcli/bin/symrdf -g 1R2\_500\_1 query** (look for suspended devices)

Unmount PFS on Source

**\$ /nas/sbin/rootfs\_rdf fs1 –Restore**

**Note:** Restores file system from R2STD

## **OPERATIONS PERFORMED FOR SNAP OR REFRESH WITH ‘NEARCOPY’:**

- Establishes BCV against R2 volumes on R-2 side
- Monitors operation until all BCV’s are in synchronized state
- Freezes the R-1 Source filesystem and ceases I/O to the file system and temporarily unmounts fs
- Proceeds to split the BCV volumes on R-2 side
- Thaws the R-1 Source file system, remounts, and resumes I/O

### **SYMMETRIX Microcode Requirements:**

5265 supports only the last STD-BCV pair for establishes and restores

5266 supports the last (8) STD-BCV pairs for establishes and restores

### **SYMMETRIX BCV’s:**

Located in Drive Map on Disk Adaptor Tab: BCV’s show up in teal coloring

**INLINES:** A7,D [will show BCV volumes under Type column with blue “B”]

A7,DC [shows standard volumes with BCV’s established against it]

8D,,,’GDAT’ [History of BCV’s—Splits show up as “I” in the ‘DC ACT’ column]

E7, [displays devices for a specific director]

**After snapshot:** BCV volume shows up in red as “NR BCV” and a corresponding green “B” shows up for the standard device. BCV then shows up as the M3 device for the Standard

### **TimeFinder Logs/Troubleshooting:**

Verify TimeFinder scripts on Celerra: \$crontab -l [/usr/local/BCVscript: BCVerrorlog/BCVlist/BCVlog/BCVmaint

Logged Information: /nas/log/symapi.log /nas/bin/server\_log /nas/log/cmd\_log.err /nas/log/cmd\_log

### **Example of BCV Error in Cmd log.err:**

5-22-2001 13:50:54 db:201:nas\_fs -S c1dm1fs50 -n c1dm1fs50\_snap2: [“Volume not available”—no more BCV volumes available to do a snap!!]

### **Examples of Symapi.Log Activity:**

5/22/2001 22:00 Celerra CS STARTING a BCV ‘INCREMENTAL\_ESTABLISH’ operation for 1 [STD-BCV] pair:[10f-3C2]

22:00:39.449 The BCV ‘INCREMENTAL\_ESTABLISH’ operation SUCCEEDED.

22:46:11.205 STARTING a BCV ‘SPLIT’ operation for 8 [STD-BCV] Pairs [123-2B5, etc.]

### **TimeFinder F/S and Symm Meta Volumes are operational in the EMCNAS versions below.**

2.1.12; 1.2.50; 2.2.15.4 + [i.e., cannot use SYMM metavolumes in NAS versions lower than these]

## **USING CELERRA TIMEFINDER/FS FOR SNAPSHOTTS, MIRRORING, & CLONING FS:**

**I. Introduction:** Symmetrix Logical volumes [d3, d4, etc.] are typically visible by all DataMovers!

Only (1) FileSystem should be on a STD or BCV

If a FileSystem spans (3) symm volumes, then the BCV also needs to span (3) symm volumes

Symm 5266 code can do “InstantSplits”, which occur in background

**II. Create Original File System:** #time nas\_fs -n ufs8 -c mtv8

**III. Create BCV Snapshot File System:** #time nas\_fs -S ufs8 [Uses first series of rootfs devices in list=ufs8\_snap1]

BCV Types: 1=slice 2=volume 3=meta 4=bcv

**Note:** After all BCV volumes have been used once for snaps, you have to delete the old ones before you can conduct more snaps!

**IV. Conducting Mirror:** Permanently unmount the Snap FS to be mirrored!!

\$server\_umount server\_2 -p ufs8\_snap1 \$time nas\_fs -M on ufs8\_snap1 [create mirror—Type=mirrorfs]

**V. Mount Snapshot FS ReadWrite:** \$server\_mount server\_2 -F -o rw,nolock,accesspolicy=NATIVE ufs8\_snap1 /ufs8\_snap1

**VI. Unmount Snapshot File System and Delete:** \$server\_umount server\_2 -p ufs8\_snap1 \$nas\_fs -d ufs8\_snap1

**VII. Cloning BCV:** \$/nas/sbin/rootnas volume -C mtv8 disktype=bcv

**VIII. Restoring a Snapshot File System:** Unmount STD volume first, then BCV, then restore

#server\_umount server\_2 -p ufs8 #server\_umount server\_2 -p ufs8\_snap1 #/nas/sbin/rootnas\_fs -R ufs8\_snap1

**CREATING SNAPSHOT FILESYSTEM:** #nas\_fs -S fs2 [STD volumes are either mirrored or SnapShot onto BCV volumes]

**Note:** Tracks on STD to BCV are mirrored until 2 seconds of synchronization remain, then fs is frozen [unmounted], and client access is broken. BCV then splits off and STD File System unthaws, or is remounted and made available. Might need to create a BCV Volume first in order to save a Snapshot to.

Step 1: \$nas\_volume -n bcv1 -c -M roottd15,roottd16,roottd17,roottd18

Step 2: \$nas\_fs -S globix1 -v bcv1

### **EXAMPLE OF SNAPSHOT FILE SYSTEM IN PROGRESS...:**

```
# nas_fs -i fs-1_snap1
id      = 67
name    = fs-1_snap1
acl     = 0
in_use  = False
type   = mirrorfs [mirrorfs designation indicates that Mirroring is On]
volume  = v431
rw_servers=
ro_servers=
backup_of = fs-1 Tue Aug 27 22:03:37 EDT 2002
remainder = 9091 MB (3%)
symm_devs = 000185700438-29B,000185700438-29F,000185700438-2A3,000185700438-2A7,
000185700438-2AB,000185700438-2AF,000185700438-49B
disks   = roottd3,roottd4,roottd5,roottd6,roottd7,roottd8,roottd131
```

### **MIRROR COMPLETED:**

```
# nas_fs -i fs-1_snap1
id      = 67
name    = fs-1_snap1
acl     = 0
in_use  = False
type   = mirrorfs
volume  = v431
rw_servers=
ro_servers=
backup_of = fs-1 Tue Aug 27 22:03:37 EDT 2002
remainder = 0 MB (0%)
symm_devs = 000185700438-29B,000185700438-29F,000185700438-2A3,000185700438-2A7,
000185700438-2AB,000185700438-2AF,000185700438-49B
disks   = roottd3,roottd4,roottd5,roottd6,roottd7,roottd8,roottd131
```

**Note:** Next step would be to break Mirror & Split off the BCV Volume—then reverts to Type=uxfs [#nas\_fs fs-1\_snap1 -M off]

**Mirroring:** To “mirror” an existing BCV, the BCV must be unmounted. Then issue the **nas\_fs -M on** command.

**Mounting Snapshot FS:** Snapshots are made onto BCV Metavolumes [BCV’s are created manually using “rootnas\_volume” command]. ‘Mount’ a BCV volume READ-ONLY, but mounting “R-W” destroys the BCV-STD relationship.

**#server\_mount server\_2 -perm -o ro snap\_fs2 /mntpoint** FS permissions and inode numbers are maintained in the BCV copy.

### **FORCING SNAPSHOT FILESYSTEM TO MOUNT “RW”:**

**\$server\_mount server\_2 -F -o rw fs8\_snap1 /fs8\_snap1**

**Multiple Snapshots:** Code 5265 limited to only last incremental BCV for “Restores”  
Code 5266 can “Restore” up to 8 previous incremental “Snapshots”.

**Restoring a Snapshot File System:** #rootnas\_fs -R ufs1\_snap1

**BCV to STD Volume:** [BCV filesystem volume to be restored to STD]

STD volumes are mirrored on the symmetrix as BCV volumes and can be used for Testing or Backup purposes.

Timefinder is oriented towards File Systems: #nas\_disk -l [will show root\_d3, root\_d4 for BCV volumes]

**Deleting a Snapshot File System:** \$nas\_fs -d snap\_fs2

**#nas\_fs -i ufs1** [details about a FileSystem]

**Snapshot Fails:** Snapshots may fail if new drives or DataMovers are added [SYMAPI\_C\_DEVICE/GATE error]

1. Run \$/nas/symcli/bin/symcfg discover [Updates the Symmetrix device database]

\$/nas/bin/server\_devconfig server\_2 -p -s -a [Lists devices found]

\$/nas/bin/server\_devconfig server\_2 -c -s -a [Adds any new devices found]

Reboot DataMover and repeat for each Datamover affected

**Note:** If this doesn’t work, may need to failover & retry

### **TIMEFINDER/FS FEATURES**

**vs.**

### **SNAPSURE CHECKPOINT**

- |                                        |                                    |
|----------------------------------------|------------------------------------|
| --Full Mirrors                         | --Increments                       |
| --Made on BCV's                        | --Made on STD's                    |
| --Detached copies can be mounted RW    | --Export SavVol to DataMover as RO |
| --Full Restores ONLY                   | --File Level Restores              |
| --System CPU handles the load          | --DataMover CPU handles load       |
| --Grouping of FileSystems with NAS 4.0 |                                    |

**SNAPSURE:** Introduced with 2.2+ Code

Does not use BCV's as in TimeFinder.

## **CELERRA METAVOLUMES—CLONING VOLUMES:**

--Metas are only used for Open System Hosts

--Metas can contain up to 255 devices

--Volumes Map in SYMMWIN shows Meta Group, Meta Position, and Meta Stripe [no=not striped; 2=striped]

Q—Why do we require a MetaVolume for FileSystems in Celerra? A—allows for On-Line extension of FileSystem; and, allows large grouping of physical disks into a single Logical Volume. Also, uses less SCSI addresses.

A metavolume is arranged in addressable logical blocks, from Logical Block Address 0-N

### **CELERRA VOLUME MANAGEMENT:**

Managing Disks and/or Volumes attached to Celerra [Slice; Stripe; Meta; BCVs]

### **CELERRA DISK TYPES:**

BCV=Business Continuance Volumes for Timefinder/FS operations

STD=Standard Volume used for ordinary file systems

R1STD=Standard volumes that have been mirrored

R1BCV=BCV volumes that have been mirrored

### **CELERRA VOLUME CLONING:**

**\$nas\_volume -C volume\_name -o disktype=svol:dvol [STD|BCV]      Code 2.0.28.3+/4.0.x**

**\$nas\_volume -Clone d2 disktype=BCV root\_d2:disk15**

**\$nas\_volume -Clone stv1 d3:d8,d4:d9,d5:d10,d6:d11**

Nas\_volume -Clone makes an exact copy of a volume of either a BCV or STD volume

svol:dvol →represents Source and Destination volumes, respectively

Can also restore a file system copy to the original location.

## **CELERRA DISASTER RECOVERY SOLUTIONS vs. REMOTE BACKUP SOLUTIONS:**

### **DISASTER RECOVERY:**

Celerra only supports disaster recovery with synchronous SRDF where there is 100% synchronization of data between production and remote sites. If “point in time” captures of data meets a customer’s criteria for “disaster recovery”, then TimeFinder FarCopy can also be used as a DR solution.

### **REMOTE BACKUP SOLUTIONS [Non-DR solutions]:**

TimeFinder NearCopy, FarCopy, Celerra Replicator

### **CELERRA SRDF:**

#### **MAINTAINING HEALTHY SRDF ENVIRONMENT & CONDUCTING FAILOVER TESTING:**

See primus emc131411 for information on maintaining and testing SRDF environments. Check the link to download the latest chk\_srdf\_groups.sh script, and run on Source & Destination Celerras prior to running failover. The script performs two basic and fundamental integrity tests:

I. Checks to ensure that all RDF devices match between the Source and Destination sides using /nas/symcli/bin/symdg. Source side RDF1 devices should add up to same number of RDF2 devices on the target side in the basic device groups. Target RDF1 devices should add up to the same number of RDF2 devices on the Source side. If they do not, one suggested fix would be to run #nas\_rdf –init on Source and Destination.

II. Verifies that all devices in the RDF groups are “synchronized”, without which a failover will likely not succeed.

**Symm Minimum Code:** 5567.24.13.S

Symmetrix Remote Data Facility supports disaster recovery when used in synchronous mode. Celerra SRDF writes data to local and remote volumes synchronously. Local & Remote Storage systems must be within 60Km or 37 miles for synchronous operation.

**Modes:** *Active-Active or Active-Passive* configurations using synchronous mode campus—37.5 miles limit!

--Synchronous Mode only for Disaster Recovery situations

--Semi-synch or asynchronous mode for 'data' volumes only using R2 Copy

--Cannot have dual Control Stations in use for Celerra SRDF failover, restore [Except with new SW Patch—contact TS2]

**Note:** Dual Control Station support added with NAS 4.2.5.1 and higher

Provides for "remote mirror copy of data" between Celerras at different locations using SRDF Communications via a "Remote Adapte/RA" [R-1 → R-2] using a T3 or Escon WAN link. Celerra "SRDF" requires Symm 4.0/4.8 minimum running 5265 microcode. Only 'supported' when use Celerra CommandLine "NAS-to-SYMM" API. The top RA port [top port] is used for RA1--RA2 comms. Celerra SRDF supports only "journal 0" between symmetrixes. Logical volumes on primary R1 side are mirrored on the R2 side. RLD –Remote Link Director—RA1 and RA2, provide SRDF link between R-1, R-2 sides, respectively.

**Note:** Normally have 240 ids per SCSI port; SRDF 50-50 split reduces this to an effective total of 120SCSI ids.

## **PURPOSE OF CELERRA SRDF:**

--Provides for a Disaster Recovery solution [Active-Active or Active-Passive]

--Provides for remote backup of data [Farcopy & Nearcopy Timefinder/FS implementations]

--Provides for data center migration ability & use of Symmetrix Data Migration Services [Manual process, heavy planning]

--Provides for recovery from planned outages

## **HOW CELERRA SRDF WORKS:**

→NAS commands invoke SYMCLI commands on Control Station to accomplish tasks (/nas/sbin/nas\_rdf)

→Only single Source SYMM supported for Celerra SRDF

→Failover and Restores are invoked manually

→Synchronous modes keeps R1 & R2 devices in sync [Target notifies Source Host of 'write completion']

→Active-Active & Active-Passive can use multiple RLD's (Remote Link Directors)

→Only supports primary Control Stations

→BCV's on local R1 [and on remote R2 devices with RPQ]

→SCSI or Fibre Datamovers over SRDF Fibre Channel or ESCON

→Gatekeeper devices are not part of the SRDF devices

→Semi-Synchronous Mode not supported for "disaster recovery" [journal 1 mode---first write request acknowledged]

→"Farpoint" supports one outstanding I/O from different volumes—also not for 'disaster recovery' operations

## **SETTING DEBUG WHEN TROUBLESHOOTING SRDF:**

**#export SYMAPI\_DEBUG=-1**

**#export SYMAPI\_DEBUG\_FILENAME=/home/nasadmin/symapi\_debug.log**

Exit the shell to revert back from debug logging

**Note:** Don't forget to export symapi\_debug to a file. In certain situations, with debug turned on, symcfg or symcli commands may fail and output debug info to terminal.

## **SRDF CONFIGURATIONS:**

### **ACTIVE-PASSIVE SRDF (Synchronous Mode):**

(1) Production Celerra & Storage System and (1) Backup Celerra & Storage System

**Note:** Active side will have (6) R1 and (1) R2 device for Control Volumes

--DR Solution

--Campus 40 miles ESCON/Fibre

--Supplemented with NearCopy for Backups

### **ACTIVE-ACTIVE SRDF (Synchronous Mode):**

(2) Production Celerra & Storage Systems, each Backing up the Other [Each Symm has R1 & R2 Volumes]

**Note:** Each side should have (6) R1 devices and (4) R2 devices for Control Volumes

--DR Solution

--Campus 40 miles ESCON/Fibre

--Supplemented with NearCopy for Backups

### **NEARCOPY (Synchronous Mode):**

--Campus distance 40 miles

--Not a DR solution but can be supplemented with SRDF AA or AP

--Backup Solution RO

### **FARCOPY (Not Synchronous—Adaptive Copy WP Mode):**

--Adaptive Copy, Write-pending

**Note:** DOS partition, LUN 00, should be setup in synchronous mode vs. Adaptive mode

--No Geographic limitation for distance

--Not a DR solution

--Backup solution RO

### **FARCOPY ++ (Not Synchronous):**

--Adaptive Copy

--No Geographic limitation for distance

--DR Solution

--Backup Solution RO

### **SRDF/A (SNOW—Symmetrix Native Ordered Writes)—Asynchronous Mode:** NAS 5.4 and Microcode 5670 +

→ Asynchronous mode (Uni-directional) SRDF that is not a DR solution (i.e., data will be lost)

→ Provides for consistent point-in-time copy to Target side (R2) that is only slightly behind R1 side

→ Requires DMX hardware with 5670 code

→ SRDF/A defined at RDF Group level & all SRDF/A volumes will be in async mode

→ SNOW supports all existing SRDF topologies & Hosts

→ Uses (2) COVD (Cache Only Virtual Devices) devices for every SRDF/A volume on the R2 side only

→ SRDF/A over IP requires Qualifier

→ Both Failover & Failback are manually invoked

→ Identical network configurations required, one-to-one failover only

→ Target Celerra can have its own local data movers

**Purpose:** Extended distance solution that does not have performance issues—designed to replace FarCopy

#### **Features:**

--Hosts can read data from R2 side in the event the local source mirror fails

--Supports any host type

--Failover and failback

--Supports other SRDF technologies

#### **Setup:**

--Uses a single SRDF group per Symm pair in the bin file--“Reserve SNOW Resources”

**Note:** All changes are done at the group level and not individual devices.

--Introduces concept of COVD (Cache Only Virtual Devices) on R2 side—(2) COVD's are set for every R2 device

--Writes are sent across link in the correct order (doubly linked lists)

**SRDF/A Cache split into (3) groups/cycles:** Capture, Transmit, Restore

→ N—Cache cycle that captures new writes on the Source R1 side for Host writes

→ N-1—Cache cycle that transmits the dataset chunks of data from R1 to R2 (via the established cycle time)

→ N-2—Cache cycle that takes transmitted dataset chunk from R1 and makes consistent point-in-time dataset on R2 side

**Note:** Cycle Switch occurs once minimum cycle team (30 secs) has expired and when the N-2 has restored all its data to R2 side and the R-1 has completed its transfer. Once this criteria is met, the next cycle time begins.

#### **Three SRDF/A States:**

Both N and N-2 are Active states

N-2 is an Inactive State

Not-Ready State is set if SRDF/A if links down, R2 devices Not Ready, etc.

#### **Dataset Cache Model:**

R1 Active Side contains dataset changes in N cache

R1 Active Side contains dataset transmission changes in N-1 cache, which also spans to R2 Inactive Side as N-1

R2 Inactive Side contains dataset changes that are written to R2 side and are consistent, called N-2

#### **Tolerance Mode:**

Consistency disabled: Tolerance = ON

Consistency enabled: Tolerance = OFF

With Tolerance OFF, SRDF/A will become inactive if SRDF Links are lost or any R2 device becomes Not Ready

With Tolerance ON, SRDF/A will remain active with R2 disk failures, making only single device inconsistent. Tolerates short-term SRDF link interruptions (Link Limbo—10 secs by default), but will go inactive if links remain down. Can replace R2 devices.

#### **Failover:**

--Failover and Failback are manually invoked

--Data Movers are 1:1 from Source to Target side, and both sides can also have local DM's with local File Systems

--R2 RDF Standby Data Mover must have identical network configuration as Source, as well as access to R2 data volumes

--Graceful failover would retain all changes made in N-1 and N-2 sides, but not N, while ungraceful failover would lose contents of N-1 and N.

--place CS0 lun 002 out of SRDF group A from R1 side and into group B for R2 Control Volumes

--Max throttle is set to 60 secs, max time that SNOW will remain active once WP ceiling is reached, provided cache can handle it

#### **SETTING UP SRDF/A:**

1. Run /nas/sbin/nas\_rdf –init on Source, then Target side to setup SRDF/A, creating RDFADMIN account and password, as well as passphrase, when prompted

## **#nas\_cel -list**

2. Set async mode on Target side:      **#/nas/symcli/bin/symrdf -g 1R2\_500\_11 set mode async**
3. Set Consistency Mode Tolerance Off:    **#/nas/symcli/bin/symrdf -g 1R2\_500\_11 enable**
4. Query state of SRDF/A at any time using: **#/nas/symcli/bin/symrdf -g 1R2\_500\_11 query -rdfa**

## **LISTING DEVICE GROUPS:**

**#/nas/symcli/bin/symrdf list**

**#/nas/symcli/bin/symrdf -g 1R1\_1 query** [Querying R1 Device Group]

## **ACTIVATING SRDF/A FAILOVER (Target Site) or RESTORE:**

1. Real disaster scenario, shutdown Source data movers and Control Station (for testing, leave Source side running and let script shutdown)

2. Run Activate on Target Side:

**#/nas/sbin/nas\_rdf -activate**

3. Verify State after Failover:

**#/nas/symcli/bin/symrdf -g 1R2\_500\_1 query**

**Note:** Look for “Failed Over” in output.

**#df -h**

**Note:** Also run df -h on target Control Station and verify that **/net/500/nas** directory is present—this is the /dev/sd1 partition that becomes the active NAS database on the failed over site.

**#nas\_disk -l**

**Note:** All disks should reflect R2STD

**#nas\_server -l**

**Note:** All Servers should reflect acl of 2000 and not be in a faulted state

## **4. SRDF/a Restore to Source Side:**

- a) Making Consistent Snaps before doing Restore:

**# fs\_rdf <filesystem name> -Link suspend**

- b) Perform the import and snap on the target side

- c) Resume SRDF link:

**# fs\_rdf <filesystem name> -Link resume**

- d) Do not power-up Source CS or DMs

- e) **#/nas/sbin/nas\_rdf -restore** [on target side]

**Note:** Debug log kept in /tmp/nas\_rdf.debug.log on Target side. RDF links set to Synchronous mode for the Restore operation.

5. Query R2 Device Group after Restore:

**#/nas/symcli/bin/symrdf -g 1R2\_500\_1 query -rdfa**

6. Verify Disks after Failback:

**#nas\_disk -l**

**Note:** If devices show up as STD, run nas\_diskmark -m -a to make them revert to R1STD

## **SRDF/A BIN FILES:**

→RDF mode SRDF, Reserve SNOW Resources to Yes

→CS0 must not be in SNOW Volume group on each side, R1 & R2, ALL disks displayed on SOURCE side as R1STD, but only (6) Control Volumes displayed on Target Side Symmetrix, again as R1STD devices

→Volume map for R2 is normal SRDF Active-Passive Volume map

→(2) COVDs created for every device in SNOW group

## **SNOW INLINES:**

Session: 8D,,,SNOW

Status of Session: 8D,00,,SNOW

Verbose Session: 8D,00,192,SNOW

SNOW Help: F0,CE,SNOW,HELP

A7,RASN →Check SRDF links

E0, →Displays cable connections

## **Activating SNOW via InLines—always start with Target Side first:**

FO,CE,SNOW,ACTV,0 (Target)

FO,CE,SNOW,ACTV,0 (Source)

## **VERIFYING TIMEFINDER SCRIPTS:**

**/var/spool/cron**

**# cat rdfadmin**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

```
# DO NOT EDIT THIS FILE - edit the master and reinstall.  
# (rfadmin installed on Thu Jun 3 19:24:51 2004)

```

## **SRDF TIMEFINDER/FS FARCOPY & NEARCOPY SUPPORT:** NAS 2.2.49.2/4.0.12.1 [Uses diff. commands]

Nearcopy uses Synchronous Campus Mode to create RO copy of FS that can then be exported on Remote File server. Farcopy can use Semi-Synchronous Mode for CS Volumes and Adaptive Copy modes for data devices except for Fibre target & luns of 00, 06, and SCSI target of 10 (Also known as R2 Copy). FarCopy makes a copy of PFS on R1 side to a local R1 BCV. The R1 BCV is then copied to the R2 BCV via SRDF. The R2 BCV is then copied to a STD volume that can then be exported RO.

## **CELLERRA SRDF CONFIGURATIONS:**

- I. SRDF ACTIVE--ACTIVE: Synchronous; Campus to 60km; Escon/Fibre; Disaster Recovery; Use with Near Copy
- II. SRDF ACTIVE--PASSIVE: Synchronous; Campus to 60km; Escon/Fibre; Disaster Recovery; Use with Near Copy
- III. SRDF NEARCOPY: Synchronous; Campus to 60km; Escon/Fibre; No Disaster Recovery; RO Backups
- IV. SRDF FARCOPY: Asynchronous; Adaptive; No limits; No Disaster Recovery; RO Backups
- V. SRDF FARCOPY RPQ: Asynchronous; Adaptive; No limits; Disaster Recovery; RO Backups

## **CELLERRA SRDF PREREQUISITES:** Symm 4.0+, 5265.48.30 and NAS 2.1.15.16

## **SRDF DISASTER RECOVERY ACTIVE-ACTIVE & ACTIVE-PASSIVE SUPPORT:** NAS 2.1.15.6

- Solutions apply to entire Celerra-to-Celerra Failover--no individual DataMover failover supported
- R1 & R2 volumes are synchronized in 'real-time'
- Only Synchronous Mode supported--means that every write request on R1 side must be acknowledged on R2 side
- For performance reasons, use of FC or Escon Link Repeaters is not recommended
- Both Modes require BI-DIRECTIONAL SRDF on Symmetrixes
- R1 devices must have R2 devices of equal size, emulation type
- Filesystems built on RDF Datamovers must be built on RDF volumes
- Network topologies between the two Celerras must be the same for 'failover' [try to use same Subnets of each side]
- R1 CS0 must be able to communicate over network to R2 CS0
- Failover from SCSI-to-Fibre & vice versa supported
- DataMover hardware can be different
- If using External Usrmapper, consider the impact of 'failover' operations
- Must maintain 1:1 relationship for R1 DataMovers and R2 Standby DataMovers
- Dual Control Stations on each Side not supported--cannot failover using dual control stations, will cause NAS DB corruption

## **STEP I. SRDF INITIALIZATION:**

**#/nas/sbin/nas\_rdf -init** [Initializes SRDF between two Celerra-Symmetrix pairs; configures Control Station to use SRDF; Identifies the R2 and R1 Celerras and the R1 to R2 volume mappings; Prompts for creation of remote admin account for R2 side, "rfadmin"; Prompts for definition of Standby DataMovers to be used for the R2 side]

## **STEP II. SRDF ACTIVATION:**

Conducting failover from Primary to Backup Celerra:

- a) Halt the Primary Celerra
- b) Log into the Backup or R2 Celerra using the RFADMIN account

**#/nas/sbin/nas\_rdf -activate** [Places R1 volumes in RO mode, and R2 in RW mode]

- c) Standby DataMover assumes IP & MAC Address of Primary, as well as all File Systems, Exports, & Shares

## **STEP III. SRDF RESTORE:**

Log into the R2 'Backup' Celerra and issue **#/nas/sbin/nas\_rdf -restore**

Data on R2's are copied to R1 and then mirrored; Primary DataMovers reboot and then assume IP address & file systems from R2

**Note:** NAS 5.5.30.x resolves an issue whereby restores would fail unless the target CS was rebooted first

## **RUNNING NAS RDF -INIT ON R2 SIDE OF ACTIVE PASSIVE SRDF FAILS:**

**# /nas/sbin/nas\_rdf -init**

Discover local storage devices ...

done

Contact cnt1 ... is alive

Please enter the passphrase for RDF site :

Passphrase:

Retype passphrase:

CRITICAL FAULT:

Unable to mount /dev/sdj1 at /nas/rdf/500

**Resolution:**

1. Rename R2 /nas/site/cshosts file
2. Run # /usr/sbin/userdel -r rdfadmin [This will delete all references to the original RDFADMIN account on R2 Control Station]
3. Run #/nas/sbin/nas\_rdf -init [This prompts for new RDFADMIN account and password, Passphrase password, and re-establishment of relationships between the R2 STANDBY data movers and the R1 production data movers. Successful completion of the -init will also create a new CSHOSTS file on the R2 Control Station].

**OTHER TROUBLESHOOTING TIPS FOR –INIT FAILURES:**

- Ensure that /.etc/hosts file is up-to-date.
- Verify /nas/site/cshosts or /nas/sys/cshosts file information--possible that this file may need to be renamed to allow a fresh –init. ----
- The -init could fail if the HTTP daemon is not running on R1 and R2 Control Stations, as the nas\_cel command needs to establish a secure connection between the two Control Stations in order to setup RDF communication.
- Passphrase also needs to be the same between the two sides.

**MAIN DIFFERENCE BETWEEN ACTIVE-PASSIVE AND ACTIVE-ACTIVE SRDF:**

Active-Active has R1 and R2's on each side that are active at all times while Active-Passive R2 side cannot be used for production as its dataMovers are dedicated only as Standbys

**HOW CAN I DETERMINE IF A CONFIGURATION IS ACTIVE-ACTIVE OR ACTIVE-PASSIVE?**

1. BIN Files
2. Or, on each Celerra, look at /nas/site/cshosts file--it should only contain an entry for R1 CS on the R2 side

**ACTIVE-PASSIVE & ACTIVE-ACTIVE SRDF:**

**I. CELERRA ACTIVE-PASSIVE SRDF SUPPORT(R-1 to R-2 Celerras):**

**CONFIGURATION REQUIREMENTS:**

- Must have (2) Symms and (2) Celerras
- Zone Control Station only to single FA zone and single Symm
- Either Active-Passive or Active-Active configurations require bi-directional RDF to operate
- Active side contains only R-1 RDF volumes
- Target Passive side will contain only R-2 RDF volumes
- Failover is for the total box, not individual Servers
- After failover is initiated, any local DM's will not be operational
- R-1 DataMovers need to be configured to failover to R-2 Standby DataMovers when RDF failover is invoked. Prior to failing back, all DataMovers/CS0 on R-1 side must be shut down before initiating failback command.
- SRDF Standby Target DM's must have same Ethernet & network configuration as primary Source DM's [GbE, FE, etc]
- Control Stations must have a network path to each other
- SRDF Standby must see all data volumes outlined in R2 Symmetrix BIN file
- Primary Datamover is paired to only one SRDF Standby in a 1 : 1 relationship

**Note:** Make sure to pair the Primary & Standby RDF Servers with same slot number

**REQUIRED BIN CONFIGURATION ACTIVE-PASSIVE:**

- R2 side must be able to access Control Luns of R1 side
- R1 side must be able to access boot lun 00 on the target side (/nas/dos)
- Source Bin file sees devices as RA2/RF LUNs 06, 07, 08, 09, 0A, 0B for Target side
- Target Bin file sees Source Luns as RA2/FS Luns 00, 01, 02, 03, 04, 05
- Source R-1 data volumes should be mapped to same device numbering scheme on Target, but will be R-2 volumes

**Flag Settings on R2 Devices on Symms:**

RDF R2 Not Ready if Invalid=no

RDF R2 Not Ready=no

**/nas/site/cshosts** [This file should be empty on R-1 CS0; On R-2 CS0 should have entry for R-1 IP Address--created by nas\_rdf -init]

**CONTROL STATION CONTROL VOLUMES:**

**FROM PRIMARY R1 BIN FILE:**

R1 CS0 & R1 Datamovers must always have Target & LUNs of 00, 01, 02, 03, 04, 05

R2 CS0 must always have Target & LUNs of 10, 11, 12, 13 if SCSI and 6, 7, 8, 9 if FIBRE

**Note:** R2 CS1 never gets mapped at all!!

**SETTING UP ACTIVE-PASSIVE (R-1/R-2) SRDF:**

- Step 1. Initializing SRDF on SOURCE: Login to R-1 Celerra as nasadmin, su to root and run **#/nas/sbin/nas\_rdf -init**
- Step 2. At prompts, associate R-1 datamovers with standby R-2 datamovers by slot # [recommend using slot-for-slot matching]
- Step 3. Initializing SRDF on TARGET: Login to Remote R-2 Celerra as nasadmin, su root and run **#/nas/sbin/nas\_rdf -init**  
**Note:** Local R-2 Storage is discovered and R-1 Control Station contacted
- Step 4. TARGET CS: When prompted, enter the "RDFADMIN" Username & Password to create this special RDF account  
**Note:** At this point, 'discovery' of remote R-1 devices occurs
- Step 5. TARGET CS: Assign Standby Servers to Primary Servers using "ID" numbers  
**Note:** R-1 and R-2 DataMovers must have a 1 : 1 relationship
- Step 6. TARGET CS: Verify creation of R-2 Standby Datamovers: **#nas\_server -l** [Logged in as RDFADMIN]

## **WHAT DOES THE "nas rdf -init" COMMAND DO?**

- Run first on R1 side, then R2 side
- Establishes the relationship between R1 & R2 devices & RDF Standbys
- Discovers local dos, root, nas devices (/dev/sda1; /dev/sdc3; /dev/sde1), using **nas\_disk -l**
- Creates cshosts file on R2 side
- Discovers remote dos, root, nas devices (/dev/sdg1; /dev/sdi3; /dev/sdj1)
- Mounts R2 remote root device & reads /etc/sysconfig/network & /etc/hosts files for remote CS0 hostname & IP address
- Pings R2 CS0 to verify network connectivity
- Reads /nas/sys/callhome.config to obtain remote site name
- Determines if CS can be a failover target
- Uses server\_devconfig server\_2 -p -s -a to locate diskmarked devices with "value=2 (local root\_ldisk, remote root\_ldisk)
- Creates RDFADMIN User account when run on R2 side to manage R2 Standby Datamovers (Can only 'see' these datamovers using this User account)
- Sets up communication path & devices for CS using nas\_rdf chand process (root\_rdf\_volume; nas\_cel -i)
- Adds Symm DEV002 to special group "cs\_500" (/dev/sdc; /dev/sdi) so that these devices will not be included in the failover & fallback operation
- Creates the "1R2\_500\_1" RDF Group of local R2's & remote R1's. Sets up Datamover relationships and ACL of 2000 for RDF Standby Datamovers

## **TROUBLESHOOTING TIP:**

If any Celerra devices have been added or reassigned after the initial setup of RDF, re-run **#/nas/sbin/nas\_rdf -init** on R-1 & then R-2

## **ACTIVE-PASSIVE FAILOVER—SRDF ACTIVATE:**

- Step 1. **#/nas/sbin/nas\_rdf -activate** (Target Side)

**Note:** Login as rdfadmin account, su to root, do failover [su - rdfadmin ]. Activate makes source SA's write-disabled; SRDF Link Suspends; Target SA's write-enabled; NAS DB fsck'ed; SRDF DM's Activated

- Step 2. Verify communications between R1 & R2 Control Stations [telnet, ping, etc]

- Step 4. Ensure that R-1 /nas/site/slot\_param file is copied over & is the same on the R-2 Control Station

- Step 5. Verify the status of RDF Groups: **\$/nas/symcli/bin/symdg list**

### **R-1 RDF DEVICE GROUPS:**

| Name         | Type        | Valid      | Symmetrix ID        | Devices    | GK's     | BCV's    |                                                |
|--------------|-------------|------------|---------------------|------------|----------|----------|------------------------------------------------|
| <b>1R1_1</b> | <b>RDF1</b> | <b>Yes</b> | <b>000285500353</b> | <b>198</b> | <b>0</b> | <b>0</b> | [Only 1 RDF Group on R1 Side--R1 Data Devices] |

### **R2 RDF DEVICE GROUPS:**

**\$/nas/symcli/bin/symdg list**

| Name             | Type        | Valid      | Symmetrix ID        | Devices    | GK's     | BCV's    |                                       |
|------------------|-------------|------------|---------------------|------------|----------|----------|---------------------------------------|
| <b>1R1_1</b>     | <b>RDF1</b> | <b>Yes</b> | <b>000285500186</b> | <b>6</b>   | <b>0</b> | <b>0</b> | [R1 Control Volumes]                  |
| <b>cs_500</b>    | <b>RDF2</b> | <b>Yes</b> | <b>000285500186</b> | <b>1</b>   | <b>0</b> | <b>0</b> | [R1 Control Volume to be failed over] |
| <b>1R2_500_1</b> | <b>RDF2</b> | <b>Yes</b> | <b>000285500186</b> | <b>197</b> | <b>0</b> | <b>0</b> | [R1 Data Volumes to be failed over]   |

- Step 6. Verify the Synchronization/Tracks Invalid Status of RDF Groups on R-2 Celerra:

**\$/nas/symcli/bin/symrdf -g 1R2\_500\_1 query** [No Invalid Tracks & All Devices Synchronized]

Target (R2) View      Source (R1) View      M O D E S

| ST<br>Standard<br>Logical<br>Device | A<br>T<br>E | LI<br>R1 Inv<br>Tracks | N<br>R2 Inv<br>Tracks | A<br>K<br>S | T<br>Dev<br>E | M                |                  |                        | RDF Pair<br>STATE |
|-------------------------------------|-------------|------------------------|-----------------------|-------------|---------------|------------------|------------------|------------------------|-------------------|
|                                     |             |                        |                       |             |               | R1 Inv<br>Tracks | R2 Inv<br>Tracks | o<br>d<br>e<br>Dom ACp |                   |
| DEV001                              | 000         | WD                     | 0                     | 0           | RW            | 000              | RW               | 0 0 SYN DIS OFF        | Synchronized      |
| DEV002                              | 001         | WD                     | 0                     | 0           | RW            | 001              | RW               | 0 0 SYN DIS OFF        | Synchronized      |
| <hr/> -----output abridged-----     |             |                        |                       |             |               |                  |                  |                        |                   |
| DEV197                              | 005         | WD                     | 0                     | 0           | RW            | 005              | RW               | 0 0 SYN DIS OFF        | Synchronized      |

```
Total ----- -----
Track(s) 0 0 0 0
MB(s) 0.0 0.0 0.0 0.0
```

Step 7. Verify Status of R-1 & R-2 DataMovers:

#### **R-1 DATAMOVERS:**

```
# nas_server -l
id type acl slot groupID state name
1 1 1000 2 0 server_2
2 1 1000 3 0 server_3
3 4 1000 4 0 server_4
```

# nas\_server -i -a [Output is abridged to show 'RDFstandby' properties only]

RDFstandby= slot=2

RDFstandby= slot=3

RDFstandby= slot=4

#### **R-2 DATAMOVERS:**

```
$ nas_server -l
id type acl slot groupID state name
1 4 2000 2 0 server_2
2 4 2000 3 0 server_3
3 4 2000 4 0 server_4
```

**Note:** Must log in as RDFADMIN account to 'see' RDF Datamovers!

Step 8. Verify accuracy of "cshosts" file on R-2 Control Station:

\$ cat /nas/rdf/cshosts [R2 Side Only--created by the #nas\_rdf -init command]

1:celerracs0-md:500:10.252.24.164:/dev/sdj1:/dev/sdg: [IP Address of R1 Control Station]

**Note:** File should not be populated on R-1 Control Station for Active/Passive--file located /nas/site later codes

Step 9. Permanently unmount any Checkpoint or BCV Snapshot FileSystems on R-1 Side prior to failing over!

Step 10. Conduct Disaster Recovery Failover by 'halting' all R1 DataMovers & CS0: \$server\_cpu ALL -h now #/sbin/init 0

Step 11. Login to R-2 Celerra as "rdfadmin", su root, and initiate failover command: #/nas/sbin/nas\_rdf -activate

### **ACTIVE PASSIVE CONFIGURATION FROM R2 SIDE ON NS SYSTEM:**

#### **# nas\_cel -l**

```
id name owner mount_dev channel net_path CMU
0 ncsp2l 0 192.168.21.13 00028789037301F9 →R2 Side
1 NCSP1L 500 /dev/ndj1 /dev/ndg 172.27.2.13 00028789037102D3 →R1 Side
```

#### **# cat /nas/site/cshosts**

1:NCSP1L:500:172.27.2.13:/dev/ndj1:/dev/ndg:00028789037102D3:

0:ncsp2l:0:192.168.21.13:::00028789037301F9:

#### **# nas\_disk -l**

```
id inuse sizeMB storageID-devID type name servers
1 y 11499 000287890373-01F9 R1STD root_disk 1,2
2 y 11499 000287890373-01FA R1STD root_ldisk 1,2
3 y 2076 000287890373-01FB R1STD d3 1,2
4 y 2076 000287890373-01FC R1STD d4 1,2
5 y 2076 000287890373-01FD R1STD d5 1,2
6 y 2076 000287890373-01FE R1STD d6 1,2
```

#### **# df -h**

| Filesystem       | Size        | Used        | Avail       | Use%       | Mounted on                                                                       |
|------------------|-------------|-------------|-------------|------------|----------------------------------------------------------------------------------|
| /dev/hda3        | 2.0G        | 960M        | 953M        | 51%        | /                                                                                |

### **WHAT DOES THE "nas\_rdf -activate" COMMAND DO?**

→Runs on R2 side to initiate failover

→Command fails over R1 to R2 devices, the NAS\_DB, and R1 to R2 Standby datamovers

→Depending on Customer activity, failover may take some time to complete--Follow screen prompts

→When successful, the R-1 Volumes on Primary become Read-Only, SRDF link is suspended, and R-2 Volumes become Read-Write  
→RDF Standby DataMovers are then activated--R-2 merges track tables & devices from R-1 & restores SRDF Link  
→R-2 DataMovers assume IP Address, MAC Address, File Systems, and Export Tables of R-1 DataMovers  
→Specifically, this script discovers local dos, root, nas devices (/dev/sda1; /dev/sdc3; /dev/sde1), Reads /nas/rdf/cshosts file & then identifies remote /dev/sdj1 as /nas partition--mounts these as RO to its local /nas/rdf/500 mountpoint  
→Reads remote /etc/sysconfig/network & /etc/hosts files & pings R1 CS. Issues 'symrdf -g 1R2\_500\_1 -noprompt failover -all'  
→Unmounts & remounts "/nas" directory & then mounts /dev/sdg1 "/nas/dos" directory from R1 side  
→Updates Gatekeeper information on local symmetrix, copies NAS\_DB over, then initiates datamover failover using "server\_standby -activate rdf"

## **RESTORING/FAILING BACK ACTIVE-PASSIVE SRDF--R-2 to R-1 SIDE—SRDF RESTORE:**

Step 1. Restore power to R-1 Symmetrix and bring up SRDF link

**Note:** Make sure that no changes have been made on R1 side, such as adding devices, running rdf\_init, etc.

Step 2. Have PSE Lab conduct HealthCheck of R-1 & R-2 Symmetrixes

Step 3. Best chance of successful “restore” is to have the tracks between R2 and R1 devices as close to be synchronized as possible. Run the following command on R2 logged in as rdfadmin & root in a while true loop to keep the RDF devices synchronized:

**#/nas/symcli/bin/symrdf -g 1R2\_500\_1 -noprompt -all -until 500 update**

**Note:** srdf –restore script also calls on the –until 500 update function, but doing this first lessens R2 to R1 Track Table Merge operations.

Step 4. Only when sync’ed should you begin the restore:

**#/nas/sbin/nas\_rdf -restore**

**Note:** Alternatively, specify a higher track number before merging track tables, such as “-restore –until 1500 update”, etc.

### **RESTORE SCRIPT ACTIONS:**

Initiate command, checks for /dev/sda1 (dos), /dev/sdc3 (root), & /dev/sde1 (nas) on remote R1 side, defaults to 500 tracks for sync purposes, reads local /nas/site/cshosts file, reads remote /nas/sys/callhome.config file, prompts user if the remote side is ready for Storage restoration, reads remote /etc/sysconfig/network & /etc/hosts file, pings remote CS0 (to make sure that it is NOT yet running—will shut it down if it replies), loops through #symrdf -g 1R2\_500\_1 -noprompt -all -until 500 update, and then when the tracks reach 500 or lower, will ask if the remote side is ready for Network restoration (Power on the R1 Celerra and allow it to come up. Or, answer “no” to exit script and run “restore” later. Script then fails back Servers with server\_standby -restore rdf, umounts and fsck’s remote /nas partition (/dev/sdj1), verifies that all tracks are updated: #/nas/symcli/bin/symrdf -g 1R2\_500\_1 -noprompt -all -until 500 update , reboots all Data Movers on R1 side (nas\_mcd -e rdfrestore), verifies that all tracks are updated, then fails back devices using: #/nas/symcli/bin/symrdf -g 1R2\_501\_1 -all -noprompt fallback. Script loops to keep devices synchronized, pings remote CS0, runs #nas\_mcd -e <r1cs0>. Script then reboots any panicked servers, verifies all volumes synchronized, suspends RDF link (#symrdf -g 1R1\_1 suspend), runs #server\_standby ALL -restore rdf, resumes RDF link (#symrdf -g 1R1\_1), reboots all DM’s on R1 side again, reboots CS0 on R1 side, NAS\_DB data copied from R1 to R2 side, volumes are synchronized, changed RW on R1, ready on link, and set to WD on R2 side.

### **OTHER THINGS UPDATED:**

R1 /nas/volume/disks updated with R1 serial number, camdisk files on restored Servers updated, local hardware config files updated, R1 data movers activated, R2 side data movers rebooted as RDF Standbys, etc.

Step 5. If the restore operation fails due to network connectivity issues, continue with the following steps on the R-1 Celerra:

a) Login as nasadmin on R-1 Side and execute; **#/nasmcd/sbin/nas\_rdf -restore**

Verifies all devices synchronized, starts restore of R1 CS, then copies back NAS\_DB & verifies that 1R1\_1 RDF group is write-enabled. Completes failback of datamovers & starts Box Monitor on R1.

### **TROUBLESHOOTING:**

→Investigate the /tmp/nas\_rdf.debug.log files to determine where failure or hang is occurring (script failure, this log is NOT there)  
→Output of symcli commands found in /nas/log/symapi.log

## **DISCUSSION: SRDF FAILOVER/FAILBACK IN REAL DISASTER SCENARIO**

1. Initiate failover command on R2 side
2. But because R1 side is down hard, its R1 devices will not be changed from RW to RO.
3. Failing Back: When ready to failback, power up R1 Symmetrix, bring up RDF Links, then write disable the R1 devices (/nas/symcli/bin/symrdf -g 1R2\_500\_1 write\_disable r1 -force). Check for R1 Invalids using \$/nas/symcli/bin/symrdf -g 1R2\_500\_1 query. If invalids exist, then force update using \$/nas/symcli/bin/symrdf -g 1R2\_500\_1 update -force.
4. Once completed, log in to R2 side as "rdfadmin" user and issue #/nas/sbin/nas\_rdf -restore

## **NAS UPGRADES & BEST PRACTICES BEFORE MAKING SRDF LINKS NOT READY:**

**Note:** In certain situations, such as NAS Upgrades, the SRDF links should be taken offline.

1. Synchronize all R1 to R2 devices using Symmetrix Inlines
2. Break SRDF Links

3. Conduct NAS Upgrade
4. Restore SRDF Links

## **CELERRA SRDF BEST PRACTICES:**

- In BIN file, map all RDF devices to all channels
- Use same Target & LUN ID's on both R1 & R2 sides
- Maximize the use of LUNs for performance reasons (more LUNs in use the better)
- Minimize distance between sites
- Add multiple RDF links between Sites for increased performance (3 or more RDF links)
- Use Fibre v. Escon and do not use "link extenders"
- Though depends on Customer environment, use only Single Striped Meta Volume for each Celerra FileSystem (8k -32k stripe)
- Try to have same IP Subnets for both Sites
- Take into account network speed/duplexing settings, location of Usrmapper, WINS, DC servers, Viruschecker, NDMP Servers, etc.
- Use dedicated 1:1 R1 to R2 datamovers only, as well as RDF-only FileSystems, & use same slot numbering scheme
- Always use (1) & only (1) Control Station per Celerra [do not yet support dual control station environments]
- After any & all RDF Volume changes, run #/nas/sbin/nas\_rdf -init on R1, then R2 side

## **REMOVING DATA MOVERS FROM SRDF RELATIONSHIP:**

1. #nas/sbin/nas\_rdf -init [Answer "none" to the respective pairing questions on both R1 & R2 sides]
2. #nas\_server -l & #nas\_server -i -all [Verify ACL & Ownership info of DMs]
3. #nas\_server -acl 1000 <mover> [Restores ACL to correct value for NAS and owner=nasadmin]
4. #nas\_server -info -all [Verify DM type is correct—issue server\_setup to change if necessary]
5. If required removed the rdfadmin user --#**/usr/sbin/userdel -r xxxx**

## **SRDF MIGRATIONS & MULTICAST CAPABILITY:** Multicast SRDF from one Symm to many

Prior to NAS 4.x, SRDF sys calls were issued by SIL [Symm Interconnect Layer], which cannot interpret  
RDF\_MULTICAST\_ENABLE or Concurrent RDF bits]

With NAS 4.x and above, we use Sym API to make sys calls, which can recognize multicast bits

--cannot do Symm SRDF Migration from Symm to NS Clariion systems

## **MAXIMIZING SRDF PERFORMANCE:**

- Present more luns per RDF filesystem & stripe (Rule is 1 I/O per lun when using Synchronous mode)
- Using more than 3 RDF Links for better throughput (Example: Single Fibre link @500 I/O's/sec.=4MB/sec throughput)
- Use more Clients to spread out writing to filesystems (More Clients mean more data streams writing in parallel)

## **TROUBLESHOOTING SRDF FAILOVER/FAILBACK ISSUES:**

- R1 & R2 Control Stations must be able to talk to each other over network [Not critical for failover, but is for failback]
- Rerun #nas\_rdf -init on Source CS if network settings or control station names have changed
- Primary datamover must have only (1) dedicated standby datamover [don't need to be the same hardware]
- IP subnets should be the same but scripts can work around this
- File Systems must be built on RDF devices, not Standard devices
- Failover can occur Fibre to SCSI or vice versa
- If RDF devices have been added, run \$server\_devconfig -p -s -a to update Celerra database, followed by nas\_rdf -init  
(Problem might manifest itself when a particular server panics & will not recover)
- Ensure that R1 & R2 /nas/site/slot\_param files are the same
- Look at Server Logs
- Look for dumps in /nas/var/dump
- Verify hostnames in /nas/server/slot\_x/hostname
- Repopulate the contents of /nas/server/slot\_x/param on R1 side during Restore [does not copy over automatically]
- Examine file system structure [recommendations are for 16 or 32k stripe depths on metavolumes]
- Verify whether BCV or Checkpoint file systems are mounted
- Look for non-failed over/back devices (\$/nas/symcli/bin/symrdf -g 1R2\_500\_1 query)
- Ensure Customer is not creating heavy network traffic during Failover/Failback operations (will take very long time)
- NDMP Tape drives on R1 side may panic on a restore (Fixed in NAS 2.2.39.2)
- For any IP addressing or Hostname changes, re-run #/nas/sbin/nas\_rdf -init on both sides

## **SRDF FAILOVER:**

### **WHAT TO DO IF BOTH SOURCE & TARGET SITES HAVE VOLUMES WRITE-ENABLED:**

**Note:** Situation can occur if Source symmetrix has not ‘write-disabled’ the device group—this is called a “split device group”

**#/nas/symcli/bin/symrdf -g 1R2\_500\_1 query** [From R2 Side]

## **MISSING CSHOSTS FILE:**

“nas\_rdf –init” command prompts for creation of RDF Logon Account when one existed previously: Ensure that the /nas/site/cshosts is present—an incomplete or missing cshosts file will cause the “nas\_rdf” script to call for creation of a new RDFAdmin account.

## **SRDF NAS UPGRADE ISSUE:**

There is a possible Active—Passive SRDF Issue when upgrading from NAS 4.2 to 5.1.18 in that a nas\_rdf –init needs to be run on the R1 Control Station, then on the R2 Control Station. However, it may error out on the R2. If so, rename /nas/site/cshosts file and run nas\_rdf –init and re-establish the RDFADMIN account, the Data Mover relationships, and the PASSPHRASE account—the –init should then complete successfully.

### Symptoms:

#/nas/sbin/nas\_rdf -init command issued and hangs on R2 side without producing error

#/nas/sbin/nas\_rdf -init command issued and fails on R1 side with following error because it could not ping the R2 Control Station: "Unable to contact node nas2 at 10.0.248.22"

## **CONTROL STATION ISSUES:**

- Loss of RDF Link communication
- R1/R2 Control Stations missing "hostname=" entry in the "/etc/sysconfig/network" file [each CS checks the other's hostname here]
- R1/R2 Control Stations missing IP Address & Hostname entry for each other in "/etc/hosts" file [Checked by each CS during -init]
- IP connectivity interrupted or not functioning, causing either R1 or R2 Control Station to not be able to "ping" the other
- R1 & R2 local symapi database is inconsistent and requires updating prior to running the #/nas/sbin/nas\_rdf -init command
- Control Station hardware failed, requiring replacement
- R2 script emulates an R1 configuration if it cannot detect the correct Control Volumes for an R2 configuration—check BIN files

## **Possible Remedies:**

--Verify R1/R2 Control Stations' /etc/hosts file to ensure that each other is referenced here by IP Address and Hostname  
--Verify R1/R2 Control Stations' /etc/sysconfig/network file to ensure that Hostname entry is correct

--Verify IP connectivity between the R1/R2 Control Stations & troubleshoot accordingly

--Verify RDF Link is operational between Sites

--Update R1 & R2 Control Stations' local "syma

a.) #mv /nas/symapi/db/symapi\_db.bin /nas/symapi/db/symapi\_db.old [R1 & R2 side]

- b.) #/nas/sbin/nas\_rdf -localinit [R1 & R2 side]

- Note:** Generally, the -localinit update of the symap

problems, a good practice would be to start over by running the -localinit update. The local symapi database on each side must be intact before any RDF operations between the two sites can work.

--Update R1/R2 SRDF Configurations by running from R1 side first, then R2:

- a.) R1 Control Station: #/nas/sbin/nas\_rdf -init [If no errors encountered, proceed with next step]
- b.) R2 Control Station: #/nas/sbin/nas\_rdf -init

--Verify Status of RDF Devices by running the following on R2 side:

- a.) #/nas/symcli/bin/symdg list [Obtain list of RDF Groups to query for 'Synchronization' and 'Invalid Tracks' status]
- b.) #/nas/symcli/bin/symrdf -g 1R2\_500\_1 query

**Normal Entries show RDF Devices are Synchronized and have no Invalid Tracks:**

DEV001 002 WD 0 0 RW 002 RW 0 0 SYN DIS OFF Synchronized

DEV002 004 WD 0 0 RW 004 RW 0 0 SYN DIS OFF Synchronized

**Entries might normally indicate a problem, but in this example, are "direct-attached" devices used by another Host:**

08C 11D R1:1 ?? RW NR SYN DIS OFF 0 0 RW WD Suspended

0DA 0C7 R2:1 NR WD RW SYN DIS OFF 0 0 NR NR Invalid

0DB 0C8 R2:1 NR WD RW SYN DIS OFF 0 0 NR NR Invalid

## **II. CELERRA ACTIVE-ACTIVE SRDF:** Min. Microcode: 5265.48.30 NAS Code: 2.1.15.16

Bi-Directional SRDF--both sides configured with R-1& R-2 DataMovers & Symm volumes. Only one side of SRDF volume pair can be write-enabled at a time. Synchronous Mode ONLY [Journal 0]. Each side has an Active and Passive component [R-1 & R-2]. An SRDF Standby server on Primary side must be matched on the Failover side in a 1-to1 relationship. That is, a Primary datamover must have an RDF Standby designated, and vice versa.

### **DATAMOVER PREREQUISITES:**

--SRDF Standby must have same network configuration as primary DM

--SRDF Standby must have same data volumes outlined in R2 Symmetrix BIN file

--Primary Datamover is paired to only one SRDF Standby in a 1 : 1 relationship [Pair Primary & Standby with same slot number]

### **BIN FILE PREREQUISITES:**

RDF R2 Not Ready if Invalid—set flag to ‘no’

RDF R2 Not Ready—set flag to ‘no’

Primary R1 Control Station maps to R2 Control Station volumes [scsi=10-13; fibre=06-09]

### **SETTING UP ACTIVE-ACTIVE SRDF--R-1 to R-1:**

- Step 1. **Login to local Celerra** as nasadmin and execute: #/nas/sbin/nas\_rdf -init  
[Disks are discovered locally for SRDF and the Remote Celerra/Symmetrix is contacted]
- Step 2. Create new user account to administer local R-2 Standby Servers for the Remote Celerra  
New Login: rdfadmin-localname  
New password: \*\*\*\*\* Re-enter password: \*\*\*\*\*  
[Discovery process then begins for Remote Celerra from Local]
- Step 3. Setup local server(s) as RDF Standby for Remote by specifying "ID" number, not "Slot" number of datamover
- Step 4. Then associate Primary local datamovers as Standby(s) for Remote by entering "Slot" number when prompted! Log out.  
**Note:** After set-up on Local Celerra, run \$nas\_server -l --note that the RDF Standby Server designated in Step (3) is not listed! It is accessible only when logged in as the special "rdfadmin-local" account created in Step (2).
- Step 5. **Login to Remote Celerra:** #/nas/sbin/nas\_rdf -init  
[Local disk discovery occurs for SRDF volumes & remote Celerra is contacted]
- Step 6. "Please create a new login account to manage RDF site 'remote'"  
New login: rdfadmin-remotename  
New password: \*\*\*\*\* Re-enter password: \*\*\*\*\*  
[Discovery of remote Celerra's volumes takes place]
- Step 7. Setup local datamover as Standby for the remote Celerra by "ID" number  
**Note:** Ensure that you match this "ID" with the "Slot #" of the Primary Server designated on the Remote Celerra!!
- Step 8. Associate a Primary datamover with a Standby on the "remote" Celerra by "slot" number [the two slot #'s should match]

### **ACTIVE-ACTIVE SRDF FAILOVER:**

- Step 1. Login to Celerra at site experiencing failure and power-off the Celerra
- Step 2. Login to remote Celerra as "rdfadmin-remotename" and activate failover: #/nas/sbin/nas\_rdf -activate  
[At prompt, continue failover and answer "Y"; R1 volumes on failed site become RO, SRDF link suspends, and R2 volumes on failover symmetrix to RW]
- Step 3. RDF Failover continues and Standby Server(s) are activated [device track tables from R1 and R2 are merged and SRDF link brought back online]

### **RESTORING ACTIVE-ACTIVE SRDF:**

- Step 1. Power up Symmetrix on site to be restored & ensure SRDF link is operational
- Step 2. Login to Remote Symmetrix site running as failed over Celerra [Use "rdfadmin-remote" account]

- Step 3. #/nas/sbin/nas\_rdf -restore [SRDF link suspended, track tables merged, link restored]
- Step 4. When prompted, power up the Celerra on the site to be restored, and continue with Remote Site restoration by saying "Y" to restore. Remote Celerra Datamovers are rebooted and give up control of their identity and volumes back to original site. R2 devices on Remote Site become RO once again while R1 volumes on Local Site are set RW]
- Step 5. If restore "fails" continue with following steps at Local Site being restored:
  - a) Login as nasadmin and execute command #/nasmcd/sbin/nas\_rdf -restore

**BIN Files:** "RDF R2 Not Ready if Invalid" and "RDF R2 Not Ready" flags set to "NO"

**Creating SRDF Standby DataMover on R2 for R1:** \$server\_standby server\_4 -create rdf=6 [Server\_6 on R2 is standby unit]

### **TROUBLESHOOTING SRDF:** Primary source: /nas/symapi/log/symapi.log

|                                            |                                                                                   |
|--------------------------------------------|-----------------------------------------------------------------------------------|
| #/nas/site/cshosts                         | [File shows Other Celerra if Active-Active; If blank, should mean Active-Passive] |
| #/nas/symcli/bin/symcfg list               | [Local & Remote RDF]                                                              |
| #/nas/symcli/bin/syndg list                | [shows RDF Device Groups]                                                         |
| #/nas/symcli/bin/symrdf -g 1R1_1 query     | [Device details of an R-1RDF Device Group]                                        |

| #/nas/symcli/bin/symcfg list -v  more      | [Provides Switched RDF Environment information]                                   |

### **ACTIVE-ACTIVE SRDF & RDF CHAND:**

'Unable to connect to host'—\$nas\_fs -M off or \$fs\_timefinder -M off commands fail

Rdf\_chand requires that both R1 & R2 Control Station processes communicate via root\_rdf\_channel gatekeeper slice—if this slice volume does not exist on each side, then Mirror off command will fail.

### **SRDF LOGS:**

#/nas/log/nas\_rdf.log \*New with NAS 5.1:

#/nas/log/symapi.log

**Note:** Use \$nas\_server -a -i command to see RDF relationship of DataMovers

### **EXAMPLE SRDF MIGRATION: Symm to Symm Only!**

1. Stop any Timefinder and Checkpoint operations & verify that Crontab jobs are commented out
2. Break Standby DM relationships with Primaries
3. Halt DMs
4. Halt CSs
5. Power off Celerra
6. Synch up R1 & R2 sides and verify no invalid tracks
7. Break SRDF Link
8. Load new bin on R2 Symm to change to STD volumes
9. Apply new Fibre Channel Zone sets
10. Remove DMs and CS1 from slots
11. Bring up CS0 & verify operation
12. Check nas\_disk list, IP connectivity, and Usrmapper service
13. Bring up CS1 & test failover of CS
14. Modify /nas/volume/symm and /nas/volume/disks files with new Symm serial # and Symm device ID number
15. Move /nas/dev files to backup location
16. Move /nas/server/slot\*/scsidevs files to backup location  
[#cd /nas/server; tar -cvpBf - slot\_\* /scsidevs | (cd /home/nasadmin/backup /server\* ; tar -xf -)]
17. Copy /nas/server/slot\*/camdisk files to new location
18. Move /nas/symapi/db/symapi\_db.bin file to new location
19. Insert Standby server first and run setup\_slot

**Note:** Compare devconfig output from previous copy to new devconfig [server\_devconfig server\_4 -p -s -a ltee /tmp/cmd-out/devcfg-psa\_s4.post diff /tmp/cmd-out/devcfg-psa\_s4.pre /tmp/cmd-out/devcfg-psa\_s4.post]

20. Verify disk listings are correct, IP connectivity of DMs, etc  
[#nas\_disk -l | tee /tmp/cmd-out/n\_disk-l.post diff /tmp/cmd-out/n\_disk-l.pre /tmp/cmd-out/n\_disk-l.post]
21. Run server\_devconfig ALL -c -s -a
22. Verify mounts, exports from previous copies to present output
23. Repeat verification process for other DMs
24. Define and test DM failover

## **CLARIION CORE CURRICULUM:**

### **COMPARISON OF CX SERIES:**

CX200→200MB/sec; 15 hosts/array; 256 LUNs; 4 FC-AL or 2 FC-SW host ports; 1GB cache; 30 drives Fibre or ATA

CX400→680MB/sec; 64 hosts/array; 512 LUNs; 4 host ports; 2GB cache; 60 drives

CX600→1300MB/sec; 128 hosts/array; 1024 LUNs; 8 host ports; 8GB cache; 240 drives

### **CLARIION CX600 STORAGE SERIES:**

High-speed, redundant arrays using Fibre Channel topology and fibre channel disk drives

#### **CX600 CONFIGURATION:**

CX600 series uses SPE (Storage Processor Enclosures)

Min. configuration requires the CX600 SPE, the DAE-O/S [first 5 drives contain dedicated space for O/S, 15 Drive DAE, SPS Module

Each SP contains (4) fibre ports for direct-connect to Hosts—uses PowerPath sw on Host for failover

#### **CX400/200 CONFIGURATION:**

This series uses the ‘DPE’ (Disk Processor Enclosure), 1<sup>st</sup> five drives with dedicated O/S space, SPS Module, and Standard DAE

Each SP on CX400 contains (2) Fibre ports for direct-connect, while CX200 uses only a single port for each SP

**Note:** DPE’s are built into the LCC cards for the CX400/200

### **CLARIION RAID TYPES & HOT SPARE:**

#### **RAID-0:**

Data distributed across 3-16 disks for performance, no fault tolerance—disk failure = data lost (no parity)

Used for performance as I/O is spread across many channels and controllers

#### **RAID-1:**

Data Mirrored to a second disk

#### **RAID-1/0:**

Combines mirroring and striping for performance, using 2-16 disks, used for high I/O systems, mirrored raid 0

**Note:** See emc183839. RAID 1/0 will be supported in the 5.6.39.x release. RAID 1/0 devices are mirrored, similar to RAID 1, but can be in groups of 2, 4, 6, 8, 10, 12, 14, or 16 disks. Celerra will not diskmark Raid type 1/0 devices and skips them:

# nas\_diskmark -m -a

Discovering storage (may take several minutes)

Warning:

17716810659: server\_2 c0t3l3 skipping unmarked disk with health check error,

APM00073801838 stor\_dev=0x0033, RAID10(2), doesn't match any storage profile

# server\_devconfig server\_2 -p -s -a|grep -v no

chain= 0, scsi-0

tid/lun= 3/3 type= disk sz= 20479 val= -99 info= DGC RAID 10 03263300330033NI diskerr= unmarked

#### **RAID-3:**

Use 5 or 9 disks; uses striping across volumes for perf.; parity is always on the same disk

Not used with CX Clariion series, only legacy FC4700

#### **RAID-5:**

Striping and parity striped across all drives (20% vol. space used for parity); 3-16 disks; Good on Reads but slight perf. hit on Writes  
Striping uses XOR algorithms

**Note:** Celerra/Clariion configurations support only RAID 5 & RAID 1

#### **HOT SPARE:**

A Hot Spare is normally required for every 30 disks and can be used with RAID 1, 3, 5, etc.

Typically flare will invoke the Hot Spare with a data drive failure & data is rebuilt to the Hot Spare

### **BASIC CLARIION SETUP OF DISK DRIVES:**

1. Create Raid Groups
2. Create and Bind Luns from Raid Groups
3. Map and assign Luns to Hosts and default SP owner

### **CLARIION FIBRE CHANNEL:**

--Clariion Storage Systems are configured to work with two main Fibre Channel Topologies—‘Direct-Connect’ Arbitrated Loop or Switched Fabric connected switches.

--Copper fiber is used primarily for short distances (up to 30M) for internal cabling in the array, while fibre optics are used for longer distances (SWL up to 500M & LWL up to 10k) and Host connectivity to the array [HSSDC High-Speed Serial Data Cables, & LC Lucent Connectors, respectively]

**Note:** All fibre switch ports on Clariion or Symmetrix fabric-connected ports must be set to same speed as DM ports. Default port speeds are 2GB. Mixing of speeds not supported. Auto negotiation is not supported.

### **CLARIION CACHE FUNCTIONALITY:**

- Read Cache is independent on each SP
- Write Cache is mirrored to peer SP
- Primary purpose of cache is to prevent ‘data loss’

- All Reads and Writes are completed in cache
- SPS modules exist primarily to ensure that write cache can be properly ‘destaged’ to disks in the event of a power outage
- Vaults are sections on the first five DAE-OS disks that cache destages to in emergency situations
- Read Cache uses ‘prefetch’ and LRU algorithms, first meaning that next ‘read’ will most likely be from next sequence of data on disk, and LRU means that oldest unused cache is overwritten with newer cache to enable better access to ‘current’ data
- All write cache mirrored between SP’s via the CMI peer bus [acknowledgements to Hosts must wait for this operation]
- When write cache is disabled, Host writes to directly to destination drives and acknowledgement is sent back to complete
- Low Watermark cache flush default is 40%--anything below this value is considered ‘idle flushing’
- Max of (4) threads can be assigned to flush cash if reaching the High Watermark [Forced Flushing can occur with write cache full]
- Cache is enabled at the Array level, but can also be enabled/disabled at the LUN level

### **WRITE CACHE DISABLED:**

- Requires that both SPs be operational
- Requires at least one fully charged SPS battery
- During FLARE upgrades
- Faulted SPS pwr supply
- Faulted vault drive in Encl 0

### **CLARIION STORAGE PROCESSORS (CX600):**

- Personality Module consisting of 4-ports for Host connectivity and (2) SP’s
- BE0 & BE1 ports to connect to the disk arrays & extend to additional DAE’s
- Aux 0 & 1 ports are NOT used in CX models
- Serial connection for system configuration
- Connection to SPS module
- Cat 5 Ethernet management port (Navisphere)
- Green and Amber indicator lights
- (2) power supply modules
- (3) Fan Modules containing (6) fans, hot-swappable, but requiring at least (5) fans to keep array up [2 minute shutdown with less]

### **CLARIION STANDY POWER SUPPY MODULE:**

- Input power switch from AC source
- Output receptables for SPA and DAE-OS
- RJ11 jack with db9 male connector to connect to CX600 SPE for monitoring

### **CLARIION DISK DRIVE SPECS:**

FC Drives 10K RPM (73, 146, & 300GB models); 140IO/s 2-8KB random requests; 10MB/s bandwith for sequential 128KB requests  
FC Drives 15K RPM (73 & 146GB); 180IO/s random requests; 12MB/s bandwidth for sequential requests  
PATA Drives 5400RPM 320GB; 50IO/s random; 7MB/s sequential  
SATA (Serial Advanced Technology Attachment) Drives 7200RPM (250 & 500GB); 60IO/s random; 8MB/s sequential  
LCFC Drives 7200RPM (500GB); 80IO/s random; 8MB/s sequential

**Note:** Drive capacity ratings can be misleading, as a 36GB drive is 36,000,000,000 bytes in base 10 used by mfg, but only 33GB in computer systems using Base 2

### **CLARIION DISK ARRAY ENCLOSURE (DAE):**

- 0-15 disk enclosures, with each disk dual-ported to LCC-A and LCC-B
- Contains SPB and SPA power supplies
- Contains SPB and SPA Link Control Card modules [LCC’s]
- Up to 15 disks per DAE, each drive shows amber fault light or green for normal
- DAE-OS Vault drives 0-3 required for XP O/S bootup, drives 0-4 required for enabling write cache
- Total of (8) DAE’s per bus loop (120 drives), for a maximum of 240 drives

### **CLARIION ATA DAE2 DISK ENCLOSURE:**

- Maxtor 250GB Tomcat Disk Drives, 5400 RPM, data written in 512 byte blocks
- Requires that first enclosure OS drives be RAID 5 Fibre Channel (true for all Clariion arrays)
- Requires Navisphere 6.4 to manage

### **FIRST FIVE ARRAY DISK DRIVES:**

- CX600 = DAE2-OS; CX400/300 = DPE2-OS
- First 6GB of each of the five drives is reserved for system environment
  - Flare database is triple mirrored across 28MB/disk on disks 0-2
  - PSM is triple mirrored across 0-2 and keeps SPA & SPB synchronized
  - Drives 0-4 contain 2176MB/disk vault area to destage write cache
  - SPA’s OS is mirrored on Disk 0 & 2 while SPB is mirrored on Disks 1 & 3

### **CLARIION DISK PROCESSOR ENCLOSURE CX400/200:**

- Contains SP’s where LCC cards are in the CX600
- SPA is directly connected to first 15 drives via backplane

--Min. configuration DPE + SPS

## **CLARIION RAID GROUPS & LUNS:**

Raid Groups are created to pool disks together and are carved up into usable Logical Units for Host Systems through the use of LUNs  
Luns are striped across the RAID Group and therefore must be of the same RAID type

**Note:** Prior to Flare 12, could only have 32 Luns per RG. Can now have 128 luns/RG.

## **RAID GROUP EXPANSIONS:**

--Raid Groups can be expanded with active LUNs attached

--Raid Groups can add drives within the limits of the Raid Type [max of 16 drives per Raid 5 RG, etc.]

--In the case of multiple LUNs, newly added disks do not change LUN size--free space is pooled at bottom of RG for expansion

--In case of single LUN Raid Groups, new disks added will increase the size of the LUN [optional]

--In fragmented RG's, consolidate free space in RG's by using defrag if a single large LUN is desired

## **LUN EXPANSIONS:**

### **METALUNS:**

Purpose of metaluns are to increase spindle count for increased performance of LUNs, and to be used for LUN migration to change LUN type

--Creating new LUNs and adding to a 'base' LUN; concatenated or striped metaluns

--With CX600, can add 16 components to a metaLUN, which in turn can have 32 Flare Luns per component

--CX400 can add 8 components to a metaLUN

### **Concatenating:**

--creates metaLUN components for increasing LUN size

--either protected or unprotected

--any size scheme except all FC or all ATA drives

### **Striping:**

--requires use of same Disk drives, same Raid scheme, and same sizes as base LUN

--restripes data across all space once new luns are added

## **CLARiiON LUN MIGRATION**

### **CLARiiON CX-to-CX3 CONVERSIONS (aka Data-in-Place Upgrade)**

→Clariion offers a migration path from CX to CX3 series arrays with FC drives—see February 2007 White Paper “Upgrading to CLARiiON CX3 UltraScale Series Storage Systems”

→Submit CCA for LUN Migrations that involve Celerra

→Upgrading from CX series results in 2Gb/s loop speeds (Purchase new CX3 array to get 4Gb/s capability)

→CAP2 Conversion Readiness tool is used to determine if User or Private LUNs need to be relocated prior to the hardware Upgrade

→Requires PS engagement

→CLARiiON Procedure Generator for “LUN Migration for CX3-Series Conversions” provides link in instructions on what to do if NAS is attached to a CLARiiON array: Celerra NAS – CLARiiON Backend Upgrades 5.5 Technical Note

→Backend upgrade conversion with attached Celerra is only supported on Gateway models

→ConversionPrep NDU utility required on array [UtilityPartition NDU, ConversionImage NDU pkg]

### **NAS Tech Note Recommendations:**

--CLARiiON LUN migration must be used to execute migration of NAS LUNs

--NAS Control LUNs must be migrated to Fibre Channel drives

--NAS Control LUNs must be moved to a single RAID group, with Source & Target LUN sizes identical by Block count

--NAS Data LUNs should be moved to a RAID group not already containing NAS LUNs

--NAS Data LUNs should (really needs to say “must”) be migrated to target disk technology compatible with the source

**Note:** Must migrate to same Raid Type, same Raid Protection—e.g., r5 (4+1) to r5 (4+1), same drive types

### **IF CAP2 TOOL REQUIRES LUN MIGRATIONS:**

1. Create Destination LUNS (destination LUNs must have same block count as source LUNs)

2. Use Navisphere to Migrate source to destination LUN and select migration rate of High

3. Do not continue with migration if a message indicates that target LUN is larger in size (because this will extend the LUN, which isn't allowed for Celerra)

4. Wait for LUN migrations to complete before continuing with CX to CX3 Upgrade procedure

### **EE Guidance on LUN Migrations on Celerra:**

--Do not use CLARiiON LUN extension to increase LUN size for an existing NAS LUN (see emc157859)—use nas\_fs -xtend

--Migrate LUNs where source & destination blocks are identical

--Migrate LUNs onto same RAID type (R5 vs. R3 or also means 4+1 to 4+1?) and physical disks

--Migrate LUNs to same Owner SP as source

## **WHY ARE LUN EXPANSIONS BAD FOR CELERRA LUNS?**

Diskmarks are written 128 sectors (512 bytes/sector) from the end of a LUN when first diskmarked by Celerra. Also, the first 8k block (sectors 0-15, 8192 bytes) is moved to the 2<sup>nd</sup> to the last 8k block of a LUN, meaning that the 1<sup>st</sup> and last 8k blocks are free for

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
MPFS client signatures. Both the diskmark and the 2<sup>nd</sup> to last 8k block are addressed from the END of the LUN, not from the beginning of the LUN. Celerra will lose diskmark if lun is expanded, and also data when first block of lun is used.

#### **512 bytes per Sector**

#### **16 Sectors per 8K block**

#### **Diskmark located at 8<sup>th</sup> 8K block from the END of LUN**

### **CLARIION SOFTWARE FEATURES:**

#### **Access Logix→Allows heterogeneous hosts to be attached to an array via “Storage Groups”**

→Provides Lun masking to Hosts for Shared arrays (Array-based SW that is NOT enabled by default)

**Note:** Access Logix used with NS600G/700G & CFS-14/CX600/CX700 on Shared SANs. Access Logix is NOT used with captive backends such as NS600/700. Access Logix Base Code contains “1” in 3<sup>rd</sup> field [2.05.1.60.5.xxx].

#### **To enable Access Logix:**

#### **Navisphere Manager>Properties>Storage Access>Select “Access Control Enabled”**

**SnapView Version 2.0**----→Point-in-time online virtual copy of LUNs--up to 8 per lun; Full synchronous copies called ‘clones’  
SnapView Snapshots and BCV’s

**MirrorView**→Remote DR solution over FC or T3 lines using synchronous mirroring—Source LUNs can have up to (2) mirrors to other Storage systems which can participate with Host writes.

**SANCopy**→Used to migrate data at a block level between LUNs, within an array or to other arrays, Symmetrix systems, and misc. supported 3<sup>rd</sup> party systems. Requires installation of a software enabler on the array. Uses the SAN to copy the data and does not use a Host. Considered the optimal method for migrating data within a CLARiiON system. Supports iSCSI beginning with Flare 26. Launched via Navisphere Wizard or from Navicli.

**PowerPath**—Host resident software delivers intelligent I/O path management, I/O balancing, and automatic failover capability

**Non-Disruptive Upgrade**--NDU upgrades of CX series are non-disruptive if data has path to both SPs & Hosts are using PowerPath.

### **CLARIION ARRAY INITIALIZATION & SETUP:**

#### **SETTING UP A NEW CLARIION ARRAY:**

1. Cable array for direct attached arbitrated loop Hosts or for Fabric Connected Hosts
2. Install Navi CLI, Navi Host Agent, Windows UIs, Windows Management Server, & Java Runtime Environment software on Windows 2000 Server or Laptop [d:>Host Software>W2K>Service Toolkit>ServiceT.exe]
3. Initialize array by powering on
4. Connect serial cable from Windows 2000 Server to SPA and create DialUp Networking PPP Connection:  
Network and Dial-up Connections>Make New Connection>Enter 3-digit area code if prompted>Network Connection Wizard>\*Connect directly to another computer>\*Guest>Communications cable between two computers (COM1)>\*Only for myself>type in name for the connection>Enter Username: clarion\_passwd: clarion!>General Tab: COM1>Configure>Set speed to 115200 and o.k.>Networking Tab: Uncheck all boxes except TCP/IP>Click on ‘connect’ using ‘clarion’ and password ‘clarion’!
5. Once PPP Session is launched and you are logged into the Array, open a Web Browser to connect to SPA:  
Default IP Address to configure Clariion Array using Web Browser: 192.168.1.1/setup
6. Set the desired IP address for SPA:  
IP Address: 192.168.2.124  
Hostname: SPA\_124  
Subnet Mask: 255.255.255.0  
Gateway: 192.168.2.1  
Peer IP Address: 192.168.2.125 [IP of SPB]
7. Click on ‘Apply Settings’ and SPA will reboot—connect to SPB while SPA is rebooting and configure IP Address for it  
**Note:** Enter Peer IP Address of SPA and ‘Apply Settings’ to reboot SPB
8. Reconnect serial cable to SPA, connect via PPP session, open browser to 192.168.1.1/setup:  
“Restart Management Server”  
**Note:** This will allow SPA to discover IP Address for SPB and syncs the PSM database. From this point forward, you no longer need the serial connection to SPA or the PPP session as you will use the Web Browser directly to the IP Address of either SPA or SPB.
9. Establish Global Security and Domain Name: c:>Program Files\EMC\ManagementUI\6.5.0.1.79\WebContent>start.html
10. Select ‘LAN Connection’ for ‘Select Connection Type’ and enter IP Address of SPA  
**Note:** Answer Yes to initialize global security and ‘Create Global Administrator’ Username and Password to be used on system
11. Click on ‘File’>Setup Domain>Select Master and enter ‘Master Node IP Address’ of SPA
12. Expand the ‘Enterprise Storage 1’ tree for the displayed CX600 system
13. Rightclick on SPA and update ‘Network’ information, set ‘Fibre Speed’, Add Privileged Users to ‘Agent’ tab, etc.  
**Note:** Repeat for SPB
14. To change Storage Domain Name, go to ‘File’>Setup Domain>Configure Domain>Change>add new domain name
15. To add Storage Domain Users, go to ‘Tools’>Security>User Management>Add>add users as required
16. For all new installations, one of the next steps will be to ‘Commit’ the Base Software package

Rightclick array>Properties>Software>Base>rightclick and select “commit”

**Comments:** First array configured is a ‘Domain Master’. User accounts have three roles, ‘Administrator’, ‘Manager’, & ‘Monitor’

17. Add or Upgrade SW packages on the array as required:

Highlight Array>Rightclick and select ‘Software Operations’>Software Installation Wizard>Browse CD-ROM for software and add: Management UI 6.5.0.3.3

**Note:** After installation of the Management UI software, you will be able to connect to the Management Server display directly from a Web Browser to the IP Address of SPA without using the ‘Start.html’ page

### **EXAMPLE OF SOFTWARE PACKAGES ON ARRAY:**

|                   |                                         |
|-------------------|-----------------------------------------|
| Base              | 02.05.0.60.5.008                        |
| ManagementServer  | 6.5.0.3.10                              |
| Navisphere        | 6.5.0.3.7                               |
| ManagementUI      | 6.5.0.3.3                               |
| Base              | 02.05.1.60.4.004 [Access Logix Base SW] |
| SnapViewUI        | 6.5.0.2.55                              |
| SnapView          | 02_20_01                                |
| SnapCloneProvider | 6.5.0.2.55                              |

**Note:** After new ‘base’ software is installed and then ‘committed’, the original base will be deleted from this list

### **INSTALLING UTILITY PARTITION AND RECOVERY IMAGE:**

1. Install Utility Partition Image and Recovery Image software using Software Installation

### **INVOKING ARRAY RECOVERY PROCEDURE:**

1. Connect null modem cable to serial port on SPA
2. Connect with hyperterminal session [9600; 8 bits; none; 1; Hardware]
3. Reseat SPA to reboot, during Extended POST, the following characters begin scrolling across the screen. At this point, type “ctrl + c” keys (or Esc key if that does not work), which allows POST to complete, and generates a “...Storage System Failure message, then enter the password indicated in the next step  
AabcdeBCDabEabcd
4. Then enter password on screen: **DB\_key**
5. Enter (3) for DDBS Service Sub-Menu at “Diagnostic Menu”
6. Select (2) Utility Partition Boot
7. After Utility Partition boots, press Enter key and select “Install Images” in Toolkit Menu
8. At ‘Select Images’ display, enter number corresponding to NDU Recovery Image installed for system
9. Install image on SPA only
10. Select (1) Reset Controller from “Diagnostic Menu”

**Note:** This will boot SPA from new image and requires (3) reboots to complete install

### **POWERPATH SOFTWARE:**

Host-based software providing Host-to-Storage I/O path management/failover and maximized performance, found predominantly on fibre channel. Support for multiple paths to logical devices so as to enable failover in the event of hardware failure. Provides dynamic load-balancing of I/O requests to logical devices across the available paths.

1. Install from CD-ROM by running ‘emcpp.w2000.3.0.5.ga.exe’
2. Enter License Key when prompted: B4P9-DB4Q-LF6W-QOSA-ML9O-VRL4
3. Reconfigure Windows Host HBA drivers for PowerPath using Emulex Driver Utility

**CURRENT VERSION:** <http://Powerlink.emc.com>

PowerPath v4.4.0 for Windows, March 2005—support for Symm Microcode 5x71 & Clariion Flare 17

PowerPath v4.4.0 for Solaris, March 2005—support for Solaris 10 & end of service life for PowerPath Volume Manager for Solaris, AIX (PPVM)—must backup data from PPVM volumes and destroy PPVM volume groups before installing this version.

### **PowerPath 4.5:**

Latest version supports EMC Symmetrix, EMC CLARiiON, Hitachi Data Systems (HDS) Lightning, HP XP, IBM Enterprise Storage Server (Shark), and HPQ storage systems. Supports Solaris, HP-UX, AIX, Linux, & Windows Servers.

### **USING ACCESS LOGIX:**

1. Install base Access Logix software
2. Open Navisphere Manager>Properties>Storage Access>Access Control Enabled
3. Create RAID Group; Bind LUNs to RAID Group; Create Storage Groups; Assign Hosts to Storage Group

### **CLARIION HOST CONNECTIVITY/TROUBLESHOOTING HOST CONNECTIVITY:**

→Fibre Channel Zoning must be correct

→Failover SW must be in place and active

→Storage Groups must be defined if Access Logix and LUN Masking used between LUNs and Hosts

→HBA Configuration setup: Persistent Binding; Initiator configuration, Failover mode, etc.; HBA registered manually or via Navi-Agent. Host HBA must log into the SP to be able to be Registered

#### **TROUBLESHOOTING TOOLS:**

- navicli commands
- HEAT grabs for Host configurations
- Switch Zoning, Port stats, logs

#### **USING NAVICLI TO VERIFY/CHANGE HBA & SP CONNECTIVITY STATUS:**

**`$ /nas/sbin/navicli -h 142.9.150.201 port -list | port -list -sp -all`**

**Note:** The port -list command provides detailed information on each Celerra HBA and what SP ports it is connected to, and the StorageGroup information. This command only works with SAN attached NSG products. Integrated NS platforms do not use StorageGroups or AccessLogix. This command also returns status of all the SP ports. In the following example, Celerra is only connected to Ports 0 & 1 on each SP, but each SP has a total of (4) ports for the NFS701G model. This command also has other options, such as -diagnose -host; -removeHBA -host; register -list

#### **Examples:**

##### **LIST OF DATA MOVER HBA's-to-SP PORTS:**

**`# /nas/sbin/navicli -h 192.1.4.220 port -list -hba`**

##### **DISCONNECTING HOSTS FROM STORAGEGROUP:**

**`# /nas/sbin/navicli -h 192.1.4.220 storagegroup -disconnecthost -host emcnas_i0_dm2_p1 -gname`**

**Celerra\_emcnas\_i0**

##### **REMOVING HOST INITIATOR RECORDS FROM SP:**

**`# /nas/sbin/navicli -h 192.1.4.220 port -removeHBA -host emcnas_i0_dm2_p1`**

Remove the following initiator records for: emcnas\_i0\_dm2\_p1

50:06:01:60:C1:E0:53:35:50:06:01:61:41:E0:53:35 SP B-2

Only logged out but registered initiator records will be removed. Do you want to continue (y/n)?

##### **REMOVING HBA INITIATOR RECORDS BY HBAUID FROM SP:**

**`# /nas/sbin/navisecli -h <sp_IP> port -removeHBA -hbauid 10:10:10:10:10:10:10:10:10:10:10:44:55:66:77:88`**

(y/n)?

##### **REMOVING ALL HBA RECORDS:**

**`# /nas/sbin/navicli -h 10.241.168.179 port -removehba -all`**

Remove the following initiator records for all attached hosts:

50:06:01:60:C1:E0:D9:54:50:06:01:60:41:E0:D9:54 SP A-0

50:06:01:60:C1:E0:D9:54:50:06:01:61:41:E0:D9:54 SP B-0

50:06:01:60:C1:E0:D9:54:50:06:01:68:41:E0:D9:54 SP A-1

50:06:01:60:C1:E0:D9:54:50:06:01:69:41:E0:D9:54 SP B-1

Only logged out but registered initiator records will be removed. Do you want to continue (y/n)? y

**Note:** If command fails because the Data Movers are logged-in, shutdown the Celerra or reboot the blades

##### **CREATING INITIATOR RECORDS FOR SPECIFIC PORTS IN STORAGEGROUP:**

**`# /nas/sbin/navisecli -h <sp_IP> storagegroup -setpath -hbauid 10:10:10:10:10:10:10:10:10:10:10:44:55:66:77:90 -sp b -spport 2`**

##### **ADDING & REGISTERING DATA MOVER HBA's TO SP's AND STORAGEGROUP:**

**`# /nas/sbin/navicli -h 192.1.4.221 storagegroup -setpath -gname Celerra_emcnas_i0 -hbauid`**

**50:06:01:60:C1:E0:53:35:50:06:01:61:41:E0:53:35 -sp b -spport 2 -ip 128.221.252.2\* -host**

**emcnas\_i0\_dm2\_p1 -failovermode -arraycommarray 0 -unitserialnumber array**

\***Note:** Data Mover 2 would use 128.221.252.2 and 128.221.253.2 for its internal IP address, while DM3 would use 252.3 and 253.3

##### **Information about each HBA:**

BITS 123 – 100 [Represent WWNN ID assigned by IEEE]

BITS 99 – 96 [Represent WWNN padded to 0]

BITS 95 – 64 [WWNN bitwise ‘OR’ of 0x80000000 and the 32 bit WWN from Seed prom]

BITS 63 – 60 [WWPN IEEE type]

BITS 59 – 36 [Company ID number set by IEEE]

BITS 35 – 32 [Differentiates among multiple ports with same Node Name]

BITS 31 – 0 [32-bit WWN seed from prom on midplane]

**INDICATOR LIGHTS ON SYSTEM BOOT:**

BIOS Test: Green LED On; Amber LED blinks once every 4 seconds

POST Test: Green LED On; Amber LED blinks once every second

NT Boot & Driver Load: Green LED On; Amber LED blinks 4 times per second

Successful Boot: Green LED On; Amber Off

### **INTERNAL DISPLAY LIGHTS:**

(4) Green LEDs in a Row 0 1 0 0 [Green + Yellow LED row decodes to number error code 41]

(4) Yellow LEDs in a Row 0 0 0 1

**Decimal:** 8 7 6 5 4 3 2 1 0

**Binary:** 1000 0111 0110 0101 0100 11 10 1 0

### **HYPER TERMINAL SETTINGS:**

9600 baud; 8 data bits; no parity; 1 stop bit; no flow control

### **NAVISPHERE MANAGER INDICATORS:**

T [Means component or system is in transition] F [Means component(s) have failed] X [System inaccessible] ? [Unsupported]

### **CLARIION ARRAY EVENT/ERROR MESSAGES:**

**FIBRE DISK MIRROR DRIVE EVENTS:** Events all begin with 7124

7 1 2 4 **4** 0 0 5 [Translates into a warning: ‘Attempt to reconstruct primary after a verify error.’]

0=Informational 4=Warning 8=Error C=Critical Error

### **CLARIION SNAPVIEW:**

Main purpose is to provide online backups using point in time “snapshots” or full copies called “clones” of LUNs

Requires SnapView NDU, Clone Provider NDU, CLI Provider NDU, and SnapView UI for Navisphere

#### **SNAPSHOTS:**

Point-in-time virtual copy of LUN, requiring about 10-20% space

SnapShot Cache resides on the disk drive’s ‘private lun’ while SnapShot Lun resides in SP memory

SSLUN [SnapShot Source LUN] and SCLUN [SnapShot Copy LUN, stored in SP RAM] and one Snapshot Cache area per SSLUN

**Conducting a SnapShot:** Up to 8 concurrent snapshot sessions per LUN

1. Source LUN is ‘stabilized’ and put into ‘hot backup mode’, db is offline
2. Snapshot Session started
3. Source Lun restarted, taken out of ‘hot backup mode’
4. Snapshot is activated
5. Backup software backs up snapshot [mount the snapshot]
6. Snapshot deactivated & Snapshot Session stopped

#### **Limitations:**

--min. of 2 cache luns [private lun area] per Source LUN, total of 100 per Clariion array

--default snapshot chunks are in 128 64k blocks

--max of 8 Snapshots per source LUN, 300 per Clariion

--max of 8 Snapview Sessions per Source LUN, 100 per Clariion

#### **SnapClone:**

Full point-in-time copy of a LUN, equal in size to Source LUN

Max 8 active Clones per source LUN, 50 total per Clariion

## **FIBRE CHANNEL:**

### **(2) categories of fibre:**

**Multimode:** 125-400micron core allowing light source multiple paths down fiber—hence ‘multimode’—shorter distances than Single Mode; Cable color is orange

**Single Mode:** 2-8micron core, spans very long distances; cable color is yellow

**Light Source:** Multimode Fibre commonly uses LEDs for its lightsource while Single Mode uses Lasers.

**Transmission Methods:** TDM (Time Division Multiplexing) & FDM (Frequency Division Multiplexing). Combinations of the two are called WDM (Wavelength Division Multiplexing)

Fibre signals are pulsed as 0 & 1 bits onto copper wire or as “on & off” pulses of light via LED or Laser light sources

Fibre can travel long distances through the use of “regeneration” techniques using OEO (Optical/Electrical/Optical) or FA (Fibre Amplifiers).

#### **Fibre Channel Connectors:**

FC—connectors are screwed on

SC—connectors are plugged into sockets

LC—connectors are smaller but similar to the SC

ST—connectors are placed into sockets and turned ¼” to lock

MT—connectors are the smallest

#### **Fibre Optic Distances:**

SWL Multimode = 500M LWL Single Mode = 10K

#### **Copper Cable Distances :**

Both twinaxial and HSSDC support distances up to 30M

### **CELRRA FIBRE CHANNEL:**

→Supports switched fabric Class 3 service

→Receiving Host is always responsible for flow control with fibre channel

→FCP Class 3 FC does not perform retransmissions—relies on timeouts, but then must resend entire I/O stream

**Fibre Channel:** Serial interface, 100-200mb/sec, Copper Cable distance is 5-20m; Fiber Cable distance is 150m – 10km. Arbitrated Loop can have 126 devices, Switched Fabric 16 million. Supports SCSI, TCP/IP, VI & IPI, HIPPI

→Fibre channel is full duplex block-oriented high-speed serial network protocol 1-10Gbps [Celerra operates at 100MB/sec].

→Encoding schemes called 8b/10b control data flow & transfers using SOF (Start of Frame) & EOF (End of Frame). Frames can be up to 2148 bytes. The "fabric" of a Fibre Channel topology consists of (1) or more Switches connect to one or more port through F\_Port & N\_Port nodes.

**NODES:** Nodes represent equipment or devices such as HBA's, or SP's with built-in Fibre Channel Interfaces

**PORTS:** Ports represent the cable connections on the Node or Device

**Note:** For Fibre Channel Control Stations and DataMovers--Access up to 256 SCSI addresses per SCSI channel

### **TWO TYPES OF FIBRE CHANNEL TOPOLOGIES :**

#### **ARBITRATED LOOP (FC-AL) :**

**Note:** Also known as 'Direct Connect' or 'Point-to-Point', similar to 'token-ring' Hub technology in that only one device can be communicating to the Storage Processor at a time, therefore sharing the 'loop'.

→ALPA's are unique 2-digit numeric identifiers in hex for each port on an Arbitrated Loop topology, ranging from 0xef to 0x01, lowest to highest priority, respectively.

→Loop ID's are a decimal representation of the ALPA, 0-125 [lowest to highest]

→Loop Initialization Process [LIP] is the automatic login and arbitration for unique ID and for speed with the loop for new or disconnecting devices

**Note:** Loop ID's and ALPA's help maintain communication on the 'loop' via 'arbitration'.

→Daisy-chain of two or more devices using a FC Hub with one Port controlling the loop.

→Only one conversation on the 'loop' at a time.

→500 Meters, 2Gb/sec, 126 devices per loop, but Clariion imposes a limitation of 120 devices

→Limited to a single O/S type.

**Note:** PBC's [Port Bypass Circuit] allow for the protection of the loop while devices are accessing or leaving, or failing

→LCCs [Link Control Cards—FC-AL interface] are the actual built-in hub on each Clariion Storage Processor used in the 'loop'

**Note :** If one Host goes down in loop, if using Fibre Channel Hub architecture and Loop Initialization Process, the faulty or missing Host is updated in the ALPA tables [Arbitrated Loop Physical Address tables]

#### **SWITCHED FABRIC (FC-SW) :**

'Fabric' which consists of one or more dynamic switches connected via ISL (InterSwitch Link)

500 Meters, 2GB/sec, 2-to-24th ports per fabric

Multiple conversations can occur simultaneously over the SW Network

Multiple O/S can participate on Network by using Zoning to isolate ports

More hosts allowed

Any port can have conversation with another port

Limited to 16 switches total per fabric

FC-4 Type=SCSI Persistent Binding

Class 3=HBA/driver solution

### **GENERAL FIBRE CHANNEL FABRIC RULES:**

--all nodes should be within 3 hops of each other

--max of 16 switches in a single fabric

--mult. Equal costs paths recommended between all switches or (2) ISLs

--min. of (2) ISLs between two direct communicating switches

--Brocade "trunking" to consolidate bandwidth is recommended

--Principal core switch should be at the logical center of the fabric

### **WELL KNOWN SWITCH ADDRESSES:**

Broadcast: 0xFFFFFFF

Fabric Login Server: 0xFFFFFE

Name Server: 0xFFFFFC [All Nodes login and register with Name Server]

## **CLARIION HBA/ARRAY DEVICE DRIVERS FOR EMULEX:**

Clariion Arbitrated Loop=direct connect via arbitrated loop hub

Clariion Fabric for switched fabrics

## **EMC SUPPORTED TOPOLOGIES :**

Arbitrated Loop for Direct Connections

Switched Fabric

## **FIBRE CHANNEL OSI MODEL :**

Physical Layer—FC-0

Datalink Layer—FC-1 to FC-3

Transport/Networking Layer—ULP, FC-4

FC-4 for SCSI allows SCSI Initiator and Target to communicate over Fibre Channel using ;

FCP\_CMND, FCP\_XFER\_RDY, FCP\_DATA, FCIP\_RSP

## **FIBRE CHANNEL PORTS:**

Many types of Fibre Channel Ports, but in “Switched Fabric” [i.e., non-arbitrated loop!], we only use (3) types:

### **N\_Port:**

N\_Ports are hardware endpoints [Celerra HBA or Symmetrix FA] that connects to the FC topology. N\_Ports transmit and receive Fibre Channel frames in Switched Fabric environments.

### **F\_Port:**

N\_Ports connect to the FC Switch Ports, called F\_Ports, bringing that connection into the “Fabric”[Celerra or Symm to Switch]

### **E\_Port:**

Expansion port connecting two switches together—called ‘cascading’ switches [ISL’s—Inter-Switch-Links].

Total of 14 FA Ports per Symmetrix [7 FA’s, each having two ports]

**Login Process:** N\_Port host logs into fabric on F-Port switch

### **NL\_Port:**

Loop port used in ‘arbitrated loop’

### **FL\_Port:**

Used to connect fabric to Public Loop

## **FIBRE CHANNEL TERMINOLOGY:**

WWN—Unique 64-bit address broadcast by HBA on startup [Aliases are names given to WWNames]

Hops—Number of ISL’s a frame needs from time entering to exiting the F\_Port fabric

ISL—InterSwitch Link connects two E\_Ports on two different switches [aka “Cascading”]

Fan-In—Number of Host ports zoned into a single SYMM Fibre Channel FA[Director] Port

Fan-Out—Number of SYMM FA Ports consolidated into a single Host.

Zoning—Grouping together of a bunch of WWN’s or Aliases [ZoneSet—group of Zones]. Main purpose is to isolate each HBA from others in the fabric, called “Single HBA/Initiator Zoning.”

Hard Zoning—consists of WWN and physical Switch Port numbers—not the recommended approach

Soft Zoning—Recommended method, using WWNs and aliases instead of physical switch port numbers

Zone Configs—a collection of Zones to be activated simultaneously—can only have a single Active Zone Set at any given time

Full Mesh Topology—All switches interconnected with only a single hop between any two nodes [Dual ISLs recommended]

Core/Edge Topology—More common switch fabric, where “Core” switches are located in the center of the fabric in a “Mesh” configuration, while “Edge” switches are located at the edge of the fabric with single ISL

## **CONTROLLING ACCESS TO VOLUMES:**

Use VolumeLogix to manage what Hosts see what Volumes on the BackEnd by mapping HBA to FA to Volumes [LUN Masking].

## **THREE TYPES OF FC ZONING :**

Port Zoning—‘Hard Zoning’ of ports together at the Switch—not recommended

WWPN Zoning—more flexible Zoning allows for movement of physical cables from port-to-port [EMC zoning method]

Mixed Zoning—Combination of Port-to-Port and WWN Zoning

## **Fibre Channel Celerra Implementation:**

Fibre Channel connection to Symmetrix using SCSI protocol-over-Fibre-Channel via Class 3 Switched Fabric.

## **TARGET & LUN SUPPORT ON CELERRA:**

SYMM=max of 2048 devices

SCSI=240 LUNS

FIBRE=256 LUNS SYMM 5 [Note: This is a Symmetrix limitation. Celerra could otherwise support up to 4096 LUNs]

FIBRE=128 LUNS SYMM 4

Single Topology per Host

Multiple HBA's per Host of same type

### **FIBRE CHANNEL TOPOLOGIES:**

Public Loop: Shared bandwidth, connects to switch using FL\_Port

Private Loop : Shared bandwidth, not connected to a switch—isolated loop.

Point-to-Point Fabric : Dedicated bandwidth connection—N\_port to F\_port on switch

**SWITCHED FABRIC Class 3 [FC-SW]:** FC is a serial data transfer interface operating over copper and/or optical fiber at speeds up to 100MB/sec. Networking and I/O protocols [such as SCSI] are mapped to FC constructs, encapsulated, then transported within Fibre Channel frames. Supports SCSI, TCP/IP, and ESCON and Hosts : HP, Sun, SGI, NT, Sequent, IBM AIX, Celerra. Class 3 is SCSI 3 protocol [Upper Level Protocol—ULP] encapsulated over Fibre Channel without guaranteed delivery—no ACK. SCSI over Fibre is good for 500 Meters at 2Gb/sec. FC SW provides for dedicated bandwidth and virtual paths between ports.

### **DataMover Fibre Channel Specs: 506, 507, 510**

**EMULEX LP8000:** Emulex LP8000DC/N1; Two Ports Full Duplex; Multimode Cable with SC Connectors; FC5M-50M/FC10M-50M cables ; Supports 506/507/510 DMs running 2.1.24.4/2.2.15.4 NAS and SYMM 5265.43.26

**Note:** Emulex LP8000 only supports 1GB speed. Known problem with excessive emulex driver ‘jitter’ on the top port of the card, causing connectivity issues with McData 140M switches—for this issue, use only bottom port for Golden Eagle Control Stations.

**EMULEX LP9000:** 2GB Fibre HBA's for 510 DM's; IP Flag off by default; Current Bios levels 1.63a2 BIOS & 3.90a7 firmware

**EMULEX LP9002:** 2GB HBA's for 510 DMs ; Requires SC-LC or LC-LC cables ; LP9002 Board 250-735-900 for straight DM Host ; Board #250-734-902 for Tape Drive Support

**AGILENT HBA:** NS600, 700, & NSX Series

### **Control Station Fibre Channel Specs:**

**QLOGIC HBA:** Qlogic QLA-2212 Two Ports Full Duplex Multimode Cable with SC Connectors

**Prerequisites:** Linux O/S and BIN file to support FC-SW [CS0 should see all Data Volumes & GateKeepers]

**BIN File Flags:** PP, UWN, SCSI T & ARB bits set; SCSI C Flag cleared

When connected, orange or green light should illuminate—if not, reverse the orientation

**Note:** FC Control Stations were susceptible to rebooting after Zone changes due to a 30 timeout value. Value increased to 90 seconds with NAS 4.2.17.0, same timeout value as for FC Data Movers.

### **BOOTING FROM CLARIION ARRAYS:**

All CFS/CNS14 Control Stations should be zoned to a single HBA port only, using HBA0, to SPA. Fibre drivers do not support dual paths. Redundancy pathing is provided if CS1 is used, which is zoned to SPB.

### **Replacing Fibre Control Station:**

1. Replace hardware & find new WWN for CS0
2. Remove old hardware's WWN
3. Create replacement Zone on FC Switch for new Control Station
4. After Logon: #/nasmed/sbin/setup\_slot -init cs [#/nasmed getreason]
5. Failing Over CS0 Primary to CS1 from the Console of CS1 : **#/nasmed/sbin/cs\_standby -takeover**

### **FIBRE CHANNEL SWITCH SUPPORT MATRIX:**

#### **SWITCH TYPE:**

EMC Connectrix DS-8B or 16B

EMC Connectrix DS-16B2

EMC Connectrix ED-12000B, DS-16M

EMC Connectrix DS-16M2

EMC Connectrix DS-24M2

EMC Connectrix DS32B2, DS-32M

EMC Connectrix DS-32M2

EMC Connectrix ED-64

EMC Connectrix ED-64M

EMC Connectrix ED-140M, 1032 v 2.0

EMC Connectrix ED-48000B enterprise director (32-256 full duplex 4Gbit/sec ports)

EMC Connectrix DS-220B SAN switch (8-16 4Gbit/sec ports)

BROCADE SilkWorm 2400, 2800, 3800, 3900

BROCADE 12000

BROCADE DS-24M2, 32M2

#### **FIRMWARE LEVELS:**

2.5.1.b or later

3.0.2a or later

V2.00.00

V4.01.00 or later

V2.00.00

04.00.00

2.00.00 or later

4.01.00 or later

FUJITSU-SIEMENS PSFS-B161

MCDATA ED-5000, 6064

MCDATA ES-3016, 3032

MCDATA Intrepid 6140

MCDATA Spheron 4500

CISCO MDS 9216, 9509 (Multilayer Fabric Switches, 2Gbps and 1/2/4 or 10Gbps switches, respectively)

**Comments:**

All switches support Fan-Out Ratio of 6 :1 and Fan-In Ratio of 1 :6/Volume Logix 2.2.1/256 LUNS

Up to 16 switches can be cascaded [merged] together in a single ‘Fabric’

DS-8B & 16B are being discontinued

BROCADE=DS; MCDATA=ED

**Warning:** Celerra DM or CS cannot boot from port 0 on Brocade 3900 or 12000—BIOS issue [Fixed with later code]

**BROCADE DS-16B vs. McDATA ED-1032 SWITCHES :**

--Telnet or use GUI to manage Brocade (McData is GUI only)

--Default Zoning is to allow all ports to talk to all nodes (McData has all Zoning disabled by default)

--Brocade uses NL, G, U, or QL Ports (McData does not)

--McData Switches do not work with Arbitrated Loop topologies, only Switched Fabric

--McData Enterprise Director switches can generally perform ‘firmware’ upgrades while Online, Brocade DS cannot

**CISCO 9216/9509 FIBRE CHANNEL SWITCH ISSUES WITH CELERRA:**

NAS 5.2 installs or existing Celerras may experience a loss of FC connectivity, especially after firmware upgrade (Cisco 9120 sw 2.0(3)). Cisco switches have two admin modes: FX & AUTO. Switch ports may need to be set to FX emulation in order to work on firmware levels 1.2.1a and higher. See emc107196.

**CISCO SWITCH COMMANDS:**

# show tech-support (Fabric Manager map, write this to a file)

# show flogi (view HBA’s or SP’s logged in)

# show fcns (nameserver database and statistics)

# show interface brief (summary of interface and ports, as well as connected devices)

**PORT EMULATION SHOWS AUTO:**

#show interface brief

fc1/3 1 auto on notConnected swl -- --

**CHANGING PORT EMULATION TO FX:**

MDS9509# config t

MDS9509(config)# interface fc1/3

MDS9509(config-if)# switchport mode FX

MDS9509(config-if)# do show interface brief

---

Interface Vsan Admin Admin Status FCOT Oper Oper Port

Mode Trunk Mode Speed Channel

Mode (Gbps)

---

fc1/1 1 auto on down swl -- --

fc1/2 1 SD -- up swl SD 1 --

**fc1/3 1 FX** -- notConnected swl -- --

**FIBER MEDIA :**

**Single-Mode Fiber :**

Longest distances, uses 9 micrometer cable and LongWave Laser (LWL), 10km

**Multi-Mode Fiber :**

50 or 62.5 micron cables using ShortWave Laser (SWL), 500 or 300 meters, respectively

**Note :** Lucent ‘LC’ Connectors support either Fiber Cable Type

**FIBRE CABLE LENGTHS FOR CELERRA:**

3, 5, & 10 meters

**FIBRE MEDIA SPECS:**

|                          | <b>LongWaveLaser</b> | <b>ShortWaveLaser</b> | <b>ShortWaveLaser</b> |
|--------------------------|----------------------|-----------------------|-----------------------|
| <b>Transmission rate</b> | <b>9 micron</b>      | <b>50 micron</b>      | <b>62.5 micron</b>    |
| 100MB/s                  | 10,000 meters        | 500 meters            | 300 meters            |
| 200MB/s                  | 2,100 meters         | 300 meters            | 150 meters            |
| 400MB/s                  | 2,100 meters         | 175 meters            | 90 meters             |

## **FIBRE CHANNEL FRAMES :**

Total frame is 2148 bytes, with 2112 bytes of data

Header consists of S-ID (Source ID), D-ID (Destination ID), & Frame Type (08=SCSI over FCP Type)

Address field=3 bytes, consisting of Domain ID, Logical Port Number, and AL\_PA Loop ID (00=Brocade ; 13=McData)

McData : Domain ID's from 1-31 range

Brocade : Domain ID's from 1-239

## **PORT ADDRESS USAGE BY TOPOLOGY:**

Arbitrated Loop Private : Does not use Domain ID or Logical Port Number, just AL\_PA

Arbitrated Loop Public : Uses all three (Domain ID, Port Number, & AL\_PA)

Switched Fabric : Uses only Domain ID & Port Number

## **RESERVED PORT ADDRESSES IN FC :**

FFFFFE—Fabric Login Server

FFFFFC—Directory Name Server

## **WORLD WIDE NAMES (WWN) :**

128-bit Unique Identifier in a Loop or Fabric [64 bits identifies Node—WWNN; next 64 bits identifies Port—WWPN]

### **WWPN:**

When referring to WWN's, we most commonly mean the World Wide Port Name, which is a unique 64-bit value

Recommended Zoning using WWPN be used (as opposed to the WWNN, which can change)

**Two types of WWN's:** WWPortNames and WWNodeNames

**WWN SUN HOSTS :** Grep for WWPN in /var/adm/messages for EMULEX & /qla2200 for Qlogic

**SYMMETRIX :** Inlines E1,,0 and E1,,1 (See WWN Hi and Lo)

NT>Programs>Emulex Configuration Tools>Doubleclick LP7000

### **Composition of WWN :**

1st 4-bits identify format

Next 24-bits identify company or OUI

Last 36-bits reserved for company use

### **OUI's :**

006069 = Brocade

00<sup>E</sup>002 = Crossroads

006048 = EMC

0000C9 = EMULEX

## **CELLERRA BLADE WWN's—8 Byte field: Mfg ID; HBA Port; WWN Seed:**

# .server\_config server\_2 -v "fcip show"

FCP ONLINE HBA 0: ALPA 000001 WWN: 500601603b200c8c QE4

FCP scsi-0: HBA 0: ALPA 0000ef SP-a00: 500601603b200c4d Class 3

FCP ONLINE HBA 1: ALPA 000001 WWN: 500601613b200c8c QE4

FCP scsi-16: HBA 1: ALPA 0000ef SP-b00: 500601683b200c4d Class 3

# server\_log server\_2 -s |grep -i wwn

2009-03-23 12:47:45: FCP: 6: ONLINE HBA 0: ALPA 000001 WWN: 500601603b200c8c →Blade WWN HBA0

2009-03-23 12:47:50: FCP: 6: ONLINE HBA 1: ALPA 000001 WWN: 500601613b200c8c →Blade WWN HBA1

**500601603b200c8c**

→500601 represents Mfg ID

→60 represents HBA port, in this case HBA 0

→3b200c8c represents the WWN Seed, from enclosure\_0 resume prom

## **SWITCHED FABRIC LOGIN PROCESS :**

I. FLOGI—Fabric Login Table—each Host or Disk requires an FC ID. After HBA Link or Loop is initialized, Node Port transmits FLOGI frame to Well-Known Fabric Port "FFFFFE"—receives 'ACC' response if successful from Name Server. If a device logs in successfully, it will display in the FLOGI table.

### **Information Registered with FFFFFC Directory Service :**

S\_ID—Port Identifier ; PN—WWPort Name of N\_Port ; Class of Service—Class 3 ; FC-4 Types—SCSI-3 ; Port Type—N\_Port

II. PLOGI—Port Login. Node conducts 'N\_Port' login by transmitting PLOGI frame to destination N\_Port node—receives 'ACC' frame if successful. Process whereby a Port registers with Name Server and obtains attributes of other hosts.

### **Typical Port Login Exchange between Nodes :**

Host Address—S\_ID ; Frame Size—Buffer Size ; Flow Control & Version—TOVs ; Port Name--WWPN

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
III. PRLI—Process Login. SCSI 3 requires a process login so that SCSI protocol can BIND with FC protocol—Applications.

#### **MAPPING OF SCSI-3 to FCP :**

FCP\_CMND—Send SCSI Command service

FCP\_XFER\_RDY—transports offset & requests byte count objects of Send Data-In and Receive Data-Out Services

FCP\_DATA—Transports data object of Send Data-In and Receive Data-Out protocol

FCP\_RSP—Send Command Complete

**RSCN:** Registered State Change Notification is a FC Service that informs hosts about changes in the fabric (SCR), but each Hosts much query the Name Server to obtain the new information.

#### **TROUBLESHOOTING INLINES :**

A7,B or E7 : Check Volumes seen on FA Port

Run INQ query tool from Host

8F : Shows FA Status, Bit Settings, & Login History (Use command to determine if logged into switch)

E0 : Run to see if FA port sees light (not login)

FC,AAAA : Fibre Channel commands

#### **ISL Fibre Channel Limitations for Celerra:**

Celerra HBA's must be physically connected to the same switch as the Symmetrix FA's. This is a known Celerra limitation since the Celerra boots from devices on the Symmetrix and this is not presently negotiated successfully across the Interswitch Link [ISL] between the two fibre channel switches. The Celerra FA's cannot boot from Symmetrix if connected to multiple Fibre Channel Switches that are connected together using ISL. Up to (4) ISL's can be integrated together.

--If using ISL, use only in-family switches (i.e., brocade to brocade, etc)

--Zone switches using only WWN, not Port Zoning, which does not work well with ISL's

--Use only single switch-to-switch ISL link—multiple switches not supported

**Note:** The term “cascading” is commonly used to denote that an ISL is in use. The term “trunking” is generally applied to Brocade’s method of using multiple ISL’s as a single high-bandwidth trunk.

#### **Symptoms:**

--Celerra HBA's have valid Binding Tables and are logged into the fabric and Symmetrix FA's, yet upon booting up, cannot see Symmetrix devices. Performing setup\_slots does not correct this condition.

--Celerra might actually boot up to a "Contacted 5" state, yet in actuality, root filesystems are not mounted. When running the \$server\_devconfig -probe command, no Symmetrix devices are visible.

--Celerra will boot up successfully from Symmetrix if the Symmetrix FA is connected to the "same" Fibre Switch as the Celerra

--Celerra will not boot up or setup\_slot when the Celerra FBA is connected to (1) Switch and the Symmetrix FA is connected to a (2nd) ISL-linked Switch

#### **Fibre Channel Adapter/Switch Adapter :**

Connectrix SCB Spider—DP3-SCB1/DP3-SCQ1 [Microcode 5567.38.22; SYMAPI 4.3.1; NAS 2.2.49.2 +]

4 Port FA—DP3-FCD4/DP3-SCD44

**Latest 4-Port FA for Symmetrix :** DP3-FCD42G [2GB FA with minimum 5567 microcode]

#### **IBM LTO ULTRIUM TAPE DRIVE:**

**Problem:** \$server\_mt server\_3 -f tape1 status

Cannot format the device

**Cause:** I/O Check condition is occurring and sense information cannot be obtained from server\_mt command

**Fix:** Change ‘Host Type’ on Pathlight from ‘Generic’ to ‘autosense/NT’

#### **CELLERRA TIMEOUT PROBLEM:**

IBM Ultrium LTO2 Fibre Tape drives have timeout value of 17 minutes while Celerra has a timeout of 3 minutes. This can cause backup failures if we timeout too soon while waiting for tape device to reply to commands. NAS 5.1.20.4012 & higher will increase our timeout to (30) minutes.

**Symm Inlines :** FC,SWIT,A ; FC,FABR,A ; E1,,0 ; E1,,1 ; 8F,,,0 ; 8F,,,1

#### **Fibre Channel BIN File Director Flag Settings :**

PP, UWN, SCSI T & ARB, VCM [if using VL] are SELECTED; A, NP, TP, GVSA, VCM, C2S, and SCSI C are CLEARED

**BIN File :** FC (3) digits represent Virtual Bus, Virtual TID, and Virtual LUN. SCSI (2) digits represent Target ID and LUN.

#### **FAN-IN & FAN-OUT TOPOLOGY:**

Fan-In typically implies that there are (6) DataMover FBA's zoned with (2) Symmetrix FA's

A 32-port fibre switch can therefore support (24) datamover links to (4) Symmetrix links

Fan-Out implies that a single datamover can be zoned to see up to (6) symmetrix devices [3 symm's @2FA's each]

### **Fibre Channel DataMovers:**

Use only FC connection to Symmetrix!! SCSI Adapter is for Tape Drive support!!

HA—Each DM Fibre Port should be connected to the Fabric via a distinct data path, and then to different blades on the Fibre Switch—also, connections between Switch and SYMM FA should be on different switch blades. In otherwords, both ports should see same volumes but via different FA port and from different FA cards!

Identifying DataMover WWNames in Server Log: **\$server\_log server-x -a | grep WWN**

New 2GB Emulex LP9002 HBA's for 510 Datamovers will show WWN using **\$server\_sysconfig server\_x -pci**

### **Fibre Channel Zoning for DataMovers:**

--Single HBA Zoning—Single DM HBA port is zoned to one or more FA ports (i.e., multiple Symm FA's)—conversely, an FA may reside in multiple Zones

**Note:** One good reason for this is that it cuts down amount of time required for resets after Registered State Change Notifications (RSCN) & only ports within same Zone will have to log back into the Fabric. It also most closely resembles the 'single initiator' mode of SCSI.

--Both DM HBA Ports should see same Volumes but map via different FA Port and FA card on SYMM

--Keep each DM HBA port in separate Zone for load balancing

--Each DM FC HBA Port should be connected to Switches with low-numbered Ports (& each to different switches for HA)

--SYMM FA Ports should be connected to Switches with high-numbered Ports

--DM HBA Ports need to be zoned at switch for multiple SYMMS

-- Standby DataMover should be connected to a different Symmetrix FA Port

--DataMover & Control Station can share the same FA Port, but this is not recommended!!

### **How to Zone New Datamover FC HBA's Using Connectrix Switches:**

Step 1. If using Connectrix Switches, setup Port-to-Port Zoning for Datamovers to be upgraded using Connectrix Manager

Step 2. After Hardware install and setup\_slot, reconfigure Connectrix Zones for WWN

**Note:** This can all be done "on-line" and without any interruptions for a Connectrix Switch but not for a Brocade!!

### **FibreChannel Celerra Configuration:**

--Control Station must use Target & LUN 0/0. If a previous configuration of Volume Logix [aka, VCM] on the Symmetrix has used TID 0/0, then the VolumeLogix must be moved!

--Maximum of 14FA ports per Symmetrix [7 FA's with 2 ports each]

### **FibreChannel Failover on DM:**

--Upper port used for booting

--If either port is disconnected, other port will assume all traffic but could take up to 2 minutes for this transition to occur

--If both ports are disconnected, DMF will occur within 2 minutes

--Should never disconnect Fibre Cables from DMs online

**Comment:** Current NAS behavior is as follows: Loss of a single path will cause HBA to failover to alternate controller and port. Loss of both paths will initiate data mover failover to Standby server.

### **MIGRATING DATAMOVER FIBER CABLES FROM ONE SWITCH TO ANOTHER:**

1.) Match cables by name to respective Switch Ports

2.) Match WWNs on Celerra HBA's to respective Switch ports

3.) Create new Zonesets for new Switch Ports and HBA Ports

4.) Use Standby Server as test and move FC Cable to new Switch port

5.) Confirm connectivity to Symm down new path by using **server\_devconfig -p -s -a**

6.) Failover Primary Servers to Standby Server first, then move Cable paths on each Primary Slot

### **MOVING HBA1 FROM ONE FA TO ANOTHER :**

**Intro:** Moving Fibre HBA1 from Even FA to an Odd FA

1. Create new zoneset and activate

2. Servers need to reboot in order to update binding tables for new FA WWN

3. Do **server\_devconfig -probe** to ensure that DM can see symm devices down both FA's

4. Conduct **server\_devconfig -create** in order to update database files

5. Reboot server to allow kernel to register new volume information

### **REMOVING FA FROM DM AND ADDING A NEW FA:**

1. Document current configuration:

#/nas/sbin/log\_config →Monthly dial home script that produces output of Celerra configuration and information

#.server\_config ALL -v "fcp show" →Shows which channels are online

#.server\_config ALL -v "fcp bind show" →Shows current binding table  
#nas\_volume -i -a →Shows current information on Controll, Target, and LUNs  
#server\_devconfig -p -s -a & -l -s -a →Devices in NAS database & verifying Access Logix use  
#/nas/symcli/bin/symbcv list →Split any bcv's off first as seen from nas\_disk -l  
2. Stop CIFS on all DM's  
3. Permanently unmount all file systems on DM's [Save copy of mount file first]  
4. Clear binding tables: \$.server\_config ALL -v "fcp bind clear"  
5. Confirm by running: \$.server\_config ALL -v "fcp bind show"  
6. Halt all DM's: \$server\_cpu server\_x -h now  
7. Activate new zoneset for new FA  
8. Reboot data movers and confirm that new FA is being seen by running "fcp bind show"  
9. Create new chains in Celerra camdisk database by running \$server\_devconfig server\_x -c -s -a  
10. After verifying that all devices are visible down both paths, remount all File Systems and start CIFS  
11. Update SYMAPI database: #mv /nas/symapi/db/symapi\_db.bin & #/nas/sbin/nas\_rcf -localinit & #/nas/sbin/nas\_rdf -init

## **CELERRA WWN's:**

**\$ /nas/sbin/setup\_backend/zone -s 2 showdm** (command to collect WWN's for DMs)

Checking for Data Mover 2.

Collecting Data Mover WWNs...Done.

DM List:

DM Port:20 WWN:50:06:01:60:90:60:16:f8:50:06:01:60:10:60:16:f8  
DM Port:21 WWN:50:06:01:60:90:60:16:f8:50:06:01:61:10:60:16:f8  
DM Port:22 WWN:50:06:01:60:90:60:16:f8:50:06:01:62:10:60:16:f8  
DM Port:23 WWN:50:06:01:60:90:60:16:f8:50:06:01:63:10:60:16:f8

## **EXAMPLE OF 'PROBLEM' BINDING TABLE:**

**# .server\_config server\_2.faulted.server\_3 -v "fcp bind show"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0002: WWN 50060482c0946954 HBA 0 FA-05ba Bind Pending →Problem—not bound to Fabric—no path to backend  
Chain 0018: WWN 50060482c094695b HBA 1 FA-12ba Bind Pending →Problem—not bound to Fabric—no path to backend  
Chain 0034: WWN 50060482c4698712 HBA 0 FA-03ba Bound →Only real path to backend, though Chain 0034 is not normal  
Chain 0050: WWN 50060482c469871d HBA 1 FA-14ba Bind Pending →Problem—not bound to Fabric—no path to backend  
\*\*\* Dynamic Binding Table \*\*\*

Chain 0002: WWN 0000000000000000 HBA 0 ID 0 Inx 00:81 Pid 0002 S\_ID 000000 Non  
Chain 0018: WWN 0000000000000000 HBA 1 ID 1 Inx 01:81 Pid 0018 S\_ID 000000 Non  
Chain 0034: WWN 50060482c4698712 HBA 0 ID 0 Inx 02:00 Pid 0034 S\_ID 691013 Sys  
Chain 0050: WWN 50060482c469871d HBA 1 ID 1 Inx 03:00 Pid 0050 S\_ID 6a1013 Sys

**Note:** Run "fcp show" to display WWNs for Data Mover HBAs

## **DEVCONFIG PROBE SHOWS SINGLE PATH ONLY:**

**chain= 34, scsi-34**

```
symm_id= 000185706012 celerra_id= 0001857060120563
tid/lun= 0/0 type= disk sz= 4153 val= 1 info= 556812563300
tid/lun= 0/1 type= disk sz= 4153 val= 2 info= 556812565300
tid/lun= 0/2 type= disk sz= 2076 val= -99 info= 556812567300 diskerr= unmarked
tid/lun= 0/3 type= disk sz= 2076 val= -99 info= 556812568300 diskerr= unmarked
tid/lun= 0/4 type= disk sz= 2076 val= -99 info= 556812569300 diskerr= unmarked
tid/lun= 0/5 type= disk sz= 2076 val= -99 info= 55681256A300 diskerr= unmarked
tid/lun= 0/15 type= disk sz= 3 val= -99 info= 55681256B300 diskerr= unmarked
tid/lun= 1/0 type= disk sz= 34856 val= 3 info= 556812533300
tid/lun= 1/1 type= disk sz= 34856 val= 4 info= 556812537300
```

**Note:** Problem here is that only a single path has true connectivity to the backend, as seen by Chain 0034 "Bound". Chains 0002, 0018 & 0050 show "Bind Pending" and no I/O can traverse any of these Chains. The other problem is that this is Fibre Channel, and the normal Chains that should be bound for dual FBA's are Chains 02 & 18, not 34 or higher. This Server's Binding Tables require immediate repair as there is no failover to the Backend, only a single path.

## **REBUILDING BINDING TABLES**

## **CLEARING BINDING TABLES & UPDATING CELERRA CAMDISK DATABASE:**

**Warning!** The following procedure should not be conducted without TS2 consult. Special care must be taken on systems with multiple storage backends, which may require temporary suspension of zones for the secondary storage systems, and other additional steps. Clearing the Binding Tables is potentially a very destructive action that could result in the entire loss of data on any file system mounted to the Server and should not be done on the “production” server’s slot—the primary means of clearing binding tables should be done by failing over the Server to its standby, then performing the binding table work on the unused slot.

### 1. Run “fcp bind show” on Production Server to document, then failover to Standby Server

### 2. Clear the Binding Table on the “unused” non-production faulted slot:

```
# .server_config server_2.faulted.server_3 -v "fcp bind clear 2"
```

**Note:** If you absolutely have to run on production slot and there are multiple backends, permanently unmount the production file systems before using this procedure. This action clears the persistent bind table.

### 3. Verify above action:

```
# .server_config server_2.faulted.server_3 -v "fcp bind show"
```

\*\*\* Persistent Binding Table \*\*\*

\*\*\* Dynamic Binding Table \*\*\*

```
Chain 0002: WWN 0000000000000000 HBA 0 ID 0 Inx 00:81 Pid 0002 S_ID 000000 Non
Chain 0018: WWN 0000000000000000 HBA 1 ID 1 Inx 01:81 Pid 0018 S_ID 000000 Non
Chain 0034: WWN 50060482c4698712 HBA 0 ID 0 Inx 02:00 Pid 0034 S_ID 691013 Sys
Chain 0050: WWN 50060482c469871d HBA 1 ID 1 Inx 03:00 Pid 0050 S_ID 6a1013 Sys
```

### 4. Conduct Setup Slot on Unused Slot:A

```
# /nas/sbin/setup_slot -init 2
```

Initializing server in slot 2 as server\_2.faulted.server\_3

Discover disks attached to server in slot 2 ...

server\_2.faulted.server\_3 : done

server\_2.faulted.server\_3 :

Warning 4017: server\_2.faulted.server\_3 : is out\_of\_service, use server\_standby  
to fix

Error 4008: server\_2.faulted.server\_3 : is restricted dart

**Note:** Do not be alarmed by the error messages—allow the setup\_slot to complete

### 5. Verify Binding Tables were rebuilt:

```
# .server_config server_2.faulted.server_3 -v "fcp bind show"
```

\*\*\* Persistent Binding Table \*\*\*

```
Chain 0002: WWN 50060482c4698712 HBA 0 FA-03ba Bound →Chain now correctly bound
```

```
Chain 0018: WWN 50060482c469871d HBA 1 FA-14ba Bound →Chain now correctly bound
```

\*\*\* Dynamic Binding Table \*\*\*

```
Chain 0002: WWN 50060482c4698712 HBA 0 ID 0 Inx 00:00 Pid 0002 S_ID 691013 Sys
```

```
Chain 0018: WWN 50060482c469871d HBA 1 ID 1 Inx 01:00 Pid 0018 S_ID 6a1013 Sys
```

### 6. Conduct Devconfig Probe:

```
# server_devconfig server_2.faulted.server_3 -p -s -a
```

server\_2.faulted.server\_3 :

SCSI devices :

chain= 0, scsi-0 : no devices on chain

chain= 1, scsi-1 : no devices on chain

**chain= 2, scsi-2**

symm\_id= 000185706012 celerra\_id= 0001857060120563

tid/lun= 0/0 type= disk sz= 4153 val= 1 info= 556812563190

tid/lun= 0/1 type= disk sz= 4153 val= 2 info= 556812565190

-----abridged-----

**chain= 18, scsi-18**

symm\_id= 000185706012 celerra\_id= 0001857060120563

tid/lun= 0/0 type= disk sz= 4153 val= 1 info= 556812563300

tid/lun= 0/1 type= disk sz= 4153 val= 2 info= 556812565300

### 7. Conduct Devconfig –create to update Camdisk File (if required):

```
# cat camdisk
```

1:c34t0l0+556812563190+,c50t0l0+556812563300+:

2:c34t0l1+556812565190+,c50t0l1+556812565300+:

3:c34t1l0+556812533190+,c50t1l0+556812533300+:

**Note:** Camdisk may not always be completely updated after setup\_slot!

```
# server_devconfig server_2.faulted.server_3 -c -s -a
```

server\_2.faulted.server\_3 : done

**#cat camdisk**

```
1:c2t0l0+556812563190+,c18t0l0+556812563300+:  
2:c2t0l1+556812565190+,c18t0l1+556812565300+:
```

**8. Reboot Data Mover to refresh memory with correct device list, and verify Binding Tables and Probe again**

**9. Fail production Server back to home slot**

**ALTERNATE PROCEDURE TO CORRECT TRESPASSED LUNS AND UPDATE CAMDISK FILES:**

**Situation:** Use this procedure if the binding tables do not need to be rebuilt—correcting for trespassed luns. Situation is that camdisk files do not show all (4) paths to backend, though when probe is conducted, all (4) paths are visible. Previous attempts to trespass luns back to Owner SP have failed.

**Step 1 Verify Trespassed Luns:**

**# /nas/sbin/navicli -h 10.241.168.57 getlun -tresspass -status**

**Note:** Best way to see if there are trespassed luns—will show all trespassed luns, regardless of which SP used to run cmd

**# /nas/sbin/navicli -h 10.241.168.57 getlun 5 legrep "Default|Current"** (checking status on single lun)

Current owner: SP A

Default Owner: SP A

**#/nas/sbin/navicli -h <ip of spa> getlun -default -owner**

**Note:** Try to fail luns back to correct SP Owner—if that fails, then proceed with step 3

**Step 2 Verify Chains using Probe for each Data Mover:**

**#server\_devconfig server\_x -p -s -a**

**Step 3 Temporarily Unmount all Production File Systems and Verify:**

**#server\_umount ALL -a**

**#server\_mount ALL**

**Step 4 Trespass each Lun to Respective SP Owner:**

**# /nas/sbin/navicli -h <ip of spx> trespass lun <lun#>**

**Step 5 Confirm that LUNs remain on Owner:**

**# /nas/sbin/navicli -h <ip of spa> getlun -default -owner**

**# /nas/sbin/navicli -h 10.241.168.57 getlun -tresspass -status**

**Step 6 Conduct Devconfig -create to Update Camdisk:**

**#server\_devconfig server\_x -c -s -a**

**Step 7 Verify Camdisk files and Probe matches:**

**#ls -la /nas/server/slot\_x/camdisk\***

**#server\_devconfig server\_x -p -s -a**

**Step 8 Remount all File Systems:**

**#server\_mount ALL -a**

**USING TS2 NAVILUN14.PL BACKEND CHECK SCRIPT (SangDon Shin):**

→Checks status of Backend luns

→Detects any trespassed luns and can fail them back if desired

→Displays Celerra HBA login status from SP perspective

→Displays fs disk & RG information and status of physical disks

→Checks validity of HBA-to-Storage Group relationship

**CLEARING & REBINDING FCP TABLE:**

**# .server\_config server\_2 -v "fcp bind show"**

**# .server\_config server\_2 -v "fcp bind clear"** →clears persistent bind table

**# .server\_config server\_2 -v "fcp bind rebind"** →Recreates persistent bind table

**Note:** Reboot Data Mover

**# .server\_config server\_2 -v "fcp show"**

**# .server\_config server\_2 -v "fcp bind show"**

**# .server\_config server\_2 -v "camshowconfig" (Luns 0-6 on Chains 00)**

**Other Commands:**

**# .server\_config server\_2 -v "fcp bind showbackup 2"**

**# .server\_config server\_2 -v "fcp bind restore"**

**# .server\_config server\_2 -v "fcp rediscover=Y"** [where Y = HBA0 or HBA1]

```
# .server_config server_2 -v "fcportreset=2" [forcing HBA2 to log back into fabric]
# .server_config server_2 -v "fc init"
# .server_config server_2 -v "fc rescans"
```

### **AVAILABLE FIBER CHANNEL COMMANDS IN NAS 5.5:**

**Caution:** These are not trivial options—do not experiment on customer systems!

```
# .server_config server_2 -v "help fc"
```

**Usage:**

'fc' options are: bind ..., flags, locate, nsshow, portreset=n, rediscover=n rescan, reset, show, status=n, topology, version  
 'fc bind' options are: clear=n, read, rebind, restore=n, show showbackup=n, write

**Description:**

Commands for 'fc' operations:  
 fc bind <cmd> ..... Further fibre channel binding commands  
 fc flags ..... Show online flags info  
 fc locate ..... Show ScsiBus and port info  
 fc nsshow ..... Show nameserver info  
 fc portreset=n ..... Reset fibre port n  
 fc rediscover=n ..... Force fabric discovery process on port n Bounces the link, but does not reset the port  
 fc rescan ..... Force a rescan of all LUNS  
 fc reset ..... Reset all fibre ports  
 fc show ..... Show fibre info  
 fc status=n ..... Show link status for port n  
 fc topology ..... Show fabric topology info  
 fc version ..... Show firmware, driver and BIOS version

**Commands for 'fc bind' operations:**

fc bind clear=n ..... Clear the binding table in slot n  
 fc bind read ..... Read the binding table  
 fc bind rebind ..... Force the binding thread to run  
 fc bind restore=n ..... Restore the binding table in slot n  
 fc bind show ..... Show binding table info  
 fc bind showbackup=n .. Show Backup binding table info in slot n  
 fc bind write ..... Write the binding table

### **VIEWING FIBRE CHANNEL STATISTICS ON CELERRA HBA's:**

1. Set FCP Stats on HBA's:

```
$ .server_config server_5 -v "printstats fc reset"
```

FCP stats Reset and Enabled

2. Review statistics:

```
$ .server_config server_5 -v "printstats fc"
```

Total I/O Cmds: +0%-----25%-----50%-----75%-----100%+ Total 10

|                                               |    |

  +-----+
  +-----+
```

**Note:** Available 5.4 only

### **MOVING DM FROM ONE SWITCH TO ANOTHER:**

1. Clear persistent binding table on Standby Server
2. Failover Production Server to Standby
2. Clear binding tables on original Server slot [faulted]
3. Halt faulted DM and move Switch connections
4. Activate new Zone set on switches
5. Reboot faulted DM & confirm binding tables
6. Run server\_devconfig on faulted mover
7. Failback server

### **CAUSES FOR DATA MOVER CHANNELS TO GO OFFLINE, REQUIRING PORT RESET:**

--reboot of FC Switch [Brocade firmware upgrade requires reboot of switch]  
--removal of Zone to tape library may not stop probing of devices until reset is done  
--zoning to remove a path, then adding back may require port reset  
--firmware upgrades on Connectrix  
--cable was out during DM boot

### **HOW TO CONDUCT FCP PORT RESET ON DATA MOVER HBA's:**

1. Verify HBA Paths that should be available:

**# .server\_config server\_2 -v "fc bind show"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 50060167006007c0 HBA 0 SP-a7 Bound

Chain 0016: WWN 5006016f006007c0 HBA 1 SP-b7 Bound

2. Verify IO counts by running the following command several times:

**# .server\_config server\_2 -v "printstats scsi"**

Controller: IO-pending Max-IO IO-total Idle(ms) Busy(ms) Busy(%)

|  | 0:  | 17 | 217611 | 342359404 | 614656 | 0% |
|--|-----|----|--------|-----------|--------|----|
|  | 16: | 16 | 100016 | 342931080 | 38781  | 0% |

3. Issue Port Reset on affected HBA:

**# .server\_config server\_2 -v "fc portreset=0"**

1142623373: DRIVERS: 4: FCDMLT 0 [2.4.1] Scsi Port Bus Reset

1142623373: DRIVERS: 4: FCDMLT 0 [2.4.1] TPM Notify: st=0xa000002, flg=0x200, cmd=0x1

1142623373: DRIVERS: 4: FCDMLT 0 [2.4.1] Auto Neg Speed : In sync fmstat=0x80000000

1142623373: DRIVERS: 4: FCDMLT 0 [2.4.1] Auto Neg Speed : Current Speed: 2Gbps

4. Verify IO Total increases on affected path:

### **VIEWING PERSISTENT BINDING TABLE INFORMATION:**

**#/nas/sbin/workpart -r**

**NAS 5.3.18 Version:**

**# /nas/sbin/workpart -r**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

workpart\_magic = **0xfacebeaf** →Unique signature for NAS 5.3

**NAS Version 5.4.20:**

**# /nas/sbin/workpart -r**

Read Work Partition layout from LBA 0x43000, 528384 bytes.

After read:

Dump of Work Partition Structure (size 528384 bytes):

workpart\_magic = **0xbeaf0001** →Unique signature for NAS 5.4

### **DETERMINING IF WORKPART HAS BEEN UPGRADED TO NAS 5.4/5.5 OR HIGHER:**

**# /nas/sbin/workpart -c** (this check command is only avail. With 5.4+)

Newer Version Workpart Layout Found!

134

# /nas/sbin/rootnas\_volume -s root\_rdf\_channel (systems prior to 5.4 are 1 MB in size)

total = 2 avail = 2 used = 0 ( 0% ) (sizes in MB)

## **VolumeLogix:**

**Set IMPL flag to A080 if using Volume Logix with Celerra** (Normally set to 000 if no Celerra present).

**Purpose:** Once turned on, Volume Logix allows access to only those volumes behind FA ports that are configured to be accessed by a Host. Volume Logix is a combination of Symm Microcode and host-based software (NT or Sun) used to control Volume access in Fibre Channel environments. VolumeLogix issues a SCSI “not ready” to Hosts that are not “assigned” or granted “access” to volumes in the VCM database. WWN’s of each Host HBA is put into a Table on the Symm FA Port. VCMDB is constructed from WWN’s and volumes behind the FA’s.

### **SYMMETRIX:**

Symm 4, microcode 5265.49.31, 16-cylinder Gatekeeper which stores the VCMDB

Volume Logix flag can be turned on each individual FA port

**BIN File Settings:** Set Director port bits: T, ARB, UWN, PP, and VCM if using VolumeLogix

### **IMPL Flag=A080**

Use “SO” Host Emulation if using VolumeLogix in Mixed Host environment!

Use “S” Host Emulation if using only Celerra Hosts

Set VCM GateKeeper volume Target & Lun “FE” [NAS Versions 2.2.25.5 & Lower ONLY]

Set VCM GateKeeper volume Target & Lun “OE” [NAS Versions 2.2.25.5 & Higher]

**Note:** DataMovers and Control Station can share same FA port if using Volume Logix

**Server Devconfig Output:** Look for “SZ=7” for VCM Gatekeeper [7MB=16 cylinders]

**Fibre Channel Symmetrix Flags for BIN File Setup of Celerra:** FBA Host=SERVER\_CELERRA\*; FBA IMPL Flags=A000; FBA Multi-Access = Yes; PP=Selected [Point-to-Point enabled]; UWN=Selected; SCSI Flags “T” and “ARB”=Selected; SCSI Flag “C”=Cleared; VCM=Selected if using Volume Logix; A, H, V, NP, TP, GVSA, C2S Flags=Cleared; [\*FBA Host=Mixed if a Sun Host and Celerra will be connected to the Symmetrix]

### **Fibre Channel Media & HBA Adapters:**

Emulex LP-8000DC HBA’s [Dual ports per adapter; Full Duplex 100MB/sec; Multimode cabling using SC Connectors]

Fiber optic cable; 50/125mm and 62.5mm, with distances of 500 & 300 meters between ports

**Note:** Yellow or Green light should activate when connecting HBA port [N\_Port] to Switch port [E\_Port]

### **Fibre Channel Switches: “Class 3 Switching”**

Brocade SilkWorm 2800 [aka, Connectrix DS-16B]; 16 Ports; 16 ZoneSets [Each ZoneSet can have up to 256 Zones]

### **Connectrix ED-1032 Cabinet:**

Houses up to (2) ED-1032 Switches; Version 2.0 for each switch=32 ports; 64 ZoneSets

[256 Zones/set]; Version 1.0 has capacity of 16 zone sets for 31 zones per set

**Note:** Connect Celerra or Host connections to low-numbered ports and Storage-side connections to high-numbered ports  
Connectrix Switch has two WWN’s—Port WWN=Connectrix Port; Attached Port WWN=Attached Celerra or Symm WWN  
McData ES-5000

### **Fibre Channel Port Zoning:**

1. Use Symmetrix Volume Management [bin file map] to control FA ports; setup special FC flags on Symm
2. Use Connectrix or DS-16B switches to configure initial Connectrix Zoning
3. Symm should have VCM 16-cyl Gatekeeper Device configured for “Volume Logix” volume manager--must be visible to all FA ports Volume Logix would be used on a Unix Client to manage the Zoning; also can do Zoning from Switch
4. Symm FA Config: WWNaming; Point-to-Point for SW
5. Volume Logix: Software used to control access of Fibre Channel fabric date & Symm FA port devices. All FA ports should see Volume Logix gatekeeper

### **Fibre Channel Zoning Rules:**

Zone by WWN of Celerra HBA or WWN or Symmetrix FA Port

Each Celerra HBA Port should reside within its own Zone, that is, no other HBA’s in the same zone

A Symmetrix FA Port can reside in Multiple Zones, making it available to Multiple DataMovers

Both Ports on a Celerra HBA must see same Symmetrix volumes but be connected to different Symmetrix FA Ports for HA Standby DM HBA Boot Port should be on different FA Port than Primary DM HBA Boot Port

Fan-In Ratio: Up to (6) HBA Ports per Symm FA Port allowed; i.e., 6 HBA Adapters per Zone, different DataMovers

## **FIBRE CHANNEL TOPOLOGY ON GATEWAY:**

**\$ .server\_config server\_2 -v "fc topology"**

FCP HBA 0: F\_PORT D\_ID FFFFFC Node 100000051e0419e4 Port 100000051e0419e4 →D\_ID WWNs for Clariion

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

FCP HBA 0: N\_PORT S\_ID 890900 Node 50060160b9a00e09 Port 5006016039a00e09 →S\_ID WWNs for Celerra  
FCP HBA 0: scsi-000 D\_ID 8a1c00 Node 5006016090600510 Port 5006016210600510

FCP HBA 3: OFFLINE ALPA 000001 Node 50060160b9a00e09 Port 5006016339a00e09

### **FIBRE CHANNEL TOPOLOGY ON INTEGRATED:**

**# .server\_config server\_2 -v "fc topology"**

FCP HBA 0: FC-AL ALPA 000001 Node 50060160c1e05335 Port 5006016041e05335  
FCP HBA 0: scsi-000 ALPA 0000ef Node 50060160c1e043a3 Port 5006016241e043a3  
FCP HBA 1: FC-AL ALPA 000001 Node 50060160c1e05335 Port 5006016141e05335  
FCP HBA 1: scsi-016 ALPA 0000ef Node 50060160c1e043a3 Port 5006016a41e043a3  
FCP HBA 2: OFFLINE ALPA 000001 Node 50060160c1e05335 Port 5006016241e05335  
FCP HBA 3: OFFLINE ALPA 000001 Node 50060160c1e05335 Port 5006016341e05335

### **VIEWING DM BINDING TABLES:**

**\$ .server\_config server\_6 -v "fc bind show"**

\*\*\* Persistent Binding Table \*\*\*

Chain 0002: WWN 50060482bfd1fb0c HBA 0 FA-13a

Chain 0018: WWN 5006048000000000 HBA 1 FA-01a

\*\*\* Dynamic Binding Table \*\*\*

Chain 0002: WWN 50060482bfd1fb0c HBA 0 ID 0 Inx 00:00 Pid 0002 S\_ID 211413 Sys

Chain 0018: WWN 0000000000000000 HBA 1 ID 1 Inx 01:81 Pid 0018 S\_ID 000000 Non

FCP Base Chain: 2, Dump Chain: 2, Dump Slot: 6

Adapter Chain Offset 0:2:2 1:18:18

Existing CRC: 8a86935d, Actual: 8a86935d, CRC Matchs

**Commentary:** Above example shows an inconsistent Binding Table--evidenced by multiple zeroes. In this example, it may be that someone rezoned the Connectrix for Slot\_6, or disconnected the Fibre Port, etc. Any zone changes made to the Celerra that changes Port Channel assignments are reflected immediately in the Binding Table. Datamovers conduct "Persistent & Dynamic Bindings".

### **INTERPRETING OUTPUT OF "fc bind show":**

S\_ID refers to the Fibre Zone & Switch ID: 01=Zone 00=Brocade [011f00 Sys]

"Sys" means that this port is connected to a LUN0 (usually system or boot device), while "Non" would indicate a non-system volume

**# cat slog3.jan28 |grep -i wwn**

2005-01-27 08:50:11: CAM: 4: FCP ONLINE HBA 0: S\_ID 690913 WWN: 10000000c9394790 →Data Mover WWN HBA 0

2005-01-27 08:50:17: CAM: 4: FCP ONLINE HBA 1: S\_ID 610913 WWN: 10000000c9394791 →Data Mover WWN HBA 1

**Note:** The "13" represents a McData switch

2005-05-10 16:30:06: FCP: 4: ONLINE HBA 0: ALPA 000001 WWN: 5006016810601550 (direct-connect)

2005-05-10 16:30:10: FCP: 4: ONLINE HBA 1: ALPA 000001 WWN: 5006016910601550 (direct-connect)

### **RECOMMENDED CONNECTRIX ZONING WITH MULTIPLE SWITCHES:**

--All Boot ports should be connected to one switch

--All non-boot ports should be connected to the other switch

**LINUX CONTROL STATION:** Linux Fibre Channel does only "Dynamic Binding Table" updates. Also, Slot\_2's GateKeeper is the default gatekeeper that the Control Station uses. If slot\_2 is not working, will go to next GateKeeper on list for /nas/dev

### **DETERMINING WWN FOR BOTH CELERRA & SYMMETRIX HBA:**

**1. .server\_config server\_3 -v "fc show"**

FCP ONLINE HBA 0: ALPA 000001 WWN: 5006016810601550 DX2 [DataMover WWN S\_ID]

FCP scsi-0: HBA 0: ALPA 0000ef SP-a1: 500601611060172f Class 3 [Symmetrix WWN D\_ID]

FCP ONLINE HBA 1: ALPA 000001 WWN: 5006016910601550 DX2 [DataMover WWN S\_ID]

FCP scsi-18: HBA 1: D\_ID 021000 FA-14a: 50060482bfd1fad Class 3

1015516486: ADMIN: 4: Command succeeded: fc show

**Note:** This command will also indicate whether HBA is ONLINE or OFFLINE

ONLINE means that the HBA is logged into the Switched FC Fabric & has a physical connection

## 2. \$ server\_log server\_2 -a -s |grep -i wwn

```
2005-12-23 21:19:05: FCP: 4: ONLINE HBA 0: S_ID 614113 WWN: 10000000c92e6cb1 (DM HBA0 WWN)  
2005-12-23 21:19:12: FCP: 4: ONLINE HBA 1: S_ID 613213 WWN: 10000000c92e6cb2
```

## **CORRECTING INCONSISTENT BINDING TABLES FOR CELERRA FIBRE HBA's:**

**Caution:** Do not run fcp bind clear or init if multiple backends are involved & never without TS2 advice!

Step 1. Run the "fcp bind show" on the Server that is being rezoned or moved from one FA Port to another & record the info

Step 2. \$ls /nas/dev [Record GateKeeper info; shows all GK's in use by SLOT #--pay attention to the Chain being moved or rezoned--this will be removed later]

```
c18t0l15s2 c18t0l15s5 c2t0l15s3 c2t0l15s5 c18t0l15s6  
c18t0l15s3 c2t0l15s2 c2t0l15s4 c2t0l15s6
```

Step 3. Conduct the actual Zone changes on the Connectrix, etc.

Step 4. Reboot DataMover\_6 [in this example]

Step 5. Verify Binding Table ["fcp bind show"]

Step 6. Probe to create new devices for Slot\_6: \$server\_devconfig server\_6 -p -s -a | -c -s -a

Step 7. #cd /nas/dev & remove the GateKeeper for Slot\_6: **c18t0l15s6**

```
$more /nas/server/slot_6/scsidevs [1:gk21:0:c2t0l15:55665100A290:000184502251:]
```

Step 8. Update the /nas/sympapi/db database by running: #/nas/sbin/nas\_rdf -localinit

## **HOW TO DETERMINE IF MULTIPLE SYMMETRICES ARE ATTACHED:**

**/nas/bin/nas\_symm -l      or      \$nas\_disk -l**

### **Miscellaneous Fibre Channel Notes:**

Point-to-point Serial Data Transfer Interface using Optical Fiber or Copper Wire @100MB/sec.

**Support:** Switched Fabric=Switches (No Arbitrated Loop support!!) FC Class 3 service, connectionless, using N, F, and E\_Ports

**Note:** Because our FC method does not support arbitrated loop, we plug into a Connectrix or DS-16b Switch from a Datamover, which then goes to the Symmetrix. Cannot plug a Datamover Fibre channel connection directly into the SYMM.

### **Tracing Fibre Channel Path from DataMover to Symmetrix:**

| Name     | ControllerID | DMHBA  | DMWWN      | FAPort | FAWWN  |
|----------|--------------|--------|------------|--------|--------|
| Server_2 | >c2          | >hba-0 | >.....cd35 | >3a    | >7b42> |
| Server_2 | >c18         | >hba-1 | >.....cd7a | >14b   | >7b5d> |

### **FIBRE CHANNEL SOFTWARE SUPPORT:**

**SYMM:** 5265.43.26

**DATA MOVERS:** NAS 2.1.15.6+ and 506+ DataMovers

**CONTROL STATIONS:** NAS 2.2.25.5+

Dual, Full Duplex Emulex LP-8000DC dual HBA Ports [100Mbps throughput] using Multimode cable with SC connectors

Fan Out ratio of 6:1 [6 DM ports to 1 Symm FA port]

**Target & LUN Support:** Total of 540 targets can be visible on a Symmetrix, but only 128 from a single FA port.

**Extended LUN Support [FFF]:** DM Vol.Map Bits increase to support 4k targets=FFF, as opposed to FF for SCSI.

**Zoning on Brocade [DS-16B] Switch:** >switchShow; >cfgClear; >cfgCreate "celerra"; >aliCreate "cst9" [aliases for DM, and for Symm]; >zoneCreate "cstdm9"; >cfgEnable "celerra" >cfgShow [displays zoning information]

**Brocade DS-16B Switch Rules:** Max of (4) may be combined into one fabric; Max of (1) hop between any two switches; Max of (4) ISL's between two switches; Min of (2) ISL's between switches; FanOut 6:1; Max 0-8 E\_Ports per single switch [ie, switch to switch]

### **Fibre Channel HBA Adapter:**

Celerra 'discovers' FC devices on startup--N\_Ports query the Name Server for list of logged-in fabric devices, then registers them.

A Fibre Channel DataMover can address up to 4096 SCSI Addresses

## **CELERRA BOOT PORT FOR FIBRE FBA ADAPTER:**

*Top port of the Emulex is the Boot Port, Port A*

*Bottom port is the Data port, Port B*

**Pre 2.1.15.20 Code: FC Boot Port:** If Port A fails, DataMover must failover to a Standby unit!!! [If you unplug Port A, same thing]

Code 2.1.24.4: Both Top Port [C0] and Bottom Port [C1] are used as Boot and Data Ports!

**Capacity [Fan-out] v. Consolidation [Fan-in]:** Fan-Out means that a single Celerra can access multiple Symmetrix devices.

Fan-In means that a single Symmetrix FA port is shared by up to (6) DataMover connections as a 'shared' port; 6:1 ratio

## **LOCATING WWN FOR FIBRE CHANNEL CS:**

### **#dmesg |grep qla0**

scsi-qla0-adapter-node=200100e08b24dc0e;  
scsi-qla0-adapter-port=210100e08b24dc0e;

scsi-qla0-target-0=50060482c094decc;

**Note:** Above output is for Que Logix Adapter

## **CONNECTRIX--Fibre Channel Switches [EDM-1032]:**

### **ENTERPRISE DIRECTOR CABINETS:**

EC-1100: Houses up to (2) ED-1032 Switches; 10BaseT Ethernet Hub for Management; ZipDrive BackUps; MultiTech Modem

EC-1200: (2) ED-1032 or (12) DS-32/16M switches

ED-1230: Up to (3) ED-140M Directors & Connectrix SP

--Switched Fabric can use all (32) Connectrix ports in Full-Duplex mode, 100MB/sec, for aggregate bandwidth of 3.2 GB/second!

--4-ports/card GSM/GXX; 9 micron Single Mode 20km GXX Port Card; 50 micron Multimode 500m; 62.5 micron Multimode 325m

### **ENTERPRISE CONNECTRIX MANAGER (ECM):**

--Latest Connectrix Mgr SW: 7.0.x

--Latest McData Firmware: 5.0.1

--Runs on Laptop Service Processor but can be accessed remotely from Connectrix Client on Windows

--Most Management should be done via this interface, not Embedded Web Manager

--Normal operation is to have an IP configured for the ECM Laptop and for each Switch in the Cabinet

--Manage up to 48 Switches

## **CONFIGURING THE BROCADE DS-16B2 SWITCH:**

1. Connect to serial port from Windows Host with Hyperterminal session:

Setup HyperTerm as COM1 with 9600; 8; 1; None; None

2. At prompt, login: switch2a:admin>admin password

3. Set IP Address of Switch: admin>ipAddrSet

4. Disable Switch: admin>switchDisable

5. Configure Domain ID for Switch: admin>configure [Set Domain ID]

6. Verify license: admin>licenseShow

7. Reboot switch: admin>fastboot

8. Open Web Browser and enter IP Address of switch

9. Create Blocking Zone on Switch prior to plugging Hosts into Switch

Zone Administration>Create Zone called ‘Blocking Zone’ & add any port to the zone

Click on ‘Config Settings’ and create ‘Blocking Config’ & add ‘Blocking Zone’ to config

10. Actions>‘Save Config’ and then ‘Enable Config’

11. Create Aliases for each port and move respective port into the Alias

12. Create Zones and add alias members to proper zones

13. Create Config and add Zones to config [Save and then Enable Config]

## **SETTING UP NEW ZONES & ZONE SET:**

1. EMC Connectrix Manager>Fabrics>configure>Zoning Library [Contains all Zones created across all Switches managed by ECM]

>Zones>File>New>Zone Name: A1-Sun1-1pfco

2. Add HBA WWN of Host HBA and FA WWN of Symmetrix

--Repeat Steps above to create a Zone for each HBA-to-FA path

3. ZoneSets>File>New>Lab1>Add the Zones created previously to the new ZoneSet

**Note:** Create maximum of 1024 zones per zone set

### **ED-140M:**

140-port 2Gbps Switch; Online firmware upgrades; up to (3) ED-140M Directors per ED-1230 Cabinet

CTP Card: Control Processor Card contains System Service Processor and Embedded Port subsystems. SSP runs O/S, Applications, Communicates with Ports, Controls Serial & Ethernet Management Ports, Stores Config & Parameters in NVRAM. IML Button on the CTP, when held for 3 seconds, reloads firmware on Directory and resets both CTP cards without powering down or affecting operational Fibre Links—however, network connections are dropped & clients will have to log back into Fabric.

Port Map: 0-127

### **ED-64M ENTERPRISE FIBRE CHANNEL DIRECTOR:**

--64-ports, 4-ports per card; Uses Multimode 50 or 62.5 micron cables using Full Duplex 100MB/second speeds per port

--IML—Resets the CTP’s (Control Processors of the Switch)

### **DS-16/32M DEPARTMENTAL DIRECTORS:**

--16 or 32 Ports, Multimode 50 or 62.5 micron, Full Duplex 100MB/port

--Small Form Factor Optics (SFFO): Short & Long Wave cables using LC Connectors

--SFFO Card has green LED's that indicate Logins, yellow LED's that indicate traffic

## **DS-8B/DS-16B DEPARTMENTAL DIRECTORS:**

Setup using “Blocking Zone” as these switches see all ports by default [Create Zone, then add zone to a Config]

Commands: switchshow; supportshow; version; configure; switchenable; switchdisable; zoneshow; zoneadd; cfgadd; cfgcreate; cfgsave

### **MERGING:**

When “merging” or “cascading” these switches, must have different Domain ID’s per switch, but same BB Credit & same RA & ED TOV. Also must be at firmware 2.3 or higher.

1. Disable (1) of the Switches after ensuring that they have different Domain ID’s
2. Disable Zone Config on ‘disabled’ switch
3. Run ISL cable between two switches
4. Ensure that Both Switches have same Config
5. Enable Offline Switch
6. Add zones from Offline Switch to Fabric
7. Save Zone Config
8. Enable Zone Config
9. Save Zone Config again

## **DS-16B-2: Brocade Introduces ISL Trunking**

16-port switch with 2Gbps autonegotiate speed; supports ISL Trunking [allows up to (4) ISL’s to merge into single logical link with aggregate throughput of 8Gbps; trunkshow]

## **UPGRADING CONNECTRIX MANAGER AND SWITCH FIRMWARE WITH CELERRA:**

Latest ECM SW: 7.x

Latest McData Firmware: 5.x

**Note:** Ordinarily, switch upgrade activities should not impact Celerra, that is, if they are properly dual-pathed to different fabrics and you upgrade firmware in one fabric at a time. However, for the Control Station, we use only a single path, so shutdown the CS prior to upgrading firmware on switch to which it is connected. Also, conduct ‘Healthcheck’ of Data Movers after Connectrix work is completed just to make sure that we are still logged into the fabric and seeing devices properly, etc. Best method for verifying is to watch appropriate ports on the switch for I/O. However, in the event that I/O stops, conduct the following procedure on the appropriate HBA port:

## **FIBRE SWITCH INTEROPERABILITY:**

**Comment:** Interop means that you can “merge” or “cascade” different switch types into a single “Fabric” ED-1032, ED-64M, DS-32M, DS-16M, DS-8B, DS-16B—all can be used together

### **Prerequisites:**

1. Requires use of ECM Manager 4.1 or ESN Manager 1.1 [Being replaced by SAN Manager—ESN is EOL]
2. Max of (12) DS per Fabric
3. Supports only WWPN Zoning
4. Supports Switched Fabric only
5. Solaris 2.6, 7, 8 Hosts require JNI FC64-1063-EMC (SBus) HBA running 2.5.9 EMC driver  
NT/2000 Hosts require Emulex LP8000-EMC 1.27a3/1.27a5 drivers  
Linux 6.2 requires QLogic QLA2200/66 or QLA2200F/66 running 2.10.10 driver
6. DS-8B/16B requires 2.3.0 firmware if connected to ED-1032  
ED-1032 requires 3.2; ED-64M requires 1.2

**Fan-In v. Fan-Out:** Usually refers to the ratio of ports going “into” or “out of” the Symmetrix.

**Fan-In or Capacity Expansion:** (1) Server HBA can be zoned via Connectrix to go into multiple Symmetrix FA ports

**Fan-Out or Consolidation:** (6) Datamover Server HBA ports can be zoned via Connectrix to go into (1) shared Symmetrix FA port

**Current Firmware:** ED-1032 = 6.00.00.45; ED-64M, DS-32M, DS-16M = 1.2.0

### **Connectrix Logs:**

Audit Log—Configuration Changes      Event Log—Port/Hardware Problems      Hardware Log—hardware

Link Incident Log—Loss-of-Signal[Synchronization]—Occurs if cable unplugged from an attached node

## **SUPPORTED FIBRE CHANNEL SWITCHES: “Class 3 Switching”**

Brocade Silkworm 2800 [aka, Connectrix DS-16B]; 16 Ports; 16 ZoneSets [Each ZoneSet can have up to 256 Zones]

Connectrix ED-1032 Cabinet; Houses up to (2) ED-1032 Switches; Each switch=32 ports; 64 ZoneSets [256 Zones/set]

**Note:** Connect Celerra or Host connections to low-numbered ports and Storage-side connections to high-numbered ports

Connectrix Switch has two WWN’s—Port WWN=Connectrix Port; Attached Port WWN=Attached Celerra or Symm WWN

**Connectrix Enterprise Directors:** ED-64M & ED-1032 [Normally used as backbone switches in the fabric environment]

**Connectrix Departmental Directors:** DS-32M; DS-16M; DS-16B; DS-8B [Used as 'edge' switches]

**Operating Mode:** McData Fabric Mode; Open Fabric Mode; Non-Interop Mode; Interop Mode

**Connectrix Configuration:** Obtained from “ED-1032 Configuration Report” for SW1 & SW2 [16 ports per switch, totaling 32 ports]  
Shows Ports 0-31 and Nodenames attached.

**TroubleShooting Connectrix Setup:**

- Verify that unique Domain ID is used
- Verify that multiple switches are setup for Inter-Op Mode
- Verify Zone Set is active
- If ISL used, note Celerra limitations here [Celerra cannot boot up properly across an ISL link!]

**WWN—World Wide Name:** Attached N-Port node’s manufacturer HBA name or nickname. FC-4 Type=SCSI for FC-SW.  
64-bit number [10:00:08:00:88:44:50:ef]

**LINK RESET ERROR IN SERVER LOG:** 2003-06-17 07:53:55: CAM: 4: FCP HBA 0 OFFLINE: Link Reset

**POSSIBLE CAUSES FOR "Link Reset" ERROR:**

1. Bad fibre cable on HBA to switch, or from Switch to FA port--reseat or replace cables as required
2. Bad GBIC card on the Connectrix Switch--reseat or replace GBIC card as required
3. Partially completed Zoneset activation--reactivate Zoneset for affected HBA if above hardware checks out
4. Bad FA Port: Symm Inlines: 863E shows error on FA, probable cause is bad cable; 8F,,, shows Link Status and WWN Logon info; If 8F,,, doesn’t display WWN Status but has no 863E error, then switch may have a bad GBIC

**FIBRE CHANNEL PORT OPERATIONAL STATES & LED LIGHTS:**

No Green Light: No cable [no signal], plugged into port. Or, switch port blocked.

No Green Light with Yellow Triangle: Offline, Link Incident, Link Reset, or Not operational.

No Green Light with Red/Yellow Blinking Diamond: Port failure.

No Green Light, Blinking Amber, & Yellow Triangle: Testing or Beaconing in progress.

Green Light On: On Line and device communicating [blinking green when activity occurring!!]

Green Light On & Yellow Triangle: Invalid attachment or configuration.

Green Light, Blinking Amber, & Yellow Triangle: Testing or Beaconing in progress.

Flashing Green, but no flashing Amber—adapter has completed POST, but no valid link to FC or driver may not have loaded

Solid Green, flashing Amber—Post completed, link up on FC, and driver loaded

**Two Types of Switched Fabric Fibre Channel Zoning:**

1. Port-to-Port Zoning—Zones by physical switch port numbers [useful when setting up a new Fibre host & you don’t have WWN]
2. WWPN Zoning—recommended method, with zones defined by WWPortN’s of nodes and switch ports

**Note:** Specifically, **Single-HBA WWN Zoning** is recommended v. Port-to-Port Zoning. Celerra needs this to log into a single port during bootup or discovery, otherwise may try logging into all ports that it sees.

**ZONE RULES FOR FIBRE:**

--Zoning is fabric-wide, meaning that is applied to the whole fabric

--Zones can span switches

--Only a single Zone Set can be active on a switch at a time

**TROUBLESHOOTING GREEN vs. BLUE CONNECTIVITY STATUS OF HOST INITIATORS VIA NAVISPHERE:**

**Intro:** There are occasions where the “fcp bind show” will actually show an HBA with a persistent and dynamic port connection, but devconfig –probe will not be able to see the devices down the path. Navisphere port list command also shows that the path to the specific SP port is up. Navisphere might show the WWN connectivity record as a “blue” icon, when normal connectivity is reflected by a “green” icon.

**Resolution:**

There could be potential hardware port issues anywhere along the path, from HBA to Switch port to SP port. In one case, the “fcp bind show” did not trigger the path to reconnect to storage, nor did the “fcp rediscover=0”, nor did the nas\_storage –check –all.

1.) Block and unblock the Switch port should resolve the connectivity issue

2.) Log into **Navisphere>Storage Groups>Celerra\_nyip2>Properties>Hosts>Advanced>find the ‘Host Connection Path’ in question and if the box is unchecked**, check the box and apply—this should also force the path to refresh to the missing Chain or Storage path

**CELERRA SNAPSURE [Celerra Checkpoint]:**

Introduced with NAS 2.2--“nas\_fs” commands

NAS 4.0 and above allows refresh without client unmounting Checkpoint filesystem, introducing new “fs\_ckpt” commands  
NAS 4.2 [SnapSure V2] and above provides “restore”, automatic extensions when HWM is reached, single volume for all Checkpoints, and a “.ckpt” NFS entry in PFS that points to top of all snapshot directories.

NAS Upgrades from 4.2.5.1 or higher no longer requires deletion of existing Checkpoints!

## **CHECKPOINT FEATURES:**

- Checkpoint writes the first modification to any PFS block since the Checkpoint was created, to the SavVol
- NAS 4.2, Checkpoint SavVol will be same size as PFS if Checkpoint is less than 5GB
- SnapSure uses only STD volumes, not BCV's—it is not a “copy” of the PFS!
- Cannot FSCK a checkpoint filesystem
- Can extend a Production File System while a Checkpoint is established
- Checkpoint SavVol auto-extends when HWM [High Water Mark] is reached [NAS 4.2 uses pool of (8) disks]
- Can only mount Checkpoints on same DataMover as the PFS [Production File System]
- Must delete Checkpoints in order of creation, or oldest first
- SnapSure maintains itself even if Celerra or Servers are rebooted
- Create multiple SavVols for same PFS [Pre-4.2 code] if doing multiple Checkpoints over time
- Can extend an “active” SavVol, but not a “full” SavVol

**Note:** This is no longer true. A full SavVol can be extended manually with NAS 5.2 and higher.

--Bitmap flag on means a checkpoint blockmap is available. Bitmap flag off means last to read from PFS

--Can restore all or part of the file system to a given point-in-time using Checkpoints

**Limitations:** Checkpoints must be deleted in the order of their creation, if using multiple Checkpoints for same PFS.

## **CHECKPOINT (SNAPSURE) TERMINOLOGY:**

**Checkpoint:** Read-only logical point-in-time bitmap image of a production filesystem

**Checkpoint Window:** Time of initial Checkpoint SavVol creation to the time it becomes “invalid”, full, or deleted

**PFS Applications:** Applications that perform RW's to the PFS data blocks—normal day-to-day operations

**Checkpoint Applications:** Applications that use the ‘point-in-time’ PFS image or Snapsure File System, for RO operations

**SavVol:** Standard Celerra meta volumes which are used by Checkpoint to intercept writes to PFS. If the corresponding bitmap value is 0, then the existing PFS data is copied off to the SavVol before the file system write is allowed to proceed. Subsequent writes to the same block will see a bit value of 1 and allow the data to be written directly to the PFS (i.e., PFS data and metadata is only copied over to SavVol once, during the first change to the PFS state). This is why it is best to use Checkpoints to create a series of “SavVols” in order to capture incremental changes, etc., say on a daily basis [NAS 4.2 and higher uses single SavVol]. If PFS >than 10GB, SavVol will be created as 10GB and increments by 10GB at the 90% HWM. Use 0%HWM if you do not want SavVol to be auto extended.

## **DETERMINING SAVVOL INFO FOR PFS WITH SNAPSURE:**

**Note:** For any production file system greater than 10GB, the default SavVol size is 10GB. For any pfs under 10GB, the SavVol will equal the pfs size, unless otherwise provisioned. Each pfs will have its own dedicated SavVol.

**Note:** Default creation and extension size of the SavVol is 20GB beginning with NAS 5.6.44

**# export NAS\_REPLICATE\_DEBUG=1**

**# nas\_fs -l**

```
id    inuse type acl  volume   name      server
25      n    11  0    0     vpfs25 →While this is not the SavVol, a vpfs is created for each pfs when Checkpoints are in use
```

**# nas\_fs -i fs01-test\_ckpt1**

```
id    = 26
```

```
name   = fs01-test_ckpt1
```

**volume = vp94** →vp94 is the SavVol for pfs ‘fs01-test’—this is usually how to find the SavVol ID

**# nas\_fs -s fs01-test\_ckpt1**

```
volume: total = 2000 avail = 1880 used = 120 ( 6% ) (sizes in MB)
```

```
ckptfs: total = 1968 avail = 1968 used = 0 ( 0% ) (sizes in MB) ( blockcount = 4096000 )
```

**# nas\_volume -s vp94**

```
total = 2000 avail = 0 used = 2000 ( 100% ) (sizes in MB)
```

**Bitmap\_Blockmap:** Memory structures used by SnapSure to keep track of file system state and changes

**BITMAP:** Only the most recent checkpoint of any given file system contains the “bitmap”, which is 1 bit/8k PFS block [bit 0, 1]

**BLOCKMAP:** All checkpoints contain a “blockmap”, which is 8bytes for every 8k block in the Checkpoint

## **SAVVOL MEMORY QUOTAS:**

|     |                     |               |
|-----|---------------------|---------------|
| 507 | 204MB max mem quota | 163MB mem HWM |
| 510 | 2100MB              | 1680MB        |
| 514 | 2800MB              | 2240MB        |

**Rule of Thumb:** Checkpoints use 1MB of RAM for every 1GB PFS

## **GENERAL CHECKPOINT GUIDELINES:**

### **Rule #1:**

If the most recent checkpoint becomes damaged or deleted, all other previous checkpoints become useless

***Caution:*** Always protect the most current Checkpoint Refresh, as it contains the “bitmap” image required by all other previous Checkpoints!

- Checkpoint File Systems are created using Standard (STD) MetaVolumes & based on a Production File System (PFS)
  - Checkpoint creation quiesces & freezes the PFS while the Checkpoint bitmap volume of the PFS is being created [see NAS 5.2]
  - Checkpoints operate at the Celerra Volume Manager layer and use 8kb chunks, while actually writing blocks in 8.5kb chunks that include a 512byte header.
  - Each “Checkpoint” requires its own Meta Volume {STD}
  - Checkpoints are RO
  - Checkpoints must be mounted on same DataMover as PFS
  - Multiple checkpoints must be deleted in the order in which they were created
  - Total SavVol storage should not exceed 200GB per DataMover [old info, no longer current]
  - Memory utilization is capped at 70% during creation or extensions
  - Ideally, create the SavVol the same size as the PFS
- NOTE:** Checkpoints do not support complete file system restores

## **UNSUPPORTED VERSIONS:**

NAS 3.x and MPFS “HIGHROAD”

## **NAS 4.0 FEATURES:**

- Clients do not need to unmount during a checkpoint “refresh”
- Celerra automatically extends checkpoint by 10% of PFS size when a certain %full value is reached
- \$fs\_ckpt command replaces the "nas\_fs -Checkpoint"
- \$fs\_ckpt pfs1\_ckpt1 -refresh [updates the oldest checkpoint]

## **NAS 4.2 FEATURES:**

- Checkpoints for a single File System will use a single SavVol
- Maximum of (32) Checkpoints per file system
- Auto-extend feature at HWM if disk space is available—if not, then oldest Checkpoint is marked “invalid” & is then reused
- Auto-extend feature only works if using automatic SavVol, not manually created SavVol
- Auto-mounting of SavVol for NFS-only in 4.2.x

## **NAS 5.0 FEATURES:**

- Separate Checkpoint directories are contained within the “uxfs” for each Checkpoint created for a PFS as “.ckpt\_ckptx” entries

## **NAS 5.1M2 FEATURES:**

- Total number of checkpoints per PFS is 32
  - Not possible to modify a Checkpoint Schedule after it has been setup from Celerra Mgr or CLI
  - Some Checkpoint tasks may not be visible or manageable from Celerra Manager
  - With ATA environments that exceed 6 TB on the Celerra, SnapSure is limited to a single Checkpoint per file system
- NAS 5.2 FEATURES:**
- Subfolders now contain hidden .ckpt directories
  - Out of order deletion of checkpoints are now supported [merges blockmap entries to older checkpoint before deleting]
  - Supports 32 checkpoints per file system—submit RPQ for supporting more
  - Checkpoints will automatically be mounted after being taken
  - Can now rename a specific checkpoint
  - Checkpoint creation pauses PFS by suspending writes but not reads, while checkpoint is being created
  - Checkpoint refresh freezes PFS by suspending both reads and writes

## **NAS 5.3 FEATURES:**

- New Checkpoint Schedules Tab showing schedules, date, time, and state of each [hourly, daily, weekly, monthly intervals]
- Note:** Start On schedule can be modified, but not for Next Run, State, and Recurrence, or name of Schedule. Checkpoint Scheduling uses the APL GUI middleware layer, built on top of CS core exec layer.

## **LOCATION FOR CHECKPOINT SCHEDULES CREATED FROM WEBUI:**

### **/nbsnas/tasks/schedule**

- rw-r--r-- 1 nasadmin root 834 Nov 1 11:29 laip2.1 →Example of a Checkpoint schedule
- rw-r--r-- 1 nasadmin nasadmin 1 Nov 1 11:29 .sched\_id →Schedule ID number

## **STANDARD MODE SCHEDULING:**

Recurrence—ability to setup a recurring time, start & end dates

Hourly—one for each selected hour

Daily—up to 7 days

Weekly—up to 4 weeks

Monthly—up to 3 months

→Ability to name virtual checkpoint directories for customer—set following param:

**param cvfs virtualDirName=snapshot** (example name)

**Note:** Default is to use “ckpt” as the virtual directory name for Checkpoints on the PFS

### **VOLUME SHADOW COPY SERVICE (VSS):**

→Support for Microsoft VSS (Volume Shadow-Copy Service)

→Provides direct access to point in time copies of volumes, providing restore capability

→Support for XP & Win2k3 clients for NAS 5.3/5.4

→Windows Service is called “Volume Shadow Copy”

→VSS can be used for Full, Incremental, Differential, & Copy backups

#### **VSS uses several components:**

Requestor, Writer, Provider. The Requestor controls the backup and restore service using API calls to Windows (Legator NetWorker, Replication Manager, etc). The Writer is an Application that can support VSS, such as Exchange 2003, SQL 2005, etc., and creates datasets for the snapshot backups. The Provider (System, Software, Hardware component, such as Legato RM) actually creates the backup & presents to Host, or ‘Snapshot Shadow Copy’.

**Note:** Clients must install software to support VSS

#### **Client Software:**

→Celerra iSCSI Target Software CD [Windows Celerra VSS Provider; Linux CBMCLI pkg; AIX pkg]

→Ensure Windows system MaxRequestHoldTime parameter is changed to 600 decimal to tolerate iSCSI LUNs going offline during snapshots

→CBMCLI pkg for Linux is used to manage snapshots with cbm\_iscsi; cbm\_security; cbm\_replicate commands

#### **Two Types of Shadow Copies:**

→Plex copies (mirrored), not supported

→Differential copies, differences from original volumes are saved (supported)

#### **Celerra VSS Provider for iSCSI Version 1:**

→Supports Windows 2008 except for multiple imports; auto-recovery of transportable shadow copies; NTFS TxF transactional recovery of transportable shadow copies

→Runs as a service on Windows

→Celerra VSS provider does not support Shared Folders; Importing shadow copies to clustered servers; Plex shadow copies

→Celerra VSS does support differential Shadow Copies

→Celerra VSS allows VSS-enabled backup applications to make shadow copies of Celerra iSCSI luns

#### **MS UTILITIES:**

C:\>vssadmin list providers | list writers

C:\>vshadow -p c:\ (Using local NTFS requestor to perform backup of c: drive)

**param cifs allowSnapSureVss=0** [disables VSS support—Shadow Copy for Shared Folders (SCSF)]

**param cifs allowSnapSureVss=1** [default; enables VSS support—allows access to previous file versions via checkpoints]

### **CVFS (Checkpoint View File System):**

NAS 5.0 introduces “virtual” .ckpt entry in all directories on PFS & provides access to Snapshots from PFS

**Note:** 5.0.x contains bug in that only the first PFS created with a Checkpoint has the hidden .ckpt directory—fixed with NAS 5.0.14.0

#### **CVFS VERSION 1:** NAS 4.2

Only NFS clients can access checkpoints, and then only from the root of the PFS’s hidden .ckpt directory. CVFS1 supports DOS 6.0 file naming conventions only.

### **ENABLING/DISABLING CLIENT ACCESS TO CHECKPOINTS FOR SVFS V1:**

**param cfs showChildFsRoot=1 | 0**

**Note:** When set to 1, mounted Checkpoints will be visible to NFS clients as subdirectories of the root of the PFS—0 disables this

#### **CVFS VERSION 2:** NAS 5.1

NFS & CIFS clients can access checkpoints of the PFS via virtual links and hides the .ckpt directories when an ls -la or dir is run.

### **ENABLING/DISABLING CVFS VERSION 2 CHECKPOINT ACCESS FOR CLIENTS:**

**param cfs showHiddenCkpt=1 | 0**

**Caution:** AR57334 states that the showHiddenCkpt param applies only for CVFS v1-style checkpoints, and that setting param to 0 will disable CVFS v2 checkpoints completely

#### **PURPOSE OF CHECKPOINT:**

--As a source of data for applications that do not require live data

--Typically used for incremental backups by copying the Checkpoint to tape

--Most practical for restores of individual files or folders

**Note:** Checkpoint is not intended to be a complete Backup solution nor to restore whole file systems! Restores of whole PFS could cause SavVol to fill, which could render the Checkpoint “invalid” and unusable.

## **HOW CHECKPOINT WORKS:**

### **PFS SIDE:**

→ Writes are intercepted at the Volume level. If Blocks have not been modified since last SnapShot taken, then the blocks are first saved off to the SavVol and then the write to the PFS is allowed. If Blocks have already been modified once, then writes are executed directly to the PFS. Reads are executed against the PFS.

### **SAVVOL SIDE:**

→ Reads are intercepted at the Volume level. Writes are prohibited. If blocks have been modified since last SnapShot, then Reads are executed on SavVol. If blocks have not been modified, then reads are done against the PFS.

→ Copies are done at the Volume level and are executed as a copy on the first modify of a data block. During initial SavVol creation, a bitmap image of the production file system is created. After initial creation, changes to the Production File System [PFS] are first written to SavVol as “data blocks”, changing the bitmap values from 0 to 1--subsequent writes to the same blocks will be written to the PFS. Multiple Checkpoints can be taken to span a period of time for a production file system—mount the Checkpoint File System from any Unix Host to retrieve files. Otherwise, a Checkpoint “Restore” will restore the whole checkpoint bitmap changes.

Checkpoint file systems remain "persistent" until SavVol is filled or unless deleted. PFS can even be extended while Checkpoints are active and established.

→ By default, the SavVols can use up to a max of 20% of all available disk space on a system [tunable in the /nas/sys/nas\_param file]

## **HOW READS & WRITES OCCUR USING CHECKPOINT:**

**Writes:** After initial Checkpoint SavVol is created for the Production File System, all its Bitmap values are represented by 0's. Any new writes to the PFS are then intercepted at the Volume level--original data blocks are first moved to the SavVol, data changes are then written to the PFS, its bitmap values for the changed blocks are updated to 1's. It is important to understand that this bitmap value change from 0's to 1's are only done once for any given Checkpoint—Subsequent changes to any data blocks that already have a new value of 1 are done directly to the PFS. In otherwords, Checkpoints record only the first series of changes to data after initial creation.

**Reads:** Similar to ‘Writes’--also intercepted at the Volume level. Bitmap values of 1 are read from the SavVol, values of 0 are read from PFS.

**Performance Impact:** Some additional overhead is required to conduct the first modification to a PFS Block, as the PFS Block has to be Read and then Written to the Save Volumes, while the original modification needs to be written to the PFS Block.

## **CHECKPOINT PROCESS:**

- Creation of a Checkpoint causes a pause of the PFS for Writes only
- Conducting a Checkpoint Restore causes a pause of Reads & Writes
- Checkpoints are automatically restarted if Server is rebooted
- During Restore, a rollback Checkpoint is taken in case the restored copy was not the desired one
- Refresh operations may cause CIFS clients to have to reconnect—NFS Clients should have no trouble
- Checkpoints consume memory in order to maintain the Bitmap/Blockmap images

## **SNAPSURE V1 vs. V2:**

- V1 Checkpoints became inactive if Save Volume became full
- V2 Checkpoints inactivates the oldest Checkpoint if the SavVol becomes full
- V1 Checkpoints required deletion of oldest-to-newest in exact order
- V2 Checkpoints allows for deletion of any Checkpoint

## **SAVVOL VOLUME & SIZE:**

SavVols are created on metavolumes. Specify the SavVol by name and size in GB or % of PFS. Minimum SavVol size=64MB [NAS 5.2 min = 32MB]. Ordinarily, if PFS is less than 5GB in size, then SavVol will equal the size of the PFS. For SnapSure 4.2 and higher, only a single SavVol is used for all CheckPoints. Creation of the first CheckPoint will create a SavVol—to specify a SavVol HWM different than the default of 90%, use the following command to create SavVol before implementing CheckPoints:

**\$fs\_ckpt fs1 -Create -o %full=75**

**Note:** The default HWM for the checkpoint SavVol is 90%, which means when the SavVol is 90% full, it will be auto-extended by a default size of 10GB. HWM defaults have changed from NAS version to version—75% old versions, 90% is the HWM in later NAS versions including 5.6. The HWM can be changed by manually creating a new CheckPoint and specifying--SavVol size or % of PFS size, as well as the type of AVM volume pool, can also be specified when creating the SavVol.

### **CHANGING CHECKPOINT SAVVOL HWM FROM DEFAULT 90%:**

**# fs\_ckpt file7 -C -option %full=50**

**# fs\_ckpt file7 -l**

```
id ckpt_name creation_time inuse fullmark total_savvol_used ckpt_usage_on_savvol
57 file7_ckpt1 12/03/2009-13:14:30-EST y 50% 43% 9%
```

### # nas\_fs -info file7\_ckpt1|grep full

full(mark)= 50% → This is the Checkpoint SavVol HWM, the point at which the SavVol will auto-extend

### **SAVVOL HWM NAS 5.6:**

→ Default value is set at 90%, at which point the SavVol will auto-extend by 20GB

→ If you set the HWM to 0% (using fs\_ckpt -C –option %full=0), then the SavVol will not auto-extend. Instead, when more space is needed, the oldest checkpoint will be deleted to reclaim space, and this is repeated everytime the SavVol needs more space

### **MANUALLY EXTENDING SAVVOL:**

#### # nas\_fs -xtend <ckpt name> size=<integer>[T|G|M]

### **EXTENDING SAVVOL USING CELERRA MANAGER:**

Select the "File Systems" tab, highlight the filesystem name, rightclick and select "Checkpoints>Extend Checkpoint Storage", and on the input screen, enter the desired SavVol extension size in MB in the "Extend Size by (MB):" box, and accept all other default values.

### **NAS 5.6 SAVVOL AUTO EXTEND:**

**Note:** NAS 5.6 QOSsize represents the default auto-extension size of the SavVol

#### cmd log:

2009-12-03 14:16:32.215 db:0:27704:S: /nas/sbin/rootnas\_fs -x file8\_ckpt5 **QOSsize=20000M →20GB**

2009-12-03 14:16:35.164 db:0:27704:E: /nas/sbin/rootnas\_fs -x file8\_ckpt5 QOSsize=20000M

#### server log:

2009-12-03 14:16:52: SVFS: 4: 1: FSID:69 SavVol:127 MaxSize:0 MB %Full(hwm=30) reached (t:3140622644124770)

2009-12-03 14:16:56: ADMIN: 6: Command succeeded: volume extend 127 129

### **DETERMINING SAVVOL SIZE FOR PFS WITH NAS 5.5:**

#### # nas\_fs -size fs01-test\_ckpt1

volume: total = 2000 avail = 1880 used = 120 ( 6% ) (sizes in MB)

**ckptfs: total = 1968 avail = 1968 used = 0 ( 0% ) (sizes in MB) ( blockcount = 4096000 )**

**Note:** With production fs size of 10GB or greater, the SavVol size will be created as 10GB

### **FINDING SAVVOL INFORMATION FOR SNAPSURE CHECKPOINTS:**

**Note:** SnapSure SavVols are different from IP Replication SavVols

#### 1. Find a Checkpoint name for the Production File System:

##### # nas\_fs -i fs1

```
id      = 54
name    = fs1
acl     = 0
in_use  = True
type    = uxf
worm   = off
volume  = v135
pool    = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
ckpts   = fs1_ckpt1
```

#### 2. Run query on a checkpoint to find Checkpoint SavVol Volume Pool name and Volume Pool File System name:

##### # nas\_fs -i fs1\_ckpt1

```
id      = 56
name    = fs1_ckpt1
acl     = 0
in_use  = True
type    = ckpt
worm   = off
volume = vp138 →Volume Pool SavVol name
pool    = clar_r5_performance
member_of = vefs55 →Volume Pool File System name
```

Alternatively, use the following Query command to locate SavVols, though if running IP Replication, will need to sort through the list as this command dumps info on IP Replication & SnapSure Checkpoint SavVols:

**# nas\_fs -query:Type=uxfs -format:"%q" -fields:Checkpoints -query:\* -format:"ID=%s, Name=%s, VolumeID=%s, VolumeName=%s\n" -fields:ID,name,VolumeID,VolumeName**

```
ID=31, Name=rep1_src_repl_restart_1, VolumeID=112, VolumeName=vp112  
ID=38, Name=rep1_src_repl_restart_2, VolumeID=112, VolumeName=vp112  
ID=43, Name=rep2_src_repl_restart_1, VolumeID=124, VolumeName=vp124  
ID=50, Name=rep2_src_repl_restart_2, VolumeID=124, VolumeName=vp124  
ID=56, Name=snapper_ckpt1, VolumeID=138, VolumeName=vp138
```

## **AUTOMATIC EXTENSION OF SAVVOLS IN NAS 5.2:**

Normally, if SavVol reaches its HWM, the SavVol will automatically extend. If an extend fails [i.e., no more storage allocated], then the remaining SavVol space above the HWM will be used. If more space is still required, the oldest checkpoint will be deleted and its space used. This pattern will repeat until all old checkpoints are consumed. If more space is required, the SavVol will become inactive and all CheckPoints will become invalid.

**Note:** Simply deleting Checkpoints in the middle of a sequence will not necessarily free up any additional space for the SavVol

## **RESOLVING SAVVOL FULL PROBLEM:**

Occasionally, due to certain problems [no more physical diskspace, code bug, etc.], the SavVol can be filled to capacity and not be able to auto-extend itself. In these situations, the various Checkpoints begin to go invalid as they fill. Following are some generic steps to recover:

1. Manually extend the SavVol once more diskspace has become available

**# nas\_volume -xtend fp1368 d1000**

**Note:** Find the savVol itself by running nas\_fs -i against any checkpoint—the SavVol will be the “volume=vp175” entry.

2. Delete any inactive Checkpoints that may have resulted, first making sure that the invalids are permanently unmounted from DM
3. Refresh the deleted Checkpoints if desired

## **RESIZING REPLICATION SAVVOL ON DESTINATION (5.6.38+) (Shrink SavVol/Resize SavVol):**

**Note:** No capability to “shrink” the SavVol. Must delete all the checkpoints for a given file system so as to delete the SavVol.

- 1) Obtain details of Replication Session on both sides
- 2) Delete destination side checkpoints
- 3) Create new checkpoint on Source file system
- 4) Refresh the Replication session on the Source side
- 5) Delete the Replication sessions on both sides (nas\_replicate –delete <session> -mode both
- 6) Create new checkpoint on Source file system
- 7) Perform incremental copy of checkpoint created in Step 3 with checkpoint created in Step 6  
\$ nas\_copy –name <copy\_name> -source –ckpt <ckpt\_step 6> -destination –fs <dest\_fs> -from\_base <ckpt\_step 3> -interconnect id=<interconnected> -overwrite\_destination -background
- 8) Confirm nas\_copy has completed, then recreate Source Replication session from info in Step 1  
\$ nas\_replicate –create <session\_name> -source –fs <source\_fs> -destination –fs <destination\_fs> -interconnect id=xxx –overwrite\_destination -background

**Note:** If SavVol needs to be deleted on Source side, then do a –reverse first, then apply the above procedure, ending with –reverse back. But, source side needs all checkpoints & internal checkpoints deleted to remove SavVol, which means Replication needs to be torn down, so this is really not practical.

## **CHECKPOINT EXTEND FAILS:**

Checkpoint extend script [extend\_ckpt] can inadvertently extend a checkpoint multiple times, leading to failure. Possible workarounds would be to increase the size of the SavVol and then tailor the “extend\_ckpt” script as follows:

```
if [$used -le $hwm ]; then  
fi
```

## **AVM STORAGE MANAGER & CHECKPOINTS NAS 5.2:**

AVM will try to match the storage profile for creating a SavVol with that of the PFS when possible. If not possible, AVM will resort to allocating storage using QOS [introduced NAS 4.2] for SavVols. Quality of Service (QoS) is a mechanism to help ensure that there is always space available in the pool for filesystem creates, extends, or checkpoints—also reflected with the flag is\_dynamic is true. QoS is only used for system-defined pools, not user-defined.

## **HIGH WATER MARKS (HWM) IN NAS 5.2:**

By default, a HWM of 90% is used with the SavVol before an extension of the SavVol occurs. Server Log will show the HWM during a CheckPoint refresh:

**2004-04-06 23:04:12: ADMIN: 4: Command succeeded: file refresh ckpt 34 260=252 hmw=90**

To conserve storage system space, you can set the HWM to 0%, meaning that the SavVol will not be automatically extended. Instead, Checkpoint will delete oldest checkpoints first to conserve space. However, the caution here is that if not monitored closely, you run the risk of running out of old checkpoints and rendering the SavVol inactive and all CheckPoints useless. Setting SavVol to 100% simply means that all space is used in the SavVol before an extension is made.

**ERROR MESSAGE WHEN CHECKPOINT CANNOT AUTO-EXTEND:**

Sep 17 14:42:59 2002 NASDB: 7; 10 /nas/bin/nas\_fs -x fs1-ckpt2

QOSsize=5000M error 3007; volume is unreachable

**CHECKPOINT OPERATION:**

**CREATING CHECKPOINTS NAS 4.2/5.1:**

**Step 1:**

Option 1. **\$fs\_ckpt fs1 -Create** [If not specified, will use first (8) STD Volumes available to create Checkpoint pool]

Option 2. **\$fs\_ckpt fs1 -C mtv1 -o %full=70**

**Note:** Using option “%full=70” will create HWM and point at which the Checkpoint will be automatically extended

Step 2: Create Mountpoint and Mount Checkpoint FileSystem to DataMover

Step 3. Export Checkpoint

**Caution:** Never permanently unmount a PFS to which a Checkpoint is still mounted!

**RENAMING A CHECKPOINT:**

1. Temp Unmount Checkpoint first: \$server\_umount server\_2 fs1\_ckpt1 /fs1\_ckpt1

2. Rename: \$server\_mount server\_2 -o cvfsname=Monday snap1\_ckpt1 /fs1\_ckpt1

**SCHEDULING CHECKPOINTS USING WEBUI:** NAS 5.1.13.0 and higher

Checkpoint refreshes can be setup using the WebUI Manager Interface or by Linux CS cron job using a script. Schedule interval using WebUI is Hourly, Daily, Weekly, Monthly, though only a single schedule can be in place for any single PFS. It is not yet possible to “change” a schedule, once created. You must remove the current schedule by changing the recurrence of the CheckPoint on the PFS to “never”, apply, and then set the new schedule. You can delete a ‘scheduled’ checkpoint if it’s in an ‘active’ status on the WebUI display, but not if it’s in a ‘pending’ status.

**NAS 5.3:**

Schedules can now be changed without deleting and recreating—change from one time to another.

**Note:** Do not schedule CheckPoint refreshes from 00-05 minutes past the hour as it may fail due to the NAS Database backup that occurs at (1) minute past each hour. Also note that Schedule times are driven by Control Station timezone.

**SCHEDULING STATES:**

**Pending:** Schedule has not yet run the first task

**Active:** Schedule has run at least one task and others are still waiting

**Paused:** Schedule has been stopped—missed tasks will not run

**Completed:** Schedule completed and no more tasks waiting

**MANUALLY DISABLING CHECKPOINTS SCHEDULED FROM WEBUI:**

Checkpoint Refreshes created from the WebUI run using “cron\_plus” and are located in the /nas/site/cron.d/nas\_users file. You can also change the ‘scheduled’ times in this file, but the WebUI will not reflect the changes.

**1. # vi /nas/site/cron.d/nas\_user** [Comment out CheckPoint refreshes]

# SnapSure Checkpoint job 1 of 1

#0 6 \*/1 \* \* nasadmin /nas/sbin/cron\_plus 75721061798813\_2 0 2147483647 -f /nas/site/fs\_wst\_exhibit\_1

# SnapSure Checkpoint job 1 of 1

#0 6 \*/1 \* \* nasadmin /nas/sbin/cron\_plus 96251064884803\_2 0 2147483647 -f /nas/site/fs\_gsmo\_eishome\_1

# SnapSure Checkpoint job 1 of 1

#0 5 \*/1 \* \* nasadmin /nas/sbin/cron\_plus 56521065591798\_2 0 2147483647 -f /nas/site/fs\_guts\_nasexp01\_1

**2. # touch /etc/crontab** [Forces changes into CS memory by reading the changed file]

**Note:** Actual refresh schedule is run by /nas/sbin/cron\_plus and the job files are located in /nas/site directory

**LOCATION OF CHECKPOINT SCHEDULES NAS 5.1 & 5.2:**

**/nas/volume/fscps**

**Note:** Control Station location for Checkpoint Schedules in NAS 5.1 and higher created from Celerra Manager.

**\$ ls -la**

### PRINTSTATS OUTPUT OF CHECKPOINTS FOR SERVER 3:

#### # .server\_config server\_3 -v "printstats svfs"

\*\*\*\*\*

\* Checkpoint statistics for those PFS with checkpoint FS: \*

\*\*\*\*\*

Checkpoint statistics for FS 38:

-----  
Per PFS totals:

Snapped volume:  
snappedRd 156066 2888364 18  
snappedWt 384367 235714217 613

0 SnapshotVol reads: 29 savVol reads, -29 cloneVol reads  
384367 SnappedVol writes: 384364 snapWrites, 0 nonSnapWrites

Checkpoint statistics for FS 42:

-----  
Per PFS totals:

Snapped volume:  
snappedRd 6 135 22  
snappedWt 2340 95982 41  
0 SnapshotVol reads: 0 savVol reads, 0 cloneVol reads  
2340 SnappedVol writes: 2340 snapWrites, 0 nonSnapWrites

**NOTE:** Only DeltaVol read times (thus SnapshotVol reads) include I/O time--other times are just overhead time on I/O, not I/O time.

### EXTENDING CHECKPOINT SAVVOL:

#### # nas\_fs -xtend fs1\_ckpt1 -volume mtv1\_a

**Note:** Automatic for NAS 4.x whenever HWM of SavVol is reached

NAS 4.0 extends automatically by 10% of PFS original size

NAS 4.2 extends automatically by 500MB

### RESTORING CHECKPOINTS:

Option 1: Restore files or folders manually from a remotely mounted Unix Client to the exported Checkpoint filesystem and Production File System using a Unix copy command. In the case of CIFS, use Windows Explorer to access a network Share

Option 2: Restore from commandline while PFS is mounted:

**# /nas/sbin/rootfs\_ckpt fs1\_ckpt1 -Restore**

**Note:** A new Checkpoint is automatically created in 4.2.x prior to conducting the actual “restore” operation

## **NAS 5.2 CHECKPOINT RESTORES:**

Restores can be done online to the PFS. SnapSure creates a new CheckPoint prior to the restore. Important that a HWM of 75% be indicated for the restore operation to ensure success. If the SavVol has to be automatically extended, the first Restore attempt may fail—try the operation again.

## **EXAMPLE → RESTORING FROM CHECKPOINT:**

**# /nas/sbin/rootfs\_ckpt fs1\_ckpt1 -R -o %full=75**

## **EXAMPLE OF CHECKPOINT RESTORE vs. REFRESH:**

Customer has (10) Checkpoints (ckpt1-10) of a PFS captured on a single SavVol, and wants to do a ‘Restore’ of “ckpt5”. What happens? The ‘Restore’ operation will first create a new “ckpt11” of the PFS in case the ‘Restore’ is not actually wanted, and will then conduct the ‘Restore’ without affecting any of the other checkpoints. A ‘refresh’ operation, on the other hand, will delete the oldest Checkpoint in order to create the new Checkpoint.

## **DELETING CHECKPOINTS:**

**# nas\_fs -d checkpoint\_name**

**Comment:** Normal rule is always delete the oldest Checkpoint of a PFS first. Must permanently “unmount” CheckPoints before deleting—use the –Force flag if required to unmount.

## **ALTERNATE METHOD FOR DELETING CHECKPOINT:**

**#.server\_config server\_3 -v "file delete ckpt ckptFSID PFSID SaveVol=Fsvol force"**

**#.server\_config server\_3 -v "file delete ckpt 948 102 605=569 force"**

**Note:** 948 is ckptID for ckpt fs 102. 605 is ckpt volume number and 569 is volume number for PFSID

## **CONDUCTING CHECKPOINT REFRESHES:**

--NAS 2.2 Checkpoint refresh option requires that a Checkpoint be unmounted first

--NAS 4.x Checkpoint refresh option does not require that Checkpoint be unmounted

**# fs\_ckpt fs1\_ckpt1 -refresh**

**Note:** In the case of multiple Checkpoints for a single PFS, “refreshes” must takes place on the oldest Checkpoint first. A ‘refresh’ is really a deletion and a re-creation of the checkpoint. With 5.2 out of order deletion and refresh, if the checkpoint is not the oldest, the checkpoint is compacted and merged with other checkpoints. ‘Refresh’ failures are logged in the “sys\_log”. If scheduled checkpoint refreshes fail, determine why, correct, then either manually refresh or let the next scheduled refresh occur. Do not allow ‘refreshes’ to occur while the NAS Database backup is occurring, which starts at (1) minute past each hour.

## **VERIFYING CHECKPOINTS FOR A PFS:**

**# nas\_fs -i fs1**

ckpts = fs1\_ckpt1, fs1\_ckpt2, fs1\_ckpt3

**Comment:** After a “refresh” of a checkpoint, the order will change from “left-to-right” as “oldest-to-newest”. Refreshes can also be scheduled at specific intervals using “Celerra File Server Manager”

## **VIRTUAL ENTRIES ON PFS WITH NAS 4.2:**

Production File System: FS1

Checkpoint Virtual Directory Entry for PFS: .ckpt\_fs1\_ckpt1

**Comment:** Mount the datamover’s file system from Unix Host to view or restore files from the checkpoint directory

## **CREATING CHECKPOINT CALLED “ENG CKPT1” FROM METAVOLUME “MTV1”:**

1. Create Checkpoint: **\$nas\_fs -n eng\_ckpt1 -Checkpoint eng -volume mtv1 -o %full=80**
2. Create Mountpoint, Mount & Export to same DataMover as PFS [Read-Only]
3. Auditing SavVol Space: Check Server Log HWM Entries & look at “used =65%” section of **\$nas\_fs -i eng-nb**
4. Extending a Checkpoint: **\$nas\_fs -xtend eng\_ckpt1 -volume mtv1\_a**
5. Deleting Old Checkpoints: **\$nas\_fs -d eng\_ckpt1**
6. Restoring a file from a Checkpoint FS using a Unix Host: \$cp /source/ckptfile1 /target/ckptfile1

**Note:** If not specified, Checkpoint will create a default SavVol that is 10% the size of the PFS

**Caution: For 2.2 NAS code, if you do not extend a SavVol before it becomes full, it is rendered inactive and unusable!**

## **TROUBLESHOOTING CHECKPOINTS:**

**Information Needed by Eng:** Server Log; Command Log; Crash Dump, if applicable

# cat /nas/sys/nas\_param

ckpt:10:50:20: →NAS 5.1 values

# cat /nas/sys/nas\_param

**ckpt:10:100:20:** →Default values 5.5.32.4, same since NAS 5.2

**Note:** First value of ‘10’ indicates the ‘polling rate interval’ for the Control Station in seconds; ‘100’ represents the max rate in MBps that changes will be written to the file system; ‘20’ represents the percentage of space that the system will allocate to CheckPoints & Replicator from all storage [adjust this value up as required but do not go below 20%]. If the 20% threshold is reached, errors may be logged in cmd\_log.err or nas\_log.al.err as ‘Volume is unreachable’ or ‘Volumes are not available’—if this happens, increase the 20% to a higher value.

## **NAS 5.6:**

# cat nas\_param|grep ckpt

**ckpt:10:200:20:**

### **CMD LOG.ERR (nas\_log.al.err):**

Volume is unreachable [Extend 20% storage allocation in nas\_param file]

### **SYS LOG:**

Apr 5 22:05:49 2004 SVFS:0:1 Slot 2: 1081228183: FSID:45 SavVol:260 Full(hwm)reached (t:13547361908090806)

**Note:** Look for messages related to Checkpoints, as in the SavVol HWM message here

### **CMD LOG:**

2004-04-06 23:00:05.779 db:201:18762:S: /nas/bin/fs\_ckpt ufs201\_tue\_0 –refresh

2004-04-06 23:00:08.149 db:201:18762:E: /nas/bin/fs\_ckpt ufs201\_tue\_0 –refresh

**Note:** Look for evidence that Checkpoint refresh started and completed successfully

### **SERVER LOG:**

2004-04-06 23:04:10: SVFS: 4: The filesystem:34 froze.

2004-04-06 23:04:10: SVFS: 4: currctx, SnapshotVolName:Sh26034

2004-04-06 23:04:10: SVFS: 4: oldestctx, SnapshotVolName:Sh26034 :

2004-04-06 23:04:10: SVFS: 4: pause() requested on fsid:27

2004-04-06 23:04:11: SVFS: 4: pause() done on fsid:27

2004-04-06 23:04:11: SVFS: 3: SetSnapShotInactive(): Checkpoint Delete

2004-04-06 23:04:11: SVFS: 4: D34\_0 Permanent InActive

2004-04-06 23:04:12: SVFS: 4: resume() requested on fsid:27

2004-04-06 23:04:12: CFS: 4: Resuming fs 27

2004-04-06 23:04:12: UFS: 4: Cleaners into 12548e80, cg 43dc0640, dirty 12549c40

2004-04-06 23:04:12: UFS: 3: filesystem is read-only: quotas not turned ON.

2004-04-06 23:04:12: ADMIN: 4: Command succeeded: file refresh ckpt 34 260=252 hmw=90

**Note:** Look in Server Log for details. The real PFS is FSID:27 in this example, and the Checkpoint refresh taking place is FSID:34

### **NAS EVENT FACILITY:**

NAS\_DB, Severity = Error, Event ID 211 = missed scheduled task, Event ID 212 = scheduled task fails

### **SCHEDULER LOG: [NAS 5.3]**

**/nas/log/webui/apl\_sched.log**

### **CRONTAB SCRIPTS:**

00 23 \* \* 1-5 /home/nasadmin/scripts/ckpt\_ufs201.sh > /tmp/ckpt\_ufs201.log 2>&1

20 23 \* \* 1-5 /home/nasadmin/scripts/ckpt\_ufs301.sh > /tmp/ckpt\_ufs301.log 2>&1

**Note:** Above example is not a good idea to be running Checkpoint refresh at 11:00 p.m.—reschedule for 11:15 so as not to interfere with NAS DB backups.

### **REVIEW FILE SYSTEM INFO:**

# nas\_fs -i ufs201\_tue\_0

```
id      = 34
name    = ufs201_tue_0
acl     = 0
in_use  = True
type    = ckpt
volume  = vp260
profile = symm_std
member_of = vefs28
rw_servers=
ro_servers= server_2
ckpt_of= ufs201 Tue Apr  6 23:00:07 PDT 2004
used   = 64%
full(mark)= 90%
```

**CheckPoint Information in Server log:** Logged as “SVFS” entries

### **Common Server Log Message for Checkpoint FileSystems:**

2002-06-13 19:51:26: SHADOW: 3: Error IsReadOnly from writeBlock

2002-06-13 19:51:26: SHADOW: 3: Error from write block: 26

**Note:** Normal message for Read-Only file system

## **1. Examine Checkpoint File System:**

```
$ nas_fs -i -s eng-nb [PFS=eng]
id      = 254
name    = eng-nb
acl     = 0
in_use  = True
type    = ckpt
volume  = eng-nb
rw_servers=
ro_servers= titanic
checkpoint_of= engineering Thu Mar 21 11:07:39 EST 2002
used    = 51%
full(mark)= 50%
symm_devs = 002804000222-058,002804000222-038
disks   = d84,d52
disk=d84  symm_dev=002804000222-058 addr=c0t6l1-19-0 server=titanic.....
```

## **2. Verify Status of Production File System and Checkpoints Attached:**

```
# .server_config titanic -v "file display ckpt 218" [FSID from PFS nas-fs -l]
1016817011: SVFS: 3: Checkpoint on FSID:218 (from oldest to the most recent):
1016817011: SVFS: 3: ****
1016817011: SVFS: 3: SavVol:260
1016817011: SVFS: 4: CheckPoint is Active, and Persistant. hwm:50
1016817011: SVFS: 4: FsVol #CFSBlocks:17846272, (at the time the CheckPoint was created)
1016817011: SVFS: 4: SavVol #CFSBlocks:2099561, #CFSBlocks used:1347527, #CFSBlocks free:752034
1016817011: SVFS: 4: BitMapMemUsage:2244656 Bytes, BlockMemUsage:131448 Bytes
1016817011: SVFS: 3: ****
1016817011: SVFS: 3: No more Checkpoint on FSID:218
1016817011: ADMIN: 4: Command succeeded: file display ckpt 218
3. $server config server 2 -v "printstats svfs"
```

Various statistics about checkpoints on the Server

## **4. Examine Server Logs:**

### **Checkpoint File System is Filled and Rendered INACTIVE!:**

```
2002-03-20 14:26:50: SVFS: 3: 2: FSID:23 SavVol:256 Inactive
2002-03-20 14:26:50: SVFS: 3: CKPT_INACTIVE_EVT: FSID:23 SavVol:256
2002-03-20 14:26:50: SVFS: 3: Save Vol full!! Unmounting CKpt file system 250
2002-03-20 14:26:50: CFS: 4: DNLC: erased 0 entries
2002-03-20 14:26:50: CFS: 4: Calling waitForQuiesce, refCounter 16
```

### **Checkpoint High Water Mark is Reached, Logging a Warning in the Server Log:**

```
2002-03-19 19:08:01: SVFS: 3: Recover successful for SavVol:260, FsVol:235 FsType:uxfs
2002-03-20 09:11:39: SVFS: 0: 1: FSID:218 SavVol:260 Full(hwm) reached
2002-03-20 09:11:39: SVFS: 3: CKPT_HWM_EVT: FSID:218 SavVol:260 Full(hwm) reached
```

## **5. Using VVS commands on Checkpoint volumes:**

### **# .server\_config server\_2 -v "vvs list"**

```
1201641099: VCS: 6: There are 34 version sets
1201641099: VCS: 6: Version set 118_800: type=2 refCount=4 numVersions=13 maxVersions=127
1201641099: VCS: 6: Version set 139_1362: type=2 refCount=4 numVersions=13 maxVersions=127
1201641099: VCS: 6: Version set 136_1366: type=2 refCount=4 numVersions=17 maxVersions=127
1201641099: VCS: 6: Version set 133_1370: type=2 refCount=4 numVersions=12 maxVersions=127
1201641099: VCS: 6: Version set 6250:fs6250_T18_LUN2_APM00072500829_0000: type=1 refCount=4 numVersions=1
maxVersions=2002
1201641099: VCS: 6: Version set 6251:fs6251_T18_LUN3_APM00072500829_0000: type=1 refCount=4 numVersions=1
maxVersions=2002
1201641099: VCS: 6: Version set 5086_5104: type=2 refCount=4 numVersions=1 maxVersions=127
```

### **# .server\_config server\_2 -v "vvs listversion vsid=5086\_5104"**

```
1201641217: VCS: 6: numWVersions = 0, maxWVersions = 16
1201641217: VCS: 6: vn=-1 type=1 ref=3 name=5086
```

### **# .server\_config server\_2 -v "vvs getattribute vsid=168\_171 name=RepConsistencySignature"**

```
1254868962: VCS: 7: VVS::getAttrlen : attrName=RepConsistencySignature attrLen=4
1254868962: VCS: 7: VVS::getAttribute attrName=RepConsistencySignature attrLen=4
1254868962: VCS: 6: vvs getattribute: name=RepConsistencySignature, length=4, value=[]
```

### **# .server\_config server\_2 -v "vvs setattribute vsid=764\_768 name=RepConsistencySignature value=0"**

```
1244337295: VCS: 7: VVS::setAttr attrName=RepConsistencySignature attrlen=1
1244337295: VRPL: 7: VPM::doRepTLogIO ioMode=1 ioData=2
1244337295: VRPL: 7: VPM::doRepTLogIO ioMode=1 ioData=1
```

1244337295: VRPL: 7: VPM::setVersionSetRepConsistencySignature  
1244337295: VRPL: 7: VPM::doRepConfigDataIO ioMode=1  
1244337295: VRPL: 7: VPM::doRepTLogIO ioMode=1 ioData=1  
1244337295: VCS: 6: vvs setattribute: name=RepConsistencySignature, length=1, value=0

### **CREATING CHECKPOINT:**

**\$ fs\_ckpt id=pfs1 -name ckpt1 -Create ProdVol -o %full=75** [default is 90%]

### **DELETING CHECKPOINTS:**

**\$nas\_fs -delete pfs1\_ckpt1**

### **PROBLEM DELETING CHECKPOINT:**

**Situation:** File System will not delete, shows as unmounted in data mover database files, yet shows as ‘In Use’ with nas\_fs –l.  
Running nas\_fs –d says that file system is still owned and in use by server\_2.

#vi /nas/volume/filesys

26:fs13\_ckpt1:0:y:7:::1:1061918359::0::24:

**Note:** Change ‘Y’ value to ‘N’ and remove number ‘1’ for server\_2

**#nas\_fs -delete fs13\_ckpt1**

### **ALTERNATE METHOD FOR DELETING CHECKPOINT:**

**.server\_config server\_3 -v "file delete ckpt ckptFSID PFSID SaveVol=FsVol force"**

**\$server\_config server\_3 -v "file delete ckpt 948 102 605=569 force"**

**Note:** 948 is ckptID for ckpt fs 102. 605 is ckpt volume number and 569 is volume number for PFSID

### **PREVENTING MERGE THREAD FROM RUNNING IN DART ON REBOOTS:**

**# .server\_config server\_2 -v "param fulldescription SVFS nomerge"**

SVFS.nomerge 0x020ecf18 0x00000000 0x00000000

**Note:** Setting to 1 will prevent SnapSure’s out-of-order delete process from restarting, useful if needing to delete checkpoints.

### **VIRTUAL ENTRIES ON PFS WITH NAS 5.0:**

Production File System: FS1

Checkpoint Virtual Directory Entry for PFS: .ckpt\_fs1\_ckpt1

New “hidden” Checkpoint directory: .ckpt

**Comment:** Mount the datamover’s file system from Unix Host to view or restore files from the checkpoint directory. Although permissions are inherited from the Parent directory, Checkpoint will enforce the permissions of the files themselves.

### **CHECKPOINT TIMESTAMPS:**

Checkpoints used to display in GMT time, but with NAS 5.1.19.51, timestamp represents local DM time

### **TURNING OFF CVFSv1:**

**param cfs showChildFsRoot=0**

**Note:** Newer Checkpoint style is CVFSv2—CVFSv1 entries are not hidden. A major change with CVFSv2 is that the refreshed checkpoint directory name, as found in the hidden .ckpt under the production file system root, is now updated with the time and date that DART created the refreshed checkpoint, giving the customer a better way to figure out which checkpoint is which on the CS. But note that the “ls –l” Unix or Windows timestamp of the directory itself is related to the last modification time of the root of the PFS itself, not the actual time of the refresh—so the Unix date of the directory could be days or months older than the refresh name itself.

### **Accessing Hidden Checkpoint Directory From Unix Client:**

Step 1. From Unix Host, go to File System mountpoint on DM, then \$cd .ckpt

Step 2. ls –al [Directories are listed by FS ID]

### **Accessing Hidden Checkpoint Directory from Windows Client:**

Step 1. Windows Explorer—Map drive letter “G:” to sharepoint of Production File System to which Checkpoints have been made

Step 2. Highlight Top Level of Drive Mapping from Explorer

Step 3. Go to Explorer Address Bar: Address G:\.ckpt

Step 4. You can now browse the .ckpt folder and any checkpoint folders within

### **Accessing From DOS Prompt:**

C:>\G:

G:>\cd .ckpt [dir to list]

Note: Individual Checkpoints show up as uniquely numbered folders [Jun 12 11:29 06120300.074]

## **CONFIGURING SNMP TRAPS/EMAIL NOTIFICATIONS:**

See SNMP section. Facilities and Event IDs available are as follows:

- 70      1 = HWM SavVol reached
- 2 = Checkpoint has become inactive
- 91      1 = Scheduled CheckPoint creation has failed
- 2 = Scheduled Checkpoint refresh has failed
- 137     10 = Auto-extension of SavVol failed
- 101 = Memory quota exceeded for Checkpoint creation, extension, or replication

## **CELERRA MPFS--MULTI-PATH FILE SYSTEMS old name→“HighRoad”**

### **TWO BASIC ARCHITECTURES:**

- I. EMC Celerra MPFS over Fibre Channel (NS20FC/NS40FC—CX3-40F/Gateways)
- II. EMC Celerra MPFS over iSCSI (NS40 for MPFS—CX3-40C/Celerra with CLARiiON CX3/CX4 arrays/Celerra Gateway with iSCSI MDS—CX3-20C/CX3-40C/CX4-960/CX4-240/CX4-120)

### **GENERAL MPFS INFORMATION:**

- Latest revision of MPFS 5.0 takes the best features of the SAN (High Bandwidth) and combines with the ‘data sharing’ capabilities of NAS, using either traditional Fibre Channel or both Fibre Channel & iSCSI
- Hosts send file requests to Celerra over the IP network (NFS/CIFS), and metadata passed back to client using FMP, but actual data streams are exchanged directly between Host and Storage using SAN FC connection or iSCSI-to-Switch and then to storage (DM does not do iSCSI directly)
- Clariion & Symmetrix storage allowed [Clariion since NAS 5.3]
- Linux & Windows Clients use special MPFSi software for driver and agent
- It’s estimated that 11% of the traffic consists of Control Path communications (metadata exchanges between MPFS client & DM MPFS Server), while the other 89% consists of the Data Path workload between Client and Storage via switch
- Clariion LUN trespass supported natively, does not require PowerPath
- Improved single thread IO performance
- MPFS disk protection module
- Default FMP threads=16, with max FMP threads 128 [Each thread uses 16K memory, so 128 threads=2048K]
- # server\_mpfs server\_2 –set threads=32 (persistent change)
- Default FMP port for Data Mover=4656
- MPFS Unix clients require port 6907 to listen for the MPFS Server, while Windows clients require Port 625

### **LATEST MPFS CLIENT RELEASE:** Dec 2009

v5.0.32.9 Linux

v5.0.92.6 Windows

### **5.0.20.7 LINUX MPFS RELEASE NOTES:** August 2008

- Increased support from 128 to 256 LUNs, though LINUX clients will need to use HVM to mount
- Support for Cisco MDS 9222i switch
- CSA will be integrated into the setup of NS40 for MPFS (NAS 5.6.39.5), and NS20/NS40 FC
- MPFS client support for Fleet arrays

### **HVM HIERARCHICAL VOLUME MANAGEMENT:**

- New tree-based volume structure based on FMP and minimum NAS 5.6 code, turned on by default
- Purpose is to cache more info on file to disk mappings, useful for large files with random I/O access

### **Disabling HVL Feature:**

**# mount -t mpfs -o hvl=0,rw,rsize=32768,wszie=32768,mpfs\_keep\_nfs dm2:/data1/data1 /mnt/**

→Support for Rainfinity Global Namespace Appliance (GNA)

## **EMC CELERRA MPFS: SAN & NAS INTEGRATION**

### **Theory of Operation:**

Application servers are connected to storage via the SAN, as well as to the IP network. The Servers initiate file calls (IO), but the resident MPFS agent intercepts the calls and delivers them the Celerra over IP (NFS or CIFS), with the Celerra acting as a Metadata controller, providing appropriate offset locations for the data. Subsequent Reads, Writes, & Commits are then handled directly by the FMP protocol between the MPFS client and the Storage system using block calls.

→Control Path represents the communication between Host, MPFS driver, and Celerra file systems via NFS, CIFS, or MPFS protocols for metadata and small IO operations

→Data Path represents communication between Host, MPFS driver, and Storage system via iSCSI or Fibre Channel SAN using File Mapping Protocol

1. MPFS Hosts are connected to the SAN & NAS network, and initiate file requests as either an NFS or CIFS client
2. The MPFS agent on the Hosts intercepts I/O calls and sends file access requests to Celerra via CIFS or NFS, and the Celerra retrieves the metadata information from storage
3. Metadata operations are handled by Celerra via CIFS or NFS as a “metadata” controller (CONTROL PATH), providing block allocation and locking for the Client
4. Data Reads, Writes, Commits are handled by FMP protocol directly between Client & Storage over FC or iSCSI SAN using Blocks (DATA PATH)

## **CURRENT NAMING CONVENTION:**

MPFS for iSCSI (aka MPFSi)

MPFS for Fibre-channel (aka MPFS)

MPFS for Windows v5.0 will support either FC or iSCSI MPFS environments

MPFS for Linux v4.3 will support either FC or iSCSI MPFS for RHEL and SuSE

## **LINUX & WINDOWS MPFS VERSIONS:**

→Fall 2008 Mustang MPFS release supports NS20FC (up to 90 drives and 60 MPFS FC Hosts), CSA configuration for MPFS for NS20FC and NS40FC, Fleet arrays connected to Celerra Gateway models, Rainfinity Global Namespace for Linux, Cisco MDS 9222i switch

→March 2008, MPFS v5.0.15.1 for Linux and MPFS 5.0.787.1 for Windows supports either FC or iSCSI MPFS

→March 2008 Corvette release adds support for RedHat 5, Windows XP Fibre Channel & 64-bit O/S support, HP-UX Itanium ia64 64-bit O/S support, SYR enhancements, Rainfinity Global Namespace support for Windows, small file performance improvements, Improved random I/O performance, enhanced diagnostics, fewer installation packages

→Enhanced mpfsctl command to list LUNs

→mpfsinfo tool for Windows and Linux enhanced

→mpfsinq tool enhanced for Windows and Linux

→Supports Clariion arrays using iSCSI combo cards (CX3-20C & CX3-40C)

→Support for Windows XP, 2003, XP 64-bit O/S

→Support for Linux RHEL 5.0

→128-896TB capacity support using NMFS [128TB capacity NS40 Blades; 896TB capacity for Gateways]

## **LIMITATIONS:**

→Snapsure and Replication are not supported

→Cannot mix Symm & Clariion backends

→Connectrix iSCSI-to-Fibre Channel bridges: MDS9216I, 9216A, 9506 & 9509 v1 & v2, 9513 SAN OS 2.1 (2b)/SAN OS 3.0 (2a)

→Combo card NS40 with CLARiiON CX3-20C or CX3-40C backend running Flare 22

## **CURRENT MPFS SOLUTIONS:**

→NS40 Integrated using CX3-40C iSCSI card on the array for iSCSI solution

→NS40 FC Integrated using CX3-40F array for Fibre Channel solution

→NS40G, NS80G, NSX Gateway using iSCSI solution for mid-tier [Client-to-array iSCSI, not Celerra iSCSI]

→NS40G, NS80G, NSX Gateway using iSCSI or Fibre Channel solutions for high-end [MDS iSCSI or FC switch]

## **CURRENT MPFS CLIENT O/S SUPPORT (March 2008):**

RHEL 3 U7+, RHEL 4 U4+, & RHEL 5 U1+ [all for x86, x64, ia64]

Novelle SuSE SLES 8 SP4 (x86), SLES 9 SP3+ (x86, x64, ia64), SLES 10 (x86, x64, ia64), & SLES 10 SP1 (x86, x64, ia64)

Windows 2000 SP4 (x86), 2003 R2 & SP2 (x86, x64), XP SP2 (x86, x64, iSCSI only)

Solaris 8 (SPARC), Solaris 9 (SPARC), Solaris 10 (SPARC, x86, x64)—All are for Fibre Channel support only

IBM AIX 5.2 (PowerPC), 5.3 (PowerPC)—All are for Fibre Channel support only

HP Unix 11i v1 (PA\_RISC), 11i v2 (PA\_RISC)—All are for Fibre Channel support only

## **UPDATED UNIX SUPPORT:** Dec 2009

Version 4.0.23.1 for HP-UX, AIX, Solaris; Support for 10Gbps iSCSI, increased Host support on arrays

## **HOST MPFS AGENT FAMILIES:**

MPFS for Linux v4.0; MPFS for Linux 4.1/4.2; MPFS for Linux v4.3; MPFS for Linux v5.0 (March 2008)

MPFS for Windows v4.0; MPFS for Windows v5.0 (May 2007, but updated with latest Corvette release)

MPFS for Unix v4.0 (no major update since 2004, but updated to support Solaris 10 FC-only)

## **ACTUAL MPFS VERSIONS:**

### **MPFS for WINDOWS:**

EMCmpfs.win.4.0.15.0.exe (Fibre Channel only)

EMCmpfs.win.5.0.12.100.tar.Z (FC or iSCSI)

**Note:** The 5.0 release supports Windows 2003, XP, VMWare, etc

**MPFS for LINUX (Fibre Channel & iSCSI):**

EMCmpfs.Linux.4.3.20.1.tar.Z, 128TB NMFS file systems, GA May 2007

**MPFS for UNIX (Fibre Channel only):**

EMCmpfs.hp-ux.4.0.18.3.tar.gz [AIX, HP-UX, Linux, SunOS]

**MPFS over iSCSI Version 5.0.12.0 for Windows (formerly WINROAD, Windows MPFSi, etc):**

**MPFS over Windows 5.0.12.0:** GA May 2007

- Minimum NAS version 5.4.24.8 & 5.5.27.5 for supporting W2K3 32 or 64-bit OS running MPFS v5.0.12.0 client, & 32-bit XP SP2
- Max. of 128TB storage on Data Movers under a single mountpoint using NMFS, for NAS 5.5.27.5, with maximum single file system size of 16TB [Backend hardware includes NSX, NS40, or NS80]
- Celerra can be configured for MPFS and also serve file systems for NFS & CIFS
- MPFS 5.0.12.0 supports iSCSI initiators with no more than 128 disks underneath the file system
- Note:** MPFS over iSCSI does NOT use the Celerra as an iSCSI Target. The Windows Client is the Initiator and the Connectrix/Cisco MDS SAN switch, or Clariion combo card, is the iSCSI Target and is used as the bridge between iSCSI and Fibre Channel protocols
- Recommended Windows iSCSI initiator version 2.03 or later
- Clients can connect using either MPFS over FC directly, or through the MPFS over iSCSI configuration already mentioned
- Designed to provide high performance for HPC grid computing clients
- Does not support Celerra Replicator or SnapSure on the MPFS Data Mover
- Recommended storage stripe element size is 256, with minimum 32KB
- Supported on Symm 5000, 8000, DMX
- Supported on Clariion CX300/400/500/600/700 CX3-20C CX3-40C with Flare 24 & Access Logic (?—doesn't support CX600?)
- Data LUNs can use RAID 1, 3, or 5 but Management LUNs must be 4+1 RAID 5
- Do not span file systems across Storage platforms
- MPFS does not respect RO options for Celerra mounts & exports (NFS)
- Maximum of 256 SCSI or iSCSI devices presented to Host
- MPFS over iSCSI requires iSCSI-to-Fibre Bridge Switch: Connectrix or Cisco MDS 9509/9506/9513/9216A/9216i
- Documentation will provide Quickstart Guide, Product Guide, Best Practices White Paper, Troubleshooting Guide, Tools
- MCME/MCMI, Penant, PSC, SVC tools

**CELLERRA MPFSi PIHC (MCM-E/MCM-I) TOOL FOR LINUX (Post Install HealthCheck):**

→ New tool November 2006 for verifying an MPFSi installation and configuration according to known Best Practices, that includes Celerra, Storage, Switch, & Client components—Phase I release

**Note:** With NAS 5.6.47 release and CSA support for configuring MPFS on the Data Mover and Linux client, the MCM tool support is being discontinued

→ Verifies things like Cisco MDS 2.1.2-6 firmware, zoning, NAS version, MPFSi drivers, Storage, MPFSi disks are accessible, kernel OS version, Proxy Initiators are evenly distributed on SPs and can be reached, checks AccessLogix mapping of ALUs to switch zone mappings, can run a performance daemon on Clients to obtain statistics, etc.

→ Client & Server portion of tool can run on Windows or Linux (mpfssi\_server.zip & mpfssi\_client.zip) with java1.5 JRE minimum

→ Tool intended for Field & Service engineers

→ MPFSi Monitor gui allows easy creation of a site, where the IP address & logon info for CS & Switches are entered, at which time Celerra DM's, Storage, Switch, File Systems are discovered automatically. Clients need to be added via Hostname or IP address

**PIHC Server Application:**

Used for Hosts, Celerra, Storage, & Switch information in the GUI program for the ‘site’

To run this service on a Windows client, do the following:

1. Unzip to a folder: mpfssi\_server.zip
2. JAVA\_HOME=c:\jre1.5.0\_08
3. MPFSI\_SERVER\_HOME=c:\mpfssi\_server
4. Run server.bat file

**PIHC Client Application:**

Allows reporting of config info from Linux clients, and client performance monitoring daemon

1. Unzip to a folder: mpfssi\_client.zip
2. JAVA\_HOME=c:\jre1.5.0\_08
3. MPFSI\_CLIENT\_HOME=c:\mpfssi\_gui
4. Run client.bat

**PHASE II—January 2007:**

→ Add a report function so as to be able to output the configuration and parameter settings seen in the GUI, to a report file

→ Add a scheduler function for the performance statistics, which will be useful for troubleshooting performance issues

→ Importing Host information into GUI

→ Auto configuration capability

**MCM-I/MCM-E—MPFS Configuration Manager:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
New name for the old PIHC tool. MCM-E is foreengineering mode (more capability), accessed same manner as Navisphere on Clariion: ctrl + shift +f12, password messner. MCM-I is for customers. Tool is used for Site Setup/Configuration, Backend & Host information, and Management of Hosts.

## **MPFS TOOLS—PENANT Pre-Sales Existing Network Analysis Tool:**

Engineering has developed a Penant (Pre-Sales Existing Network Analysis Tool) tool that will use Ethereal or Wireshark sniffer (tshark is the default) to capture network traffic, then performs a text readout that characterizes the IO in the environment. Penant.pl script will total and provide % on Reads vs. Writes for CIFS & NFS traffic, analyzes access patterns (Random vs. Sequential), analyzes amount of Data vs. Metadata transmitted, file sizes, IOPs, and overall throughput. Tool will also become useful during CS troubleshooting engagements. There is the capability to limit actual data captured by using snaplink, which truncates data packets so as to obtain more manageable captures.

## **PRE-SALES CONFIGURATION TOOL—CSC Celerra Solution Configurator:**

XLS spreadsheet tool to assist in validating and building a basic MPFS model, based on throughput needed and number of hosts in a given environment

### **MPFSi 5.0 Windows Client Setup (Win2k3 & XP):**

1. Install and connect Initiator to Target
2. Install MPFSi client software and reboot
3. Check via Explorer to see if MPFS Volume Properties are displayed & enable the MPFS shares

**Note:** Default connection uses TCP/IP, 8192 block size, make sure connection is checked Persistent; Strict Flush Policy would apply only to special applications that require each IO be committed

4. Console checks:

C:\mpfsctl version | list | stats | reset

C:\net view \\compname

C:\mpfsctl enable <compname> <sharename> | disable

### **EMC Celerra NS40 for Celerra MPFSi:**

**Note:** The NS40 used for MPFSi with the Clariion CX3-40C combo card, is a standard NS40 Integrated, pre-Napa 8 model

→May/June 2007 EMC released a standalone NS40C Integrated version of the NS40 that is configured with the iSCSI combo cards on the dedicated backend array. The actual NAS models are the NS41C-A or B or -FD, or NS42C-A or B or -FD models, which are really standard NS40 Integrateds, but targeted only for MPFS and sold with the NS40-AUXC (EMC rack) or NS40-AUXC-FD (field racked) CX3-40C array. Supports up to 120 MPFS iSCSI hosts. The Celerra itself does not serve as an iSCSI Target.

### **NS40C INSTALLATION:**

→The NS40C installation is really divided into two separate sections—the routine NS40 Integrated Celerra installation, followed by the MPFSi configuration of the Clariion storage system and MPFSi Clients

→Use the following Powerlink destination as the primary source of NS40 MPFSi information:

### **Celerra MPFS over iSCSI>Installation/Configuration:**

[http://powerlink.emc.com/km/appmanager/km/secureDesktop?\\_nfpb=true&\\_pageLabel=servicesDocLibPg&internalId=0b0140668014e854&\\_irt=true](http://powerlink.emc.com/km/appmanager/km/secureDesktop?_nfpb=true&_pageLabel=servicesDocLibPg&internalId=0b0140668014e854&_irt=true)

→The “EMC Celerra MPFS for NS40/NS40FC Integrated (Linux and Windows Clients) Quick Start Guide Oct 2007” provides information and references the Engineering documentation guides for more complete installation of the NS40 Integrated [Celerra Network Server NS40/NS40 DC NEBS Integrated Configuration Phase 1 and 2 Setup Guide and Celerra Network Server Integrated and Gateway Configuration Phase 3 Setup Guide]

→Linux or Windows clients install the MPFS client, connect to the Celerra for FMP metadata transactions using normal network IP, and have direct connections to the backend array via iSCSI for data transfers.

→The “EMC MPFS NS QuickStart Practitioner’s Guide July 25, 2007” provides more in-depth background in how to best implement the Celerra solution for MPFSi

### **MPFS PARAMETERS/RESTRICTIONS:**

- Minimum stripe size is 32k--volume not 8k aligned
- MPFS cannot support more than 4000 devices or use a disk volume with a number higher than 4000
- NAS 4.1.4.0 Requires File System stripe sizes of 32K or greater in order to mount as MPFS Volumes [32768]
- Quotas are not supported with MPFS
- Checkpoint Snapshots are not supported with MPFS
- Striping on SYMMETRIX is recommended, not on the Celerra! [Use 128k striping]
- Symm RDF supported but not Celerra SRDF
- TimeFinder supported for 3.0.16.x and above
- Use VolumeLogix for Fibre Channel installations

### **LINROAD TOPOLOGY→NEW IP SAN & IP NAS INTEGRATION:**

Similar as conventional MPFS, but builds on the availability of iSCSI technology, NFS or CIFS Clients use MPFS driver to intercept traffic and communicate to HighRoad Server, but are iSCSI-connected to Connectrix MDS9509 with iSCSI IPS module, Symmetrix or Clariion storage for high-speed data transfer, with meta-data again transported over IP Network using FMP protocol.

→Phase I using just Linux Clients will be based on RH3/SuSe 8.0

→Not a Celerra iSCSI solution

→NAS 5.4 & higher

## **CELERRA MPFS FOR iSCSI:**

→MPFSi v4.1.10.0 supports Linux RHEL 3 [Linux iSCSI initiator & Connectrix MDS 9509 or Cisco Catalyst 6509 switch with iSCSI bridge to iSCSI target]—uses only the IP-SAN switch iSCSI target, not the Celerra, CLARiiON, or Symmetrix iSCSI target

→MPFSi v4.2.12.0 supports Linux RHEL 4

→MPFSi v4.3.13.0 (Jan 2007) supports Linux RHEL 3 & RHEL 4

→Minimum one Connectrix MDS switch for FC to iSCSI bridging using SAN OS 2.1(2b) or 3.0(2a)  
Connectrix MDS 9216A, 9216i, 9506 & 9509 v1 & v2, 9513

→Both Symmetrix & Clariion backends supported, with latter using RAID 1, 3, or 5 Storage Groups

→Cannot use both MPFS & MPFSi clients on the same Host

→NAS Versions 5.4.24.5 & 5.5.22.0 support MPFSi 4.1 – 4.3 clients

→NAS Version 5.3 minimum for MPFS 4.0 clients

→iSCSI target is the SAN Switch or Clariion, not the Celerra or Storage system

**Note:** Only the NS40 Integrated is qualified with the Clariion backend (CX3-40C) for MPFS over iSCSI

→Max. of 256 luns per Host initiator for Linux RHEL 3, but 300 luns RHEL 4

## **HOW MPFS WORKS:**

→Clients connect to Storage via FC/SAN or iSCSI/FC

→Clients connect to out-of-band “metadata” controller, in this case the Celerra Server

→MPFS layer separates Metadata FS Information [Control Data] from the Data FS [Payload Data] by intercepting Client Opens, Closes, Reads, & Writes

**Note:** MPFS Client intercepts file write call and asks Data Mover to allocate blocks on disk for the file, and after extent list is sent back to the client, the client writes directly to storage disk, then informs Server when complete

→All non-data Client requests use NFS/CIFS layer for metadata information which includes file block map, attributes, directory info

→FMP—File Mapping Protocol, is used to exchange file layout information between MPFS client and Data Mover using NFS or CIFS

**Note:** The FMP Protocol sits on top of Network Access Protocols serving as a Redirector

→For SAN, metadata is transferred over IP Network, while data is transferred over SAN (MPFS over SAN)

→For IP-SAN, metadata and data is transferred over IP Network (MPFS over iSCSI) using either Cisco/Connectrix MDS Switch, or directly from the Clariion using CX3-20C/CX3-40C FC/iSCSI combo model. iSCSI requests are translated into FC Channel Data Blocks (CDBs) by the Clariion or MDS Bridge.

**Note:** A private network could be setup with a separate NIC for iSCSI traffic

**iSCSI TARGET:**                   **iSCSI INITIATOR:**

MDS Switch or

MPFS Client

Clariion array

## **Linux Client Tweaking:**

Increase max read-ahead kernel param from default 31 to 8192 by adding following line to /etc/sysctl.conf

**vm.max-readahead = 8192**

## **Linux Configuration:**

Should already have iSCSI initiator drivers installed, but if not, use iscsi-initiator-utils

Add following lines to /etc/iscsi.conf to identify port on MDS switch

DiskCommandTimeout=10

DiscoveryAddress=172.17.2.22

## **Troubleshooting:**

→Check that iSCSI virtual-target definitions include all LUNs for both SPs

→MDS Switch does not allow iSCSI port WWN to see both SPs

→Accesslogix Storage Group does not allow iSCSI port to see all LUNs from both SPs

Run iscsi-ls to see if client can see both SPs

Run mpfsinq to see if all dvols can be seen

Check /var/log/messages fil

Run mpfsdiscover to re-discover Celerra LUNs

## **MPFS CLIENT COMMANDS/CONFIG INFO:**

# **mpfsinfo -v <mpfserver>**

# **mpfsstat -d 2**

**Note:** info on I/Os issued to disk

# **mpfsinq** (active & passive paths to storage)

# **cat /proc/mpfs/params** (MPFS parameters)

# **cat /proc/mpfs/devices** (kernel devices)

# **cat /proc/mpfs/hrdp** (disk protection)

**/etc/mpfs.conf** (MPFSi configuration file, kernel parameters such as globPrefetchSize)

**/etc/sysconfig/EMCmpfs** (mpfs discover daemon & parameters—runs every 15 minutes to check for paths & trespassed luns)

#### **MPFSi Improvements:**

Extent-based flush to optimize metadata flushes to reduce Server overhead (dirty pages maintained until committed via FMP flush)  
FMP protocol enhancement to offload the volume tree traversal work to the Clients and not the Server

FMP Clients also make better use of cache to reduce RPC calls

CIFS Clients can now better determine IP Address context for multi-homed clients

#### **BEST PRACTICES INFORMATION:**

→Do not use AVM, setup User-defined storage pools

→RHEL3 supports 255 scsi devices; RHEL4 supports 300 scsi devices

→Use TCP protocol

→RAID 3 is recommended for ATA drives on Clariion

→Configure CX3 Clariion with Read cache size 256MB/SP, Write cache size 2938/SP, water marks 70% low 90% high, page size 8KB, and use 64KB stripes in (2) striped volumes across (2) pairs of (9) Luns, meta-concatenated

→For DMX-3, use 24 volumes on 24 separate disks and create 256KB striped volumes

→Create Celerra filesystems using stripe size 256kb for CLARIION and 32kb for Symmetrix

→Load balance LUNs across SPs

→Change Linux iSCSI initiator timeout in /etc/sysconfig/iscsi for reboots: ESTABLISHTIMEOUT=60

→iSCSI Best Practices Guide Connection Failure timeout values in /etc/iscsi.conf file are “ConnFailTimeout=45”

→Do not run CAVA or use multi-homed NICs on Windows system running MPFSi client

→File Systems built on either all FC or all ATA drives, not mixed [Using ATA & LCFC drives are NOT recommended]

**\$ ./ftplibboot/setup\_backend/zone -s 2 showdm** (command to collect WWN's for DMs)

Checking for Data Mover 2.

Collecting Data Mover WWNs...Done.

DM List:

DM Port:20 WWN:50:06:01:60:90:60:16:f8:50:06:01:60:10:60:16:f8

DM Port:21 WWN:50:06:01:60:90:60:16:f8:50:06:01:61:10:60:16:f8

DM Port:22 WWN:50:06:01:60:90:60:16:f8:50:06:01:62:10:60:16:f8

DM Port:23 WWN:50:06:01:60:90:60:16:f8:50:06:01:63:10:60:16:f8

**\$ ./zone -spa 10.241.168.55 -spb 10.241.168.56 showsp** (checks IP connectivity & collects WWN's SPs)

Checking network connectivity to 10.241.168.55 / 10.241.168.56 ...Done.

Collecting backend WWNs...Done.

SP List:

SP Port:A0 WWN:50:06:01:60:90:60:05:10:50:06:01:60:10:60:05:10

SP Port:A1 WWN:50:06:01:60:90:60:05:10:50:06:01:61:10:60:05:10

SP Port:A2 WWN:50:06:01:60:90:60:05:10:50:06:01:62:10:60:05:10

SP Port:A3 WWN:50:06:01:60:90:60:05:10:50:06:01:63:10:60:05:10

SP Port:B0 WWN:50:06:01:60:90:60:05:10:50:06:01:68:10:60:05:10

SP Port:B1 WWN:50:06:01:60:90:60:05:10:50:06:01:69:10:60:05:10

SP Port:B2 WWN:50:06:01:60:90:60:05:10:50:06:01:6a:10:60:05:10

SP Port:B3 WWN:50:06:01:60:90:60:05:10:50:06:01:6b:10:60:05:10

**Add following entry to /etc/auto.misc file to allow auto-mounter to mount MPFS file systems:**

mnt -fstype=mpfs /server/fs

#### **SUPPORTED MDS SWITCHES:**

MDS 9506; MDS 9509; MDS 9513; MDS 9216A; MDS 9216i (Cisco MDS SAN-OS Release 2.1(2b))

MDS 9506v2; 9509v2; 9513 and MDS SAN-OS 3.0

#### **MDS 9000 Best Practices:**

→Use proxy-initiator mode only

→Use store & forward mode only

→Use dynamic target mapping

→Use iSCSI TCP send buffer size of 16384

### **HIGHROAD DATA PROTECTION (HRDP):**

Devices that are configured for the MPFS service at boot time are protected from use by other programs using HRDP. To verify devices & protection seen by Linux host after bootup:

```
# mpfsinq  
# dd if=/dev/sdc count=1  
dd: opening '/dev/sdc': No such device
```

**Note:** Use dd to test if disk is protected by HRDP—above message return indicates device is protected

**# /usr/sbin/hrdp**

**Note:** Use above command to protect devices added after bootup

### **NOT SUPPORTED BY MPFS:**

--VirusChecker; Checkpoints; Quotas; CDMS; SRDF; Celerion FC4700-2 Storage; File Locking Policies; FSN/VLAN; I18N

--Fiber Channel Control Stations are not supported

--With NAS 5.2 and higher, Checkpoints can be used on file systems that are also in use for MPFS, though MPFS is not supported for checkpoints themselves.

### **MPFS UNIX/WINDOWS CLIENT & SW SUPPORT**

→PowerPath 4.5.x – 5.0.0 required for CLARiiON only, optional for Symmetrix

→Supports all Symm & Clariion backends, latter with RAID 1, 3 or 5 Storage Groups

→MPFS 4.0 clients do not support iSCSI for Windows or Linux

→MPFS 4.0 clients require minimum NAS Version 5.3.10.4

### **MPFS WINDOWS CLIENT Win2k/Win2k3 Fibre Channel Only:**

Version 4.0.15.0 with NAS 5.4 & 5.5 support, PowerPath 4.5.0, 4.5.1, etc.

### **MPFS CLIENTS FOR UNIX HOSTS 4.0.18.x/4.0.19.x (min. code 5.3.10.4 and above) Fibre Channel:**

NAS MPFS for Unix Clients 4.0.19.1

EMCmpfs\_aix\_4.0.19.1.iso

EMCmpfs.hp-ux.4.0.18.3.tar.Z

EMCmpfs.linux.4.0.18.3.tar.Z

EMCmpfs.sunos.4.0.18.3.tar.Z

**IRIX 6.5.9:** EMC HighRoad client 3.1 with NAS 3.0.21.3 or 3.0.22.0

**WINDOWS NT 4.0/2000:** Latest Client: EMCmpfs.win.4.0.13.1.exe

### **POWERPATH CLIENT SW:**

Version 3.0.5 NT and 3.0.6 for Windows 2000/2003

Red Hat Linux version 3.0.6 RHEL 32-bit; Improve Read performance by adding line to /etc/sysctl.conf vm.max-readahead=8192

Solaris 7, 8, 9 and HP-UX 11.11 version 4.3

### **VolumeLogix: Version 2.2.1**

**Note:** Direct-attached via SCSI or Fibre Channel. Startup scripts go into rc1.d & rc2.d. (1) mpfsd daemon runs. Add MPFS filesystems to /etc/vfstab [192.1.4.21:mpfssun - /mpfs mpfs - yes - ]. Be aware that most clients have required patch levels.  
[http://powerlink.emc.com/support/sw\\_downloads/index.jhtml](http://powerlink.emc.com/support/sw_downloads/index.jhtml) [go here to download latest MPFS clients]

### **BASIC MPFS over iSCSI CONFIGURATION STEPS:**

1. MPFS client with iSCSI HBA or sw initiator driver
2. MPFS client with single or dual NICs (NFS or CIFS for one; iSCSI for other)
3. MDS switch with FC/iSCSI configured, or Clariion with FC/iSCSI configured
4. Install MPFS client
5. Configure Data Mover and enable MPFS on file system
6. Start MPFS service on Client

### **Linux TCPDump Trace:**

Step 1. #/usr/sbin/tcpdump -s 2000 -w /tmp/dump1 host 192.1.5.44 and 192.1.5.23

Step 2. Starts capture between the two nodes; Use “ctrl + c” to stop capture

Step 3. Display Capture: #/usr/sbin/tcpdump -vvex -r /tmp/dump1 |more

### **To List MPFS File Systems:**

```
$ mount -v |grep mpfs
```

### **List Package Info:**

```
$ pkginfo |egrep -i EMCmpfs or $ pkginfo -l EMCmpfs
```

### **Look for MPFS Service:**

```
$ ps -ef |grep mpfsd
```

### **Mounting & Specifying UDP:**

```
$ mount -F mpfs -o proto=udp servername:/usr/src /usr/src
```

**MPFS Share Properties:** Defaults to “Asynchronous Flushing” for client writes. Can change to “Strict Flush Policy” if flushing after every write is important. Default “Block Size” is 8192 bytes. If SRDF used, then “Read-Only” too.

**MPFS Server Setup:**

**# server\_setup server\_2 -P mpfs -o start=n** {-o stop} [where n= number of threads to use—default=16]

**MPFS Threads:** Max.=128 FMP Port=4656 Adding, Deleting, or Setting:

**\$ server\_mpfs server\_4 -set threads=50 {-a 16; -d 16}**

**Note:** Stopping the MPFS service requires about 30 seconds for any Clients to timeout so that the service can be stopped

**Interfaces:** Process RIP—view stats using “server\_rip” command

**TAPE BACKUP SUPPORT FOR MPFS 3.0:**

Use “server\_archive” command to backup using PAX and NDMP to tape drives.

Add Following to Param File on DataMover: /nas/server/slot\_2/param

**param NDMP nbuf=<number for ndmp>** [Derived by # tape drives multiplied by 5]

**param PAX nbuf=<number for PAX>** [Derived from # tape drives multiplied by 4]

**Highroad Network Backup Support:** EMC Data Manager (EDM) 4.6 +

**SETTING UP MPFS LINUX CLIENT FOR iSCSI:**

1. Download & untar Linux MPFS client

2. ./install-mpfs [Installs, starts daemon, and discovers devices]

3. Verify rpm version & daemon:

# rpm -q EMCmpfs

# ps -ef |grep mpfssd

4. Enable MPFS license:

# mpfslicense <16\_digits>

5. Configure iSCSI:

# vi /etc/iscsi.conf and add following to end of file

PingTimeout=30

DiskCommandTimeout=30

PortalFailover=no

HeaderDigest=never

DataDigest=never

InitialR2T=no

ImmediateData=yes

DiscoveryAddress=x.x.x.x [Clariion iSCSI port configuration

# vi /etc/initiatorname.iscsi

# GenerateName=yes →Comment this line out as shown

InitiatorName=iqn.2006.com.emc.mpfsi: <linux\_name> →Add this line to file

6. Start iSCSI service & grep for iscsi process:

# service iscsi start

7. Configure disk protection

8. Verify:

# mpfsdiscover -v

9. Mount Celerra file system from Linux client & verify:

# mount -t mpfs -o tcp,mpfs\_keep\_nfs, rsize=32768, wsize=32768, noatime xxx.xxx.xxx.xxx:/export\_name /mpfs\_celerra\_mount

# mount # mpfsinq # iscsi-ls # cat /proc/mpfs/devices [Celerra devices] # cat /proc/hrdp [Disk protection] # /usr/sbin/hrdp [run to protect devices]

**SUN SOLARIS MPFS CLIENT:**

O/S: 2.6, 2.7, 2.8 #showrev -p #uname -r

Default Protocol on Sun is TCP

MPFS client software is 3.0.20\_b001 for MPFS 3.0.16.5+

**SETTING UP SOLARIS AS MPFS CLIENT:**

1. Install Software:

#/usr/sbin/pkgadd -d /cdrom/8.0 [Enter 1 at prompt, then License Key, Reboot]

2. Map Symmetrix Data Volumes to Solaris “sd.conf” file: [Values derived from BIN file]

#vi /kernel/driv/sd.conf

3. Reboot Solaris System

4. Label new Disk Drives using #format command [Labels disk only for Solaris internal use]

```
--Use #mpfslabel command to allow Solaris to access raw disk, including last (2) cylinders, if required  
#prtvtoc [Use this to verify label prior to running mpfslabel command]  
#mpfslabel /dev/rdsk/c1t0d16s2  
#prtvtoc [Use again to verify mpfslabel command]  
5. Verify MPFS Package Install & Daemon are running:  
#pkginfo -l EMCmpfs  
#ps -ef |grep mpfsd  
6. Mount Solaris to MPFS File System on DM:  
#mount -F mpfs -o rsize=32768,wsize=32768 192.10.4.28:/mpfs1 /mnt  
7. Verify Mounted MGFS FileSystem:  
#mount -v |grep mpfs  
#mpfscctl [Utility to Tune & Manage MPFS]  
#mpfscctl stats [MPFS Stats: /etc/fs/mpfs directory]  
#inq [Outputs info on MPFS Symmetrix devices]
```

**Note:** Information resides in: #/kernel/driv/sd.conf

## **LABELING MPFS VOLUMES FOR SUN SOLARIS:**

**/var/adm/messages** File Error: “Corrupt Label—Wrong magic number”

Means that the mpfs devices were not labeled correctly when setting up the SUN client and need to be labeled:

### **Step 1. LABEL VOLUMES FIRST FOR SUN HOSTS:**

- a.) #format [allows you to see mpfs devices from the Sun client]
- b.) format>label Y format>quit [Label each mpfs volume manually!!!!]

**Note:** Labeling the MPFS volumes from the Sun Client is harmless & will not destroy disk label or data

**Warning:** Failure to ensure that this is done will result in poor MPFS performance

### **Step 2. LABEL VOLUMES FOR MPFS:**

- a.) #mpfslabel /dev/rdsk/c1t0d16s2
- b.) Verify using PRTVTOC command: #prtvtoc /dev/rdsk/c1t0d16s2

## **TROUBLESHOOTING SUN MPFS CLIENTS:**

**Software Installation:** #pkginfo -l EMCmpfs

**Verify Process Running:** #ps -ef |grep mpfsd [/etc/fs/mpfs/mpfsd]

**Verify Disk Labeling:** #format #inq

**MPFS Client Version:** #mpfscctl version

**Sun Version:** #showrev -p

## **MPFS STATISTICS: # mpfscctl stats mpfscctl reset** [look for 'fallthroughs' to NFS and 'RPC errors']

Use “mpfscctl stats” to display statistics showing internal operation of the EMC HighRoad client. By default, statistics accumulate until system reboot. Use mpfscctl reset to reset the counters to 0 before executing mpfscctl stats.

**Logs:** /var/adm/messages [If var gets filled, MPFS performance will suffer] /etc/system /kernel/driv/sd.conf nfsstat

**Traces:** Use TCPDump or NetMon for Traces

## **USING MPFSCOLLECT TO GATHER ESCALATION INFO FOR MPFS:**

# mpfscollect /fs1/trace.mpfs 65536 & (binary output—run the trace during problem or problem recreation on clientside)  
# pkill mpfscollect (kill the trace process after required information is collected)

## **MPFS COMMAND SET:**

**\$ server\_setup server\_3 -P mpfs -o start=32 | stop | delete**

```
$server_mpfs ALL [FMP Threads=16 [default] FMP Open Files=468 FMP Port=4656]  
$server_mpfs server_2 -set threads=128 [Setting Threads for MPFS]  
$server_mpfs server_2 -Stats  
$server_mpfs server_2 -S file=filename [Stats for an MPFS file]  
$server_mpfs server_2 -add 16 | -delete 16 [Adding or Deleting MPFS Threads]  
$server_mpfs server_2 -default [Resets MPFS variables to defaults]  
$.server_config server_2 -v "param ip"  
$.server_config server_2 -v "param nfs"
```

**\$ server\_mpfs server\_2 -mountstatus** [Verifies mounted filesystems are MPFS compliant]

\$server\_mpfs server\_2 -add 64 | -delete 32 | -Default [to revert to default threads] | -Stats [HighRoad Statistics]

**\$ server\_mpfsstat server\_2 | ALL | -z (reset) | -file filepath | -session sessionid | -list**

**Note:** Many new options added. –sessions will show MPFS statistics by session

### \$ server\_mpfsstat server\_2 -list

server\_2 :

```
-----  
Active MPFS sessions  
(clientid/timestamp)
```

```
10.170.36.35      0 sec      0 usec
```

**Note:** -list shows active MPFS sessions on the Data Mover

### \$ server\_mpfsstat server\_2 -file fs1/test/kl44444.tmp

**Note:** Above cmd looks at statistics for specific file

|           |          |                                                                                  |
|-----------|----------|----------------------------------------------------------------------------------|
| Total     | avg msec | high msec                                                                        |
| getMap(): | 22530    | 1.08                                                                             |
|           |          | 164 → This row shows the Read I/O activity—getting FMP locak and “map” of blocks |

**Note:** Locks are shared Read

### \$ server\_mpfsstat server\_2 -session

getMap(): →Relates to Read activity; FMP locking and mapping of blocks being read; locks are shared for reads

### \$ server\_mpfsstat server\_2

allocSpace(): →These two values show Write IO traffic statistics; FMP locking and allocation of blocks for writing, locks exclusive  
commit():

### \$server\_mpfs server\_6 -mountstatus

server\_6 :

```
fs      mpfs compatible?  reason
```

```
-----
```

```
cw_fs46    mounted
```

```
fs_tcpdump yes
```

```
cw_fs30    mounted
```

```
cw_fs26    mounted
```

```
cw_fs22    mounted
```

```
root_fs_common yes
```

```
root_fs_6   yes
```

### \$ server\_mpfs server\_6 -S

server\_6 :

Server ID=server\_6

FMP Threads=16

Max Threads Used=7

FMP Open Files=3

FMP Port=4656

HeartBeat Time Interval=30

### \$ server\_nfsstat server\_2

**Note:** Output useful to see how metadata calls are going and also to see if data has fallen through to NFS—see v3read, v3write, etc.

#### Debugging Windows Client Issues:

**\$ .server\_config server\_2 -v “logsys set severity FMP=LOG\_DEBUG”**

**\$ .server\_config server\_2 -v “logsys set severity SMB=LOG\_DEBUG”**

## WINDOWS 2000 MPFS COMMAND SET:

|                              |                                                    |
|------------------------------|----------------------------------------------------|
| C:>mpfscctl /?               | [Help info on MPFS]                                |
| C:>mpfscctl enable   disable | [Establishes session & sets MPFS share properties] |
| C:>mpfscctl stats            |                                                    |
| C:>mpfscctl list             | [List of MPFS shares]                              |
| C:>mpfscctl version          |                                                    |
| C:>mpfscctl log on   off     | [Enables logging]                                  |
| C:>mpfscctl stats            | [MPFS Client Statistics]                           |

## MPFS PERFORMANCE LIMITATIONS:

Broad rule-of-thumb is that you should see a range of MPFS performance from **20-30Mbps**

**Note:** Ensure that the /var directory is not full if logging is set [re-direct logging to another location]

## ENHANCING UNIX/SOLARIS PERFORMANCE WITH MPFS:

Step 1. Mount Solaris Client to MPFS File System:

**# mount -F mpfs -o rsize=32768,wszie=32768 server\_2:/src /usr/src**

Step 2. Edit Celerra slot\_param or server param file & reboot:

**param ip setMsgSize64k=1** [configures large packet support]

### **param nfs v3xfersize=32768**

**Note:** Some switches do not support 64k size—use this param to change transfer size of data packets for NFSv3 for Reads and Writes

**# .server\_config server\_3 -v "param fulldescription ip setMsgSize64k"**

ip.setMsgSize64k 0x010ca978 0x00000001 0x00000001

### **NEW DEFAULT V3XFERSIZE NAS 5.5:**

param nfs.v3xfersize 0x00008000 0x00008000 [Hex 8000 = decimal 32768]

### **INCREASED NFSv3 PERFORMANCE:** Celerra NAS Code 2.2.37.1+

NFSv3 Transfer Sizes of 32K now supported

TCP Transmit High increased to 128kb; transmit Low now 64kb

Use server\_nfsstat and look at v3getattr, lookup, access, info statistics for MPFS-related information

Use "v3xfersize" values of 8192, 16384, 32768, 65536 for NFS Version 3 Reads & Writes

### **Changing the max number of blocks cached by NFSv3 asynchronous writes [default value is 32]:**

#### **param file asyncthreshold=32 (default)**

**Note:** Parameter related to NFSv3 asynchronous writes for filesystems and has to do with buffering for backend I/O. Default value=32. Setting value to (1) would impact system performance by flushing changes to disk more frequently, hence impacting Write Performance on ‘NFS’ Data Movers—NFS typically uses larger file transfers and a setting of 1 would slow down writes because each write action would have to be acknowledged. With the default value set, up to 32 write actions could be sent without waiting for a Celerra acknowledgement. Some sites may increase this value to (256) per Best Practice for Performance for NAS 5.5 to enhance NFSv3 performance, but this may destabilize the system and cause panics.

**Caution:** With Sun Solaris Clients (supports only 16384 transfer rates), might want to set the Celerra to also use same rate

**\$server\_config server\_x -v "param nfs v3xfersize=16384"**

### **NFSv2 PERFORMANCE:**

max rsize/wsize for NFS v2 is 8192 bytes

NFS v2 does not support 32768 byte read/write size

Confirm with nfsstat -m (if it is supported) or in a network trace

### **NT4.0/WINDOWS 2000 MPFS CLIENTS:**

--Uses UDP protocol by default

--Must use IE 5.01 with PowerPath 2.1 to prevent NT from writing disk signatures to MPFS volumes

--Must NOT write disk signatures on SYMM volumes from NT! Use PowerPath to protect SYMM volumes

[If mixed Sun/NT clients, label the Sun disks first]

--FileSystems are restricted to no more than (6) SYMM volumes for code under 3.0.15.19

--NT can access up to 120 disks on a single SCSI channel

--User limit feature not supported in NT Server Manager for Celerra MPFS

**Note: MPFS Client Software is Installed on NT Clients that will be used to Access FileSystems**

--MPFS support driver is added under “devices” and MPFS Helper is setup as an NT “service”

--Both R-1 and R-2 Symms are connected directly to the NT Servers via UW SCSI

Step 1. Install NT Client software for MPFS

Step 2. Ensure that PowerPath client for NT is also installed [prevents NT from writing signature to MPFS Volumes on Symm!!]

**Note:** Not needed for strictly NFS or CIFS environments.

Step 3. Create MPFS share from prompt or via Server Manager: c:\mpfsctl enable 193.1.21.182 mpfsshare

Step 4. Turning Logging On for Troubleshooting: c:\mpfsctl log on {off}

**MPFS DEFAULTS FOR NT:** UDP Protocol \*MPFS Enabled Block Size: 8192

**MPFS Client Setup for Unix/Solaris:** Requires direct SCSI connection to Symm & Solaris patch required if version 2.6 or lower

Step 1. Setup the “sd.conf” file so as to match the Symmetrix Device list for TID’s—ie, add devices to the table

/kernel/driv/sd.conf #vi sd.conf and add appropriate entries [see following for syntax]  
“name=”sd”class=”scsi”; target=1 lun3;

Step 2. #reboot -- -r

Step 3. Run #format command to format each new disk device and then “label” each device

Step 4. #reboot -- -r [if configured correctly, should see no errors on bootup]

Step 5. Add Unix Client Software for MPFS: Mount CD-ROM: #mount -F hsfs -o ro /dev/dsk/c0t2d0s0 /cdrom

Use Package Add Utility: #/usr/sbin/pkgadd -d /cdrom/SOLARIS/sunos-5.8

The following packages are available:

1 EMCmpfs Multiplex File System [Add License number--Installs to /etc/fs/mpfs] [\$pkginfo -l EMCmpfs]

Step 6. Mount the remote Celerra File System as MPFS:

**#mount -F mpfs -o 193.1.21.182:/mntmpfs /mnt**

**Note:** Mount NFS for troubleshooting [/var/adm/messages]. Check NFS & Disk connectivity using “format” or “inq” command  
**MPFS Client Servers set “MPFS Properties” on the mapped Celerra FileSystem Share [FS1]**

Enable MPFS    SRDF    READ Only    TCP/IP   Status: Connected

Valid Traffic: Yes   Server Name: dm32-ana0   Share Name: fs1

**MPFS Client Servers setup Remote Share Access Properties at Command Prompt:**

- a.) mpfsctl srdf add 8701E 91006 {lside rside}
- a.) mpfsctl enable dm32-ana0 fs1 SRDF RO [this is the ‘share’ command for mpfs]
- b.) mpfsctl list {stats}

### **MPFS QUOTA SUPPORT:** Introduced with NAS 5.0

Server must reserve file system blocks for Quotas via ‘allocSpace’ requests from Clients. If there are no other Shares or Write Locks on the resource, the MPFS Client obtains Write-lock from Server, conducts Writes, informs Server of completion.

**MPFS Block Policy Quotas:** Server reserves blocks for Client via allocSpace requests, issues Quota Exceeded Error to Client

**MPFS File Size Policy:** Server reserves quotas during allocSpace based on potential file size changes. Server keeps track of highest pre-allocated block offset and last block write-locked by Client.

### **MPFS AV SUPPORT:** NAS 5.0

Since FMP protocol conducts no Reads or Write operations, MPFS Client handles I/O by reading data directly from device mapping list (getmap) provided by Server. MPFS Client conducts Writes to device after obtaining pre-allocated extents information from Server (allocSpace). CheckRead and checkWrite operations are used, as well as Read/Write locking mechanisms. MPFS AV operations work mainly at CIFS SMB protocol level for MPFS Clients, substituting FMP Open and Close to call AV service.

### **NEW EMC FUSION V2.2 (Ibrix High-performance & scalable MPFSi Solution—aka Chimay):**

- Solution that will be based on Ibrix Fusion software on an Intel platform, supporting 16TB file systems and small random IOs
- Entry-level gateway appliance
- Segment Servers, running RedHat Linux Enterprise 4.0, will supply metadata information to Clients and export file systems
- Compute/Client Nodes run application that accesses file systems for NFS or CIFS Samba, using EMC Fusion Client sw
- Single Fusion Manager runs on Linux RH Ent. 4.0, & manages cluster environment
- Storage Arrays—CX, CX3, AX, Symm 8000, DMX, DMX-2, DMX-3, etc.

### **CELLERRA ANTIVIRUS AGENT (CAVA—now part of the CEPA framework):**

**GA:** NAS 2.2.39.1, CAVA 1.8.9 Agent; CAVA 3.4.0 with NAS 5.4 (however, CAVA 2.2.4 can still be used with NAS 5.4), CAVA is 3.5.8 for NAS 5.5.30.x release. CAVA 3.6.2 is being released in 5.5.32 to support new Symantec SAVSE v5.1. CAVA has undergone a name change with the release of NAS 5.6, and now falls under the CEPA framework starting with version 4.0.2.

### **CEPA RELEASES:**

NAS 5.6 CEE (aka CEPA) 4.0.2

NAS 5.6.46 CEE 4.5.1

### **CELLERRA VIRUSCHECKER:**

Virus protection of network file systems for CIFS protocol only

### **MCAFEE 8.0 VIRUSSCANING OPTIONS:**

- Delete files automatically (supported)
- Clean files automatically (supported)
- Deny access to files (not supported)

### **Server Log:**

2008-11-17 06:55:15: VC: 3: -----> Checker 10.241.169.137 answers ACCESS\_DENIED and retry is disabled

→Setting “Deny access to files” does not take any action, and will generate an Access Denied to the CIFS client or application, and allows the file to be accessed again

### **SUPPORTED AV VENDORS/ENGINES:**

→Symantec Norton AV 7.6/8.0/8.1 Corp. Edition for Windows NT/2000/Symantec NAVCE 9.0

Symantec SAVSE for NAS, v4.3.17.40 with CAVA/CEE 3.5.7.1, 3.5.8, 3.6.2, 4.0.2-4.5.1

Symantec SAVSE for NAS, v4.3.12/14 with CAVA/CEE 3.5.7.1/3.5.6, 3.5.7.1, 3.5.8, 3.6.2, 4.0.2-4.5.1

Symantec SAVSE v5.1, 5.2 CAVA 3.6.2, CEE 4.0.2-5.1—new support for ICAP (Internet Content Adaptation Protocol) protocol for SAVSE interface, new DLL and new installer changes

→NAI-McAfee NetShield 4.5 SP1 for Celerra & VirusScan 8.0i/8.5i Patch 2, 8.7i with CAVA/CEE 1.8.9, 2.2.4, 3.4.0, 3.5.6, 3.5.7.1, 3.5.8, 3.6.2, 4.0.2-4.5.1

- Trend Micro's ServerProtect for EMC NAS 5.3.1 & 5.5.8 with CAVA/CEE 1.8.9, 2.2.4, 3.4.0, 3.5.6, 3.5.7.1, 3.5.8, 3.6.2, 4.02-4.5.1
- CAI InnoculateIT 6.0 & 7.1 for Windows NT/2000 (CA eTrust r8, r8.1) with CAVA/CEE 1.8.9, 2.2.4, 3.4.0, 3.5.6, 3.5.7.1, 3.5.8, 3.6.2, 4.0.2-4.5.1
- Sophos Anti-Virus v3.82, 5.x/6.x family, v7.0.2, v7.3, v7.5, v7.6 with CAVA/CEE 1.8.9, 2.2.4, 3.4.0, 3.5.6, 3.5.7.1, 3.5.8, 3.6.2, 4.0.2-4.5.1
- Kaspersky Anti-Virus for Windows Servers Enterprise Edition v6.0, with CEE 4.5.1 and NAS 5.6.46
- NTP Software QFS for NAS version 6.0+, & Northern Parklife Northern Storage Suite for EMC v8+: NAS 5.6.36-5.6.46 CEE/CEPA versions 4.0.2-4.5.1
- Varonis DatAdvantage v4.0.6, NAS versions 5.6.45-5.6.46, CEE versions 4.5.0.4-4.5.1

## **64-bit WINDOWS O/S IS NOT CURRENTLY SUPPORTED:**

→We do not currently support 64-bit O/S for the CAVA executable (emc164335). The main symptom is that VirusChecker cannot make contact with CAVA servers that run the 64-bit O/S.

**Note:** 64-bit support introduced with NAS 5.6.45 and CEE version 4.5.0.4

## **SUPPORTED CAVA VERSIONS:**

Cava 1.8.9 supported with NAS Versions 2.2, 4.1, 4.2

Cava 2.2.4, 3.4.0, 3.5.6 supported with NAS Versions 5.x and higher

Use CAVA 3.4.0 and higher if using McAfee VirusScan 8.0i

CAVA 3.5.8, 3.6.2

CEE\_CEPA 4.0.2 (NAS 5.6)

CEE\_CEPA 4.2.1 (NAS 5.6+)

## **CAVA LIMITATIONS:**

→CAVA works only with CIFS protocol

→NFS or FTP protocols do not trigger virus checking

→Monitors entire fs or certain file extension types.

→Beginning with NAS 4.2, have the ability to invoke viruschecking during file Read

→Supports High Road file systems from NAS 5.0 and higher

→Recommended that realtime scanning of live databases not be done [do these with AV vendor sw offline]

## **CELERRA VIRUSCHECKER 3.0—CAVA NAS 5.4:**

→Enhanced notification via PopUp messages to Clients and added messages to Server Log

1) Infected file 2) DART sends PopUp notification to Client 3) DART logs time of infection & notifies of action taken by AV Engine

→Accesstimes on Celerra automatically updated whenever AV Engine conducts Virus Definition update (McAfee only right now)

**Note:** Previous CAVA versions had no user heuristics to help report back to the AV Server

## **AV SIGNATURE FILE UPDATES:**

'Scan on read if access time is less than...' can be used to require file scanning after new virus definition files have been updated on the AV client. CAVA will send the new Virus Definition signatures to DART after the AV engine notifies CAVA of the updated files, and the date will update. However, some AV Vendors do not yet update Cava properly.

### **Trend Micro:**

Starting with Trend Micro Server Protect for Celerra version 5.58 Build 1176, and Cava version 3.58, the AV application will notify CAVA when a new signature or pattern update file is available, and the signature date on the Celerra will be updated accordingly.

## **HOW DOES THE VIRUSCHECKER & CAVA SCANNING PROCESS TAKE PLACE?**

→Virus Checker Agent on DataMover monitors files and when certain conditions are met (such as when writing to a file, access time, other configuration parameters), will initiate Scan check Request to the CAVA Service that runs on the AV engine, using the ONC/RPC interface protocol, and presenting the file name path using UNC ([\\dm03\\$CHECK\filename](\\dm03$CHECK\filename)) (Path includes the default CHECK\$ share location)

→Next, the CAVA service attempts to open the file using RPC and SMB Read

→Once file is opened, the AV engine antivirus driver detects the activity, and triggers it to run a Scan. At the same time, it blocks the CAVA services "file open" request from completing until the file is properly scanned. A problem with Virus Checking is that all requests are serialized—so for large files, a single scan operation is in progress and all other requests are backlogged.

→CAVA actually passes a file's signature to the AV Server, which checks its antivirus definition files for a match. For compressed files, the whole content is passed to the AV Server for scanning.

**Note:** Default timeout for blocked file is 10 secs--thereafter file is made available.

→Once scan is complete and AV engine has taken it's action, it then releases the block on the CAVA "open file"

→CAVA performs a file request, then closes the file and sends response to DM

### **SUMMARY OF CAVA PROCESS:**

DM check request to CAVA

CAVA opens file

CAVA queries file

CAVA closes file

CAVA sends response back to DM

### **VERIFYING COMMUNICATION TO CAVA SERVICE:**

→Prior to 5.6.47, CAVA tries to connect via port 139 for CIFS, then 445 as a secondary

→After 5.6.47, CAVA tries to connect via port 445 for CIFS, then 139 as a secondary

# **/usr/sbin/rpcinfo -p 192.1.4.217** →Querying CAVA Server portmapper

```
program vers proto port
1062247 1 udp 1076
1062247 2 udp 1076 →Output abridged. CAVA RPC program is 1062247.
```

# **.server\_config server\_2 -v "pong 192.1.4.217"** →Verifying that CAVA RPC program responds from CAVA Server  
1211463226: RPC: 3: 192.1.4.217 is alive

### **EXAMPLE OF VIRUS CHECKING PROCESS:**

1. Client has file opened for writing and initiates a close on the file
2. Data Mover obtains exclusive lock and places file into virus checker queue, which is serviced by a dispatch thread
3. RPC call is made by VC to AV Server containing UNC path to file to be checked in the Queue
4. AV Server (via Checker Service) receives RPC call & generates ‘file open’ kernel request using rights of EMC V.Checking User
5. Kernel open is intercepted by VC agent and retrieves portions of locked file for inspection & followup action
- Note:** AV Server actually opens the file twice (Create AndX), once using CAVA agent, and then again using AV Client
6. Kernel call returns & AV Server Checker Service returns RPC call to Celerra.
7. Celerra receives RPC call and unlocks file

**Note:** If you do not want to use the default CIFS interface for Virus Checking, specify the CIFS interface using the CIFSServer= line in the viruschecker.conf file.

### **BEST PRACTICE VIRUSCHECKING THREADS:**

#### **1. Normal system CIFS threads allocated are 96 or 256:**

**Note:** 1GB/2GB+ on DMs. Threads used to handle CIFS requests, and virus checking requests by presenting files to CAVA

#### **2. Number of Viruschk Threads should be 25% of the total number of CIFS threads on a Data Mover:**

# **server\_setup server\_x -P viruschk -o start=64**

**Note:** Threads are used to issue VirusChecker scan requests to CAVA threads on the AV Engine. Default VirusChecking service starts with (10) threads. This value should always be less than the number of threads dedicated on CAVA servers. The thread settings are persistent.

#### **DEFAULT THREADS:**

```
# server_setup server_2 -P viruschk -o start
server_2 : done
# server_viruschk server_2
server_2 :
10 threads started.
```

#### **3. Windows AV CAVA Server Settings should be two times number of Viruschk Threads set 2@64= 128:**

#### **HKLM>Software>EMC>CAVA>Configuration>NumberOfThreads: 128**

**Note:** Default install setup value is 20 threads

#### **4. Reserved CIFS Threads used for VirusChecking:**

**Note:** Exclusively used by VirusChecking. Default=3 threads, which are used only to break deadlocks between File and VirusChecking CIFS requests

# **.server\_config server\_2 -v "param cifs maxVCThreads"**

cifs.maxVCThreads INT 0x02673858 3 3 (1,4294967295) TRUE RESTART 'Reserved threads used for Virus checking'

**Note:** If a customer had (4) CAVA servers, may want to increase this value to 4, etc.

### **DEFAULT THREAD VALUES FOR CELERRA VIRUSCHECKING:**

--Data Movers start with (10) VC threads

--AV Engines start with (20) CAVA threads

--Virus Checker reserves (3) CIFS threads for exclusive use by VC by default

## **VIRUSCHECKER AND THE DEFAULT DATA MOVER C\$ SHARE:**

Viruschecking does not scan the C\$ share of the Data Mover—this is normal and intentional behavior

## **VIRUSCHECKER TERMINOLOGY:**

**VIRUS CHECKER CLIENT:** Min. NAS 2.2.39.1+ & 'viruschecker.conf' to setup VC parameters.

1. VC Client queues files, and provides UNC path to CAVA service on AV Server based on “trigger” points
2. VC Client blocks access to CIFS files while scanning occurs
3. VC Client releases files when informed of Success or Failure of Scan by CAVA

### **Examples of Trigger Points:**

- New virus definition file on AV Engine
- File renamed on Celerra
- File copied or saved on Celerra
- File modified & closed on Celerra
- Scan on First Read is enabled [also sets up scanning based on a pre-determined time for scanning to occur]

### **VC Agent handles virus ‘infections’ based on user-defined criteria:**

- cure or repair file
- rename file
- change file extension
- quarantine file
- deleting file

VC Client is configured using ‘server\_viruschk’ command and “viruschecker.conf” file.

## **VIRUS CHECKER SERVER:**

CAVA (Celerra Antivirus Agent) Service that determines when AV Engine scans a file [CAVA Agent 1.8.9/3<sup>rd</sup> Party AV Engine] as presented by Celerra Virus Checker Client

## **CAVA (CELLERRA ANTIVIRUS AGENT):**

EMC agent running on Windows NT/2000 AV; Communicates between A/V Engine and Celerra

### **AV ENGINE:**

3<sup>rd</sup> Party Antivirus Engine running on NT/2000

### **AV USER:**

Dedicated Domain Antivirus User Account that is added to a Celerra Local Group & granted the 'Viruschecking' User Right. Use this NT Account also to install & configure NT/2000 systems running CAVA & AV Engine.

### **AV Configuration Management MMC Snap-in:**

MMC Console used to view or modify CAVA parameters located in viruschecker.conf file

### **INTERFACE PROTOCOL:**

Client/Server interface that uses ONC/RPC protocol for Scan Requests & Replies.

### **SYSTEM REQUIREMENTS:** Minimum (2) dedicated AV Servers 700Mhz/512RAM

Minimum of (2) antivirus engines, supporting up to 1000 concurrent users. 100MB Lan connection recommended. (1) RPC request per scan. Add additional AV Server for every 500 concurrent Users. For multiple AV Engines, files are scanned in a roundrobin fashion to 'load-balance' the operation.

## **KNOWN ISSUES/CONCERNS WITH AV:**

### **COMPRESSED FILES:**

- Compressed files, such as zip, require whole file be sent to AntiVirus engine for scanning, taking much longer & using more network bandwidth and resources. Also, files with unknown extensions are sent to AV Engine for scanning. HWM (High Water Mark) should be monitored to identify excessive queue buildup (Add AV Engines if consistently High)
- min. of (2) AV Engines + (1) for every 500 additional Users [Watch HWM for indicators of load—SYS\_LOG; Server Log]
- AV Engines should be dedicated systems & not used for other Windows Services, etc.
- dedicated 100MB LAN as a minimum
- no AV in NAS 3.x or HighRoad MPFS until NAS 5.0
- CIFS support only—no Unix
- NT Security only—no Share Security mode
- do not setup both AV Network scanning by AV Engines & Celerra CAVA
- ensure AV Engine SW settings mirror those on Celerra Virus Checker, such as excluded files, etc.
- always exclude Temp files and Database application files [might otherwise cause degradation of network]
- never run Virus Checker Service during data migrations!
- leave default param “maxVCThreads=3” unless directed by Engineering
- Double-zipped files may not be properly scanned [not supported by most AV Engines either]
- Outlook .PST files are not scanned by McAfee or Symantec—exclude from virus checking!

--Files from Tape Restores do not get scanned because this is not a ‘CIFS Access’ operation

**Note:** However, AR45645 identifies code issue where NDMP Restores was enabling Virus Checking on the files being restored, causing numerous problems at customer sites. Set following param to disable Scanning on NDMP Restore.

**param pax scanOnRestore=0** [NAS 5.3, 5.1.26.x, 5.2.15.x]

**# server\_param server\_2 -facility PAX -info scanOnRestore**

server\_2 :

```
name      = scanOnRestore
facility_name = PAX
default_value = 1
current_value = 1
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range     = (0,1)
description = Whether to scan virus on restore
```

#### **ADS (Alternate Data Streams) FILES:**

Files that use ADS involves two separate writes to disk, meaning that the file is actually scanned twice. In order to avoid scanning files with ADS, EMC recommends that mask=\*. not be used. Instead, specify the actual file extension types to scan, using mask=\*.EXE: \*.COM: \*.DOC: etc. If mask=\*. is being used, you can still exclude ADS files for particular file extension types that may contain ADS files by using the following exclude syntax: excl=\*.com\* See emc185502 for more details.

#### **FUNCTION OF THE CELERRA VIRUSCHECKER CLIENT:**

1. Queues & communicates filenames using UNC paths to CAVA Agent on AV Engine for scanning
  2. Aware of events & triggers scanning [e.g., new Virus Definition installed on AV Server; file renamed or saved, access time, etc]
- Note:** File is opened twice, first by CAVA, then by Virus Scanning Engine.

#### **PERFORMING COMPLETE FILE SYSTEM SCANNING (NAS 5.3):**

**\$server\_viruschk server\_x -fsscan fs1 -create** [starts virus scanning on file system]

**\$server\_viruschk server\_x -fsscan fs1 -delete** [stops virus scanning on fs]

**\$server\_viruschk server\_x -fsscan fs1 -list** [scanning status]

**# .server\_config server\_3 "viruschk scan start=21"**

#### **SYMANTEC SAVSE ANTIVIRUS SUPPORT (NAS 5.5):**

Symantec SAVSE (Symantec AntiVirus Scan Engine), a user-mode scanning engine with ICAP (Internet Content Adpatation Protocol) 1.0 protocol and client-side API for CAVA to use when scanning (Symantec building SAVSE support for NetApps, EMC, others, and eliminating SAVCE support)

→SAVSE listens on port 7777

→Scan requests will use SAVSE API and not CAVA kernel

→SAVSE will use event signaling on pattern updates

→Only ‘action policy=delete’ will be allowed for this version

→For CAVA 5.5 in general, the new version is 3.5.7.1

**Note:** CAVA runs as AV Service on Windows. DM runs DART AV agent as client to CAVA service, sending scan requests to CAVA per heuristic definitions. Upon startup of the CAVA service, CAVA discovers the 3<sup>rd</sup> party AV Engine in use. If Symantec SAVSE is found, CAVA will route all scan requests through the cavasav.dll library to SAVSE and calls the SAVSE API functions found in symcscan.dll. Through the use of a CAVA/SAVSE Connector, DART should be able to direct Scan requests to CAVA, and CAVA redirects to the SAVSE. In order for AV scanning of file systems to occur, the CAVA/SAVSE Connector must be used. The protocol used is Symantec Native, not RPC as in previous implementations of VirusChecking/CAVA.

#### **INSTALLING SYMANTEC SAV for NAS:**

**Note:** Symantec SAV for NAS 4.3.x uses NATIVE protocol for deleting infected files, but version NAS 5.1.x uses the ICAP protocol

1. Install the SAV for NAS software
2. Go to Start>Run>Services.msc and change the SAV for NAS service to run from the domain CAVA or antivirus User account and password
3. Open the SAV for NAS application>Configuration>select “Native protocol” for version 4.3 or select “ICAP” for version 5.1, port 1344
4. If using version 5.1, stop the SAV for NAS service, open command prompt, navigate to the install directory, run “java –jar xmlmodifier.jar –s /policies/Misc/HonorReadOnly/@value false policy.xml, then restart the SAV for NAS service

**Note:** If these steps are not done, CAVA will not accept scan requests

5. Select ‘LiveUpdate’ to download and install latest definition files

## **INSTALLING McAfee VIRUSSCAN:**

**Note:** Example based on McAfee 7.1, NAS 5.3.14.2, & Windows 2000 domains

**Caution:** Celerra Antivirus can ONLY be implemented for physical CIFS servers, not VDM CIFS servers—we use the default Data Mover rootfs to host the hidden CHECK\$ share used for viruschecking operations.

1. Create domain user for viruschecking using Active Directory Users & Computers interface: avuser
2. Install the Celerra Management MMC Snapin from the Applications & Tools CD for the NAS Version in use: CelerraCifsMgmt.exe [Version 3.00.012]

3. Install McAfee AV engine per documentation
4. Open “Virusscan On-Access Monitor”>Properties>Detection tab>Scan Files: check all

--When writing to disk  
--When reading from disk

--On network drives

What to scan:

--All files

5. Actions tab>When a threat is found:

Primary Action: Clean files automatically (if cannot clean, will append .VIR extension to file)

Secondary Action: Delete files automatically

## **THINGS TO VERIFY FOR CELERRA ANTIVIRUS SETUP:**

--For W2K Data Movers, use the Celerra CIFS Management snapin for Antivirus Management in order to assign the correct AV User the “EMC Virus Checking” privilege

**Note:** NAS 5.1 and below, and all NT 4.0 style data movers, can use the “Usrmgr.exe” Utility to set the AV privilege

--Default compname should match what viruschecker.conf file uses

--Perform AV Engine software install using AVUser account

--Install AV Engine software first, then CAVA (except for Trend Micro)

--Cava Service on the AV Servers must run under the credentials of the antivirus User account (if the service is properly changed to run under this account, a popup should display “The account .\virususer has been granted the Log On As A Service right.”

--Antivirus user account must be added to Celerra Local Administrator group

--Antivirus user account must be added to all AV Servers’ Local Administrator group

--For excluded/include files, settings on AV Servers should match that of viruschecker.conf file

## **SETTING UP AV USER ACCOUNT FOR WINDOWS 2000 CIFS SERVER:**

1. Create User account using Active Directory Users and Computers MMC

2. Create Local Group on DataMover using Active Directory Users and Computers

→Rightclick computer name>Manage>System Tools>Local Users and Groups>Rightclick and add New Group>Select Users or Groups, add the “avuser” account create in step 1.

### **Select Components to Install:**

→Unix User Management [Do not install--used only to support CIFS Active Directory Mapping tool]

→Dart Management

  --AntiVirus Management (yes)

  --Home Directory Management (Installed if using the HOMEDIR feature on Celerra)

  --Security Management (yes—this is the key program for setting up VirusChecker rights on Celerra)

3. Add domain “avuser” to Celerra CIFS Server’s local Administrators group

**Note:** Computer Management>Connect to another computer>\Cava\_server>Local Users & Groups>Groups>Administrators>Add

4. Create new Local Group on Celerra called “AVGroup” & add “avuser” to this group as well

5. Add domain “avuser” to each AV Server’s local Administrators group (Via Computer Management or ADUC)

**Note:** For troubleshooting purposes, add ‘avuser’ to ‘Domain Admins’ group if having permission issues

6. Grant following privileges or rights to the “avuser” account on the Data Mover using Celerra Management snapin:

a. Start>Programs>Administrative Tools>Celerra Management>EMC Celerra Management>Data Mover Management>

b. Rightclick and select ‘Connect to Data Mover’

c. Add the appropriate compname from the dropdown box

d. Expand ‘Data Mover Security Settings’>User Rights Assignment: Add following rights to “avuser”

→**EMC Virus Checking**

→**Backup Files & Directories**

→**Restore Files & Directories**

→**Generate Security Audits**

→**Manage Auditing and Security Log**

**Note:** Adding Virus Checking rights from command prompt

C:\Documents and Settings\Administrator>ntrights -u <domain>\cavauser -m <Data Mover IP address> +r SeVirusChecking  
Granting SeVirusChecking to europe\cavauser on 10.241.183.85... successful

7. Grant following privilege to “avuser” on each AV Server

Programs>Administrative Tools>Local Security Policy>Security Settings>Local Policies>User Rights Assignment:

**→Act as part of the operating system**

**Note:** In some cases, this right may need to be applied using the ‘Domain Security Policies’ snapin (policy dependent)

8. Install McAfee VirusScan Enterprise 7.1.0 on AV Servers

**Note:** Use the antivirus account to perform the software installation—means the account will need to be either local Administrator or Domain Admins

9. Install EMC CAVA 2.2.4 software on each AV Server using install defaults

InstallShield>Accept License>Complete>Install>Finish>answer ‘No’ to restart system

10. Using ‘Services’ program on each AV Server, configure the EMC CAVA service to run under the control of the “avuser” account:  
Services>EMC CAVA>Log On>\*This account: add “avuser” account here and enter that account’s password

**Note:** A PopUp should appear saying, “The account [avuser@dwarfs.com](mailto:avuser@dwarfs.com) has been granted the Log On As A Service right”

11. Reboot AV Servers & then verify that EMC CAVA service is running correctly

12. Configure McAfee AV Servers for Scanning Network Drives:

Open McAfee VirusScan Console>On-Access Scan properties>Highlight ‘Default Processes’>

**Detection tab:**

→When writing to disk (default setting, but make sure this is enabled)

→When reading from disk (default setting, but make sure this is enabled—AV Engine cannot scan Celerra files without this set)

→On network drives (Enable this setting—not enabled by default—VirusChecking will NOT work without)

**Actions tab:**

→Clean infected files automatically [default]

→Move infected files to a folder [default]

**Note:** With earlier versions, quarantining does not work, so change the ‘If the above action fails’ setting to →‘Deny access to file’. When the ‘deny access to file’ setting is set, and a virus is detected, the file is renamed with a .vir extension and left on the Celerra. Admin would have to check the Task>Activity Log to determine what viruses were found as no popup messages display on Client.

**MCAFEE 8.0 VIRUSSCANING OPTIONS:**

**→Delete files automatically (supported)**

**→Clean files automatically (supported)**

**→Deny access to files (not supported)**

13. Configure and Start VirusChecker service on Data Mover:

a.) Create viruschecker.conf file on Control Station and push to /.etc using server\_file server\_x –put command  
masks=\*.\*

excl=pagefile.sys:\*.tmp:\*.pst:\*.mdb:\*.ldb

addr=172.17.17.219:172.17.17.210

CIFSserver=Cava\_server

shutdown=cifs

b.) Start VirusChecker service & verify communication to AV Servers:

**\$server\_setup server\_x -P viruschk -o start**

**# server\_viruschk server\_2**

server\_2 :

10 threads started

1 Checker IP Address(es):

10.2.36.22 version=2, ONLINE at Fri Mar 4 23:23:48 2005 (GMT-00:00)

1 File Mask(s):

\*.\*

5 Excluded File(s):

pagefile.sys \*.tmp \*.pst \*.mdb \*.ldb

Share \\Cava\_server\CHECK\$

RPC request timeout=25000 milliseconds

RPC retry timeout=5000 milliseconds

High water mark=200

Low water mark=50

Scan all virus checkers every 60 seconds

When all virus checkers are offline:

Continue to work with Virus Checking and CIFS

Scan on read if access Time less than Fri Feb 25 19:42:07 2005 (GMT-00:00)

Panic handler registered for 65 chunks

14. Test effectiveness of Virus Checker setup by using Eicar Virus-test Files:

- a.) Stop VirusChecker service on data mover
- b.) Stop CAVA Service and McAfee AV Services on AV Servers
- c.) Download test files from [www.eicar.com/anti\\_virus\\_test\\_file.htm](http://www.eicar.com/anti_virus_test_file.htm)  
**eicar.com eicar.com.txt eicar\_com.zip eicarcom2.zip**
- d.) stage files on Celerra share and map drive from AV Server
- e.) Start all Services back up and access test files from Client—copy from one folder to another on the Celerra

## **TROUBLESHOOTING VIRUSCHECKER SCANNING ISSUES:**

→VirusChecker Service runs on the Data Mover & presents files to CAVA when certain rules apply [Scan on first read, writes, etc.]

→CAVA Service runs on AV Server and receives request to scan file from VirusChecker, Opens file & presents to AV Server

→McAfee AntiVirus Service receives request to scan file from CAVA & performs operation

1. Set debug logging on data mover:

**# server\_param server\_2 -facility viruschk -info Traces**

```
server_2 :  
name      = Traces  
facility_name = viruschk  
default_value = 0x00000000  
current_value = 0x00000000  
configured_value =  
user_action = none  
change_effective = immediate  
range     = (0x00000000,0xffffffff)  
description = Define traces displayed in the server log  
detailed_description
```

Define the traces displayed in the server\_log for virus checker: 0x00000001:in CFS: setCheckStatus, setCheckWriter, check Wait 0x00000002:in CIFS: createEvent, sendEvent, mustBeChecked (scan on read) 0x00000004:in Virus Checker: connectAnyServer, vc\_checkfile, stopThreads, exit, start 0x00000008:in CIFS applbnt: open, writeAsyncMsg, readMsg, close, rename 0x00000010:in Virus Checker: heartbeat the virus checker servers 0x20000000:Disable error login when a CAVA makes too many access without the EMC viruschecking privilege 0x40000000:Warnings 0xC0000000:Warnings + Errors

**# .server\_config server\_2 "param viruschk Traces=0xC0000004"** [Turns on Debug for AV for Warnings & Errors]

**Note:** After turning on viruschecker tracing, you may need to use server\_log server\_x -i in order to see trace output

**# .server\_config server\_2 "param viruschk Traces=0x00000000"** [Turns off Debug for AV]

**# server\_param server\_2 -facility viruschk -info Traces -v**

```
server_2 :  
name      = Traces  
facility_name = viruschk  
default_value = 0x00000000  
current_value = 0x00000000  
configured_value =  
user_action = none  
change_effective = immediate  
range     = (0x00000000,0xffffffff)  
description = Define traces displayed in the server log  
detailed_description
```

Define the traces displayed in the server\_log for virus checker: 0x00000001:in CFS: setCheckStatus, setCheckWriter, check Wait 0x00000002:in CIFS: createEvent, sendEvent, mustBeChecked (scan on read) 0x00000004:in Virus Checker: connectAnyServer, vc\_checkfile, stopThreads, exit, start 0x00000008:in CIFS applbnt: open, writeAsyncMsg, readMsg, close, rename 0x00000010:in Virus Checker: heartbeat the virus checker servers 0x20000000:Disable error login when a CAVA makes too many access without the EMC viruschecking privilege 0x40000000:Warnings 0xC0000000:Warnings + Errors

2. Download DebugView 4.31 from [www.sysinternals.com/Utilities/DebugView/](http://www.sysinternals.com/Utilities/DebugView/) v4.31 and configure on AV Servers:

a.) Install DebugView program

b.) Change registry settings to enable DebugView logging & Celerra's Cava Monitor display:

**HKLM>software>EMC>CAVA>Configuration:**

Verbose: 1

Debug: 1

3. Enable Cava Monitor on each AV Server via registry setting:

**HKLM>software>EMC>CAVA>Sizing:** Set 'Sizing' value to 1 for debug

**Note:** CAVAMon.exe is an executable found in Program Files>EMC>CAVA that can be used to collect Scanning stats and info

4. Startup network trace if conducting test in order to capture data

5. Open Debug View Program and Cavamon Program to be ready to capture test data
6. Begin testing with eicar files
7. Save Server Log to file
8. Verify that user account has been added to Administrators localgroup on Celerra and each AV Server
9. Verify that CAVA is running under the domain avuser account
10. Verify that avuser has been granted the EMC VirusChecker right by running following:

```
# .server_config server_2 -v 32768 "lg list" |grep -C avuser
```

```
1109977963: SMB: 4: user CORP\avuser 802a S-1-5-15-72ab4f17-4785586f-22081e61-fda1
```

```
1109977963: SMB: 4: Localgroup 'Users' (Ordinary users)
```

```
1109977963: SMB: 4: Sid = S-1-5-20-221 (gid:0x80800221)
```

```
1109977963: SMB: 4: Privileges = AV (0x0)
```

```
1109977963: SMB: 4: Members:
```

```
1109977963: SMB: 4: user CORP\avggroup 802a S-1-5-15-72ab4f17-4785586f-22081e61-fda1
```

11. Verify av user account has been granted proper rights via Celerra Management snapin

12. Verify Antivirus Software settings with customer [get screenshots if necessary]

13. Use following params to tweak number of Open Files cached & pending Virus Checking, and % Vnodes allowed:

```
# server_param server_2 -facility viruschk -info vnodeMax -v
```

server\_2 :

```
name      = vnodeMax
```

```
facility_name = viruschk
```

```
default_value = 2000
```

```
current_value = 2000
```

```
configured_value =
```

```
user_action = restart Service
```

```
change_effective = restart Service
```

```
range      = (100,4294967295)
```

```
description = Max number of vnodes that can pend on VC
```

```
detailed_description
```

Defines the max number of total vnode available in the system which can be pending on Virus Checking. An event is sent to the Control Station when the maximum is reached. The CIFS thread will be blocked until the Low Watermark is reached again.

```
# server_param server_2 -facility viruschk -info vnodeHWM -v
```

server\_2 :

```
name      = vnodeHWM
```

```
facility_name = viruschk
```

```
default_value = 90
```

```
current_value = 90
```

```
configured_value =
```

```
user_action = reboot DataMover
```

```
change_effective = reboot DataMover
```

```
range      = (0,4294967295)
```

```
description = Percentage of vnodes that can pend on VC
```

```
detailed_description
```

Defines the percentage of total vnode available in the system which can be pending on Virus Checking. An event is sent to the Control Station when the maximum is reached. The CIFS thread will be blocked until the Low Watermark is reached again.

## **SPECIFYING VIRUS CHECKER ACTIONS IN EVENT AV SERVERS ARE OFFLINE:**

**Comment:** Following settings dictate how Celerra, when configured to run Virus Checker, behaves when AV Servers are Offline

**shutdown=no**

**Note:** This is the default setup for Virus Checker and there may or may not be an entry in the viruschecker.conf file. Policy allows for continuing to check for AV Servers and does not shutdown VirusChecker or CIFS. However, with this policy set and with all AV Engines Offline, there is a potential for the system to eventually panic:

**DATA MOVER PANIC:**

The policy states that files must be checked. If something prevents us from checking a file in a timely fashion, then the file will languish until it is checked. The thread handling the file will pend until the check is complete. If the VC is offline, the check will not occur and the thread will continue to wait. Each write request pends and ties up a thread. As all threads become occupied, the new requests are queued up in the "collector" thread. The collector thread has no limit and continues to queue up requests on the assumption that things will get better. The requests occupy memory in the streams message block structure (msgb). After a time, the msgb memory will be exhausted and the system will panic when it can't get a msgb.

**SHUTDOWN=NO POLICY:**

```
# server_viruschk server_5  
-----output abridged-----
```

Scan all virus checkers every 60 seconds

**When all virus checkers are offline:**

*Continue to work with Virus Checking and CIFS*

**shutdown=cifs** [Loss of AV Servers will result in CIFS shutdown and loss of access to CIFS]

**shutdown=viruschecking** [Loss of AV Servers will result in VirusChecker Service shutting down, but not CIFS]

**HOW TO DETERMINE WHICH SHUTDOWN POLICY IS IN EFFECT:**

1. Cat viruschecker.conf file and look for “shutdown=”
2. For default “shutdown=no”, there does not need to be an entry in the viruschecker.conf file.

**\$ server\_viruschk server\_5**

**When all virus checkers are offline:**

*Continue to work with Virus Checking and CIFS*

**Note:** The above output reflects the default Shutdown Setting for Virus Checker, which is “shutdown=no”

**AV BEST PRACTICES:**

- Startup Viruschecker with 64 threads v. default 10 [start=64]
  - Startup CIFS threads at 128 v. default 32 [start=128]
  - Change default AV Server threads in registry from 20 threads to 120
  - Always ensure that CIFS threads are >than Viruschecker threads
  - Do not allow “real-time” on-line scanning of Application DataBases such as Exchange, SQL, Oracle, Access, etc. Rather, databases should be handled by Vendor-Specific database-scanning software or done offline. On-line scanning of DB files can cause db corruption and degrade Network performance (Exclude databases in viruschecker.conf “exclude” section)
- Note:** We have seen where virus checking will make Access database applications fail intermittently when performing operations over the network to a Celerra share.

**STARTUP BEHAVIOR FOR VIRUSCHECKER ON DMs:** 5.5.31.x AR98322

If using CLI or MMC to start viruschecker service, a viruschecker.enabled file will be created in /.etc. The viruscheck start line will no longer be added to the netd file. Now, whenever CIFS starts, if the viruschecker.enabled file exists, viruschecker will also start.

**DEFAULT VIRUS CHECKER PARAMETERS:**

**# server\_param server\_2 -facility viruschk -list**

|            |          |            |            |                                       |
|------------|----------|------------|------------|---------------------------------------|
| param_name | facility | default    | current    | configured                            |
| Traces     | viruschk | 0x00000000 | 0x00000000 | [Set to 0xC0000004 for debug logging] |
| vnodeLWM   | viruschk | 60         | 60         |                                       |
| chunkQuota | viruschk | 65         | 65         |                                       |
| vnodeHWM   | viruschk | 90         | 90         |                                       |
| Notify     | viruschk | 7          | 7          |                                       |
| vnodeMax   | viruschk | 2000       | 2000       |                                       |
| noRetry    | viruschk | 0x00000018 | 0x00000018 |                                       |

**# .server\_config server\_2 -v "param viruschk audit"**

viruschk\_audit INT 0x020e5e18 98 98 (0,4294967295) FALSE REBOOT 'NA'

viruschk\_Traces (0) [Set when debug mode desired]

**CHECKING VIRUS CHECKER SETUP ON DATAMOVER:**

**\$server\_viruschk server\_2** [Monitor requests in collector queue]

**\$server\_viruschk server\_2 -audit**

[Status of VC Client; # files checked; Progress of files being scanned--Use to monitor High Water Mark queue--may indicate need to add additional antivirus engines; Check "sys\_log" also]

**AV FILES LOCATED /.etc DIRECTORY:**

|            |   |      |     |                  |                    |                                    |
|------------|---|------|-----|------------------|--------------------|------------------------------------|
| -rw-r--r-- | 1 | root | bin | 0 Nov 8 18:58    | viruschecker.audit | [Contains list of unscanned files] |
| -rw-r--r-- | 1 | root | bin | 3193 Nov 7 15:52 | viruschecker.conf  |                                    |
| -rw-r--r-- | 1 | root | bin | 4 Nov 8 18:54    | viruschecker.date  |                                    |

**UPDATING VIRUS CHECK CONF FILE:**

Step 1. Edit Viruschecker.Conf File

Step 2. Push to Server: # server\_file server\_2 -put viruschecker.conf viruschecker.conf

Step 3. If Virus Checker Service is running, execute following to update “conf” in Memory:

**\$server\_viruschk server\_x -update**

**VIRUS CHECKER SERVICE COMMANDS:**

**\$ .server\_config server\_2 "viruschk scan start=21"** (Example of full viruschecking scan of file system)

**\$server\_setup server\_x -P viruschk -o start=# (# of threads to start)**

**\$.server\_config server\_x -v "param viruschk"** (displays viruschk config)

**\$.server\_config server\_x -v "viruschk stop or start"**

**\$.server\_config server\_x -v "viruschk restart" [\$.server\_setup server\_x -P viruschk -o restart]**

**\$.server\_config server\_x -v "printstats viruschk"** (same as audit)

**\$.server\_config server\_2 "param viruschk Traces=0xC0000004"** [Turns on Debug for AV]

**Note:** With 5.6, you may need to use \$ server\_log server\_x -i option to see trace output in the server log

**\$.server\_config server\_2 "param viruschk Traces=0x00000000"** [Turns off Debug for AV]

**\$.server\_config server\_2 -v "param viruschk noRetry=0xFFFFFFFF"** [Flush bad entries from queue]

**\$.server\_config server\_2 -v "param viruschk noRetry=0x00000018"** [Reset queue to normal]

**\$.server\_config server\_2 -v "ntcred user=avuser"**

**# .server\_config server\_2 -v "help viruschk"**

**Usage:**

viruschk start[=number of threads to start]

viruschk restart

viruschk stop

viruschk

viruschk audit[=filename]

<FS> is filesystem id or mount path

viruschk scan start=<FS>

viruschk scan stop=<FS>

viruschk scan status=<FS>

viruschk scan

**Description:**

'viruschk start' starts virus checker

'viruschk restart' restarts virus checker

'viruschk stop' stops virus checker

'viruschk' displays the virus checker configuration

'viruschk audit' displays the status of the virus checker

<FS> is filesystem id or mount path

'viruschk scan start=<FS>' starts scan on file system FS

'viruschk scan stop=<FS>' stops scan on file system FS

'viruschk scan status=<FS>' displays status of the scan of file system FS

'viruschk scan' display status of the scan of all file systems

**SERVER LOG DEBUG MODE FOR AV:**

2002-11-15 10:53:55: VC: 4: UNC='\\SP099NAS01\CHECK\$\adssync\adssync\eicar.com.txt'

2002-11-15 10:53:55: VC: 4: waiting to be checked

2002-11-15 10:53:55: VC: 4: [av005] UNC='adssync\adssync\eicar.com.txt'

2002-11-15 10:53:55: VC: 4: Sent to checker 131.99.75.42

2002-11-15 10:53:55: VC: 4: [av005] UNC='adssync\adssync\eicar.com.txt'

2002-11-15 10:53:55: VC: 4: Checker 131.99.75.42 answers SUCCESS

**CONDUCTING VIRUSCHECKER AUDITING ON DATAMOVER:**

**\$server\_viruschk server\_2** [SERVER STATUS]

5 threads started

**1 Checker IP Address(es):**

**addr=192.10.2.2 192.10.2.2 online** [offline would mean loss of communications to CAVA on AV Server]

**1 File Mask(s):** [masks=".\*"; Only one mask is defined; if there were multiple entries, separate with :]

**masks=".\*** (all files to be checked; or configure for specific extensions: masks="\*.ppt:\*.exe"]

**excl=\*.tmp (default=no files excluded) No File Excluded** [excl=; Lists extensions excluded from scanning, if specified]

**CIFSServer=dm03 \WDM03\CHECK\$** [CIFSServer=Netbios name of DataMover with default 'CHECK\$' viruschecker share]

**maxsize=0 (default=0 bytes) Max size of checked files=0** (maxsize=0x1000000)

[Min=0/Max=0xFFFFFFFF → 4GB file is max size allowed]

**maxThreadWaiting=0 (old default=16; new default=0) Max threads waiting for a file=16;** [Min=0, Max=0xFFFFFFFF]

**Note 1:** *Number of AV Servers \* number of threads running on each AV Server. It is now recommended not to set this field.*

**waitForTimeout=0** (Default value=0ms or off) Set timeout value to 30,000ms or higher to address certain conditions, such as migration of files--Min=0, Max=0xFFFFFFFF.

# Wait 30 seconds if the file is already opened by the viruschecker

**waitForTimeout=30000**

**Note 2:** The waitForTimeout option does not allow a check for lock conflicts at the beginning. All opens will block for a period up to the length of the timeout. If the check completes the open is processed. If the check hasn't completed and the timeout has expired, we process the open. If there is a lock conflict the sharing error is returned. If there are no lock conflicts the open will succeed (this is the instance where access is given to an unchecked file). If the timeout is set high enough it effectively removes the possibility of someone getting access to an unchecked file. However, this has the potential of making an Explorer window hang.

**Note 3:** Defines the time a thread will wait for viruschecking to complete file scan before requesting an open on the file.

**RPCRequestTimeout=25000** ms (default=25 secs) [After 5 retries, CAVA marked offline; Min=1; Max=0xF...]

**RPCRetryTimeout=5000** ms (default=5 secs) [Wait time for response to request before timeout; Must be lower than RPCRequestTimeout; Min=1; Max=0xFFFFFFFF]

**highwatermark=200** (default) [Number of files in Queue for scans; When value is exceeded, logs to /nas/log/sys\_log; Min=4 Max=0xFFFFFFFF → If consistently logging High Water Marks, consider bringing additional AV Server online]

**lowwatermark=50** (default) [Logs when this value is reached after a HWM event was triggered; Min=1]

**surveyTime=60** [default=60 seconds to scan for CAVA servers [Survey Time=interval of comm. to CAVA; Min=1; Max=0xF..]]

**Note:** DM pings AV servers every 60 secs by default

**When all virus checkers are offline:**

**shutdown=no** (default=no, but recommended setting is 'shutdown=cifs')

## VIRUSCHECKER.CONF FILE:

**# more viruschecker.conf**

```

#
# Virus Checker Configuration File
# (no blank line)
#
# masks=<list of filename extensions>
# - sets the list of filemasks that need to be checked.
#
# excl=<list of filenames or filename extensions> (optional)
# - sets the lists of filenames or filemasks that donot need
#   to be checked.
#
# addr=<list of IP addresses of virus checker servers>
# - sets the IP addresses of the VC Servers that we wish to connect to.
#
# CIFSserver=<name of the CIFS server in the dart> (optional)
# - sets the name of the CIFS server. If the parameter is not given,
#   the default CIFS server will be used.
#
# maxsize=xxxx (32 bits) (optional)
# - sets the maximum file size that will be checked.
#   Files that exceed this size will not be checked.
#   If the parameter is not given or is equal to 0,
#   it means no file size limitation.
#
# surveyTime=xxxx (optional)
# - sets the survey time frequency for scanning all the virus
#   checkers to see if they are online or offline. The unit is
#   second. The default value is 60 seconds.
#
# shutdown=<no | cifs | viruschecking> (optional)
# - sets the shutdown action when all virus checkers are offline.
#   no      : no action taken (default value)
#   cifs    : stop cifs
#   viruschecking: stop viruschecking
#
# highWaterMark=xxxx (optional)
# - set the high watermark value. When the number of requests
#   in progress is larger than "highWaterMark" value, a log
#   event will be sent to Control Station.
#   The default value is 200.
#
# lowWaterMark=xxxx (optional)—purpose is to log a descending threshold after a HWM event has been triggered)
# - set the low watermark value. When the number of requests
#   in progress is smaller than "lowWaterMark" value, a log
#   event will be sent to Control Station.

```

```

# The default value is 50.
#
# Note: The following parameters must be set only by EMC
#
# maxThreadWaiting=xxxx (Engineering now recommends that this value be set to 0)
# - set the maximum number of threads waiting for a file. If
#   the number of threads waiting for a file is already equal
#   to the maximum number, the next thread will be allowed to
#   access the file EVEN IT IS NOT VIRUS CHECKED.
#   The default value is 0. It means the function is disabled.
#
# waitTimeout=xxxx (Eng. now recommends that this value be set to 0]
# - set the time out which a thread waits for a file. If
#   the waiting time is reached, the thread will be allowed to
#   access the file EVEN IT IS NOT VIRUS CHECKED. The unit is
#   millisecond. The default value is 0. It means the function
#   is disabled.
#
# RPCRetryTimeout=xxxx (optional)
# - set the time out of RPC retry. The unit is millisecond.
#   The default value is 500.
#
# RPCRequestTimeout=xxxx (optional)
# - set the time out of RPC request. The unit is millisecond.
#   The default value is 25000.
#
# When a RPC is sent to the VC server, if the VC does answer
# after "RPCRetryTimeout", the Data Mover makes retries until
# "RPCRequestTimeout" is reached.
#
# Example:
#
# masks=*.EXE:*.COM:*.DOC:*.DOT:*.XL?:*.MD?:*.VXD:*.386:*.SYS:*.BIN
# masks=*.RTF:*.OBD:*.DLL:*.SCR:*.OBT:*.PP?:*.POT:*.OLE:*.SHS:*.MPP
# masks=*.MPT:*.XTP:*.XLB:*.CMD:*.OVL:*.DEV
# masks=*.ZIP:*.TAR:*.ARJ:*.ARC:*.Z
# addr=168.159.173.239
masks=*.*
excl=pagefile.sys:*.tmp:*.pst:*.mdb:*.ldb
addr=172.17.17.219:172.17.17.210
CIFSserver=ftwnas01
shutdown=cifs

```

**EDITING THE VIRUSCHECKER.CONF FILE:** [Defines VirusChecker parameters]**#/home/nasadmin/vi viruschecker.conf**

#viruschecker configuration file

**addr=192.10.2.2** [Up to (4)IP Addresses for A/V Servers→DM sends UNC path of file AV Server to scan]**CIFSserver=nas46** [NetBIOS name of DataMover; if not listed, the default Netbios name is used for DM]**masks=\*.\*** [Default: All files are scanned; Set to specific extensions up to 1024 characters per line]**Note:** Must include a mask or else no files will be scanned! Specify a set of extensions for file types to scan. Specify an 'exclude' list for those that you do not want to scan.**excl=pagefile.sys:\*.tmp:\*.exe:\*.com:\*.sys:\*.zip:\*\*\*\*\*** [Excluded File Extensions; \* ? metacharacters can be used]**Note:** NT limitation of up to 256 characters in a filename + extension; greater than this cannot be scanned**maxsize=n** [Sets max file size that will be scanned; Default =0 or no file size limit; Max size = 4GB]**highWaterMark=200** (default) [Number of requests in progress exceeds 200, an event is logged]**lowWaterMark=50** (default) [Triggered after HWM event—when number of requests drop to 50, event is logged]**RPCRequestTimeout=25000** (default—a suggestion change would be to set this value to 70000, or 70secs)**Note:** Celerra's default total timeout period is 25 secs before marking AV offline, which could happen during heavy loads, large files, or poor networks. Typical VC engine scan timeout is 60 secs.**RPCRetryTimeout=5000** (default)**surveyTime=60** (default) [Change time that VC Client checks to verify availability of AV Engines]**shutdown=no** [System default: Continue retrying RPC to AV servers--does not shutdown Viruschecker or CIFS]**shutdown=cifs** [If Viruschecker fails, will stop CIFS service & access to Shares]**shutdown=viruschecking** [Stops Viruschecking but Windows Clients can still access shares with CIFS]

## **EXAMPLE OF ‘SERVER\_VIRUSCHK’ OUTPUT:**

**\$ server\_viruschk server\_6**

```
server_6 :  
10 threads started  
2 Checker IP Address(es):  
169.37.139.156 online  
169.37.139.160 online  
30 File Mask(s):  
.avb *.exe *.com *.doc *.dot *.xl? *.vxd *.386 *.sys *.bin *.rtf *.obd *.dll  
.scr *.obt *.pot *.ole *.shs *.mpp *.mpt *.xtp *.xlb *.cmd *.ovl *.dev *.zip  
.tar *.arj *.arc *.z  
13 Excluded File(s):  
.ldb *.mdb *.maf *.mam *.maq *.mar *.mat *.mda *.mde *.mdn *.mdw *.mdz *.ppt  
Share \\NNYC11P20006\CHECK$  
RPC request timeout=25000 milliseconds  
RPC retry timeout=5000 milliseconds  
High water mark=200  
Low water mark=50  
Scan all virus checkers every 60 seconds  
When all virus checkers are offline:  
Continue to work with Virus Checking and CIFS  
Scan on read disable
```

## **EXAMPLE OF VIRUSCHECK AUDITING:**

**\$server\_viruschk server\_2 -a** [SERVER AUDIT OF ACTIVITY]

```
Total Requests : 78      [# requests in Queue & files processed by AV threads]  
Requests in progress : 0      [# of files in collector queue]  
NO ANSWER from the Virus Checker Servers : 0 >>>Used for Alerts  
ERROR_SETUP : 0      [Viruschecker server not setup correctly]  
min=3447 us, max=191727 us, average=31730  
FAIL : 0      [viruschecker failed to scan file]  
TIMEOUT : 0      [viruschecker timed out on file]  
0 File(s) in the collector queue  
0 File(s) processed by the AV threads      [Files processed by AV threads]
```

## **SETTING THE MAXIMUM VC THREADS FOR DATAMOVERS:** 2.2.35.4 & 2.2.39.1

Step 1. \$/nas/site/slot\_param

**param cifs maxVCThreads=5** [Breaks deadlocks if all Virus Checker threads in use or blocked]

cifs.maxVCThreads 0x02997038 0x00000003 0x00000003

Step 2. Update “viruschecker.conf” param file: \$server\_viruschk server\_x -update

**Note:** Default VCThreads=3

## **SETTING NUMBER OF THREADS FOR VC CLIENT:**

**\$server\_setup server\_x -P viruschk -o start=64**

**Note:** Change is not persistent on reboots!

## **PARAMETERS FOR VIRUSCHECKER.CONF:** Helps with performance issues when scanning

**Problem:** Check DOES NOT ANSWER, Retrying; Checker answers FAIL, Retrying File status=ok

RPCRequestTimeout=300000 [Default value is 25000ms or 25 seconds]

RPCRetryTimeout=60000 [Default is 5000ms or 5 seconds]

Low Water Mark: default=50 [Entry made in /nas/log/sys\_log]

High Water Mark: default=200 [Entry made in /nas/log/sys\_log]

RPCRetryTimeout: default=5000 milliseconds

RPCRequestTimeout: default=5 retries, or 25000 millesconds

waitForTimeout: default=0 seconds [Old value was 10]

maxThreadWaiting: default=0 [Old value was 16]

maxsize: default=0 bytes

CIFSServer: CHECK\$ share is created

surveyTime: default=60 seconds; scan interval to all CAVA servers

shutdown: default=no [continue retrying list of Servers]

**Best Practice:** Use Shutdown=cifs to minimize virus infection damage by having CIFS Service stop if VirusChecking fails

## **TROUBLESHOOTING/QUESTIONS:**

- Check NT Event Logs--Application Log
- Ping CAVA Servers to determine network connectivity
- Version of CAVA & AV Software + Virus Definition update level
- Run \$server\_netstat server\_x -i to ensure that there are no interface errors--could be duplexing issue
- "invalid access..."; ensure that Virus Checker User Account has proper rights assigned
- Ensure that the AV Server Scan Settings are matched with those on the DataMover Virus Checker Server
- Do not run Antivirus service during data migrations!
- Is User access or performance hindered by the a/v process?
- Can the issue be isolated to certain file extensions or scanning of very large files?
- Does stopping & starting CIFS or A/V Checker Service eliminate the problem?
- If CIFS appears sluggish & hung and has high CPU utilization, run "server\_profile" command
- In extreme cases, run the Server\_Panic command to create a dump file for Eng. Analysis
- Network Trace may also be required
- Use Debug Trace software program
- CIFS service must be started before Virus Checker can be started
- Known issue whereif AV Server Service dies or becomes unavailable, after the 'waitForTime' value of 10 seconds, file may become available to user once again yet did not actually get scanned.
- Datamover panics: Listing of unscanned files stored in ./etc/viruschecker.audit
- By default VC Client scans for AV Engines every 60 seconds

## **TROUBLESHOOTING VIRUS CHECKER ISSUES:**

### **I. RPC Error when starting viruschk service:**

"RPC Error from checker 192.10.3.2" [DM cannot communicate to A/V Server]  
[Verify network connectivity; Check CAVA Service on Windows Server; Check Virus Checker Service on DM;  
Check that EMCVirCk driver loaded—Event Viewer System Log; Server\_Log errors]

### **II. SMB:3: Invalid access from client USER1 to CHECK\$**

CFS:4: setCheckWriter(), FNN=0x3981bd0 (WRITE), FOF=0x6b97284, Wait=0, TO=0, Ref=3  
CFS:4: check Wait(), FNN=0x3981bd0 (CHECK), FOF=0x0, Wait=1, TO=0, Ref=2  
[Virus User account does not have proper Check Server privileges]

### **III. Virus Checker Service on DM Locks Up:**

User connected to C\$ share, modifies a file, DM informs Virus Checker of the "./" path which it cannot traverse, logging errors & possibly hanging server. Issue is that UNC path contains period within \\ entry. Server Logs bad path. Workaround--do not use hidden C\$ share to copy files to a datamover share. Code fixed at 2.2.49.1:  
SMB: 3: Checker 150.100.50.8 answers FAIL, Retrying  
SMB: 3: File status=OK  
SMB: 3: [av000] UNC=\\SERVER31\CHECK\$\.\mnt31\Share  
Properties\leicar.txt'  
SMB: 3: Checker 150.100.50.8 answers FAIL, Retrying  
SMB: 3: File status=OK  
    Checker 150.100.50.8 DOES NOT ANSWER, Retrying  
    Checker 150.100.50.8 answers FAIL, Retrying  
SMB: 3: File status=OK  
    Checker 150.100.50.8 DOES NOT ANSWER, Retrying  
SMB: 3: [av000] UNC=\\SERVER31\CHECK\$\.\mnt31\Share  
Properties\leicar.txt'

### **IV. Error when starting Virus Checker Service: # server\_setup server\_4 -Protocol viruschk -o start server\_4 :**

Not enough Vnodes to work !!  
Total Vnodes: 10240  
OfCache Vnodes: 15360  
Error: failed to complete command  
**Cause:** File may have been changed by NAS Upgrade, or was never updated  
/nas/server/slot\_4/file

**file initialize nodes=22528 dnlc=65536**

**Fix:** Change the file to the following values:

**file initialize nodes=65536 dnlc=262144**

Reboot or failover the Server. Virus Checker Service should now start.

## **V. EXCLUSION FILES:**

### **Following files are recommended for exclusion from scanning:**

.tmp; Access db files (.ldb, .mdb, etc); SQL db files (.sql, .sqr, etc); Exchange db files (.ost, .pst, etc); Oracle db files (.fmb, .frm)

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Why? Database files in particular are continuously being written too and will degrade network performance [Scan by AV SW]

## **VI. HomeDir Files Cause Problems:**

A HomeDir config entry with the following line will cause Virus Checker problems:

emc:\*/mnt/guest/ [The extra “/” at the end of the config line is the cause of the problem!!!]

## **VII. RPCRetry & RPCRequests:**

Symptoms: Clients hang; general performance problems; VC does not answer, retrying; VC fails but logs ‘File status=OK’

Cause: AV Server does not respond to RPC requests

**Fix:** Increase parameters

RPCRequestTimeout=300000

RPCRetryTimeout=60000

## **VIII. Wait/TimeOut Error in Server Log:**

Server Log: check Wait/time-out(), FNN=0x25d98d0 (CHECK), writer=0x0, waiting=0, timeout=1Ref=6,timerPtr=0x0

Other Symptoms: Deadlock condition with VC Server; Loss of CIFS connection or CIFS Hangs

**Fix:** Ensure that there is a “waitForTimeout” value configured in viruschecker.conf; Upgrade to 2.2.57.0 +

## **IX. Issues with Office for XP:**

Users may have trouble trying to Save Excel files

Update to Office for XP SP1

## **X. AV Client Does not Have Check\$ Privilege:**

2004-05-15 13:59:48: VC: 3: Invalid access from client 129.225.82.143 to CHECK\$

2004-05-15 13:59:48: VC: 3: Client 129.225.82.143 (129.225.82.143) is not a VC server

**Note:** AV Server agent does not have correct privilege to access CHECK\$ share. Please note that this condition can actually block all SMB threads in NAS 5.2, as seen with the Server\_CIFS output. Solution is to verify AV configuration.

## **XI: Server Log Error:**

Server <ip addr> version 2 is ERROR\_AUTH → CAVA not running with EMC VChecking User account, does not have privilege to all VC Server to connect to DM. Try mapping to [\\DART\check\\$](\\DART\check$) and same error should be seen.

## **XII: Server Log Message Indicating that File has not been Scanned:**

2006-03-01 21:14:21: **VC: 3: 6:** \root\_vdm\_7\FS007\F\IFSDAT1\w5900001.www

## **OTHER WINDOWS ERRORS IN SERVER LOG:**

2007-01-28 22:33:30: VC: 3: 8: Server 10.120.17.155: ERROR\_AUTH 1115, RPC program version 3, CAVA release: 3.5.6, AV Engine: Symantec NAV CE

2007-02-03 11:21:09: VC: 3: 8: Server 10.120.17.155: ERROR\_AUTH 1208, RPC program version 3, CAVA release: 3.5.6, AV Engine: Symantec NAV CE

2007-02-03 12:58:23: VC: 3: 8: Server 10.120.17.154: ERROR\_AUTH 53, RPC program version 3, CAVA release: 3.5.6, AV Engine: Symantec NAV CE

## **WINDOWS LINK FOR WINDOWS ERRORS:**

<http://msdn2.microsoft.com/en-us/library/ms681381.aspx>

ERROR\_BAD\_NETPATH

53 The network path was not found.

ERROR\_SHUTDOWN\_IN\_PROGRESS

1115 A system shutdown is in progress.

ERROR\_EXTENDED\_ERROR

1208 An extended error has occurred.

## **HOMEDIR SCAN ISSUE:**

**emc:\*/mnt/guest/** [AntiVirus agent cannot scan files in the homedir using path similar to the line above]

## **BUG FIXES:**

\$server\_viruschk server\_x -a → created eiffel dump if output > than 16,384 characters [Fixed 2.2.46.x]

\$server\_setup server\_x -P viruschk -o stop → RPC timeout error if >than 300 files in processing Queue [Fixed 2.2.49.2]

User connected to default C\$ hidden Share and modified a file, DataMover could not handle path [Fixed 2.2.49.1]

Virus Check enabled, reboots take very long time [Fixed 2.2.49.1]

\$server\_viruschk server\_x -a → command fails or takes long time if I18N characters present [Fixed 2.2.49.1]

CIFS hangs if A/V service unavailable, eventhough configured for 'shutdown=no' [Fixed 2.2.53.4/4.0.17.1]

Viruschecker Running → user could not create Excel file [Fixed 2.2.53.5/4.0.17.1]

## **DISABLING CIFS FILENAME PATH CACHING:**

**param cifs pathCache=0**

**Note:** Setting this value to 0 forces VirusChecker to request complete paths from CIFS for files to be scanned—default is to cache this information. Some situations may occur where wrong path information is being cached on Data Mover as in following:

\$ more /nas/rootfs/slot\_2/.etc/viruschecker.audit

\mp\_users\ct\cifs\_data\rfa5630\data\maint\.\GEN\_LOG.txt

### **SETTING UP AV DEBUGGING ON AV SERVERS:**

1. Stop the EMC Checker Server Service (or CAVA Service in newer codes) on the AV Server
2. Edit Registry for CAVA Version 1.8.9:  
HKLM>Software>EMC>CheckerServer>Config: Set "verbose" and "debug" to "1"  
Edit Registry for CAVA Version 2.2.4:  
HKLM>Software>EMC>CAVA>Configuration
3. Download DebugView v4.31 [dbgview.exe] for PC's from [www.sysinternals.com](http://www.sysinternals.com) [Win32 Debug Program]
4. Open "dbgview.exe" on AV Server>Configure Log file>Click Icon to start Capture
5. Start the EMC CheckerServer Service
6. When experiencing performance problem:
  - a) - Obtain server\_log file during problem period
  - b) - Obtain output from "viruschk audit" command
  - c) - Get copy of current "viruschecker.conf" file
  - d) - Obtain output from AV Server using the 'debugview' application and saving output to logfile

**Note:** Debug View will display debugged output from kernel-mode or Win32 drivers

### **CONFIGURING EMC AV DRIVER IN WINDOWS 2000 REGISTRY:**

**HKLM>System>CurrentControlSet>Services>EMCVirCk**

**ErrorControl=1**

**Start=2**

**Type=1**

### **CONFIGURING CAVA 1.8.9 THREADS IN WINDOWS 2000 REGISTRY:**

**HKLM>Software>EMC>CheckerServer>Configuration>NumberOfThreads: *NumberOfThreads=20 (default)***

[Number of ONC-RPC threads available for VC Client; Make this setting the same as the Virus Checker Datamover setting of maxThreadWaiting=n]

### **CONFIGURING CAVA 2.2.4 THREADS IN REGISTRY:**

**HKLM>Software>EMC>CAVA>Configuration:**

**NumberOfThreads: REG\_DWORD: 0x14 [Default value=20 decimal; New rec.=64 decimal]**

**AgentType: REG\_SZ: Driver [Do not modify this value]**

### **CONFIGURING EMC AV DRIVER VIA REGISTRY:**

**HKLM>System>CurrentControlSet>Services>EMCVirCk:**

**ErrorControl=1**

**Start=2**

**Type=1**

### **SERVER LOG ERRORS:**

ERROR\_SETUP--Viruschecker Server setup incorrectly

AV\_NOT\_FOUND--Antivirus software could not be found or executed

FILE\_NOT\_FOUND--File not found or mapped – could not be checked

ACCESS\_DENIED--File access denied to the viruschecker --check AV User Account Rights

SUSPECT\_VIRUS--possible virus infection

DETECT\_VIRUS--Virus infection detected in file, type of virus not specified

MACRO\_VIRUS--Macro virus detected in file

### **EVENTS THAT TRIGGER VIRUS CHECKING:**

- DataMover Viruschecker Client determines when a file should be scanned; Sends request to scan file to CAVA via UNC path;
- CAVA opens file for Scanning; CAVA blocks User access during scan operation; Virus Scanning Engine Opens file again and scans
- Modifying & Closing an existing file
- Creating and saving a file
- Moving or Copying a file

- Restoring a file from BackUp
- Renaming a file with different extension
- Scan on Read if Access time is earlier than reference time for CIFS clients (later NAS version 4.2)

## AV FEATURES

### **SCAN ON FIRST READ:** Introduced with NAS 4.2

A time reference is stored in EMC Checker Server and CAVA uses this to determine if a file should be scanned when opened for Read. Specifically, DART uses ‘access’ time of file during an Open to determine if file should be scanned. The ‘access’ time is cross-referenced to the time stored in the config file and in the /etc/viruschecker.date file & is persistent until changed

--Typically employed after updating Virus Definition Files—will also scan compressed files such as .ZIP files

--Limited to CIFS Clients

**HIGHROAD SCAN:** To become available with NAS 5.0. Allows for VirusChecking of files written by High Road clients.

### **TURNING ON SCAN-ON-FIRST-READ (setting Reference Time):**

**\$server\_viruschk server\_x -set accesstime=0210261330.00 [YYMMDDHHMMSS]**

**Note:** Reference Time is stored in Memory and is /etc/viruschecker.date file. Scan on First Read is disabled by default, as seen when starting viruschecker with default configuration for first time:

**# server\_viruschk server\_3**

Scan on read disable

### **SETTING REFERENCE TIME TO CURRENT TIME:**

**\$server\_viruschk server\_x -set accesstime=now**

**# server\_viruschk server\_3**

Scan on read if access Time less than Wed May 18 21:16:57 2005 (GMT-00:00)

### **DISABLING REFERENCE TIME OR SCAN ON READ:**

**\$server\_viruschk server\_x -set accesstime=none or 0**

## **SIZING TOOL FOR CAVA:**

“cavamon.exe” tool is run on AV Engines to help determine load and gathers statistics; uses heuristics to determine workload and bases environment for an average 60% load per CAVA Server

### **SETTING UP SIZING TOOL:**

1. Create “cavamon.dat” file in Program Files>EMC>CAVA directory
  - add line item entry by IP or Hostname for each AV Engine Server that you wish to monitor
2. Enable Sizing Tool via Registry Entry:
  - a.) Start>Run>regedit>HKLM>software>EMC>cava>Sizing [Doubleclick and set Value to 1 to Enable]
  - b.) Doubleclick “SampleIntervalSecs” to set interval between 1-60 for CAVA to update Sizing Tool [Default = 10 secs]
3. Start Sizing/Monitoring Tool: Program Files>EMC>CAVA>cavamon.exe
  - a.) Click on “Get Stats” to begin gathering statistics
  - b.) To determine number of AV Servers recommended, click “Size” button. This Utility collects data for (10) consecutive interval periods and then displays number of recommended AV Engines

## **ANTIVIRUS MANAGEMENT FOR NAS 4.0 +:**

MMC Snap-In Module: Start>Programs>Administrative Tools>Celerra Management

**Note:** Celerra management only. AV Servers would need to be managed through the Vendor's interface

### **INSTALLING ANTIVIRUS MMC TOOL FOR CELERRA:**

Step 1. Copy executable install program from 4.0.x Celerra "/nas/cifs/CelerraVirusMgmt.exe" to WIN2K/NT 4.0 DC

Step 2. Install with defaults

## **CELERRA I18N INTERNATIONALIZATION:** *root\_fs\_common [aka .etc\_common]*

→Celerra directly supports the translation of UTF-8 (NFS & FTP Clients) & UTF-16 (CIFS Clients) without further configuration

→File & Directory names are always stored on-disk using UTF-8

→Celerra translates Files and Directory names obtained from clients into UTF-8 format for on-disk storage, and translates back into Client’s local encoding when Files or Directories are Read

→Celerra can be configured to translate various local encoding schemes

→Internationalization allows for files & directories to be created in a local language with names consistently presented to both NFS & CIFS clients

→I18N does not provide for one code page translation to another

→Non-UTF-8 NFS or FTP clients require that native encoding be identified for the Data Mover

**Byte Order Mapping:** BOM

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Hardware platforms can present multibyte characters in different orders. Big-endian (FFFE) systems present high order byte first.  
Little-endian (FEFF) systems present low order byte first.

## **HOW CELERRA TRANSLATES & STORES UNICODE CHARACTERS:**

- I. Dart uses XLT translation table (defined xlt.cfg) to convert ASCII or Extended ASCII to Unicode (CIFS clients deliver Unicode)
- II. Dart must then convert Unicode to UTF-8 (char.-encoding scheme) to store On-Disk

**Note:** The xlt.cfg file is used for translation of NFS clients, as in the following sample

```
# cat /nas/site/locale/xlt.cfg
```

:::8859-1.txt: Any thing that didn't match above will be assumed to be latin-1

## **I18N FACTS:**

- Directories are converted when first accessed by users
- Only one Encoding type is supported per Data Mover for conversions [but up to (8) code translations can be used afterwards]
- Cannot unconvert from I18N once conversion takes place
- Supports only User-level access, not CIFS Share-level access
- Some encodings require RPQ: Latin-2; Korean/KSC; GB/GBK; Other non-UTF-8 encodings
- Limitation: Directory/Filenames limited to 255 bytes for UTF-8 formats

**CIFS I18N SUPPORT:** Celerra Supports I18N for File & Directory names created by Clients. Additionally, CIFS Clients are supported for User,Group & LocalGroup names. Share, Directory, & Domain names are only supported for ASCII. UNIX & SHARE security are not supported. Celerra Monitor is not supported.

**NFS/FTP I18N SUPPORT:** *Translates filename & directorynames--not mountpoints!*

**NAS 2.2+ & 4.0:** Supports International characters for File and Directory names.

## **I18N TERMINOLOGY:**

**INTERNATIONALIZATION:** Since Unicode can define a bit representation of every character of the world's alphabet, it allows for the ability to have consistent names & directories in various languages.

**CHARACTER SET:** The list of characters used, not fonts or Encoding

**ENCODING:** The mapping of character sets to bits used to represent data as stored on disk. Client encodings are defined by the xlt.cfg and character mapping files. All encodings are stored on Control Station in /nas/site directory. Configure DataMover encodings by DataMover; IP Subnet; IP Address; Hostname; Network protocol (NFS, FTP, All)

**UNICODE:** Unique code representation of all world language characters for computer processing. The Unicode Character Standard consists of the Basic Multilingual Plane (BMP), which consists of the first 64K characters of Unicode. The remaining Characters are contained in 17 different supplementary planes, each plane 64K in characters. UTF-32 is based on 32-bit code and references all Unicode 64k characters, and all the characters from all 17 supplementary planes.

## **UNICODE CHARACTER DATABASE:**

- Unicode version 2.0 is represented by the unidata2.txt file
- The Unicode Character Database defines default Unicode character properties and internal mappings
- File is plain ASCII text lines with fields terminated by semicolons
- Each line in the file represents the data for one encoded character in the 2.0 Unicode Standard
- So for Celerra, this file represents the Unicode definition source file

**LOCALIZATION:** Configuring machine to local language, character sets, number formatting, currency, date & time, etc.

## **UTF=UCS--UNIVERSAL CHARACTER SET-TRANSFORMATIONAL FORMAT:**

ISO 10646 defines UCS for mapping characters to most international languages onto integers between 0 and  $2^{31}$  (2,147,483,648).  
UTF-8 is a specific set of data representations that are capable of mapping UCS values into strings of ASCII hexadecimal values.  
UCS-2/UCS-4 are 16/32-bit Universal Character Sets, respectively

## **ASCII—American Standard Code for Information Interchange:**

A coding system that uses 8-bit numbers to represent letters, numbers, punctuation, & special symbols, and each character requires one byte for storage on-disk. ASCII standard applies only to codes 0-127 using lower 7 bits—8<sup>th</sup> bit is reserved for parity checking. ASCII codepage 437 and 850 are examples of ASCII codes that use high-order characters above 127.

## **UTF-8:**

On-disk disk encoding method used with Celerra, aka UCS Unicode Transformation Format. Similar to UTF-32, UTF-8 can reference the complete Unicode character space. The '8' represents 8-bit blocks used to represent each character, with a total number of blocks needed from 1-4. UTF-8 works with an algorithm that converts Unicode values to unique 1-4 byte sequences, with no embedded null characters. Latin1 is the default for Celerra, until NAS 5.4 [aka 8859-1.txt]. ASCII characters represented as 7-bit characters, and non-ASCII as 8-bit [ASCII is a subset of UTF-8, with values from 0-127]. UTF-8 supports WebNFS, FTP, TELNET, RLOGIN. ASCII values equal to or below 127 (hex 0x7F) only require 1 byte (1 8-bit block), since it uses only 7-bits to represent a character, which will be equivalent to the ASCII value itself. For characters equal to or below 2047 (hex 0x07FF) the UTF-8 representation will use two bytes. For characters from 2049-65535 (0xFFFF), UTF-8 will use 3 bytes.  
→ISO-8859-1 (Latin1) uses fixed length characters of 8 bits

## **16-bit UNICODE→UTF-16:**

UTF-16 is based on 16-bit little endian values, and is limited to 65,536 characters, [aka,UCS-2 Transformation Format], little-endian byte order, with no Byte Order mark, and no null-terminator (double byte encoding). Some of the 64k values are used to reference the 17 different supplemental Unicode planes. Used for Windows NT/2000—Windows uses Uniscribe program to reference surrogate code points for the 16-bit values reserved for the 17 supplemental Unicode planes. Celerra supports Unicode Character Database (unidata2.txt) and code page cp437.txt in the ./etc\_common/xlt directory by default--no configuration required. Celerra receives data in 16-bit format and stores on disk in UTF-8 format.

### **CODE PAGE 437:**

DOS code page used with the Windows Command prompt

Original character set of the IBM PC

Based on ASCII, but also contains International characters and Glyphs

C:\>chcp

Active code page: 437

→cp437.txt file on Celerra is the DOSLatinUS to Unicode conversion format, with DOSLatinUS in Hex, followed by Hex Unicode, then Unicode name

→UTF-16 uses character lengths of 16 bits (e.g., Windows NT)

### **EXAMPLES:**

#### **NFS/FTP UTF-8 CLIENTS:**

Celerra receives data & requires no translation to place on disk; code pages available for these clients are 8859-1; sjis; big5

#### **CIFS--WINDOWS UTF-16 CLIENTS:**

Celerra receives data in 16-bit Unicode format & translates to UTF-8 disk format & requires unidata2.txt & cp437.txt files to encode.

NFS Code Page Clients [8859-1 (Latin 1), sjis.txt, eucjp1, big5] are converted first to 16-bit Unicode from the code page stored in the /nas/site/locale directory, then stores onto disk in the UTF-8 format. When "Read Operations occur", converts Unicode to correct bytes prior to sending to Clients.

## **I18N/UTF-8 ENCODING LIMITATIONS:**

Share-Level Security not supported. Max length UTF-8 directory/file strings is 255 bytes.

Celerra Monitor/Manager not supported. Sharenames & Mountpoints not translated--remains ASCII.

### **COMMON TRANSLATION FILE SYSTEM:** Celerra specific file for translations is "xlt.cfg"

Certain character encoding configuration files located in ./etc\_common/xlt

All translation files reside in /nas/site/locale

Any changes to configuration must be made to /nas/site/locale & copied to ./etc\_common/xlt using /nas/sbin/uc\_config -update  
DataMover mounts the common file system as "root\_fs\_common", reads in the client-specific encoding translation files, and stores mappings for client encoding and UTF-8. \$/nas/rootfs/slot\_x/etc\_common/xlt is Read Only

## **COMMON TRANSLATION FILE SYSTEMS:**

**/nas/site/locale** →Contains translation files, which are then copied to DataMover “./etc\_common\xlt” using “uc\_config –update”

**./etc\_common/xlt** →Stores encoding files for interpretation by DART when I18N enabled

## **I18N DIRECTORIES: Common Translation File System Directory--→ ./etc\_common/xlt & /nas/site/locale**

**/nas/site/locale** Look for these files; cp437.txt; 8859-1.txt; sjis.txt; eucjp1.txt; big5.txt; unidata2.txt to be present

**./etc\_common/xlt** 8859-1.txt [default encoding=Latin1]; unidata2.txt & cp437.txt--supports CIFS clients [CIFS 16-bit Unicode conversions & Microsoft CIFS encoding, respectively]

**Note:** Translation files are stored in both above locations and should match between Control Station /nas/site/locale and the Data Mover in the ./etc\_common/xlt directory. Use uc\_config –update to synchronize the two locations.

**# /nas/sbin/uc\_config -i** [Use to display existing I18N configuration]

Common filesystem [root\_fs\_common] exists.

Common filesystem is presently mounted read-only on:

server\_2  
server\_3

Common filesystem is not mounted read-write anywhere.

**# /nas/sbin/uc\_config -l** [Use to list out translation files]

### **Control Station Directory /nas/site/locale:**

|            |   |          |          |        |              |             |
|------------|---|----------|----------|--------|--------------|-------------|

-rwxrwxr-x 1 nasadmin nasadmin 1280 Sep 20 06:33 xlt.cfg
```

**Data Mover /etc common/xlt Directory:**

```
-rw-r--r-- 1 root bin 10583 Oct 18 11:34 8859-15.txt
-rw-r--r-- 1 root bin 9157 Oct 18 11:34 8859-1.txt
-rw-r--r-- 1 root bin 316745 Oct 18 11:34 big5.txt
-rw-r--r-- 1 root bin 9843 Oct 18 11:34 cp437.txt
-rw-r--r-- 1 root bin 332970 Oct 18 11:34 eucjp1.txt
-rw-r--r-- 1 root bin 303241 Oct 18 11:34 GB2312.txt
-rw-r--r-- 1 root bin 622893 Oct 18 11:35 jp-euc1.txt
-rw-r--r-- 1 root bin 364422 Oct 18 11:35 jp-euc.txt
-rw-r--r-- 1 root bin 293788 Oct 18 11:35 jp-pck1.txt
-rw-r--r-- 1 root bin 295686 Oct 18 11:35 jp-pck.txt
-rw-r--r-- 1 root bin 720675 Oct 18 11:35 kr-uhc.txt
-rw-r--r-- 1 root bin 173349 Oct 18 11:35 sjis.txt
-rw-r--r-- 1 root bin 444409 Oct 18 11:35 unidata2-old.txt
-rw-r--r-- 1 root bin 715838 Oct 18 11:35 unidata2.txt
-rw-r--r-- 1 root bin 1280 Oct 18 11:35 xlt.cfg
```

**Note:** If the two lists do not match, run uc\_config with -update option to update.

**VERIFYING DATAMOVER UTF-8 FORMAT FROM CONTROL STATION:**

1. Mount datamover root from Control Station
2. \$ls -d CA\* [Verify file names]
3. \$ls -d CA\* | od -t x1 [Obtain UTF-8 code]
4. **\$/nas/sbin/uc\_config -verify 192.168.1.100 -mover server\_2**  
**192.168.1.100 is UTF-8**

**Note:** Dart code returns UTF-8 from Control Station when Internal network is used

**VERIFYING UNICODE LOCALGROUPS DATABASE:**

Celerra uses .db.localgroups file when in Unicode mode, not localgroups.db, and contains this info:

```
# head .db.localgroups
#
# Localgroups database
#
$RELEASE:4$ →RELEASE: 4$ indicates Unicode mode
```

**CELLERRA I18N TRANSLATION FILES (CHARACTER MAPPING FILES)/nas/site/locale:**

| <u>NFS/FTP/<br/>CLIENTS</u> | <u>ENCODING/<br/>CHARACTER SET</u> | <u>TRANSLATION/<br/>FILE</u>                                                                                                                                  |

| Yes                         | Big 5                              | Big5.txt →Traditional Chinese with UTF-8 conversion                                                                                                           |
| Yes                         | Unicode UTF-8                      | None →No UTF-8 conversion, all languages                                                                                                                      |
| Yes                         | Other non-UTF-8                    | None →RPQ, conversion to UTF-8                                                                                                                                |

**CIFS CLIENTS**

|     |               |                                                              |
|-----|---------------|--------------------------------------------------------------|
| Yes | Unicode UCS-2 | unidata2.txt & cp437.txt →Conversion to UTF-8, all languages |
|-----|---------------|--------------------------------------------------------------|

**Note:** cp437.txt Microsoft character mapping file required for CIFS 16-bit Unicode Clients--installed by default

unidata2.txt File represents the Unicode Character Database for Unicode Version 2.0. Required by CIFS clients for 16-bit Unicode conversion & Upper-to-Lower case--installed by default

slt.cfg Celerra's translation file that defines how File & Directory names are translated into UTF-8--edit this file for the encoding format required if the default Latin1 is not to be used--for NFS/FTP Clients using Unix or CIFS

## **8859 TRANSLATIONS:**

Translation sets are given in Octal, Decimal, Hex, and Character representations, as in following “Latin-1” 8859-1:

**Oct Dec Hex Char Description**

| Using Hostname, DNS, or NIS Name for Translation: | ::hostone.emc.com::8859-1.txt:this host uses latin1                               |

## **UTF-8 ENCODING:** UTF=Unicode Transformation Format, an 8-bit universal character encoding standard

- UTF-8 employs algorithm to convert unicode values to a 1-4 byte sequence with no null characters
- Superset of ASCII [characters range in value 0-127 for ASCII]
- Supports WebNFS, FTP UTF-8, Telnet, Rlogin, NFS, CIFS clients without further translation
- CIFS clients use "unidata2.txt" and "cp437.txt" found in /etc\_common/xlt
- Backwards compatible with all ASCII characters as 7-bit, all non-ASCII rendered in 8-bit values
- CIFS clients obtain File & Directory info in 16-bit unicode--translates into UTF-8 format [up to 65,536 characters with unique 16-bitcode assigned to each character]
- NFS clients code page located in */nas/site/locale*

## **DEFAULT CELERRA I18N ENCODING:**

Latin-1 ASCII Encoding format for NFS/FTP [aka ISO 8859-1.txt]

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
However, using the xlt.cfg file, different & multiple encoding schemes can be supported based on DataMover, IP Subnet, IP Address, Hostname, or Network Protocol

### **EDITING XLT.CFG TRANSLATION FILE:**

Text format is comprised of (6) fields  
servername:protocol:address:reserved:translation:comment  
[server\_3:nfs:192.10.2.21::8859-1.txt:using default latin1 for translations]

### **TRANSLATIONS CONTAINED IN /NAS/SITE/LOCALE:**

***8859-1.txt, cp437.txt, 8859-15.txt, big5.txt, sjis.txt, eucjp1.txt, jp-euc.txt, jp-pck.txt***

Also found DataMover slots: #ls /nas/rootfs/slot-4/.etc\_common/xlt

Other mapping files available with RPQ

### **TRANSLATION RECOMMENDATION IF NFS ACCESS TO CIFS FILES REQUIRED:**

EMC recommends maintaining only a single character set as NFS clients can only access the first mapping entry for a specific character set.

### **DEFAULT TRANSLATIONS SUPPORTED:**

**CIFS:** File & Directory names, User & Group Names, Local Groups, but NOT Sharenames [seen as ASCII]

**NFS/FTP:** File & Directory Names, but NOT Mountpoints [seen as ASCII]

With UTF-8 turned on, translations are performed by DataMover lookups to the /.etc\_common/xlt directory

#### **How Does the Translation Work?**

NFS/FTP Client session; Celerra scans xlt.cfg file for translation match and if none found, applies default "latin-1" UTF-8

**MULTI-BYTE CHARACTERS:** NFS/FTP Clients use pure ASCII, and cannot read whole 'multi-byte' character sets but must read byte-by-byte, leading to differences in file name translations. Control Station cannot use multi-byte characters!

### **CONFIGURING I18N SUPPORT—New Install: \$/nas/sbin/uc\_config -i or -l**

**INTRO:** During Celerra software install, the default ASCII translation file and the /nas/site/locale directory are created on Control Station. Any other encoding schemes require editing of configuration files located in /nas/site/locale directory, and copying to /.etc\_common/xlt using the **\$/nas/sbin/uc\_config -update** command.

**UNIX HOSTS:** #locale [Command to display client language used]

**WINDOWS:** c:>codeagent.exe [Run utility to determine language used]

1. Verify /nas/site/locale & /.etc\_common/xlt directories are present, as well as files xlt.cfg, unidata2.txt, 8859-1.txt, cp437.txt, 8859-15.txt, big5.txt, sjis.txt, eucjp1.txt

**\$/nas/sbin/uc\_config -setup** ["Common Unicode translation subdirectory already exists"--means setup is correct]

2. Determine Client protocols and translations required for the site [e.g., non UTF-8 NFS/FTP clients require translations]

**Note:** If you cannot use the default 8859-1.txt mapping file [& require either sjis.txt; eucjp1.txt; big5.txt,etc], you will need to edit the "xlt.cfg" character-mapping file and load new translation files to the /nas/site/locale directory

3. Edit /nas/site/locale/xlt.cfg file for new translation requirements

4. Copy Translation Configuration Files to /.etc\_common/xlt using **\$/nas/sbin/uc\_config -update**

**Example:** **\$/nas/sbin/uc\_config -update big5.txt -mover server\_2** [Copies over Map file for Chinese character support]

**Caution:** If no filename is specified, all translation files including xlt.cfg are copied over

5. Verify your Configuration Files:

**#/nas/sbin/uc\_config -verify 192.10.202.12 | hostname | -mover server\_2**

[Verify client configuration by IP or Hostname against the DataMover configuration]

6. Verify that conversion will work: #/nas/sbin/uc\_config -setup ['Common Unicode translation subdirectory already exists']

7. Turning On I18N [New installs]:

**#/nas/sbin/uc\_config -on -mover server\_2**

**Caution:** Do not use this command for upgrading a Celerra from ASCII mode!

8. If an upgrade, perform steps 1-6 and then convert existing data to UTF-8

**I18N CONVERSIONS:** Conversions can be problematic. For this reason, all new Celerra Installs should have I18N enabled by default. Why? Many Customers use different types of encoding pages, or formats, such as 850 or 437, and by default, Celerra converts using a single Code Page format. Therefore, if multiple types are in use, when converting to I18N UNICODE, some files or directory names are 'changed'. If I18N were used upfront, prior to using other Code Pages and creating data on file systems, then there would be no issue.

**Important Point:** I18N Conversions do not corrupt data, but may change names of certain files & directories, which must then be manually renamed afterwards. Fortunately, there are tools available to check filesystems, based on customer code pages in use, prior

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
to conversions so as to identify any problem files. A post-conversion script can be run to correct all previously identified problem files.

**Note:** You can turn the uc\_config conversion process on again if there are files that have not been converted, for whatever reason.  
**CODE PAGES:** Support up to (8) different types of character translations--the fewer in use the better with respect to 'conversions'. However, during a conversion, only (1) local character type is allowed--after the conversion can configure for other encodings

## **I18N CONVERSION STEPS:**

1. Identify what Code Pages are being used by Customer and what the Client mix is. Run "uc\_check" script against FileSystems, using the Code pages in use to find which files/directories will be 'mis-converted'. Or, use "ls -R" and pipe output to file. Once identified, a post-conversion script can be used to repair the 'mis-converted' files.
2. Verify FileSystems under 85% capacity and number of inodes available [minimum of 10% free space required]

**Note:** Minimum of 300 inodes must be available on each filesystem to be converted.

3. Customer should conduct complete Tape BackUps of all File Systems

4. Run conversion using only a single Code Page encoding scheme—afterwards, can enable additional encodings

**CIFS Client:** c:\>uc\_check.exe -codepage cp850.txt -codepage cp437.txt \dm03\share01

**NFS Client:** ./uc\_check -codepage cp850.txt -codepage cp437.txt /mntpoint

**Note:** Preferable to run the following command from Control Station to DM as follows:

**# ls -lbR /nas/rootfs/slot\_2/fs1 >ls.out** [-b prints octal escapes for non-graphic characters]

5. Update translation files prior to running conversion:

**# /nas/sbin/uc\_config -update**

6. Kick off conversion:

**# /nas/sbin/uc\_config -convert start big5.txt -mover server\_2**

**Note:** File System access and performance may be impacted during the conversion process. Customers should try to limit access to file systems during the conversion. Takes about 1 minute per 10,000 inodes to convert a filesystem.

**Caution:** Remove the ascii filter param and do not reboot Data Movers until the convert command is started.

**Use following if enabling I18N on a prior ASCII Server & Keeping Default Code Page:**

**# /nas/sbin/uc\_config -convert start 8859-1.txt -mover server\_2**

7. Mount data mover from Control Station & start find commands against all filesystems to complete conversion of all files:

**# nohup find /mnt/fs1 -name "\*" -print > /nas/var/findlog\_fs1.txt &**

**# nohup find /mnt/fs2 -name "\*" -print > /nas/var/findlog\_fs2.txt &**

**# nohup find /mnt/fs3 -name "\*" -print > /nas/var/findlog\_fs3.txt &**

**Note:** Monitor conversion process using ps -ef or jobs command

8. After conversion completes, remove "param shadow asciifilter=1" from Data Movers and reboot.

9. Turn off the conversion process:

**# /nas/sbin/uc\_config convert -stop -m server\_2** (or would remain in progress)

10. Reboot all DataMovers

11. Run script or manually correct any mis-converted files

12. Run "uc\_check" to verify results [Running against NT Shares: c:\>uc\_check.exe -high -unusual \dm03\share01]

13. Configure additional client encoding schemes if required

## **I18N CONVERSION STEPS:**

**Note:** Conversion occurs during file/directory access by users

1. Verify /nas/site/locale & ./etc\_common/xlt directories and xlt.cfg configuration files are present

**\$/nas/sbin/uc\_config -setup** ["Common Unicode translation subdirectory already exists"--means setup is correct]

2. Determine Client protocols and translations required for the site [e.g., non UTF-8 NFS/FTP clients require translations]

**Note:** If you cannot use EMC-supplied mapping files [8859-1.txt; sjis.txt; eucjp1.txt; big5.txt], you will need to edit the "xlt.cfg" character-mapping file and provide new translation files in the /nas/site/locale directory]

3. Edit /nas/site/locale/xlt.cfg file for new translation requirements

4. Copy Translation Configuration Files to **/etc\_common/xlt** using **\$/nas/sbin/uc\_config -update**

Example1: **\$/nas/sbin/uc\_config -update big5.txt** [Updates only the configuration file referenced]

Example2: **\$/nas/sbin/uc\_config -update** [Updates all configuration files]

5. Verify your Configuration Files: **\$/nas/sbin/uc\_config -verify 192.10.202.12 | hostname | -mover server\_2**

[Verify client configuration by IP or Hostname against the DataMover configuration]

6. Upgrading the DataMover: **[Do not use \$uc\_config -on command]**

a) Start Conversion: **\$/nas/sbin/uc\_config -convert start big5.txt -mover server\_2**

b) Conversion for Whole Celerra: **\$/nas/bin/uc\_config -convert start big5.txt -mover ALL**

**Note:** Once turned on, the actual conversion occurs whenever file systems or directories are accessed. Only one encoding is supported per DataMover. Use the "find" command from Unix or NT to manually convert every file and directory immediately.

Conduct this during period of low I/O on system. FileSystems will not be available. Also, do not stop conversion prior to completion of file access by clients.

**Example:** UNIX Client: #find . / -name nosuchfilename -print  
NT Client: Start>Find>File and Folders

7. Turning Off the Conversion After Completion: #/nas/sbin/uc\_config -convert stop big5.txt -mover server\_2 [Do this only after the conversion process is done or else datamover will remain in conversion mode]

## **SAMPLE XLT.CFG FILE:**

```
# The line below identifies the meaning of each of the fields in this file
# all of these fields can have data in them except for the reserved field
# which must be left empty. (No characters, not even whitespace).
#
#<server>:<prot>:<addr>:<rsvd>:<translate>:<comment>
[server_3 or Hostname; Protocol 'All', 'NFS', or 'FTP'; ASCII Name, IP Address of Client or Subnet; name of mapping file]
#
# each of the lines below are an example of how to use some of the features
# a typical installation will use. These lines are ordered from most specific
# to least specific, since the first line that matches a client's request
# will be the one that actually applies. To adapt one of the lines below
# for a particular installation, simply remove the leading '#' and change the
# address field and translation file to be correct for the particular network.
#
# The line below shows how to identify a particular client which uses an
# encoding that is different from other clients.
#
#:168.159.6.108::8859-1.txt: This client use latin-1 (iso-8859-1)
#
# The line below is an example of how to identify a set of clients by subnet.
#
#:168.159.6.0.255.255.0::8859-1.txt:Clients on the 168.159.6.0 use latin-1
#
# the default is that all clients that don't match any of the earlier lines
# will be assumed to use latin-1
:::8859-1.txt: Any thing that didn't match above will be assumed to be latin-1
```

## **TROUBLESHOOTING I18N:** Most issues will be with the xlt.cfg map file

Use /nas/sbin/uc\_config -verify command to verify xlt.cfg settings

Common problems return "# %d" line errors for incorrect text configuration in the xlt.cfg file

Server Log entries are prefaced by either CFS, UFS, XLT subjects

## **I18N XLT FILE CORRUPTION ISSUES:**

Generally manifested by access issues to Shares that have mixed case characters. XLT files are stored in .etc\_common, and unknown actions can occasional cause corruption and loss of CIFS access to Shares. NAS 5.5 will have a maintenance release that will implement a CRC32 checksum feature that will store checksums of each XLT file in "xlt.crc". Whenever any XLT file is updated or accessed, the checksum will be compared against the xlt.crc. Upon corruption, DART will log an event, run "uc\_config -update" to copy files from /nas/site/locale, and generate a CallHome event.

**# .server\_config server\_2 -v "xlt crc <filename>"**

**Note:** Use command to verify individual XLT files

## **VERIFYING I18N CONFIGURATION ON DATA MOVER:**

**# .server\_config server\_2 -v "xlt verify 192.168.2.2"**

1040166829: LIB: 5: Querying LOCAL host file by name.

1040166829: LIB: 5: Querying NIS by name.

1040166829: LIB: 5: Querying DNS by name.

**1040166829: XLT: 3: 192.168.2.2 is UTF-8**

## **ALTERNATIVE COMMAND TO VERIFY I18N SETTINGS ON DM:**

**# /nas/sbin/uc\_config -verify 10.144.1.1 -mover server\_2**

server\_2 :

10.144.1.1, is sjis.txt

## **Determining Language/Encoding Requirements for Clients:**

1. Windows NT/2000: Run 'codeagent.exe' utility

2. Unix Clients: Run #locale

3. Windows Clients Using NFS/FTP (e.g., Hummingbird): Need encoding type from vendor

**Note:** .db.localgroups file is created when I18N is turned on and supersedes the "localgroups.db" file

## **OBSERVING UNPRINTABLE CHARACTERS FROM UNIX SYSTEMS:**

# ls -lb

### **SETTING I18N PARAMETERS FOR NDMP:**

**Note:** Set following parameter when Data Mover has I18N enabled, for all NAS versions that support I18N. This will ensure that the DM will use UTF-8 translation instead of the default “Latin 1”

**param NDMP dialect=**

## **CELERRA REPLICATION:** (Celerra Replicator/Celerra IP Replication)

→See Cognac section for Replicator V2 information

### **IP REPLICATION FEATURES:**

- Introduced with NAS 5.0, with RPQ
- Provides for Synchronous block-level replication of a file system
- NAS 5.0/5.1 does not support a Disaster Recovery mode of IP Replication
- NAS 5.1 does not support R/W on SFS file system [Upgrades from NAS 5.0 to 5.1 will require SFS be R/O]
- Provides for a READ-ONLY point-in-time async copy of a “snapshot” of the PFS to either a local or remote DataMover
- Not a Disaster Recovery Solution, but useful for a RO copy that can be used to Read or Backup to Tape
- 1-to-1 or 1-to-many IP/RDF (HighRoad); Remote Copy of FS RO & 'auto-refreshed' periodically
- Local to Remote IP Copy of a FS with periodic updating (Available via RPQ only)
- PFS must be built on slice volumes, identical in size to SFS or replication will not start [“fs1 size () is not equal to sfsfs1 size ()”]

**Comment:** Once implemented, Replication is automatic—does not require shell scripts to refresh SFS. Can copy filesystem replica copies from DM-to-DM locally, or DM-to-Remote DM.

### **BASIC IP REPLICATION FACTS TO KNOW ABOUT:**

- SavVols do not auto extend for IP Replication (for SnapSure feature, it does)
- Ports 8887/8888 must be open and unblocked on the both Target & Destination data movers
- Port 8000 must be open and available to Target & Destination Control Stations
- QOS is not implemented by default—by default, we ‘burst’ data across the link using RCP. Use QOS to slowdown or moderate the IP Replication over WANs so as not to overwork the link in high latency networks
- Always set the TO & HWM values on the Destination side at half the value as on the Source (defaults are 600/600)
- Changes are only ever written to the latest, or newest Checkpoint (never write to more than one checkpoint of same PFS)
- When there are multiple Checkpoints, they are read from Oldest to Newest, with bitmaps of each checked to see if flag is set to 1
- Except for failover & reverse, most commands are run strictly from the Source Replication side
- Source side creates checkpoints for use with fs\_copy
- Destination side creates the remote copy group structure
- Both sides create the IPFS file system
- Add reproto to boot.cfg file to enable restarting fs\_copy after DM reboots

### **USES FOR CELERRA REPLICATOR:**

- DR situations
- Backup data
- Data mining
- Software testing environments
- Migrations

### **IP REPLICATION TERMINOLOGY:**

**PFS:** Production File System

**SFS:** Secondary File System—goes through Freeze/Thaw during IP Replication sequence or when refreshes occur

**Ckpt:** check point filter

**Iosz:** 8k block size used by replication system—not changeable

**Copyiosz:** 32k size used to copy data to Save Volume—not changeable

**Delta Set:** Block modifications on PFS that are replicated to the SFS

**Log/Config Volume:** Redo Log--500MB in size. Used for recovery if PFS Server is rebooted, etc.

**Save Volume (SavVol):** Volume consisting of delta sets, which are modifications to the PFS to which blocks are saved in ‘chunks’ of 128MB. Min size of Save Volume is 3.2GB and max size is 90GB. This type of SavVol is different from SnapSure in that all changes & new data are written to SavVol from “Delta Sets” [SnapSure only writes first change to SavVol after a Checkpoint is taken]. SavVols cannot be extended on-line. Represents metavolume to which Delta sets are copied.

**Comment:** SavVol size limitation is based on the “Config File Size” limitation of 500MB

**HWM Option:** Represents the Data Size that serves as a ‘trigger’ to create a new “delta set” on the PFS side, which is then copied to the SFS side via the SavVol. IPFS automatically transfers new “delta sets” from SavVol to SFS. Represents the triggerpoint at which Replicator will update SFS with changes written to PFS.

**TimeOut Option:** Also used to trigger creation of new “delta sets” which are written to SavVol. Default=10 minutes. This value should never be set to less < 6 minutes for SFS or 3 minutes for PFS.

#### **NAS 5.2 & Higher:**

**QOS (Quality of Service):** Expressed in Kbps, originally intended as a way to prioritize among multiple Replication Sessions, which session should have greater priority, if using the same physical interface. In practice, QOS is used to limit the amount of bandwidth used by Replicator so as not to overwhelm a customer’s WAN or network link. By default, a Celerra Gbe interface will burst 128kb blocks of data at Gbe rates, in effect requiring that the network buffer up to 90% of a typical burst, resulting in packet loss and a severe drop in throughput performance due to retransmissions. When no value specified, default is to send data as fast as possible. As an example, if a WAN link is capable of 100mbps, this might be the QOS value to use for replication sessions, though even with QOS, each thread will send data at 32kb blocks.

→Each Replication Session uses 16 threads to handle data transfer

→Each thread can send 32kb blocks

**AUTORO:** Option that means when there is a hold on PFS flow, make PFS RO so as to prevent falling out of sync.

**AUOTFREEZE:** If there is an overflow on PFS, freeze the PFS so as to prevent falling out of sync.

### **REPLICATION POLICY PARAMETERS:**

**Timeout:** Generates or playsback Delta sets—default value is every 600 seconds. Value of 0 pauses replication.

**HWM:** Another threshold value of changes to PFS that generates or plays back a Delta set—default = 600MB (0 MB pauses)

**Note:** Replication Policies are created on PFS and SFS. First policy processed creates the Delta set on primary or copies to secondary (i.e., Delta Sets are created when either the HWM or Timeout policy is met).

### **DATA FLOW CONTROL TRIGGERS:**

→If SavVol becomes full, replication service stops copying to primary SavVol but continues to cache PFS changes until caught up

→Svc will hold up Delta sets if current Delta Set not yet written to SFS (i.e., Playback rate too slow on SFS side)

→If Delta Set is not transferred from Primary to Secondary SavVol, errors logged on primary Control Station: “Network down”

### **REPLICATION FUNCTIONS WITH NAS 5.4:**

→Destination dto= and dhwm= can now be set from the Source side

→Contains version 2.5 Checkpoints, which can have up to 64 Checkpoints

→Bitmaps remain in memory, but blockmaps are paged out to disk

→Upgrades from NAS 4.2 & Higher converts to new 2.5 checkpoint format

→Data Mover is capped at 1GB for checkpoint use

### **REPLICATION MEMORY STRUCTURES:**

→Replication uses both a “bitmap” and “block list” to track changes

→Replication uses “bitmap” in memory on PFS, from which delset changes are created, and then moved across to Target side. For new checkpoints, the “bitmap” values are all 0, then changes are written to the checkpoint (original fs block) and the bitmap value goes to 1. The “blocklist” tracks block changes via between original block that is modified and the block number in checkpoint. The “blocklist” is rebuilt during reboots from the info contained in all the checkpoints

### **BASIC IP REPLICATION TROUBLESHOOTING:**

# **nas\_cel -l** to list out Control Station IP’s, if remote IP replication is in use

# **fs\_copy -l** to observe if any copy sessions are in progress, run command on both sides to validate

# **fs\_copy -i id=76** [id=76 taken from fs\_copy -list and depends on which side you run the cmd]

# **fs\_replicate -l** to observe current state of replication sessions, run command on both sides to validate

# **fs\_replicate -i id=264 -v 10** to observe state of playback service for delta sets, etc. (10 indicates max lines to display)

**Note:** Command outputs in (3) Sections, with times in GMT.

Top Section = Source Side, regardless of whether cmd issued on Source or Target--lists HWM/TO values, as well as SavVol Status

Middle Section = Target Side, similar in info as the Top Section

Last Section = Info on network status and transfer rates for the replication session

### **IPREPv1 TROUBLESHOOTING COMMANDS:**

“**volcast create | delete |display**”

“**iprep\_svc start | stop | display | transfer | policy |stat | detail**”

“**replica |start | stop | recover | suspend | resume**”

**“playback start | stop | recover |suspend | resume”**

**“ipfscopy start | stop | display”**

## **COMMAND SYNTAX NAS 5.5:**

**# .server\_config server\_2 -v "replicate"**

```
1148667835: DPSVC: 4: replicate { start
    srcTargetName=<srcIqn> srcLun=<srcLun>

## **FS REPLICATE SWITCHES AND USAGE:**

**# fs\_replicate -list | -info | -start | -abort | -refresh | -modify | -failover -o now -o sync | -resync | -reverse | -restart | -suspend**

**# fs\_replicate -list**

→lists out active replication sessions, from Source to Dest, & vice versa; inactive state indicates replication or playback service failure

**# fs\_replicate -info id=1 | -v 10**

→Use to obtain specific info on the health & state of current replication sessions & playback

**# fs\_replicate -start**

→Used to start replication for the first time, or to start again after a previously aborted replication session, requires that valid checkpoints are available. Destination fs must be rawfs & mounted RO. Options include to=, hwm=, qos=, and others to control transport and playback characteristics.

**# fs\_replicate -abort fs\_source,fs\_dest:cel=laip2**

→Run on Source side to stop replication & playback service.

**Note:** fs\_replicate -abort can be run separately on both Source and Destination side to abort replication, but the preferred method is to run the abort for both sides simultaneously

**#fs\_replicate -abort root\_fs\_vdm\_vdm\_source, root\_fs\_vdm\_vdm\_dest:cel=laip2**

**# fs\_replicate -refresh**

→Use to playback delta sets with options affecting to=, hwm=, and playuntildelta=; useful for kickstarting delta set copies from Source to Destination. Also used to generate new datasets on source, to be copied to destination—change HWM and Timeout values as needed. Use following option to playback only a specific number of datasets before stopping:

**\$fs\_replicate -refresh dest -option playuntildelta=91**

**#/nas/sbin/rootfs\_replicate -refresh root\_fs\_vdm\_server\_2\_vdm01 -o to=0,hwm=0**

**# fs\_replicate -modify**

→Use to modify to= (TimeOut values), hwm= (HighWaterMark), & qos= (bandwidth used in kbs/sec). If changing Source HWM & Timeout values without specifying Destination flow control values, the destination will inherit the Source values. Other -modify options are autorole=yes, autofreeze=yes.

**# fs\_replicate -modify root\_fs\_vdm\_vdm\_dest -o to=300,hwm=300**

**# fs\_replicate -modify fs\_source -o to=300,hwm=300**

### **# fs\_replicate -failover -o now**

→Used to perform Disaster Recovery failover when Source side is not available—executed from Destination side as asynchronous operation, meaning that there will be data loss. –failover -o now option conducts immediate failover without copying over source delta sets or playing back existing delta sets on target-target side goes RW immediately. At the completion of the failover, Replication is aborted and not running. If no failover options are specified, is called a ‘default’ failover, and incurs data loss, but does replay existing datasets on Target side before going RW. Use the –resync option to restart replication and copy incremental changes back to the original source in preparation for failing back (-reverse).

**Note:** Disaster failover options are –o now or default without any switches—run from Destination side.

### **# fs\_replicate -resync**

→Used to restart replication after disaster failover. –resync will first attempt to synchronize any incremental changes between Source & Destination replication sessions—original Source is running Playback Service and original Destination side is running the Replication Service. Without autocopy switch, default is to attempt to incrementally resync vdm rootfs and production file systems. If resync incremental copy fails, may need to use autofullcopy=yes option, which recopies all data back to file systems. Can also use options such as autofullcopy=yes, to=, hwm=, qos=, autoro=, autofreeze=. Use –reverse to change the flow of replication sessions. **Note:** The resync option does not change the direction of the current replication sessions—use the –reverse command to reverse the direction so that replication flows from original Source to Target, or vice versa. The –resync feature is broken in NAS 5.5. Basically, if a –resync is used, a full copy is performed because the the dataset query was moved from CS to DART, and DART does not record the correct dataset number on the destination checkpoint. This issue is fixed in NAS 5.5.24.0 and higher—see AR79069.

### **# fs\_replicate -failover -o sync**

-o sync option will synchronize Source & Destination file systems before failing over to prevent data loss—it does so by putting Source side file systems in RO state, copies all datasets from Source to Target side, then replays all datasets on Target side before Target goes RW—this is also known as a planned “administrative” failover that is synchronous and has no data loss. Executed from Source side & only if both Source & Destination sides are up and running.

### **# fs\_replicate -reverse**

```
# /nas/sbin/rootfs_replicate -reverse root_fs_vdm_vdm_dest:cel=laip2:if=rep_dest  
root_fs_vdm_vdm_source:if=rep_source
```

**Note:** Make sure you plug in the file system that is being failed over to first, then the source!

→Use this switch to perform a graceful failover from Source to Destination or from Destination to Source. This command is intended to failover replication without aborting any ongoing sessions. Also use options to=, hwm=, qos=, autoro=, autofreeze=. The –reverse essentially performs a resync of the file system (both Source & Destination fs becomes RO while changes are being transmitted) and then reverses the direction of the replication session. You would use the –reverse to perform an “administrative” or “planned” failover so as not to have any data loss, or to fallback to the original Source side to recover after a disaster failover and –resync was performed. Execute from the side that is currently running the replication service and not the playback service.

### **# fs\_replicate -restart**

→Use for planned downtime. Intended to restart replication after a –suspend was issued, or if replication is out-of-sync—as long as differential checkpoints exist, replication should be able to be restarted. Uses fs\_copy to send a differential checkpoint copy over to destination and then restart replication service, can also specify options for SavVol.

### **# fs\_replicate -suspend**

→Suspends the replication service for planned maintenance periods, creates source-side checkpoint, which is used to restart when the –restart command is run. Stops replication & playback services, but leaves fs in restartable state. –suspend must be followed by a –restart, which incrementally copies the checkpoint of source to destination.

## **SETTING UP IP REPLICATION WITH CIFS VDMs (NAS 5.5)**

### **DEBUG LOGGING:**

```
# export NAS_REPLICATE_DEBUG=1  
# export NAS_XML_DEBUG=1
```

**Note:** Dumps XML communications between DART & CS to screen and to log

### **1. VERIFY IP CONNECT BETWEEN LOCAL & REMOTE CONTROL STATIONS [LAIP1/LAIP2]:**

```
# ping 10.241.168.63
```

PING 10.241.168.63 (10.241.168.63) from 10.241.168.51 : 56(84) bytes of data.

64 bytes from 10.241.168.63: icmp\_seq=0 ttl=64 time=215 usec

**# nas\_cel -list**

```
id    name      owner mount_dev channel net_path      CMU
0    laip1      0          10.241.168.51 APM000238010400000
```

**2. SETUP REPLICATION RELATIONSHIP BETWEEN CONTROL STATIONS:**

Note: Run from Source side first, then target

**# /nas/sbin/nas\_rdf -init laip2 10.241.168.63** (Initializing Remote CS)

Contact laip2 ... is alive

operation in progress (not interruptible)...

id = 2

name = laip1

owner = 0

device =

channel =

net\_path = 10.241.168.51

celerra\_id = APM000238010400000

passphrase = rep\_admin

**3. VERIFY LOCAL & REMOTE CS REGISTRATIONS:**

**# nas\_cel -l**

```
id    name      owner mount_dev channel net_path      CMU
0    laip1      0          10.241.168.51 APM000238010400000
2    laip2      0          10.241.168.63 APM000306008720000
```

**# nas\_cel -l**

```
id name owner mount_dev channel net_path CMU
0 laip2 0 10.241.168.63 APM000306008720000
2 laip1 0 10.241.168.51 APM000238010400000
```

**Note:** The passphrase is stored on each Control Station in a file named after the Celerra serial number, in the following directories:  
/nas/http/replication/inbound/APM000306008720000  
/nas/http/replication/outbound/APM000306008720000

#### **4. SETUP DATA MOVER INTERFACES ON SOURCE & DESTINATION SYSTEMS:**

**Note:** For CIFS VDM replication, both Source & Destination CIFS interfaces must have the same name—IP addresses can be different

##### **SOURCE:**

```
reps protocol=IP device=cge0
inet=192.1.6.201 netmask=255.255.255.0 broadcast=192.1.6.255
UP, ethernet, mtu=1500, vlan=0, macaddr=8:0:1b:42:15:9d
```

##### **DESTINATION:**

```
reps protocol=IP device=cge0
inet=192.1.6.202 netmask=255.255.255.0 broadcast=192.1.6.255
UP, ethernet, mtu=1500, vlan=0, macaddr=8:0:1b:42:4e:3e
```

#### **5. SETUP DNS ON SOURCE & DESTINATION DATA MOVERS:**

**\$ server\_dns server\_2 <domain> <ip\_address>** (repeat on Destination mover)

#### **6. SETUP NTP TIME SERVICES ON SOURCE & DESTINATION SYSTEMS:**

**Note:** CS times must be within 10 minutes!

**# server\_date server\_2 timesvc start ntp 192.1.4.217**

server\_2 : done

**# server\_date server\_2 timesvc**

server\_2 :

Timeservice State

time: Tue Feb 7 12:58:05 EST 2006

type: ntp

sync delay: off

interval: 60

hosts: 192.1.4.217,

**Note:** Repeat NTP setup on Destination Data Mover

#### **7. SETUP LOCAL & REMOTE CONTROL STATIONS AS NTP CLIENT TO TIME SERVICE:**

**# /sbin/chkconfig ntpd --list**

ntpd 0:off 1:off 2:off 3:off 4:off 5:off 6:off

a.) Start NTP daemon on Source & Dest CS

**# /sbin/chkconfig --level 345 ntpd on**

**# /sbin/chkconfig ntpd --list**

ntpd 0:off 1:off 2:off 3:on 4:on 5:on 6:off

b.) Edit /etc/ntp.conf file--add the network NTP Server & comment out the other two lines as shown below:

#server 127.127.1.0 # local clock

#fudge 127.127.1.0 stratum 10 [Commented out so as not to point to itself as the primary NTP Service]

**server 192.1.4.217 minpoll 8 ## NTP Server**

c.) Add IP Address of NTP Server (s) to /etc/ntp/step-tickers file:

192.1.4.217

d.) Restart NTPD Daemon on Control Station:

**# /sbin/service ntpd restart**

```
Shutting down ntpd: [ OK ]
Synchronizing with time server: [ OK ]
```

Starting ntpd:

```
# ps -ef |grep ntp
ntp 15364 1 0 14:00 ? 00:00:00 ntpd -U ntp
root 16098 9015 0 14:01 pts/1 00:00:00 grep ntp
```

**# /sbin/service ntpd status**

ntpd (pid 28905) is running...

e.) Manually set Date & Time on Control Station:

**1. #date -s "4/09/03 16:15:15"**

**2. #/usr/sbin/setclock**

3. #date → Wed Apr 9 16:15:30 MDT 2003

Note: Repeat steps a-e for Destination Control Station, trying to get CS times as close to the Data Mover as possible

## **8. CONFIGURE INTERNAL USERMAPPER>PRIMARY ON DESTINATION DM & SECONDARY SERVICE ON SOURCE:**

Note: Setup Primary Usermapper service on Destination mover and Secondary service on Source mover

### **DESTINATION:**

```
# server_usermapper server_2 -enable
```

```
# server_usermapper server_2
```

server\_2 : Usrmapper service: Enabled

Service Class: Primary

### **SOURCE:**

```
# server_usermapper server_2 -enable primary=192.1.6.203
```

```
# server_usermapper server_2
```

server\_2 : Usrmapper service: Enabled

Service Class: Secondary

Primary = 192.1.6.203 (c) →"c" means that Secondary has contacted the Primary service

## **9. PREPARE SOURCE & DESTINATION VDM CIFS ROOT FILE SYSTEMS:**

Note: This step prepares the CIFS VDM Containers and loads the service at the appropriate state. CIFS Servers will be created at a later step on the Source side, and can only be created if the VDM is in a 'loaded' state.

### **a.) create Source & Dest VDM Containers:**

#### **SOURCE SIDE:**

```
# nas_server -name vdm_source -type vdm -create server_2 (source side)
```

id = 1

name = vdm\_source

acl = 0

type = vdm

server = server\_2

rootfs = root\_fs\_vdm\_vdm\_source →Actual name of rootfs

I18N mode = UNICODE

mountedefs =

member\_of =

status :

defined = enabled

actual = loaded, ready

Interfaces to services mapping:

```
[root@laip1 ntp]# nas_server -a -i -vdm
```

id = 1

name = vdm\_source

acl = 0

type = vdm

server = server\_2

rootfs = root\_fs\_vdm\_source

I18N mode = UNICODE

mountedefs =

member\_of =

status :

**defined = enabled**

**actual = loaded, ready** →Normal state of VDM container on Source side

Interfaces to services mapping:

```
[root@laip1 ntp]# server_mount server_2
```

server\_2 :

root\_fs\_2 on / ufs,perm,rw

root\_fs\_common on /.etc\_common ufs,perm,ro

root\_fs\_vdm\_source on /root\_vdm\_1/.etc ufs,perm,rw

```
# /nas/sbin/rootnas_fs -size root_fs_vdm_vdm_source
```

total = 111 avail = 111 used = 0 ( 0% ) (sizes in MB) ( blockcount = 262144 )

volume: total = 128 (sizes in MB) ( blockcount = 262144 )

#### **DESTINATION SIDE:**

**# nas\_server -name vdm\_dest -type vdm -create server\_2 -setstate**

**mounted pool=clar\_r5\_performance -option fstype=rawfs** → Destination VDM rootfs created Temp Unloaded state  
id = 1

name = vdm\_dest  
acl = 0  
type = vdm  
server = server\_2  
rootfs = root\_fs\_vdm\_dest  
I18N mode = UNICODE  
mounteddfs =  
member\_of =  
status :  
**defined = enabled**  
**actual = temporarily unloaded**

Interfaces to services mapping:

**[root@laip2 ntp]# nas\_server -a -i -vdm**

id = 1  
name = vdm\_dest  
acl = 0  
type = vdm  
server = server\_2  
rootfs = root\_fs\_vdm\_dest  
I18N mode = UNICODE  
mounteddfs =  
member\_of =  
status :  
defined = enabled  
**actual = temporarily unloaded**

Interfaces to services mapping:

**# server\_mount vdm\_dest**

vdm\_dest :

**Note:** The vdm root is NOT mounted on the VDM server, and shows up as <unmounted> and temporarily unloaded. Once the Source/Destination VDMs are replicated, and the destination rootfs is converted to uxf, the destination VDM becomes mounted.  
**[root@laip2 ntp]# server\_mount server\_2**

server\_2 :

root\_fs\_2 on / uxf,perm,rw  
root\_fs\_common on /.etc\_common uxf,perm,ro  
root\_fs\_vdm\_dest on /root\_vdm\_1/.etc rawfs,perm,ro,<unmounted>

**# /nas/sbin/rootnas\_fs -size root\_fs\_vdm\_vdm\_dest**

total = 111 avail = 111 used = 0 ( 0% ) (sizes in MB) ( blockcount = 262144 )

volume: total = 128 (sizes in MB) ( blockcount = 262144 )

## **10. VERIFY SOURCE & DESTINATION VDMs:**

a. Source Side:

**# nas\_server -a -i -vdm**

id = 1  
name = vdm\_source  
acl = 0  
type = vdm  
server = server\_2  
rootfs = root\_fs\_vdm\_source  
I18N mode = UNICODE  
mounteddfs =  
member\_of =  
status :  
**defined = enabled**  
**actual = loaded, ready**

Interfaces to services mapping:

**#server\_cifs server\_2**

CIFS service of VDM **vdm\_source (state=loaded)**

Home Directory Shares DISABLED

**# nas\_server -l -vdm**

```
id    acl server mountedfs   rootfs name
1     0   1           164   vdm_source
```

**# pwd**

/nas/server/slot\_2

**# cat vdm**

vdm add id=1 fs=164 name=vdm\_source

**# server\_df server\_2**

server\_2 :

| Filesystem             | kbytes | used | avail  | capacity | Mounted on       |
|------------------------|--------|------|--------|----------|------------------|
| root_fs_vdm_vdm_source | 114592 | 624  | 113968 | 1%       | /root_vdm_1/.etc |

**/nasmdc/quota/slot\_2**

drwxr-xr-x 3 root bin 80 Feb 7 13:37 root\_vdm\_1

**/nasmdc/quota/slot\_2/root\_vdm\_1/.etc****# ls -la**

```
drwxr-xr-x 2 root bin 1024 Feb 7 13:37 audit
-rw-r--r-- 1 root bin 42 Feb 7 13:37 .db.localgroups
dr-xr-xr-x 2 root bin 80 Feb 7 13:37 .etc
drwxr-xr-x 2 root bin 80 Feb 7 13:37 .filefilter
drwxr-xr-x 2 root root 8192 Feb 7 13:32 lost+found
drwxr-xr-x 2 root bin 80 Feb 7 13:37 secmap
drwxr-xr-x 5 root bin 1024 Feb 7 13:37 shares
```

**New Rootfs Created from VDM creation:****# nas\_fs -i id=164**

```
id      = 164
name   = root_fs_vdm_vdm_source
acl     = 0
in_use  = True
type    = uxf
worm   = off
volume  = v113309385
pool    = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
```

**b. Target Side:****# nas\_server -a -i -vdm**

```
id      = 1
name   = vdm_dest
acl     = 0
type    = vdm
server  = server_2
rootfs  = root_fs_vdm_vdm_dest
I18N mode = UNICODE
mountedfs =
member_of =
status   :
```

**defined = enabled**

**actual = temporarily unloaded** → This is the normal state until vdm rootfs is diff. copied over, i.e., rootfs becomes uxf vs. rawfs  
 Interfaces to services mapping:

**#server\_cifs server\_2**

CIFS service of VDM vdm\_dest (state=loaded)

Home Directory Shares DISABLED

**# nas\_server -l -vdm**

```
id    acl server mountedfs   rootfs name
1     0   1           68    vdm_dest
```

**# pwd**

```
/nas/server/slot_2
# cat vdm
vdm add id=1 fs=68 name=vdm_dest
# server_df server_2
server_2 :
Filesystem      kbytes      used      avail capacity Mounted on
root_fs_vdm_vdm_dest
    114592       624     113968   1% /root_vdm_1/.etc
/nasmed/quota/slot_2
drwxr-xr-x  3 root  bin      80 Feb  7 13:37 root_vdm_1

-rw-r--r--  1 root  bin      42 Feb  7 13:37 .db.localgroups
dr-xr-xr-x  2 root  bin      80 Feb  7 13:37 .etc
drwxr-xr-x  2 root  bin      80 Feb  7 13:37 .filefilter
drwxr-xr-x  2 root  root     8192 Feb  7 13:37 lost+found
drwxr-xr-x  2 root  bin      80 Feb  7 13:37 secmap
drwxr-xr-x  5 root  bin      1024 Feb  7 13:37 shares
New VDM Rootfs:
# nas_fs -i id=68
id      = 68
name   = root_fs_vdm_vdm_dest
acl     = 0
in_use = True
type   = udfs
worm   = off
volume = v174
pool   = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers= server_2
```

## **11. CREATE SOURCE & DESTINATION DATA FILE SYSTEMS FOR REPLICATION:**

**Note:** Source & Target replication file systems must be identical in size. Use the “samesize” option from CLI to create correct file system sizes on destination system and to specify “rawfs” since Celerra Manager does not create ‘rawfs’. For fs\_copy to work, the destination file systems need to be rawfs.

### a.) Create Source File Systems using CLI:

**# nas\_fs –name fs\_source –create size=50G pool=clar\_r5\_performance –option slice=yes**

#### cmd\_log shows fs\_source creation:

```
2006-02-07 14:11:50.721 db:0:28844:S: nas_fs -name fs_source -type udfs -create
size=50000M pool=id=3 storage=SINGLE worm=off -auto_extend yes -hwm 90% -max_size 75000M -vp no -option
slice=y,mover=server_2
2006-02-07 14:12:00.351 db:0:28844:E: nas_fs -name fs_source -type udfs -create
size=50000M pool=id=3 storage=SINGLE worm=off -auto_extend yes -hwm 90% -max_size 75000M -vp no -option
slice=y,mover=server_2
2006-02-07 14:12:02.654 server_2:0:28964:S: server_mountpoint server_2 -create /fs_source
2006-02-07 14:12:03.096 server_2:0:28964:E: server_mountpoint server_2 -create /fs_source
2006-02-07 14:12:05.081 server_2:0:29003:S: server_mount server_2 -option rw fs_source /fs_source
2006-02-07 14:12:06.995 server_2:0:29003:E: server_mount server_2 -option rw fs_source /fs_source
```

#### **#nas\_fs -l**

```
165      y  1  0  113309388 fs_source      1
```

#### **# nas\_fs -s fs\_source**

```
total = 49236 avail = 49235 used = 0 ( 0% ) (sizes in MB) ( blockcount = 102400000 )
volume: total = 50000 (sizes in MB) ( blockcount = 102400000 )
```

#### **# server\_df server\_2**

```
server_2 :
```

```
Filesystem      kbytes      used      avail capacity Mounted on
fs_source      50417984      576     50417408   0% /fs_source
```

**Note:** nas\_log.al.rll → Log shows file system deletions and changes conducted from CLI but NOT from WebUI

### b.) Mount Source file systems on VDM Server:

**[root@laip1 ntp]# server\_mount vdm\_source fs1 /fs1**

```
vdm_source : done  
[root@laip1 ntp]# server_mount vdm_source fs2 /fs2  
vdm_source : done
```

c.) Create destination file systems using CLI & samesize option:

```
# nas_fs -name fs_dest -type rawfs -create samesize=fs_source:cel=laip1 pool=clar_r5_performance -option slice=yes
```

**Note:** If using Celerra Manager to create the fs, the file system must be unmounted and then converted to rawfs. Normal state of file systems are rawfs and NOT mounted to the Destination VDM Server.

```
[root@laip2 log]# /nas/sbin/rootnas_fs -T rawfs root_fs_vdm_vdm_dest -F (was able to convert rootfs of VDM back to rawfs)
```

```
# nas_fs -T rawfs fs_dest -F
```

-----output abridged-----

## **12. VERIFY SIZES OF SOURCE & DEST FILE SYSTEMS:**

**SOURCE:**

```
# nas_fs -s id=165  
total = 49236 avail = 49235 used = 0 ( 0% ) (sizes in MB) ( blockcount = 102400000 )  
volume: total = 50000 (sizes in MB) ( blockcount = 102400000 )
```

**DEST:**

```
# nas_fs -s id=69  
total = 49236 avail = 49235 used = 0 ( 0% ) (sizes in MB) ( blockcount = 102400000 )  
volume: total = 50000 (sizes in MB) ( blockcount = 102400000 )
```

**Note:** At this point, all file systems on target side are created, unmounted, in rawfs state, with VDM service temporarily unloaded

## **13.) CREATE SOURCE CIFS VDM, JOIN TO DOMAIN, START CIFS, & CREATE SHARES:**

a.) # server\_cifs vdm\_source -add compname=source,domain=2k3.pvt.dns,interface=rep\_source

b.) # server\_cifs vdm\_source -Join compname=source,domain=2k3.pvt.dns,admin=tmatta

```
# server_cifs vdm_source
```

```
vdm_source :  
CIFS service of VDM vdm_source (state=loaded)  
Home Directory Shares DISABLED  
Usermapper auto broadcast enabled  
Usermapper[0] = [127.0.0.1] state:active (auto discovered)  
DOMAIN 2K3 FQDN=2k3.pvt.dns SITE=Default-First-Site-Name RC=3  
SID=S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-fffffff  
>DC=GEORGE(192.1.4.217) ref=3 time=0 ms (Closest Site)  
CIFS Server SOURCE[2K3] RC=2  
Full computer name=source.2k3.pvt.dns realm=2K3.PVT.DNS  
Comment='EMC-SNAS:T5.5.18.2'  
if=rep_source l=192.1.6.204 b=192.1.6.255 mac=8:0:1b:42:15:9d  
FQDN=source.2k3.pvt.dns (Updated to DNS)
```

c.) Start CIFS Service:

```
# server_setup server_2 -P cifs -o start
```

d.) Create CIFS Shares for Source VDM Server:

```
# server_export vdm_source -P cifs -n fs_source /fs_source
```

```
# server_export vdm_source -P cifs -n fs_scli /fs_scli
```

```
# server_export vdm_source
```

```
vdm_source :  
share "fs_source" "/fs_source" maxusr=4294967295 umask=22  
share "fs_scli" "/fs_scli" maxusr=4294967295 umask=22
```

## **14. REPLICATE VDM ROOTFS FROM SOURCE TO DESTINATION:**

**SOURCE:**

a.) Create first baseline checkpoint of VDM root:

```
# /nas/sbin/rootfs_ckpt root_fs_vdm_vdm_source -Create
```

```
operation in progress (not interruptible)...id      = 164
```

```
name     = root_fs_vdm_vdm_source
```

```
acl      = 0
```

```
in_use   = True
```

```
type     = uxf
```

```
worm    = off
```

```
volume   = v113309385
```

```
pool     = clar_r5_performance
```

```

member_of = root_avm_fs_group_3
rw_servers= server_2
ro_servers=
rw_vdms =
ro_vdms =
auto_ext = no,virtual_provision=no
ckpts  = root_fs_vdm_vdm_source_ckpt1
b.) fs_copy the baseline rootfs checkpoint to destination:
# fs_copy -start root_fs_vdm_vdm_source_ckpt1:if=rep root_fs_vdm_vdm_dest:cel=laip2:if=rep -option convert=no

Note: Interface names should be the same
operation in progress (not interruptible)...id      = 168
name    = root_fs_vdm_vdm_source_ckpt1
acl     = 0
in_use   = True
type     = ckpt
worm    = off
volume   = vp113309395
pool     = clar_r5_performance
member_of = vpf167
rw_servers=
ro_servers= server_2
rw_vdms =
ro_vdms =

```

[root@laip1 nasadmin]# fs\_ckpt fs\_scli -Create

-----output abridged-----

h.) →Perform incremental fs\_copy to Destination for each PFS, letting fs's convert to ufs on Destination side:

[root@laip1 nasadmin]# fs\_copy -start fs\_source\_ckpt2:if=rep fs\_dest:cel=laip2:if=rep -fromfs fs\_source\_ckpt1 -option monitor=off

-----output abridged-----

[root@laip1 log]# fs\_copy -l

Local Source Filesystems

| Id  | Source          | Destination   | Status     | %Remaining | CommState |
|-----|-----------------|---------------|------------|------------|-----------|
| 250 | fs_source_ckpt2 | fs_dest:laip2 | converting | 0          | N/A       |

[root@laip1 nasadmin]# fs\_copy -start fs\_scli\_ckpt2:if=rep fs\_dcli:cel=laip2:if=rep -fromfs fs\_scli\_ckpt1

-----output abridged-----

IP Copy remaining (%) 100..Done.

Done

Note: At this point, CIFS VDMs and Production File Systems are replicating between Source & Destination Celerras

## **DESTINATION SIDE DURING DIFFERENTIAL 2<sup>nd</sup> CHECKPOINT FS COPY OPERATION:**

[root@laip2 log]# fs\_copy -l

Local Source Filesystems

```

Id Source Destination Status %Remaining CommState
Local Destination Filesystems
Id Source Destination Status %Remaining CommState
113 fs_scli_ckpt2:1 fs_dcli N/A N/A down →What 2nd fs_copy looks like on dest. side while the differential copy is in progress. Good to document.
[root@laip2 log]# fs_replicate -l
Local Source Filesystems
Id Source FlowCtrl State Destination FlowCtrl State Network
Local Destination Filesystems
Id Source FlowCtrl State Dest. FlowCtrl State Network
102 root_fs_vdm_vdm_sou inactive active root_fs_vd inactive active alive
107 fs_source:laip1 inactive active fs_dest inactive active alive
112 fs_scli:laip1 inactive active fs_dcli inactive active alive →During 2nd fs_copy and conversion operation, the Replication Session status actually changes before the differential copy is completed, meaning that the differential 2nd copy actually converts file system to uxfs first before the copy completes.

```

Comment: At this point, replication is up and running with VDM rootfs and both PFS file systems replicating normally

**PERFORMING ADMINISTRATIVE IP REPLICATION FAILOVER WITH CIFS VDM SERVERS:**

**Note:** An administrative failover is a “planned” failover using the –reverse switch that incurs no data loss because the event is synchronous, unlike the -failover options. The following example assumes that normal IP Replication is flowing one-way from both VDM rootfs and data file systems, SOURCE to TARGET Celerra. The following procedure can be used to failover, then failback. Always run the –reverse from the active side running the replication service.

**SOURCE SIDE:****1. Unload Source VDM CIFS Server from Loaded to Mounted State (Stops the CIFS Service):**

```
$ nas_server -vdm source_vdm -setstate mounted
```

```
status :
defined = enabled
actual = mounted
```

**Note:** If VDM fails to change to ‘mounted’, try downing the interface first, then run –setstate mounted, then bring interface back up  
**TARGET SIDE:**

**2. Ensure that Target CIFS Server interface is up:**

```
# server_ifconfig server_2 -a
# server_ifconfig server_2 reps up
```

**SOURCE SIDE:****3. Failover rootfs VDM from active side running Replication (Source) to the Target side:**

```
[root@laip1 /]# /nas/sbin/rootfs_replicate -reverse root_fs_vdm_dest:cel=laip2:if=reps
root_fs_vdm_source:if=reps
```

**Note:** Both Source and Destination interfaces were online and needed when doing the –reverse method

**TARGET SIDE:****4. Load VDM CIFS Server on Target Side:**

```
$ nas_server -vdm dest_vdm -setstate loaded
```

```
status :
defined = enabled
```

actual = loaded, active

**Note:** Verify that DNS has been updated, and update manually if required (See server\_cifs output to see if dns was auto. updated).

**5. Manually start the CIFS service if required**—it may be that 5.4 requires manual start after the –setstate loaded command.

#### SOURCE SIDE:

#### **6. Failover Source file systems to Target side using Reverse Method Only:**

[root@laip1 /]# **fs\_replicate -reverse fs1\_d:cel=laip2:if=reps fs1:if=reps**

**Note:** A default –failover without options, or with the “now” option, would be used for disaster recovery failover, would incur data loss, and would be executed from the Target side. Remember to specify the Destination file system and Celerra in the first part of the command, and the Source file system at the end.

#### **7. Update Timeout & HWM Values on Source file systems:**

\$ **fs\_replicate -modify root\_fs\_vdm\_source -o to=300,hw=3**

\$ **fs\_replicate -modify fs1\_source -o to=300,hw=15**

#### **8. Update Timeout & HWM Values on Target file systems:**

\$ **fs\_replicate -modify root\_fs\_vdm\_target -o to=600,hw=6**

\$ **fs\_replicate -modify fs1\_target -o to=600,hw=30**

**Note:** The following method did not work and may be obsolete, even though still referenced in the man pages. After running the –failover –o sync, the replication session did not failover and went inactive N/A on the Source. Had to unmount the restart checkpoint on Destination side for the fs2 file system, then permanently unmount fs2, remount as ro, then convert to rawfs. On Source side, created new checkpoint, restarted replication for fs2, created another checkpoint, then copied the incremental over and this restored the Replication session.

[root@laip2 log]# **fs\_replicate -failover fs2:cel=laip1 fs2 -o sync**

#### **HOW TO DETERMINE IF REPLICATION SESSION IS WORKING:**

\$ **fs\_replicate -i id=77 -v 10**

```
id          = 25
name        = profiles_fs
fs_state    = active
type        = replication
replicator_state = active
source_policy = ReadOnly
high_water_mark = 0
time_out    = 0
current_delta_set = 46178
current_number_of_blocks = 0
flow_control = inactive
total_savevol_space = 10736640 KBytes
```

**savevol\_space\_available = 0 KBytes (Before Flow Control)**

communication\_state = alive

**current\_transfer\_rate = ~ 0 Kbits/second →Indicates that replication is broken and will need to be restarted**

**avg\_transfer\_rate = ~ 0 Kbits/second**

```
source_ip    = 164.56.49.82
source_port  = 65384
destination_ip = 129.124.103.82
destination_port = N/A
QOS_bandwidth = 3072 kbytes/sec
```

#### **NORMAL REPLICATION SESSION:**

\$ **fs\_replicate -l**

108 profiles\_f inactive active profiles\_fs:plcl1ea inactive active alive

\$ **fs\_replicate -i id=108**

```
id          = 25
name        = profiles_fs
fs_state    = active
type        = replication
replicator_state = active
source_policy = ReadOnly
high_water_mark = 30
```

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

```

```

## **CELERRA IP REPLICATION TROUBLESHOOTING:**

### **# export NAS\_REPLICATE\_DEBUG=1**

- Remote IP replication transfers commands via HTTP
- Check nas\_log.al.remote to see commands issued from source CS to destination CS
- Check nas\_log.al.tran to see commands from CS to DART, and replies
- Use nas\_fs -l and nas\_fs -i on file systems setup for replication
- Check cmd\_log, cmd\_log.err, server\_log, & sys\_log to debug fs\_copy issues, on both Source & Destination sides
- Replication must be started while destination fs is rawfs
- Both Source and Destination file systems must be exactly same size and number of blocks
- Changes on source must not be greater than the ability of delta sets to be transmitted and committed to destination
- SavVol must be of adequate size to store changes prior to being written to destination
- Celerra supports 16 replication sessions per DM
- NAS 5.1/5.2 uses Control Station command to convert destination fs from rawfs to udfs
- NAS 5.3+ uses DART code to convert destination fs from rawfs to udfs
- I18N or ASCII must be set the same for both Source & Target sides for VDMs
- Do not rename VDMs after failover or suspend operations
- Source & Target Control Stations must have time sync within 10 minutes or HTTP communications will fail (nas\_cel -l)

**Note:** Use date command to correct time/date skew

→ Verify that passphrase is valid on Source & Target

### **# nas\_cel -info id=1** (run on Source)

passphrase=iprep

### **# nas\_cel -exec id=1 “nas\_cel -info id=1”** (run on Target)

Passphrase=iprep

→ Local CS failover on Source may interrupt replication traffic (NA status)

### **\$ fs\_replicate -l**

Local Source Filesystems

| Id   | Source     | FlowCtrl | State  | Destination | FlowCtrl | State      | Network |
|------|------------|----------|--------|-------------|----------|------------|---------|
| 1307 | uslist20_f | inactive | active | N/A         | N/A      | <b>N/A</b> | alive   |

## **THINGS TO DO AND CHECK TO IMPROVE IP REPLICATION/FSCOPY PERFORMANCE:**

I. Adjust TCP Window size for each Celerra replication session—default code value is 0, which is actually a windowsize of 128kb. The highest value allowed is 2MB, or 2097152.

**Note:** With NAS 5.6, the max RCP tcpwindow size allowed is 1MB, or 1048576.

**param RCP tcpwindow=400000 (Source)**  
**param RCP tcpwindow=300000 (Destination)**

**Note 1:** Network latency is one of the key factors behind poor IP Replication performance. The TCP Window defines the amount of data that can be outstanding on the network, as put on the wire by the sender, before stopping and waiting for an acknowledgement from the Receiving side. Used by Replication service and FS\_Copy. You would increase the RCP tcpwindow size for high latency networks with low retransmits. TCPWindow size is also considered the HWM setting for TCP.

**Note 2:** The RCP tcpwindow should be set differently on both Source and Destination data movers. On Source side, this parameter is used as the HWM for replication TCP connections, while on the Destination side, it is used as the TCP window size for the Replication tcp connections.

**GENERAL FORMULA TO DETERMINE RCP TCPWINDOW:**

TCP Window Size / Latency = Max Throughput

**GENERAL FORMULA TO DETERMINE WINDOW SIZE:**

**Example:** Need throughput of 10MB/sec on the network, with a Round Trip delay of 100ms

Slowest link speed \* Network Latency = TCP Window Size

**Solution:** Multiply 100ms (.1sec) \* 10MB (desired throughput) = 1MB tcpwindow size (1048576)

10MB/s \* .1 second (100ms) = 1MB Window Size

**param RCP tcpwindowlowat**

**Note 1:** This param represents the Low Water Mark for the TCPWindow as it relates to Replication & FS\_Copy Sessions. During a TCP transmission session, if the HWM is hit, then further TCP transmissions are halted until the TCP write buffer data is acknowledged by the Receiving side, down to the point where the LWM value is reached—only then will new transmissions occur. Default param value is 0, which represents 64kb. Max value is 1MB. Ordinarily, you would increase this param value in conjunction with an increase in the RCP TCPWindow size (aka, the HWM value) so as to reduce the ‘wait’ time required to acknowledge all the data held in the TCP buffer down to the LWM before resuming the sending of more data.

**Note 2:** For Cognac, the LWM will change to remain in proportion to the HWM (TCP Window) value, should this value be changed

**II. Set QOS on Each Replication Session to limit burstiness of DART**

**Note:** Originally, QOS value was wrong, was in kilobytes per second. Now fixed and represents kilobits per second.

**III. For Packet Loss networks, consider setting Slow Retransmission timer to 400ms vs. normal 1.5sec**

**#server\_netstat server\_2 -s**

**Note:** Look for TCP packets retransmitted—used if Client Reads are being impacted. If the rate of retrans is > than .01%, could be a network issue to look at. For Write issues, retransmission rates would need to be calculated on the Client. For NFS using UDP, check RPC for retransmissions.

**param tcp fastRTO=1**

**Note:** Reducing the time for the Retransmission timer reduces overall wait times when dropped packets are occurring

**IV. Reduce Network Bursting of Data Movers:**

**Note:** Default is to ACK for every 2 packets received. Setting to 8 helps to increase throughput between ACKs.

**param tcp maxburst=8**

**V. TCP Send Window:**

Param is not enabled by default. When set, will limit Data Mover TCP transmission window size to specified value, regardless of what Client advertises for tcp window. When set to 0, DM will match the max transmit windows to the max receive window of the client.

**param tcp sndcwnd=0**

**VERIFYING IPREPSENDER SERVICE AND RCPD SERVICE:**

**\$server\_config server\_2 -v "iprepsvc display 149\_APM000338015350000 vol=858"**

**\$server\_config server\_2 -v "rcproute display group=149\_APM000338015350000"**

**\$server\_config server\_2 -v "iprepsvc start 149\_APM000338015350000 vol=858"** (restarting IPRepSender svc)

**# .server\_config server\_2 -v "rcproute display"**

1165504352: RCPD: 4: rcp:: Group:95\_APM000238010400000

1165504352: RCPD: 4: rcp:: Group:91\_APM000238010400000

**IPREPSENDER SERVICE LOG MESSAGES:**

→sys\_log will note that IPRepSender is Shutdown

→Server Log will note VRPL: 3: Chunk Header contains Bad Magic:RBLK MAGIC ad:0 vol:858

→nas\_event –list –f VRPL will show IP Rep Svc Network events

**EXAMPLE OF REVERSING THE ROOTVDM FROM DEST TO SOURCE CELERRA:**

**[root@laip1 /]# /nas/sbin/rootfs\_replicate -reverse root\_fs\_vdm\_dest:cel=laip2;if=reps  
root\_fs\_vdm\_source;if=reps**

volume: total = 8192 (sizes in MB) ( blockcount = 16777216 )

```

### **SOURCE SIDE:**

→Flow Control ACTIVE indicates that source side cannot transfer delta sets to target side (i.e., networking issues, etc.)

**Note:** Important point here is that source SavVol cannot accept more delta sets while in this state

→If State is INACTIVE, this means that the replication session is broken for that fs

### **DESTINATION SIDE:**

→An INACTIVE state could indicate a problem, or just that an fs\_copy is in progress and the target fs is still rawfs and not converted  
→Transferring means that the IP Rep Sender is sending data across the link

### **IP REPLICATION PROCESSES TO KNOW ABOUT:**

IP Rep Sender Service →Moves delta sets from Source to Target sides

IP Replication Service →Triggered by HWM/TO values

### **FS COPY COMMAND:**

**\$ fs\_copy -I**

Local Source Filesystems

| Id   | Source          | Destination     | Status  | %Remaining | CommState    |
|------|-----------------|-----------------|---------|------------|--------------|
| 1061 | usilst20_ftpu_f | usilst20_ftpu_f | started | 95         | transferring |

**Note:** Source pfs is being successfully copied to destination file system, which in this case, is named the same. During an fs\_copy, data is organized into tables of contiguous blocks of data (anywhere from 8MB up to 25GB). After each table is transferred, fs\_copy pauses to wait for remote Control Station to acknowledge that data has been received and written to the destination SavVol, before starting to transfer the next table.

**Caution:** Do not extend PFS while fs\_copy is running, NAS 5.3 and below

### **REMOVING INVALID FILE SYSTEM REFERENCES FROM SOURCE & DESTINATION:**

#### **Destination Backup Pointer:**

**# /nas/bin/nas\_cmd @fs\_ip -C <dst\_fs\_name>**

#### **Source Backup Pointer:**

**# /nas/bin/nas\_cmd @fs\_ip -U <src\_fs\_name> -f <dst\_fs\_name>:CMU=<CMU\_id>**

**Note:** CMU\_id is obtained from nas\_cel –list—last field in output

### **TO VALIDATE FS COPY % REMAINING, DO THE FOLLOWING:**

- Locate current fs\_copy session running in the source side netd file:

# cat netd

**ipfs copy start fsid=1060 rcpg=1061\_APM000433036020000 token=1124007449 address=0 qos=40960**

2. Run following command to obtain VolMCastSender information:

```
$ .server_config server_2 -v "ipfsycop display fsid=1060 rcpg=1061_APM000433036020000 token=1124007449"
```

```
1124031588: VMCAST: 5: ipfsycop fsid=1060 rcpg=1061_APM000433036020000 token=1124007449 address=0
1124031588: VMCAST: 5: DisplayIPFSCopy(): Token:1124007449 Group:1061_APM000433036020000 FSID:1060
1124031588: VMCAST: 4: ipfsycop:display() Token:1124007449 Group:1061_APM000433036020000 FSID:1060 fromFSID:0
1124031588: VMCAST: 4: VolMCast::display() Name:1060_1061_APM000433036020000 VolName:Sh20441060
NodeName:1061_APM000433036020000 refcount:1
1124031588: VMCAST: 4: VolMCastSender::display() NextBlock:102882528 TotalBlock:3758096384
```

remote\_communication:Transferring **NextBeingProcessed:103864896**

```
1124031588: RCPD: 4: rcp:: Group:1061_APM000433036020000
```

```
1124031588: RCPD: 4: rcp:: Target_num:0 Target_ip:130.200.63.30 Local_ip:141.202.27.118 Local_port:56566
```

```
1124031588: VMCAST: 4: DisplayIPFSCopy(): State:0 ReasonCode:0
```

3. Divide the NextBeingProcessed block by TotalBlock to obtain a percentage of what has actually been copied over:

**103864896 / 3758096384 = .027 or 2.7% completed**

### **EXTENT TABLES:**

FSCopy organizes data into ranges of data to be copied, called “extents”. The extent tables can be as large as 25GB in size, or up to 1024 entries—each entry in the table represents at least one 8kb file system block. The “NextBlock” value is the extent starting point for the current fscopy session, and the “NextBeingProcessed” block represents the actual block in progress. Extents are how data mover keeps track of fscopy status, say if a reboot occurs—the fscopy operation would pickup at last known NextBlock value and begin recopying from that point. One of the problems with trying to use fs\_copy -i to determine fs\_copy progress is that it only updates for each “extent” copied, and could therefore be 25GB between updates. Once a given Extent Table is copied and acknowledged on the destination side, the next Extent can begin to be copied.

**\$ fs\_replicate -l**

Local Destination Filesystems

| Id  | Source              | FlowCtrl | State  | Dest.      | FlowCtrl | State  | Network |
|-----|---------------------|----------|--------|------------|----------|--------|---------|
| 427 | usilst20_ftpu_ftp:u | inactive | active | usilst20_f | inactive | active | alive   |

**Note:** Above shows state of replication as up and running normally from source side

**# fs\_replicate -i id=25**

```
id          = 25
name        = usilst20_ftpu_ftp
fs_state    = active
type        = replication
replicator_state = active
source_policy = NoPolicy
high_water_mark = 600
time_out     = 600
current_delta_set = 66
current_number_of_blocks = 3063
flow_control = inactive
total_savevol_space = 187904000 KBytes
savevol_space_available = 187826176 KBytes (Before Flow Control)
id          = 289
name        = usilst20_ftpu_ftp:uslinas4a
type        = playback
playback_state = active
high_water_mark = 600
time_out     = 600
current_delta_set = 66
flow_control = inactive
total_savevol_space = 187904000 KBytes
savevol_space_available = 187826176 KBytes (Before Flow Control)
outstanding delta sets: <None>
communication_state = alive
current_transfer_rate = ~ 382188 Kbits/second
avg_transfer_rate    = ~ 298668 Kbits/second
source_ip            = 141.202.63.30
source_port          = 56525
destination_ip       = 130.200.63.30
```

destination\_port = 8888

QOS\_bandwidth = 40960 kbits/sec

**Note:** Use fs\_replicate -i on both sides to see more information of state of current replication session per fsid, especially to check playback activity, etc.

## **WHAT OCCURS AFTER FS COPY COMPLETES:**

- Copy completes, nas\_event collector finds entry from sys\_log to post
- the ipfs1 file system services are removed from both Source & Destination sides
- the destination fcpg file entry is removed from filesystem file
- the rcproute info is removed from both boot.cfg files

## **CLEANING UP FAILED FS COPY SESSION:**

1. Set debug mode on both Source & Target Sides:

**#export NAS\_REPLICATE\_DEBUG=1**

2. Use server\_mount to locate ipfs-mounted file systems and server\_umount to unmount from Source first, then Target

3. Examine /nas/volume/filesys file and use following commands to delete ipfs file systems and fs\_groups:

**#fs\_group -d id=34** (deletes fcpg group associated with the fs\_copy operation that failed)

**#nas\_fs -d id=33** (deletes IP replication service for checkpoint wgc3\_ckpt1\_ipfs1)

**#nas\_fs -d id=35** (deletes IP replication service for wgc3\_sfs\_ipfs1)

**Note:** If deletion fails, may need to manually edit /nas/volume/filesys file to change respective entries for above examples to “n” in the line for not-in-use, and then remove the reference count located at the 2<sup>nd</sup> to last item in the row: :29:7

4. Also check netd & boot.cfg to see that rcp entries have been removed

5. Make sure that IP Replication Debug Logging is turned off prior to commencing fs\_copy operations:

**# .server\_config server\_2 -v "logsys get severity VMCAST"**

1143253431: LIB: 4: Server log severity for facility VMCAST is 4

**Note:** If VMCAST logging is set to 4, then the logging level is normal and debug logging is not enabled

**# .server\_config server\_2 -v "logsys get severity RCPD"**

1143254192: LIB: 4: Server log severity for facility RCPD is 4

**\$ .server\_config server\_2 "logsys set severity VMCAST=LOG\_PRINTF"** (sets debug logging back to level 4)

**\$ .server\_config server\_2 "logsys set severity RCPD=LOG\_PRINTF"**

**Note:** Run commands on both Source and Destination sides

## **TURNING UP IP REPLICATION DEBUG LOGGING:**

**\$ .server\_config server\_x -v "logsys set severity VRPL=LOG\_DBG3"**

**\$ .server\_config server\_x -v "logsys set severity VMCAST=LOG\_DEBUG"**

**\$ .server\_config server\_x -v "logsys set severity RCPD=LOG\_DEBUG"**

**\$ .server\_config server\_x -v "logsys set severity VMCAST=LOG\_PRINTF"** (Set this prior to running fs\_copy)

**\$ .server\_config server\_x -v "logsys set severity VMCAST=LOG\_ERR"**

**Note:** The above command turns off IP Replication Debug logging. If VMCAST debug is invoked with 5.2 code, can actually prevent fs\_copy operation from completing correctly and may need to restart fs\_copy.

## **BEST METHOD FOR CHECKING LOGGING LEVELS:**

**# .server\_config server\_2 -v "logsys get severity RCPD"** (Logging level 4 is normal, no debug)

1143254192: LIB: 4: Server log severity for facility RCPD is 4

## **DEBUGGING FS COPY OPERATIONS:**

**\$ .server\_config server\_x -v "logsys set severity RCPD=LOG\_DEBUG"**

**\$ .server\_config server\_x -v "logsys set severity RCPD=LOG\_PRINTF"**

## **HOW TO DETERMINE IF IP REPLICATION (FS COPY) IS RUNNING OR HUNG:**

→Check sys\_log to see if fs\_copy completion message is posted (once posted, triggers fs\_copy abort & cleanup)

→verify that DM is listening to port 8888

→Run following commands at intervals and then calculate to see if progress is being made.

**Note:** “ipfscopy” is run only on the SOURCE side and the session is found in the netd file

**\$ .server\_config server\_2 -v "ipfscopy display fsid=96 rcpg=97\_APM000306008700000**

**token=1058286129"**

1058291610: VMCAST: 5: ipfscopy fsid=96 rcpg=97\_APM000306008700000 token=1058286129 address=0

1058291610: VMCAST: 5: DisplayIPFSCopy(): Token:1058286129 Group:97\_APM000306008700000 FSID:96

1058291610: VMCAST: 4: ipfscopy:display() Token:1058286129 Group:97\_APM000306008700000 FSID:96

1058291610: VMCAST: 3: VolMCast::display() Name:96\_97\_APM000306008700000 VolName:Sh13496

NodeName:97\_APM000306008700000 refcount:1

1058291610: VMCAST: 4: VolMCastSender::**display()** **NextBlock:5376** TotalBlock:209715200

state:VMCAST\_SENDER\_BROADCAST\_IN\_PROGRESS1058291610: VMCAST: 4: DisplayIPFSCopy(): State:01058291610:

ADMIN: 4: Command succeeded: ipfscopy display fsid=96 rcpg=97\_APM000306008700000 token=1058286129

**Note:** Find the appropriate “rcpg=“ line in the NETD file and run command a few times to see if “NextBlock:5376” has changed—if it has, then IP Replication is in progress. If not, then it might be hung.

### **PREVENTING RESTART OF FS COPY:**

Comment out ipfscopy line in the netd file to prevent fs\_copy sessions from being restarted (might do this in cases of rolling panics)

### **HOW TO BREAKOUT OF A HUNG FS COPY SESSION:**

# .server\_config server\_x "ipfscopy stop fsid=x rcpg=x token=x address=x" (see netd file)

# .server\_config server\_x "ipfscopy start fsid=x rcpg=x token=x address=x noconvert=1" (netd)

### **CHANGING HTTP TIMEOUT VALUE BETWEEN SOURCE & TARGET CONTROL STATIONS:**

**Note:** fs\_copy or fs\_replicate operations can timeout, causing them to hang. For a temporary workaround, increase HTTP timeout value for the Source Control Station from 300 seconds to 600 seconds in the /nas/http/conf/httpd.conf file--issue has been addressed with NAS 5.3.22.0 and 5.4.19.0 by increasing the default HTTP communication timeout value to 600 seconds (10 minutes):

1. #vi /nas/http/conf/httpd.conf and find the line associated with "Timeout 300"--should be on or around line 106:

104 # Timeout: The number of seconds before receives and sends time out.

105 #

106 Timeout 300 -->Change this value to 600

2. Identify and Kill the master Apache httpd process:

# ps fax |egrep httpd

```
18504 pts/3 S 0:00      \_ egrep httpd
17186 ? S 0:00 /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http
17187 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
17188 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
```

# kill 17186

**Note:** Do not use kill -9 to stop the Apache httpd daemon

# ps fax |egrep httpd

```
18824 pts/3 S 0:00      \_ egrep httpd
```

3. Restart Apache httpd process using following command:

# /nas/sbin/httpd -D HAVE\_PERL -D HAVE\_SSL -f /nas/http/conf/httpd.conf

4. Verify Apache process:

# ps fax |egrep httpd

```
19571 pts/3 S 0:00      \_ egrep httpd
19519 ? S 0:00 /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/http
19521 ? S 0:00 \_ /nas/sbin/httpd -D HAVE_PERL -D HAVE_SSL -f /nas/
```

### **REPLICATOR FLOW CONTROL:**

Replication Flow Control will automatically kick in under the following situations;

1.) Delta Sets on destination side are about to be overwritten by newer delta sets. Flow Control kicks in. Situation can occur if the Playback rate on the Remote side is too slow

2.) If Delta Sets cannot be transferred from Primary SavVol to Secondary side SavVol, flow control kicks in. This can happen if there is a loss of network connectivity between Source and Destination sides.

3.) SavVol becomes full on Primary side, flow control kicks in. Could happen if Primary Write rate is too fast.

### **LOCAL REPLICATION vs. REMOTE REPLICATION:**

→Local Replication is done using the same data mover on the local Celerra (Loopback Replication) or different data movers on the local Celerra—No remote Celerras are involved. Replication synchronization is started between PFS & SFS via the fs\_copy command. Subsequent PFS block changes after the initial copy are saved by the Replication Service to delta sets which are then copied to the shared SavVol used by PFS & SFS. Replication Playback Service plays back completed delta sets to the SFS.

→Remote Replication is setup between Local and Remote Celerras. Replication synchronization is started between PFS & SFS via the fs\_copy command. Subsequent PFS block changes after the initial copy are saved by the Replication Service to delta sets which are then copied to the primary SavVol. The Remote Replication Service transfers completed delta sets to the remote SavVol, where the Replication Playback Service plays back each delta set to the SFS.

### **FILE SYSTEM EXTENSIONS WHILE REPLICATION IS RUNNING:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
The default behavior is that when the Source file system is extended, replication will be suspended, the destination file system will extend first, followed by the source fs, with the replication session restarting

### **EXTEND SUCCEEDS ON DESTINATION BUT FAILS ON SOURCE:**

If the Destination side extended, but Source failed, try the following src\_only option to extend:

**# nas\_fs -xtend Groupware\_A size=102400M pool=clar\_r5\_performance -option src\_only,slice=y**

### **DESTINATION FS WILL NOT EXTEND DUE TO POOL SPACE:**

Try manually extending sfs using –Force flag and different storage pool, then extend pfs using source –only option

### **FILE SYSTEM EXTENSION WHEN USING SLICED VOLUMES vs. NON-SLICE VOLUMES:**

If the original file system was created without using the Slice=y option, then automatic file system extension using AVM will fail with the following error, and must be extended manually from the CLI. AVM uses the slice=yes option by default, but since the original file system was created without slice=y, the manual CLI command must be used instead:

CFS:3:101 fs auto extension failed: /nas/sbin/rootnas\_fs -x hadata3-1 size=10000M -o slice=n Error 3136: Should be sliced as hadata3-1 is a member of a replication session, fsname=hadata3-1 (Slot3:1159398824:)

**Resolution:** Manually extend the file system and specify the slice=y

**# nas\_fs -x hadata3-1 size=10000M -o slice=y**

### **REPLICATION SUSPEND MODE:**

**Note:** NAS 5.3 introduces ability to suspend a replication session and then use the –restart operation to restart replication later, and is meant as a way to temporarily stop replication and leave it in a state where it can be restarted. Also, you cannot suspend replication when upgrading from 5.3 to 5.4 and restart replication without converting remote file systems to rawfs and renaming the appropriate remote service to root\_suspend\_ckpt\_25\_1 (where 25=remote filesys id & 1=remote cel id)

**1. Set refresh policy on Source and then Destination file system** to prevent an out-of-synchronization issue from occurring while replication is in a suspended state:

**# fs\_replicate -refresh pfs -o to=0,hwm=0**

**# fs\_replicate -refresh sfs -o to=0,hwm=0**

**2. Suspend replication on file system:**

**# fs\_replicate -suspend <srcfs> <dstfs>[:cel=<cel\_name>]**

### **SUSPEND OPERATION EXAMPLE:**

**# fs\_replicate -suspend fs\_scli fs\_dcli:cel=laip2**

operation in progress (not interruptible)...

```
id          = 166
name        = fs_scli
fs_state    = active
type        = replication
replicator_state = active
source_policy = NoPolicy
```

Generating new checkpoint...

operation in progress (not interruptible)...id = 166

```
name      = fs_scli
acl       = 0
in_use   = True
type     = uxfss
```

```
id      = 283
name   = root_suspend_ckpt_98_2
```

#### **cmd log:**

```

**Note:** Suspend creates a checkpoint of the source, copies the delta changes over using refresh to the destination, then aborts replication session

**3. Restart replication:**

**# fs\_replicate -restart pfs:if=pfsRep sfs:cel=secondaryCS:if=sfsRep –option hwm=600,dhwm=300,to=600,dto=300**

**Note:** The –restart switch is the only viable method for resuming replication from a –suspend operation. The restart will create a new checkpoint of the Source file system and then do a differential fs\_copy to the destination file system between the latest checkpoint and the suspend checkpoint that was taken at the time that the file system was suspended. Make sure that Source file system policies are reset to a level greater than the destination so as to prevent an out-of-sync replication, which could require a complete breakdown and setup of replication between the Source and Destination file systems.

**USING THE SUSPEND COMMAND FOR REPLICATION**

- Moving either PFS or SFS from one mountpoint or data mover to another
- Changing IP addresses on data mover interface on Source or Target system
- Changing size of replication SavVol
- Upgrading sites where IP Replication is established, by suspending Production File System replication

**TECH SUPPORT GUIDANCE ON HANDLING REPLICATION SITES FOR NAS UPGRADES:**

1. Take manual checkpoint of each replication file system on the source prior to Upgrade
2. Perform NAS upgrade
3. If replication does not survive upgrade, perform abort and manual restart, which the manual checkpoint will allow you to do

**OVERVIEW OF FS REPLICATION OPERATIONS:**

**#fs\_replicate -l  
#fs\_replicate -i fs01\_1  
#fs\_replicate -i fs01\_1 -v 15**

**FUNDAMENTAL IP REPLICATION STEPS FOR FILE SYSTEMS:**

1. Create rawfs on Destination side of equal size to that of Source side, and mount RO
2. Conduct initial Checkpoint of production fs on Source side using fs\_ckpt fs01 –Create
3. Startup initial fs\_copy operation and wait until it completes--fs\_copy –start convert=no monitor=off

**Note:** Observe status of fs\_copy using -list

4. Startup Replication process using fs\_replicate -start

5. Create 2<sup>nd</sup> checkpoint of production file system using `fs_ckpt fs01 -Create`
  6. Copy over the incremental checkpoint changes using `fs_copy -start -o monitor=off` and allow the file system to be converted from rawfs to uxfss
  7. FS replication state should now be established and operational between Source and Destination

#### **VERIFYING REPLICATION BETWEEN SOURCE AND DESTINATION:**

```
# fs_replicate -l | -i
```

## Local Source Filesystems

Id Source FlowCtrl State Destination FlowCtrl State Network  
 35 fs16fsfs inactive active fs16:RDF1\_52 inactive active alive → Example shows normal IP Replication established  
 39 root fs vd inactive active root fs vdm 1:RDE1 inactive active alive

**Note:** FlowCtrl inactive is normal and is only used if special switches for flow control are invoked. The key with this output is if both sides of the IPP application service are showing a State of 'Active' and Network of 'Alive'.

```
# fs replicate -l -dst
```

```
# fs replicate -l -src
```

## WHAT IF REPLICATION SESSIONS BECOME INACTIVE?

→ Refer to primus solutions emc116166, emc180572, & emc173039, for troubleshooting and restarting Replication V1 sessions that have gone ‘inactive’.

#### **VERIFYING PLAYBACK SERVICE & DELTA SETS:**

The Playback Service reads delta set changes to the destination SavVol and updates destination file system with changes. Use the following command to verify the existence of outstanding delta sets and playback:

```
# fs replicate -i fs01 data -v 15
```

```

# ls -Replicate -fso1_data -v 13
id          = 41
name        = fs01_data
fs_state    = active
type        = replication
replicator_state = active
high_water_mark = 600
time_out    = 600
current_delta_set = 29912
current_number_of_blocks = 1800
flow_control = inactive
total_savevol_space = 20480000 KBytes
savevol_space_available = 20447232 KBytes (Before Flow Control)
id          = 28

## **CHANGING DATAMOVER INTERFACE WHEN IP REPLICATION IS RUNNING & ACTIVE:**

1. Refresh PFS to=0, hwm=0 [cuts dataset X]
2. Checkpoint the PFS (ckpt1) [references dataset X+1]
3. Refresh the PFS to=0, hwm=0 [cuts dataset X+1]
4. Refresh the SFS to=10, hwm=0
5. Wait until PFS dataset from Step 3 is replayed on Secondary
6. Abort replication on PFS, then run abort on SFS
7. Convert SFS to rawfs
8. Change the NIC interface to the new interface on each side & then restart Replication
9. Create another checkpoint of PFS (ckpt2)
10. Do differential fs\_copy of ckpt1 to ckpt2

## **VERIFYING COMMS & PASSPHRASE BETWEEN SOURCE & DESTINATION SIDES:**

### **1. FROM SOURCE:**

**# nas\_cel -l**

```
id      name      owner mount_dev channel   net_path      CMU

```

## **IP REPLICATION FAILBACK FROM SFS TO PFS:**

1. Bring the production IP address on the SFS interface down and bring the PFS interface up (bring “UP” the alternate IP address interface on SFS)

2. Use autofullcopy to resync SFS VDM rootfs back to PFS VDM rootfs—baseline copy

**# fs\_replicate -resync root\_fs\_vdm\_pfs\_vdm1:cel=sourceCS root\_fs\_vdm\_sfs\_vdm1 -o autofullcopy=yes**

**Note:** The –resync operation goes through the following sequences & finishes by cleaning up checkpoints:

Starting baseline copy...

Starting replication...

Generating new checkpoint

Starting diff copy

3. Conduct Failback from SFS Side using new “-reverse” switch

**# fs\_replicate -reverse root\_fs\_vdm\_pfs\_vdm1:cel=sourceCS root\_fs\_vdm\_sfs\_vdm1**

4. Change VDM rootfs state on PFS side to “loaded” and SFS side to “mounted”

5. Conduct Copy of Data File System from SFS to PFS Side using –resync switch

**# fs\_replicate -resync pfs:cel=sourceCS sfs**

**Note:** Change production pfs back to “rawfs” type if required using –T switch and change mount to “ro” using mount command, though pfs remains <unmounted>

6. Conduct Failback using –reverse switch

**# fs\_replicate -reverse pfs:cel=sourceCS sfs**

7. Startup CIFS service on PFS side and note that Replication & Playback policies have reverted to default of 600secs & 600MB

8. Use new –modify switch to change Secondary PFS policies back to 300secs/300MB

**# fs\_replicate -modify sfs -o to=3,hwm=3**

9. Use –modify switch to change Source PFS policies back to 600secs/600MB (if required)

**# fs\_replicate -modify pfs -o to=6,hwm=6**

10. Re-export PFS Side “pfs” share by unexporting all Shares on PFS and reexporting “pfs” share

## **SUSPENDING REPLICATION & FAILBACK SERVICE ON PFS SOURCE SIDE:**

**# fs\_replicate -suspend pfs sfs:cel=destCS**

**Note:** Operation creates a suspend checkpoint

**# fs\_replicate -i pfs**

**Note:** Returns error: Error 2242: pfs : replication/playback is not set up

## **VERIFYING REPLICATION:**

**# fs\_replicate -list**

**# fs\_copy -i id=45**

**# server\_df pfs\_vdm1**

**# server\_df sfs\_vdm1**

## **VERIFYING ROOTFS REPLICATION INFO:**

**# fs\_replicate -info root\_fs\_vdm\_pfs\_vdm1**

## **NAS 5.3 FEATURE ALLOWS CONVERSION OF UXFS TO RAWFS:**

**# /nas/sbin/rootnas\_fs -T rawfs root\_fs\_vdm\_sfs\_vdm1 -Force**

**Note:** SFS rootfs needs to be rawfs to support replication

## **NAS 5.2 & DR1 REPLICATION:**

--Introduces differential fs\_copy and incremental failback

**Note:** SFS can now be read/write after failover and then incrementally re-synchronized prior to restoring to PFS side.

--Now supports extension of SFS if PFS is extended

--CIFS asynchronous disaster recovery is now supported

--Supports loopback replication [i.e., source and destination FS on same DM]

--Supports remote replication from one Celerra to another

--Introduces VDM support for failing over CIFS Server from Source to Target Celerra

**Note:** Correct terminology for IP Replication is “Data Recovery”, not “Disaster Recovery”

## **DIFFERENTIAL FS COPY WITH NAS 5.2:** Differences between first and second checkpoints are copied over to SFS

convert=no [Option to not convert destination fs to uxfis upon completion]

qos=<kbytes> [limit transfer speed to kbs/sec]

monitor=off [return to command prompt after executing, runs command in background]

**-fromfs <fsname>** [copy delta between old and newer checkpoint] →-fromfs command always indicates a differential copy

**1. #fs\_ckpt pfs -C**

**2. #fs\_copy -start pfs.ckpt1 sfs -o convert=no**

**3. #fs\_replicate -start pfs sfs savsize=X**

**4. #fs\_ckpt pfs -C**

## 5. #fs\_copy –start pfs.ckpt2 sfs –fromfs pfs.ckpt1

### **CELLERRA IP REPLICATION SAVVOL:**

- Minimum size 1GB and max 500GB
- Remote replication uses a SavVol on Source and on Destination sides for each Replication Session
- Local replication uses only a single SavVol per Replication Session on the local Celerra
- File system changes are stored in DM memory until they can be written to the SavVol
- File system changes are stored in the SavVol until a delta set can be accumulated, which is then transmitted via IP to destination
- Changes are stored in destination SavVol until they can be written to the SFS

### **FINDING SAVVOL VOLUME POOL NAME, VOLUME POOL FILESYSTEM NAME, AND SIZE:**

1. # export NAS\_REPLICATE\_DEBUG=1
2. Find Replication sessions & query to find SavVol sizes:

```
# fs_replicate -list
```

Local Source Filesystems

| Id | Source | FlowCtrl | State  | Destination    | FlowCtrl | State  | Network |
|----|--------|----------|--------|----------------|----------|--------|---------|
| 98 | fs02   | inactive | active | dst_fs02:nyip2 | inactive | active | alive   |
| 91 | fs01   | inactive | active | dst_fs01:nyip2 | inactive | active | alive   |

```
# fs_replicate -i id=98
```

total\_savevol\_space = 25600000 KBytes **-->25GB**

savevol\_space\_available = 25559040 KBytes (Before Flow Control)

```
# fs_replicate -i id=91
```

total\_savevol\_space = 25600000 KBytes

savevol\_space\_available = 25559040 KBytes (Before Flow Control)

3. Locate name of Replicas for each replicated production file system:

```
# nas_fs -i fs02
```

ckpts = fs02\_ckpt1,fs02\_ckpt2

replicas = fs02\_rvfs

```
# nas_fs -i fs01
```

ckpts = fs01\_repl\_restart\_1,fs01\_repl\_restart\_2

replicas = fs01\_rvfs

4. Use replicas to find the Volume name and Volume Pool File System name for the Save Volume:

```
# nas_fs -i fs02_rvfs
```

sav\_volume= vp189

member\_of = vpf96

```
# nas_fs -i fs01_rvfs
```

sav\_volume= vp140

member\_of = vpf89

5. Use following query to verify SavVol size:

```
# nas_fs -s vpf96
```

total = 25000 (sizes in MB) ( blockcount = 51200000 )

```
# nas_fs -s vpf89
```

total = 25000 (sizes in MB) ( blockcount = 51200000 )

6. Query Volume Pool name to verify vpf96 name:

```
# nas_volume -i vp189
```

id = 189

name = vp189

acl = 0

in\_use = True

type = pool

chunk\_size = 128

volume\_set = v188

disks = d21

cInt\_filesys= vpf96

```
# nas_volume -i vp140
```

id = 140

name = vp140

acl = 0

in\_use = True

type = pool

```
chunk_size = 128
volume_set = v139
disks     = d11,d18
clnt_filesys= vpfs89
```

### **USING XML QUERIES TO OUTPUT SAVVOL NAMES & SIZES:**

```
# nas_fs -query:Type=uxfs:ReplicationState=source,destination -format:"%q" -fields:ReplicationSessions -query:* -format:"RepID=%s, SavVolID=%s, SavVolName=%s, SavVolSize(MB)=%s, SavVolSizeUsed(MB)=%s\n" -
fields:Id,SrcSavVolID,SrcSavVolName,SrcSavVolSizeMB,SrcSavVolUsedMB
RepID=98, SavVolID=189, SavVolName=vp189, SavVolSize(MB)=25000, SavVolSizeUsed(MB)=40
RepID=91, SavVolID=140, SavVolName=vp140, SavVolSize(MB)=25000, SavVolSizeUsed(MB)=40
RepID=105, SavVolID=151, SavVolName=vp151, SavVolSize(MB)=25000, SavVolSizeUsed(MB)=40
# .server_config server_2 -v "volpool display vol=117"
# .server_config server_2 -v "volpool display vol=117 detail"
```

### **PREVENTING SAVVOL FROM GOING INACTIVE DURING MAINTENANCE ON SOURCE:**

- Set Data Mover param 'freeze' value to 1 on Source side:

```
param VRPL freeze=1
```

- Set Source Side policy to: to=0,hwm=256 (allows DeltaSets to remain full of data)
- Create ckpt on source side (pfs\_ckpt1)
- Check for "delta\_number" in output of "nas\_fs -i pfs\_ckpt1"
- On target side wait for delta\_number to be played back to SFS
- Target side can then be taken down

### **PROBLEM WITH LARGE DELTA SETS:**

#### CaseStudy:

Customer sets high HWM, and high system activity results in very large Deltatasets accumulating for the PFS—435GB. The problem with large deltatasets is that the system may not be able to copy the changes to the SavVol fast enough. The system has (10) VRPL.ncopythreads allocated for this activity by default. In this example, the large deltatasets are causing IO's to become blocked during the copy operation, and if this lasts (5) minutes or more, the Data Mover will panic. The problem is exacerbated in that the Panic Handler cannot recover, and the Server gets into a rolling panic situation and the IP Replication session becomes Inactive.

#### Resolution:

See ARs 70711/98226/105863 and Primus emc172332. The code solution is to increase the number of threads that can be allocated for VRPL.ncopythreads, with a max of 32 allowed. Other steps that could be taken would be to decrease the HWM values so as to create smaller deltatasets. At a minimum, increase the VRPL.ncopythreads to (32) for any sites that exhibit the following panic header:

**>>PANIC: I/O not progressing LastVol touched LF313 Kind 6 (ptr=0x97e86604)**

DART stack trace:

```
0xdb283e90: 0x13d85c waitForReboot+0x90
0xdb283eb0: 0x13da59 fault_dump+0x67
0xdb283ed0: 0x13d959 PANIC+0x29
0xdb283ee0: 0x717513 _ZN9RawIO_IPR13checkProgressEv+0x10d
0xdb283fd0: 0x7173fc _ZN17IrpProgressThread5startEv+0x6
0xdb283fe0: 0x140ff0 Sthread_startThread_internal+0xe
```

#### Checking for Number of ncopythreads:

```
$ .server_config server_2 -v "replica display srcvol=<srcvol_ID>
```

#### Monitoring Deltaset copy progress:

```
$ .server_config server_2 -v "replica stat srcvol=<srcvol_ID>
```

### **CONFIGURING SAVVOL SIZE:**

#### /nas/sys/nas\_param

```
#replication:<percent_of_fs_vol>
local_rep_save_vol: 10: chunk_size=32768 [Chunk size is fixed at 128MB]
remote_rep_save_vol: 10: chunk_size=32768 [10=10% or default size of SavVol based on 10% of PFS Size—this is adjustable]
Comment: PFS & SFS “SavVol” sizes must be the same—changing the nas_param default for SavVol is not honored when establishing Replication Sessions using Celerra Mgr—will revert to the standard 10% of PFS size when creating SavVol
```

#### NAS 5.6 EXAMPLE:

```
# cat /nas/sys/nas_param
```

replication:10:

### **ERROR WHEN TRYING TO START REPLICATION:**

```
# fs_replicate -start fs1 fs2:cel=cel2
```

Error 3024: no free disks are available

**Note:** Problem can occur if there isn't enough space (10% of fs size is needed) to create the SavVol in the respective system pool. Use the “savsize=20480” option to specify a SavVol size that can be created—or, add disk space to appropriate system pool.

### **NETWORK ISSUES & SAVVOL:**

Default replication policy settings allow delta sets to be transferred to SavVol until the SavVol runs out of space, at which point replication is aborted, but the primary file system continues to function properly. There is an optional policy to disallow further writes to the PFS if the SavVol fills.

### **SAVVOL FULL ISSUE:**

**Error 4019:** failed to complete command—#fs\_replicate –refresh [Command fails with this message]

Problem would occur if SFS is not copying changes over fast enough to prevent SavVol from filling on PFS side. By default, PFS SavVol is only 10% the size of the PFS. If this issue occurs, abort Replication and reconfigure to create a larger SavVol, possibly changing HWM and TO values on each side as well.

**Rule of Thumb:** HWM & TO values should be greater on PFS than SFS side.

### **DETERMINING AMOUNT SAVVOL SPACE AVAILABLE:**

# **fs\_replicate -l** [obtain id number of any file system]

# **fs\_replicate -i id=xxx**

total\_savevol\_space = 1048576 KBytes

savevol\_space\_available = 917504 KBytes (Before Flow Control)

### **SAVVOL POLICIES THAT CAN BE SET FOR IP REPLICATION:**

\$ .server\_config server\_2 -v "param VRPL freeze"

VRPL.freeze INT 0x018f7d58 0 0 (0,1) TRUE NONE 'Enables freeze of primary when savVol full'

**Note:** Setting value to 1 would halt all IO to source PFS in order to preserve synchronization state, and can also be invoked with fs\_replicate –modify switch using “autofreeze=yes”

\$ .server\_config server\_2 -v "param VRPL readonly"

VRPL.readonly INT 0x018f7d98 0 0 (0,1) TRUE NONE 'Determines action when changes can't be tracked'

**Note:** Setting value to 1 changes source PFS to Read-Only to preserve state, also invoked via –modify switch, “autorw=yes”

### **THREE POSSIBLE OUTCOMES WHEN SAVVOL BECOMES FULL:**

→PFS will freeze, preventing any further Reads or Writes, if param VRPL freeze is set to 1

→PFS will become RO if param VRPL readonly is set to 1

→Once SavVol is full, and changes can no longer be written to DM memory, replication sessions that depend on the SavVol will become inactive

### **(3) DISTINCT PHASES OF IP REPLICATION WITH NAS 5.2:**

**FAILOVER→RESYNC to REVERSE IP REPLICATION DIRECTION→FAILBACK**

#### **NAS 5.2 IP REPLICATION FAILOVER:**

# **fs\_replicate –failover PFS:cel=NS600S SFS –o sync**

**Note:** Conducts failover from PFS to SFS and stops replication service [-o sync = primary is up; -o now = primary down].

#### **RESYNCING SFS SIDE WITH NAS 5.2—DIFFERENTIAL COPY:**

# **fs\_replicate –Resync PFS:cel=NS600S SFS**

**Note :** Incrementally copies and synchronizes the SFS, which is RW, to the PFS when in a “failover” state

#### **NAS 5.2 IP REPLICATION FAILBACK:**

# **fs\_replicate –failback PFS:cel=NS600S SFS**

**Note:** When conducting failback, nas\_cel is used to talk to destination Apache Server, a CGI script is initiated, then CGI Eiffel code executes, which assembles the fs\_replicate –start command from the remote to destination side to reverse the replication process.

#### **NAS 5.2 VERIFY REPLICATION:**

# **fs\_replicate –info PFS | SFS**

**Note:** By default, IP Replication takes place at 10 minute mark or after 600MB have been written to PFS, whichever occurs first

#### **NAS 5.2 CONDUCTING IP REPLICATION REFRESH:**

1. # **fs\_replicate –refresh SFS –o to=300, hwm=300**

**Note:** Default playback service values are 600

2. # **fs\_replicate –refresh PFS –o to=600, hwm=600**

#### **NAS 5.2 IP REPLICATION ENHANCEMENTS:**

→Auto extension of SFS when PFS is extended

→Special filesystems now hidden from view: vefs, ipfs, rufs, pufs

→Aborting an fs\_copy should now work

## **NAS 5.2 IP REPLICATION LIMITATIONS:**

- HighRoad works on PFS only, not SFS
- SRDF/TimeFinder/FS cannot be used in conjunction with IP Replication on same filesystems [except SRDF Sync DR]
- Do not use BCV's for either PFS or SFS used in IP Replication
- CDMS is not supported and MGFS file systems cannot be replicated

## **DEFAULT FS REPLICATE FAILOVER PROCESS:**

1. All deltas played back on secondary
2. Stop playback on SFS & remount SFS as “rw”
3. Refresh PFS to=0, hwm=0 & remount PFS “ro”

## **FS REPLICATE FAILOVER NOW:**

1. Stop playback on SFS & remount SFS “rw”
2. Refresh PFS to=0, hwm=0 & remount PFS “ro”

**Note:** Failover command must be run on SFS Control Station

## **FS REPLICATE FAILBACK:**

1. Refresh PFS to=0, hwm=256 & refresh SFS to=10, hwm=256
2. Wait for dataset to be identical for PFS/SFS
3. Refresh PFS to=128, hwm=128
4. Again wait for dataset to be identical for PFS/SFS
5. Remount SFS “ro”
6. Refresh PFS to=0, hwm=0
7. Wait for dataset to be identical for PFS/SFS
8. Stop playback on SFS and replicator on PFS
9. Start replication from SFS to PFS
10. Remount PFS “rw”

**Note:** Failback must be run from side that is “rw” & effectively changes the side that does replication

## **CELLERRA REPLICATOR COMMANDS:**

|                        |                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------|
| #fs_replicate          | [Used to Start/Abort/Refresh IP Replication]                                                    |
| #fs_copy               | [Used to copy data from PFS Checkpoint to SFS during initial setup]                             |
| #nas_cel/nas_rdf -init | [Used to initialize Control Stations]                                                           |
| #nas_fs -i pfs/sfs     | [Used to verify Delta Sets on PFS or SFS [Delta Set increments each time TO or HWM takes place] |

## **Other Commands:**

|                                       |                                                                              |
|---------------------------------------|------------------------------------------------------------------------------|
| #fs_replicate -failover -o sync   now | [sync=sync pfs to sfs after failover; now=disaster on primary, failover now] |
| #fs_replicate -info                   | [Current state of replicator]                                                |
| #fs_replicate -failback               | [failback to PFS]                                                            |
| #fs_replicate -reverse                | [new syntax with NAS 5.3 that replaces –failback]                            |

## **LOCAL vs REMOTE IP REPLICATION:**

→ Local Replication produces RO copy of PFS for export by same or other Data Movers (aka Loopback Replication), but shares SavVol between Source & Destination Servers

→ Remote Replication does same thing for Data Movers at remote locations but uses separate SavVol for Source & Destination

## **REMOTE REPLICATION PROCESSES:**

- Initial replication manually synchronizes both PFS and SFS after starting Celerra Replicator for first time
- Addresses of subsequent block changes to PFS are sent to Log & and applied to SFS SavVol after sync is completed
- Replication Svc creates Delta set to source primary SavVol (record of all changes to PFS for each Delta Set trigger)
- Replication Svc transfers Delta set to target secondary SavVol (one Delta Set per FS is processed at a time)
- Replication Playback Svc reads Delta set and updates SFS

## **CREATING SFS THAT IS IDENTICAL IN SIZE TO PFS:**

**Note:** As stated in earlier notes, IP Replication will not work if the SFS is not exactly the same size as the PFS. The following two procedures only work with NAS Codes 5.1.14.0 or higher

## **CONVERT NUMBER OF BLOCKS IN EXISTING META VOLUME ON FS TO MBYTES:**

1. Find meta volume(s) that filesystem is built upon:

**#nas\_fs -i fs01 →mtv1**

2. Find Volume ID # of Meta:

### #nas\_volume -i mtv1 →id =237

3. Obtain number of blocks in Meta:

#nas\_volume -query:id=237 -format:'%s\n' -fields:blocks →141418496

4. Multiply number Blocks by 512 and then divide by 1048576:  $141418496 * 512 = 72406269952 / 1048576 = 69052$  MB

5. Build SFS:

#nas\_fs -n sfs -t rawfs -c size=69052MB profile=clar\_r5\_performance -o slice=y

### CREATING SFS FROM SLICES:

1. Create slice of desired size: \$nas\_slice -n slc1 -c str1 1 0 -src mtv1:cel=remcs0

2. Create meta from stripe: \$nas\_volume -n mtv1 -c slc1

3. Create SFS FileSystem: \$nas\_fs -n sfs -t rawfs -c mtv1

### VERIFYING THAT PFS & SFS HAVE SAME FS & BLOCK SIZES:

1. #nas\_volume -query:Name==v99 -fields:Blocks (File System size)

40960

2. #nas\_volume -query:Name==v99 -fields:BlockSize (Block Size)

512

### IP REPLICATION PROCESSES:

**rvfs:** replication volume file system (Service that creates & copies ‘delta sets’ to SavVol & manages ‘Redo Log’ buffer for SavVol)

**pvfs:** playback volume file system (Service that copies from Save Volume to Secondary File System—SFS)

**vvfs:** volume pool file system (Service used for replication by allocating blocks for the volumes used in replication)

**ipfs:** ip file system (Service that handles data for IP transfer; IPFS Service checks for new Delta Sets in SavVol every second)

### REPLICATION SESSION EXAMPLE:

|                   |                              |
|-------------------|------------------------------|
| pfs_rvfs1         | [Source Replication Service] |
| pfs_rvfs1_ipfs1   | [Source IP Transfer service] |
| sfs_pv vfs1       | [Remote Playback Service]    |
| sfs_pv vfs1_ipfs1 | [Remote IP Transfer service] |

### ABORTING AN FS COPY SESSION:

Run from Source side  
# fs\_copy -abort usilst20\_ftpu\_ftp\_ckpt3

operation in progress (not interruptible)...id = 1060

name = usilst20\_ftpu\_ftp\_ckpt3

### ABORTING FS REPLICATION SESSION:

# fs\_replicate -abort fs\_source,fs\_dest:cel=laip2

**Note:** This is preferred abort method, clean up both sides simultaneously when possible

# fs\_replicate -abort new1

operation in progress (not interruptible)...id = 152

name = new1

acl = 0

in\_use = True

type = uxfs

worm = off

volume = v113309367

pool = clar\_r5\_performance

member\_of = root\_avm\_fs\_group\_3

rw\_servers= laip1-2

ro\_servers=

rw\_vdms =

ro\_vdms =

auto\_ext = no,virtual\_provision=no

ckpts = new1\_ckpt1,new1\_ckpt2

ip\_copies = repdest:laip2

**Note:** Run on Source and Destination Control Stations to cleanup entries in netd file and boot.cfg for replication service and sessions

### CLEANING UP FAILED –abort REPLICATION SESSIONS MANUALLY:

#### PRIMARY SIDE:

Need to know repGroupName, SavVol\_id, SrcVol\_id, & CfgVol\_id in order to abort a file system replication session

**SECONDARY SIDE:**

Need to know VolMCastName, MultiCastNode, SrcVolSec\_id, SavVolSec\_id, CfgVolSec\_id in order to abort the Secondary side.

**Note:** Derive source information using nas\_fs -i srcfs\_rvfs\_ipfs1 & nas\_fs -i rvfs output or from the contents of the /nas/volume/filesys, netd, and ufs file of server. Derive Secondary information using nas\_fs -i destfs\_pvfs and nas\_fs -i destfs\_pvfs\_ipfs1. Depending on whether abort was partially successful, not all entries may be present in filesys file. May also need to reboot Data Mover if commands do not execute.

**EXAMPLE FOR SOURCE SIDE CLEANUP:**

I. Use following DART commands to cleanup

|                                                                           |                                             |
|---------------------------------------------------------------------------|---------------------------------------------|
| \$server_config server_2 -v "iprepvc stop <rcpGroupName> vol=<SavVol_id>" | [stops Replication Service on Primary side] |
| \$server_config server_2 -v "rcproute remove group=<rcpGroupName>"        | [removes RCP route entry]                   |
| \$server_config server_2 -v "replica stop srcvol=<SrcVol_id>"             | [Stops replication on Primary]              |
| \$server_config server_2 -v "volpool stop vol=<CfgVol_id>"                | [Stops VolPoolManager on config volume]     |
| \$server_config server_2 -v "volpool stop vol=<SavVol_id>"                | [Stops VolPoolManager on SavVol]            |

II. Remove any required entries from netd file for iprepvc and rcproute

III. Remove volpool & replica entries from ufs file if required [used for replication recovery]

IV. Cleanup CS database

a.) # export NAS\_REPLICATE\_DEBUG=1

b.) # server\_umount server\_2 -p /srcfs\_rvfs\_ipfs1

c.) Verify that /nas/volume/filesys entry for srcfs\_rvfs\_ipfs1 shows “n” for inuse flag and has blank ref count—edit if required  
201:srcfs\_rvfs\_ipfs1:0:n:5:0::1143306484:200:9::202: [inuse & ref count fields, respectively]

d.) # nas\_fs -d srcfs\_rvfs\_ipfs1 [Verify that this entry has been removed from filesys file]

e.) # fs\_replicate –abort srcfs [Verify that session is aborted using fs\_replicate –list]

**EXAMPLE FOR DESTINATION SIDE CLEANUP:**

I. Use DART commands:

|                                                                                             |                                      |
|---------------------------------------------------------------------------------------------|--------------------------------------|
| \$server_config server_2 -v "volmcast delete <VolMCastName> <MultiCastNode> <SavVolSec_id>" | [deletes Volmcast object]            |
| \$server_config server_2 -v "playback stop srcvolsec=<SrcVolSec_id>"                        | [Stops playback service]             |
| \$server_config server_2 -v "volpool stop vol=<SavVolSec_id>"                               | [Stops VolPoolManager on SavVol]     |
| \$server_config server_2 -v "volpool stop vol=<CfgVolSec_id>"                               | [Stops VolPoolManager on Config Vol] |

II. Remove netd entries for Volmcast object

III. Remove volpool entries for SavVol & CfgVol, and playback entry from ufs file

IV. Cleanup CS database

a.) # export NAS\_REPLICATE\_DEBUG=1

b.) # server\_umount server\_2 -p /destfs\_pvfs\_ipfs1

c.) Make sure that filesys entry shows ‘n’ for inuse, has no reference count, and does not have remote reference  
125:destfs\_pvfs\_ipfs1:0:n:5:0::1143306476:124:7::: [inuse & ref count fields, respectively]

d.) # nas\_fs -d destfs\_pvfs\_ipfs1

e.) # fs\_replicate –abort destfs [Verify using fs\_replicate –list]

**# NAS\_REPLICATE\_DEBUG=1;export NAS\_REPLICATE\_DEBUG****VIEWING PFS IP REPLICATION PROCESSES:**

**\$nas\_fs -i pfs**

|                     |                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------|
| vpfss20             | [Represents Save Volume on PFS side—now seen when doing nas_fs -i on PFS file system checkpoint] |
| pfs_rvfs1           | [Replication Service]                                                                            |
| pfs_rvfs1_ipfs1     | [IP Transfer service]                                                                            |
| 22_0028060001810047 | [FS Group for the IP Transfer]                                                                   |

**VIEWING SFS IP REPLICATION PROCESSES:**

**\$nas\_fs -i sfs**

|                 |                                      |
|-----------------|--------------------------------------|
| vpfss21         | [Represents Save Volume on SFS side] |
| sfs_pvfs1       | [Playback Service]                   |
| sfs_pvfs1_ipfs1 | [IP Transfer service]                |

**TROUBLESHOOTING IP REPLICATION—RESTRICTIONS/LIMITATIONS:**

--Server Log, sys\_log, & /nas/http/error\_log

--Date on both Local and Remote Control Stations must be the same

--‘Passphrase’ passwords must also be the same on Local & Remote Control Stations

--Must use Celerra WebGUI to change Control Station Hostnames & Timezones for IP Replication to work

--PFS & SFS must be identical in size & use the same “slice” size

--‘Read Only server not found for pfs’ might mean that Checkpoint Volume was not correctly specified

--‘Replication Inactive’ in Server Log requires stopping replication service, adjusting Save Volume and Timeout/HWM values, and

restarting the Replication process—could occur if changed Data Size is greater than SavVol size  
 --Volume Pool is required for IP Replication  
 --Remote SFS must be created as “rawfs” to work [Converts to “uxfs” after FS\_Copy completes]  
 --IP Replication works for SYMMETRIX, FC4700, and CX600  
 --Backup SFS to tape if HWM=0 & TimeOut (to)=0 during replication  
 --CIFS IP Replication requires setup similar to a ‘migration’ [ie., lgdup, sharedup, etc]  
 --Can specify different DataMover to transfer Replication data to reduce loads on busy Production Servers  
 --Published Transfer rate on 510 DM is 10MBps [Actual rates may vary→Fast Ethernet=8-10MBps; Gigabit=25-30MBps]  
**Example:** At 1MBps, will take (10) hours to copy 36GB data  
 --IP Replication will become Inactive if the Delta Sets become bigger than the Save Volume  
 --Replication will fail if PFS & SFS are not identical, with “pfs size () is not equal to sfs size ()” error  
 --DataMover reboots or failovers should not stop ‘Replication’ process, though panics may result in need to start over  
 --PFS cannot be extended while running Replication Service

### **TROUBLESHOOTING IP REPLICATION ISSUES:**

```
# export NAS_DB_DEBUG=1
# export NAS_REPLICATE_DEBUG=1 [/nas/log/nas_log.al.tran | nas_log.al.trace | nas_log.al.remote]
# env |grep NAS_DB
NAS_DB=/nas
NAS_DB_DEBUG=1
#export NAS_REPLICATE_DEBUG=1 [turns on Debug; use 0 to turn off]
#echo $NAS_REPLICATE_DEBUG (Use to verify that variable has been exported)
```

**1**

**Note:** After setting debug mode, use nas\_fs -l to see if there are any \_pvfs or \_pvfs\_ipfs1 sessions, which would indicate that replication is running. Introduced with NAS 5.2

\$ .server\_config server\_2 “logsys set severity CMD-LOG\_DEBUG” →Cognac replication debug setting

# nas\_event -list -f VRPL

|    |                                                   |

### **EXAMPLE OF HIDDEN VOLUMES:**

**1.** # nas\_fs -i ckpt\_ebf1\_0041

```
id      = 392
name   = ckpt_ebf1_0041F
acl     = 0
in_use  = True
type    = ckpt
volume  = vp147
```

```
pool      = clar_r5_economy
member_of = [volume is hidden by default]
2. #NAS_REPLICATE_DEBUG=1;export NAS_REPLICATE_DEBUG=1
3. # nas_fs -i ckpt_efb1_0041
id      = 392
name    = ckpt_efb1_0041
acl     = 0
in_use  = True
type    = ckpt
volume  = vp147
pool    = clar_r5_economy
member_of = vfps104 [volume no longer hidden]
```

### **VOLUME POOL DATA:**

```
#.server_config server_2 -v "volpool display vol=285 detail"
```

```
2004-11-19 09:12:13: VRPL: 4: SuperBlockHeader ChunkSize=262144, NChunkInVol=7,
2004-11-19 09:12:13: VRPL: 4: NextChunkToAllocate=263168, NextVolGenCount=1,
2004-11-19 09:12:13: VRPL: 4: Allocate Mode=WRAP AROUND LastUsedChunk=263168.
2004-11-19 09:12:13: VRPL: 4: Header Bad:1024.
2004-11-19 09:12:13: VRPL: 4: Header Bad:1311744.
2004-11-19 09:12:13: VRPL: 4: Header Bad:1573888.
2004-11-19 09:12:13: ADMIN: 4: Command succeeded: volpool display vol=285 detail
```

**Note:** 285 = vol id of SavVol—command will also output details of Checkpoints, i.e., any volume in a VolPool

### **DISPLAYING SAVVOL INFORMATION FOR IP REPLICATION:**

```
# nas_fs -query:Type=uxfs:ReplicationState=source,destination -format:"%q" -fields:ReplicationSessions -query:* -format:"RepID=%s, SavVolID=%s, SavVolName=%s, SavVolSize(MB)=%s, SavVolSizeUsed(MB)=%s\n" -fields:Id,SrcSavVolID,SrcSavVolName,SrcSavVolSizeMB,SrcSavVolUsedMB
```

```

1106757497: RCPD: 4: rcp:: Target_num:0 Target_ip:10.241.169.58 Local_ip:10.241.169.54 Local_port:57694
1106757497: VRPL: 4: IPRepSender:: CurrentIPMailNum:5747 vol:134 ad:1024.
1106757497: VRPL: 4: IPRepSender:: QOS:0 kbytes/sec
1106757497: VRPL: 4: IPRepSender:: nextVolGenCount:1856687 lastVolGenCount:1856686
1106757497: VRPL: 4: IPRepSender::Audit() End
```

**`# .server_config server_2 -v "iprepsvc stat 34_APM000421031830000 vol=134"`**

1106757592: VRPL: 4: IPRepSender:: Stat() Begin.

1106757592: VRPL: 4: IPRepSender:: Stat() End.

**Note:** Displays the current State of the IP Replication Service—iprepsvc info is derived from Source data mover netd file

### **USING IPREPSVC TO RESTART IPREPSENDER SERVICE FOR REPLICATION:**

**`# .server_config server_2 "iprepsvc start 128_CK2000411006400000 vol=273"`**

### **USING REPLICA DISPLAY:**

```
$ .server_config server_2 -v "replica display srcvol=113"  
# .server_config server_2 -v "replica stat srcvol=113"  
# .server_config server_2 -v "volpool display vol=113 detail"
```

## **CLEANING UP VOLMCAST SERVICE ON DESTINATION AFTER UNSUCCESSFUL ABORT:**

```
#.server_config server_2 -v "volmcast delete 27 403_APM000426033100000 129"
```

**Note:** Or, comment out these lines in netd file and reboot server. Volmcast is the fs\_copy receiving service that runs on destination.

```
#.server_config server_2 -v "volmcast display 27 403_APM000426033100000 129"
```

```
#/nas/bin/nas_cmd@rootfs_ip -Remove fs_aspen_e_ipfs1
```

**Note:** Another method for deleting the Volmcast service on destination side?

## **BANDWIDTH PERFORMANCE SETTINGS:**

```
$ .server_config server_x -v "param IPREP qos=0"
```

**Note:** Default setting is 0 for unlimited bandwidth, but in practice needs to be set if multiple IP Replication sessions are being used.

## **INCREASING REDO LOG SIZE:**

### **Server Log Messages:**

RedoBuf should be extended or Config Vol to slow for vol:LF150

**Cause:** Frequency of writes to the PFS is more than the redolog can handle. The redolog keeps track of the changes to the PFS in case there is a Server reboot. To increase the redolog change the param VRPL nredobuf to 8 (default is 4)—requires reboot.

### **param VRPL nredobuf=8**

**Note:** This parameter is hidden in 5.4 and is only visible when you enter the actual param name—output below shows default and actual setting is 4. This parameter is only applicable on the SOURCE replication side.

```
$ .server_config server_2 -v "param VRPL nredobuf"
```

```
VRPL.nredobuf INT 0x01f0f4c0 44 (0,4294967295) FALSE REBOOT 'NA'
```

## **TAPE BACKUPS:**

→BackUp to tape from SFS using hwm=0,to=0 options while conducting BackUps

## **USING DRIVE OR TAPE BACKUPS TO SETUP DESTINATION REPLICATION:**

→Basic mechanics are to backup the initial Checkpoint of the production file system, and then restore to the destination file system (mounted as rawfs) from disk or from tape backup, aka tape-silvering (using NDMP)

→NDMP environmental variable must be VLC=y when backing up the initial checkpoint

→Restore the backup using the following format as the file system name (Volume ID of rawfs file system):

```
/.celerra_vol1_<#>
```

→Perform the Incremental copy using the following:

```
$ fs_copy -start Eng_User_ckpt2:if=ace0 Eng_User:cel=DR_Site:if=s2_fsn2 -fromfs Eng_User_ckpt1 -Force -option monitor=off
```

→Startup the replication session using the following:

```
$ fs_replicate -start deptvie:if=VIECIFSSV0002 deptvie:cel=BRICS1:if=BRICIFSSV0001 -tape_copy
```

## **USING THE TAPE TRANSPORT METHOD FOR REPLICATION V1 (Tape Silvering):**

### **Prerequisites:**

→Must have a valid NDMP infrastructure on Source & Destination Data Mover

→Restore operation requires rawfs file system of same size as Source, mounted on Destination Server

1. Take checkpoint of production file system

```
$ fs_ckpt fs1 -Create
```

2. Set the NDMP environmental variable that applies to the backup software in use

VLC=y

3. Backup checkpoint to tape

4. Transport tape to destination

5. Create destination file system as rawfs and same size as Source

6. Determine the rawfs file system volume ID using nas\_fs -list

7. Perform NDMP restore of checkpoint using following syntax:

```
/.celerra_vol_<fs_volume_ID>
```

8. Start Replication between Source and Destination

```
$ fs_replicate -start src_fs1 dst_fs1:cel=cs110
```

9. Create 2<sup>nd</sup> Checkpoint of Source file system

```
$ fs_ckpt fs1 -Create  
10. Perform incremental copy using fs_copy and allow Destination system to convert from rawfs to ufs  
$ fs_copy -start src_fs1_ckpt2 dst_fs1:cel=cs110 -fromfs  
src_fs1_ckpt1 -Force -option monitor=off  
11. Verify using fs_replicate -list
```

**Need following param set on destination side:**

```
PAX.allowVLCRestoreToUFS 0x01152350 0x00000001 0x00000000
```

```
# server_param server_2 -facility PAX -info allowVLCRestoreToUFS -verbose
```

```
server_2 :
```

```
name      = allowVLCRestoreToUFS  
facility_name = PAX  
default_value = 0  
current_value = 0  
configured_value =  
user_action = reboot DataMover  
change_effective = reboot DataMover  
range     = (0,1)  
description = Whether to allow VLC backup to be restored to UFS file system  
detailed_description
```

Specifies whether to allow VLC backup to be restored to UFS file system. Set it to 1 to allow VLC backup to be restored to UFS file system

## **DETERMINING FILE SYSTEM MAGIC NUMBER:**

```
# .server_config server_2 -v "file verify ufs 96"
```

```
1227108012: STORAGE: 7: opening volume 96, ref 2, ioObj e7fef704  
LVol:referenceInternal(96) refCnt=2, nVol=1  
LVol:referenceInternal(95) refCnt=3, nVol=1  
LVol:referenceInternal(93) refCnt=4, nVol=1  
LVol:referenceInternal(86) refCnt=5, nVol=0  
1227108012: STORAGE: 7: closing volume 96, ref 3, ioObj e7fef704  
1227108012: UFS: 6: filesystem_magic_number:[0x17-0x4919e393-0x0-0xd33b]  
1227108012: UFS: 6: filesystem creation time Tue Nov 11 19:57:07 2008
```

## **REPLICATION TRAFFIC:**

--Uses TCP only, with default ports set as 8888

### **NOT SUPPORTED FOR IP REPLICATION:**

--MPFS (5.3 supports running MPFS on Source side, but not on Target side)

--SRDF

--No Timefinder/FS or SnapSure Restore to PFS/SFS

--One-to-many IP Replication is NOT supported

--Non-built-in LocalGroups are not supported if using LGDUP from (1) Server to another—User permissions will be affected. Only built-in or Domain-wide accounts can be moved over while retaining User or Group permissions on PFS to RO copy of SFS

## **CELLERRA GPO (GROUP POLICY OBJECTS): NAS 5.0, 5.1 & higher**

Support limited to Kerberos Maximum Clock Skew information. GPO Daemon to run [gpod]. On startup of CIFS, Server will read GPO from cache file [/etc/gpo.cache] and then retrieve latest GPO settings from AD using machine account--refreshed every 90 minutes. GPOs are updated on CIFS Startup, every 90 minutes, & manually using \$server\_security command.

### **Commands:**

```
$server_security server_2 -i -policy gpo [Querying GPO settings for Server]
```

```
$server_security server_2 -update -policy gpo [Updating settings]
```

```
$ .server_config server_2 -v "gpo update server=mmc"
```

```
$server_security server_2 -i -p gpo server=compname [Settings for a specific compname]
```

```
$ server_security server_6 -i -p gpo
```

```
server_6 :
```

Server: peter1

Domain: t2dom3.local

Kerberos Max Clock Skew (minutes): 5

Group Policy Refresh interval (minutes): 90

GPO Last Update Time: Wed Feb 26 22:51:38 EST 2003

### **COMMENT ABOUT GPO QUERY MECHANISMS ON DATA MOVER:**

1. When using server\_security –update –policy gpo CLI commands, DART uses a MAC subsystem to get updates
2. When using MMC Snapins, an XML interface is used to get the updates
3. GPO's have become more commonly used to enforce certain domain requirements, especially since release of W2K3

### **ACCESSING WINDOWS GPO EDITOR:**

Start>Run>gpedit.msc>Group Policy Object Editor>Computer Configuration>Administrative Templates>DNS Client

### **GPO POLICY ISSUES:**

NAS code has experienced memory leaks with GPO option and sometimes requires turning off GPO with “param cifs gpo=0”, usually related to large size of user rights credentials. Disabling GPO reverts DM to default Kerberos Clock Skew of (5) minutes vs. whatever the normal Domain Policy value is set to.

Specifically, there is a bug in NAS 5.1 in which we did not correctly check for Expired Kerberos Tickets & flush from cache, particularly if we were making an LDAP query to the GPO and an update was already in progress--CIFS process would hang. Function being called is the “krb5\_cc\_retrieve\_cred”. Event can happen in domains where max lifetime of service ticket is shorter than max lifetime of a user ticket. Resolution is to disable the GPO parameters by setting to 0 for gpo=0 & gpocache=0.

### **IMPACT OF DISABLING GPO SETTINGS ON DM:**

The impact of disabling GPO is that the Data Mover will use a default of 5 minutes for the Kerberos maximum Clock Skew setting, instead of the domain assigned value. Since 5 minutes is the default (and used by most domains), this should not be an issue. DART cannot currently make use of any other GPO value other than Kerberos clock synchronization.

#### **GPO Parameters:**

**param cifs gpo=1** [Enabled by default; gpo=0 for off]

**param cifs gpocache=1** [Enabled by default; gpocache=0 to turn off]

**param cifs gpo.messages=1** [Messaging is not enabled by default--messages=0 for off; Set to 1 to start logging]

**Note:** Windows 2000 Group Policies are applied to Objects at the Site, Domain, and OU Levels, and can be thought of as policies that are applied to Computers and Users during system startup or User LogOn

### **DELETING & REFRESHING DM GPO CACHE ONLINE:**

1. Disable GPO Cache

\$server\_config server\_2 -v “param cifs gpocache=0”

2. Delete GPO Cache

# mv /nas/quota/slot\_2/.etc/gpo.cache gpo.old

3. Restart GPO Cache

\$server\_config server\_2 -v “param cifs gpocache=1”

4. Update GPO Cache

\$ server\_security server\_2 –update –policy gpo

### **QUERYING EFFECTIVE GPO SETTINGS:**

**\$ .server\_config server\_2 -v "gpocache mview\_dm2 dump"**

Enable

Defined Privileges: SeBackup, SeRestore, NetworkLogon,

## **CREATING GPO POLICY TO RENAME ADMINISTRATOR & GUEST ACCOUNTS:**

1. Admin Tools>ADUC>Properties>Group Policy>New><enter name for policy>: enter, close
2. Admin Tools>ADUC>Properties>Group Policy>Edit>expand Computer Configuration>Windows Settings>Security Settings>Local Policies>Security Options>doubleclick “Accounts: Rename administrator account”, check the “Define this policy” box, rename the account, click o.k.
3. Repeat above step to rename Guest account

## **EXPIRED KERBEROS TICKET PROBLEM: 5.1.9.4**

If DM uses expired Kerberos ticket, would panic—workaround is to set the following:

```
param cifs gpo=0
param cifs gpocache=0
param shadow stream=0
```

**Note:** May need to set above params in cases where DM continuously panics

## **ALTERNATE DATA STREAMS:**

- support introduced for up to 1000 streams per file
- no support for Streams on directories
- c:>more <testfile:stream[If alternate data streams exist, will see in output]
- Use the “lads.exe” tool to see Streams [www.heysoft.de/nt/ntfs-ads.htm]

## **Server Log Error:**

CFS:3: attempt to set a zero-length file stream name

Clients receive Semaphore timeout message

Error resulted after migration of files using EMCopy when a null stream is being sent to Celerra—locks all CIFS threads

## **Resolution is to Disable Streams Feature:**

```
param shadow stream=0
```

## **SNTP SUPPORT:**

- Implemented on DART as a client
- defacto ‘time’ standard for networks that must keep time synchronized

## **TIMESVC DEBUG LOGGING:**

```
"logsys set severity TIMESRVC=LOG_NOTICE"
"logsys set severity TIMESRVC=LOG_INFO"
"logsys set severity TIMESRVC=LOG_PRINTF"
```

“logsys set severity TIMESRVC=LOG\_PRINTF”

```
# .server_config server_2 -v "logsys get severity TIMESRVC"
```

(log level 4 is normal, non-debug mode)

1143254411: LIB: 4: Server log severity for facility TIMESRVC is 4

## **Testing SNTP Services:**

--tuna.us.dg.com/pub/dart/sntp: nptestsrv.pl—perlscript NTP test server utility

## **CIFS & NFS FTP:**

- Access to Celerra via GUI and CLI, respectively
- ftpd daemon runs by default on DM
- Time Out is 900 secs.
- For CIFS FTP, requires use of HomeDir Service running and configured on DMs

## **DART MAPPING RESOLUTION ORDER FOR USER/GROUP AUTHENTICATION:**

### **MAPPING RESOLUTION ORDER NAS 5.1 & BELOW:**

1. Global Data Mover Sid Cache (DART resolves Group SIDs and maps to GIDs)
2. Local Password & Group files (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
3. NIS Client Service (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
4. Active Directory Mapping Utility (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively)
5. UserMapper Service (External-only) (DART resolves by User/Group names to UIDs/GIDs, respectively)

### **MAPPING RESOLUTION ORDER NAS 5.2 & ABOVE:**

1. SecMap Persistent Cache [/etc/secmap] (DART resolves by Group/User SIDs and maps to GIDs/UIDs, respectively)
2. Global Data Mover Sid Cache (DART resolves Group SIDs and maps to GIDs)
3. Local Password & Group files (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)
4. NIS Client Service (DART resolves by User/Group names and maps to UIDs/GIDs, respectively)

5. Active Directory Mapping Utility (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively)
6. UserMapper Service (External or Internal) (DART resolves by User/Group SIDs and maps to UIDs/GIDs, respectively for Internal UserMapper, and by Name-to-UID/GID prior to NAS 5.2)

**Note:** Do not use uppercase characters in passwd files or NIS database—use lowercase ASCII for Celerra

## **CELERRA DATA MOVER MANAGEMENT TOOLS:** NAS 5.0 and higher

CNM—Celerra Native Manager [New interface to manage & perform limited operations on multiple Celerra Cabinets]

Celerra Web Manager→GUI interface to manage & configure Celerra File Servers on a single Celerra

Antivirus Management Snap-in to manage virus checking parameters, stop & start service

### **Prerequisites to using Celerra Home Directory Management Snap-in:**

1. Must have CIFS up and running
2. Must export the Top Level Share for the Home Directories
3. Set permissions on directories after creating
4. Snap-in can be used to associate a User with a Home Directory

Audit Policy Snap-in—Apply audit logging for DataMover Security Events

User Rights Assignment Snap-in—Manage Users or Groups with logon rights or privileges on DataMover

--JRE 1.4.0 Celerra Monitor

--Usermapper 3.0.5 for Windows Systems

## **CELERRA APPLICATIONS & TOOLS CD:** (Apps & ToolsCD)

### **CONTENTS & VERSIONS:**

**Note :** First introduced with NAS 5.0

#### **NAS 5.4.14.3:**

USERMAPPER: Version 3.1.1 [Actual versions are 3.1.4 for Linux & Solaris, with version 3.1.1 for Windows NT/2000]

CELERRA CIFS MANAGEMENT MMC SNAPINS: Version 4.00.003, Windows 2000/XP, NAS 5.4.0.5135 or higher

JRE 1.4.2 FOR CELERRA MANAGER/MONITOR: Version 2.3, NAS 5.1.12.0 +, supports Windows NT/2000/XP,Linux,Solaris

## **CELERRA CIFS MANAGEMENT MMC CONSOLE SNAPINS:**

### **Select Components:**

--Dart Management

- \* Antivirus
- \* HomeDir
- \* Data Mover Security Management (Audit Policy & User Rights Assignment)

--UNIX User Management

**Note:** Unix User management requires following param: **param cifs useADMap=1**

Celerra Installations that do not plan to use the ADMap Tool should ensure that this value is set to 0. User access issues could result if the AD Schema has not been extended and this parameter is set.

## **WINDOWS SNAPINS AVAILABLE AFTER INSTALLATION OF CIFS MANAGEMENT TOOLS:**

→[Programs>Celerra Tools>About Celerra CIFS Management](#)>Version information about packages installed

### **CELERRA UNIX USER MANAGEMENT:**

→[Programs>Celerra Tools>Celerra UNIX Attributes Migration>Celerra UNIX Attributes Source Location](#) : Migrate

Users/Groups from : \* Nis server : [Enter Info in Boxes : server name/address Domain name]

o Unix password and group files : [passwd file Browse group file Browse]

>[Celerra UNIX Attributes Users/Groups Migration](#) : Users Tab Groups Tab [select Domain by checkbox to add accounts to]

→[Programs>Administrative Tools>Celerra Management>EMC Celerra Management>Celerra UNIX User](#)

[Management>Select local or remote Domain in which to store UNIX attributes>Users or Groups](#) [add users/groups manually or by browsing to file—also delete users/groups from this GUI]

### **PURPOSE:**

With installation of Celerra UNIX User Management program, extensions are added into Active Directory “schema” that Customers can now use to centralize and manage Celerra UNIX Users or Groups—designed for “mixed mode” environments. Use these tools to assign, remove, or modify UNIX attributes for Users, Groups on local or remote Domains. Use Local Domain if only one Domain present, trusts not allowed, and there is no need to centralize UNIX User information further. Use Remote Domain if you have multiple Domains, bi-directional trusts, and want to centralize UNIX User administration.

**Note:** After importing Celerra UNIX users and groups into AD, customer no longer needs any other UID/GID mapping service—no Usermapper, no NIS database service, no local passwd & group files on data mover!

## **MANAGING CELERRA USERS OR GROUPS USING AD:**

→Users/Groups can be migrated or imported into AD from a NIS Server’s database, from source passwd and group files, and also individually from the extensions added into Active Directory for Users and Computers>T2dom3.local>Users>boyo>Properties “Celerra UNIX User” tab>Delete, Modify, or Add UID & domain GID mapping for User manually, or by browsing to NIS server or passwd file. Users/Groups can be added or deleted individually from Celerra Management>EMC Celerra Management>Celerra UNIX User Management>Users or Groups  
→Users/Groups can be deleted from the Celerra UNIX Management via Active Directory Users and Computers>T2dom3.local>EMC Celerra>User Mapper>Groups or Users>highlight users or groups and delete

## **CELERRA MANAGEMENT SNAP-IN TOOLS:**

### **Unix User Management:**

**Note:** **param cifs useADMap=1** [Requires param to work with AD]

### **Dart Management:**

- AntiVirus Management
- Home Directory Management
- Security Management

## **USER RIGHTS ASSIGNMENT CONSOLE:**

Programs>Administrative Tools>Celerra Management

→Celerra UNIX User Management

→DART Management: Antivirus; HomeDir; DART Security Settings (Audit Policy; User Rights Assignments)

### **Purpose:**

--Allows for management of Users & Groups’ rights on Celerra

**Note:** These rights cannot be managed via the Local Policy Setting GUI as is done on native Windows 2000 Servers

## **UNIX USER MANAGEMENT CONSOLE:**

### **Purpose:**

--Networks using only Windows Users will map SID’s to UNIX UID/GID’s for file system access

--Networks using mixed-mode Windows & Unix access will map to UNIX UID/GID’s

**Comment:** When Windows 2000 Users connect to Celerra, the DART queries the AD Server to see if User is assigned a UID/GID. It also queries Active Directory to determine what Windows Groups are mapped to UNIX GID’s

### **Tools: /nas/cifs/CelerraUnixUserMgmt.exe**

CIFS Migration Tool—Migrate UID/GID’s of Windows Users & Groups to Active Directory from NIS or Passwd Files  
Tool is run and Users & Groups are listed in tree format—an Administrator can then select which mappings get added to AD  
UNIX User Tool—Adds extension to Active Directory for Users so that UID/GID’s can be specified [local domain only]  
DART UNIX User Management—Manage Users & Groups from Local and Trusted NT Domains

## **I. INSTALLING CELERRA “UNIX USER MGMT” MMC:** Install on Windows 2000 Server

1. Installshield ‘Welcome to the installshield for CelerraUnixUserMgmt V1.01.002
2. License agreement Yes
3. Start Copying Files (Default Installation): C:\Program Files\EMC\CelerraUnixUserMgmt V1.01.002
4. Installshield wizard complete

**Note:** Creates MMC snap-in to Active Directory by adding a new tab called “Celerra UNIX User” under the properties for any ‘User’.

## **II. USING UNIX USER MIGRATION TOOL:**

1. Set following parameter for DataMover to enable Migration tool: NAS 4.2.5.2/NAS 5.0.9.2

**param cifs useADMap=1**

2. Start>Programs>Celerra CIFS Management>Celerra Unix User Migration

a.) Celerra CIFS Migration Tool

b.) Migrate Users/Groups from:

\* NIS domain: \_\_\_\_\_

o Unix passwd & group file

    Passwd File: [browse to select file]

    Group File: [browse to select file]

c.) The local domain’s Active Directory does not contain an attribute database for Celerra UNIX User management. Do you wish to initialize the local database? Yes No

d.) Select “local” on remote domain to store user accounts

    Unix User Domain

    \* Store UNIX user attributes in local domain. Share local attribute database with domains

    \* Store UNIX user attributes in a remote domain: [dropdown bar to select]

e.) Celerra CIFS Users and Groups [New Containers created under OU>EMC Celerra>User Mapper]

|                                                                                 |                  |
|---------------------------------------------------------------------------------|------------------|
| <b>Users</b>                                                                    | <b>Group</b>     |
| _x_NT_BIW_MASTER                                                                | _x_NT_BIW_MASTER |
| f.) ADUC>EMC Celerra>UserMapper>Groups/Users [List of Groups or Users migrated] |                  |
| g.) Also creates entry for CIFS output:                                         |                  |

**Active Directory usermapper's domain: “not yet located”**

**Active directory usermapper's domain: "not found"**

**Note:** Running the ‘Migration Tool’ creates a new ‘OU’ in Active Directory under ‘EMC Celerra’ called ‘User Mapper’, with (2) new Containers called “GROUPS” & “USERS”. Within these new containers are the Users and Groups that were migrated into AD, from either the NIS DB or other Passwd & Group files. Properties of Users or Groups in these ‘containers’ contain the following information: Domain Name; SID; UID or GID; and description—‘emc-com-usrMapperUser’.

**Purpose:** Allows for integrated mapping of UID/GIDs to DM on a per Domain basis in AD

**Prerequisites:** Run tool on AD Server at ‘Root/Parent Domain’ as User with Domain Admins and Schema Admins membership. If using NIS, NIS domain must be in same broadcast domain as AD Server—uses Ypbnd service. If using tool across multiple Domains or Trusted Forests, the Unix User Migration Tool needs to be installed in each Domain.

#### **EXAMPLE OF ACTIVE DIRECTORY TOOL IN PLACE:**

CIFS Server (Default) REX[T2DOM3]

Full computer name=rex.t2dom3.local realm=T2DOM3.LOCAL

**Active directory usermapper's domain: t2dom3.local**

Comment='EMC-SNAS:T5.1.9.4'

if=ana0 l=192.10.3.28 b=192.10.3.255 mac=0:6:2b:3:6a:65

FQDN=rex.t2dom3.local (Updated to DNS)

### **III. ADMINISTERING UNIX USERS:**

1. Start>Programs>Administrative Tools>Celerra Management

Celerra Management Tool>Celerra Management>Celerra UNIX User Management>\*NT\_BIW\_MASTER>Users/Groups>Properties

#### **UNIX User Attributes:**

**Username:** jcarr

**UID:** 33724

**GID:** 30000

**Note:** NAS 5.4 documentation says that you can only ‘manage’ these properties locally in the domain where they are located

### **NAS FEATURES & GA CODE:**

**Note:** Most information on NAS versions prior to 5.1 is archived

### **NAS 5.0: NOTABLE NEW FEATURES:**

#### **META FILESYSTEM SUPPORT:**

Introduces minimal support for "meta" FileSystems up to 32 TB—that is, taking multiple smaller filesystems & exported as (1) Meta to Clients [Purpose is to support easier FSCK maintenance & extends, which could be done on the individual smaller FileSystems]; FS will be comprised of 'cells' with a primary cell containing directory structure; User sees only (1) file system

#### **VirusChecking MPFS:**

Virus Checking support only on MPFS clients, not the DM, for HighRoad configurations

#### **CELLERRA IP REPLICATION:** Introduced 5.0 with RPQ

#### **DART NFS CLUSTERS:**

--Provides for Read/Write Sharing of FS to multiple Hosts

--Provides for Load Balancing and Bandwidth on demand

--Control Station Manages the “cluster”

#### **iSCSI SUPPORT:**

Block Services over IP as a replacement for direct-connect SCSI (no sharing or encryption), but is complex and requires more ‘Standards’ be developed; will facilitate HighRoad deployments; Gigabit-Ethernet Network will share data (SCSI over IP) and Metadata (MPFS) traffic, eliminating costly FC cards for each Server; Subject to ECC Management Control;

Support for Exchange Server using CIFS or iSCSI v. Direct-Attached Storage

Support for Snapsure and MPFS

#### **PERSISTENT BLOCK RESERVATIONS (PBR):** NAS 5.0.11.2

→The Persistent Block Reservation counter stores “reserved” block values in the Superblock structure

→During copy operations, the Data Mover will reserve the blocks required to complete the write, and also allows the system to recover after a Server reboot, since the PBR’s remain in the Superblock, until the blocks transition to “used”

→A file system can have Used, Free, or Reserved blocks

→A PBR is a per file system counter that reserves space for dense files, such that any write from offset 0 to EOF (End of File) will succeed even if there is no space left on the disk (i.e., uses its reserved space)

→The PBR feature was introduced to allow CIFS Applications to reserve space for files so that out-of-space errors do not occur [Unix systems use sparse-files by default while CIFS does not—this feature will allow CIFS to use sparse file semantics by reserving blocks of space for files to be written to]

### **PBR-SPARSE FILE SUPPORT TURNED OFF BY DEFAULT:** To Enable...

**param cifs createDenseFiles=1**

**param ufs createDenseFiles=1**

**Note:** Migration of sparse files supported by rsync

### **NAS 5.1 SUPPORT:** EOSL Aug 2005

--IPDART NS600 now supported

--CNM, WEB UI/Monitor, Secure NFS by RPQ only

### **DETERMINING BACKEND STORAGE SYSTEMS FOR NAS 5.1:**

**\$nas\_symm -l →nas\_symm -i serial#**

**\$nas\_storage -l**

### **NAS 5.1 FEATURES:**

#### **CONTROL STATION HTTPS & X509 SSL CERTIFICATES:**

HTTPS uses HTTP over SSL for secure communication over the network. For Celerra Control Stations, the expectation is that private internal customer networks are in use, where the use of public X509 certificates (Verisign, etc) are not required, and that self-signed certificates are adequate.

→CS uses HTTP over SSL to protect traffic using self-signed X509 certificates

→CS uses Apache, OpenSSL, and mod\_ssl to handle HTTPS traffic

**/nas/http/conf**

**/nas/http/conf/httpd.conf** (Apache config file) | **ssl.crt** (certificate) | **ssl.key** (RSA private key)

**/nas/sbin/nas\_config -ssl** [Use to create new certificate]

#### **CREATING NEW SSL CERTIFICATE ON CS:**

1. **# /nas/sbin/nas\_config -ssl**

Installing a new SSL certificate requires restarting the Apache web server.

Do you want to proceed? [y/n]: y

New SSL certificate has been generated and installed successfully.

**Note:** Script calls following perl script to actually change certificate and restart Apache Server

**/nas/http/nas\_ezadm/bin/gen\_ssl\_cert.pl**

2. Reboot CS—only sure way of getting Apache properly restarted

**Note:** New installs or Control Station replacements may require regeneration of Security Certificate

### **CELLERRA AVM (Automatic Volume Management):** Introduced NAS 5.1, ATA Support 5.1.18.3

AVM is a volume creation & management tool for ease of use when creating file systems and to provide performance best practices

**Note:** AVM is invoked when using Celerra Manager, or from the CLI if specified

**# nas\_fs -n fs04 -c meta04 size=<integer>[G|M] profile=profile**

#### **AVM & STORAGE TEMPLATES:**

--storage templates are not part of AVM, but work with them

--storage templates consist of definition files for creating LUNs from specific RAID types, and scripts which create RAID groups and bind LUNs

--storage templates are not used with SAN Gateway Arrays, only with Integrated Arrays

--storage templates for fibre channel disks create 2 LUNs per RG, one owned by SPA and the other SPB

--storage templates for ATA drives create 2 LUNs per RG, both owned by either SPA or SPB, supporting only RAID-5

### **CELLERRA STORAGE POOLS:**

Containers that hold storage for use by file systems, checkpoints, & other Celerra objects, for both system-defined & user-defined pools

#### **SYSTEM-DEFINED STORAGE POOLS:**

**symm\_std**

Highest performance and availability using Symmetrix STD disk volumes in RAID 1 configurations

**symm\_ata**

Highest performance at low cost using Symm ATA disks in RAID 1 configurations

**symm\_std\_rdf\_src**

Highest performance and availability using storage mirrored for SRDF sites or locally using TimeFinder/FS

**symm\_std\_rdf\_tgt**

Highest performance and availability using storage mirrored for SRDF sites or locally using TimeFinder/FS on R2STD disk volumes

**symm\_ata\_rdf\_src**

Highest performance and availability at low cost using mirrored storage to SRDF sites or locally using TimeFinder/FS on R1ATA

**symm\_ata\_rdf\_src**

Highest performance and availability at low cost using mirrored storage to SRDF sites or locally using TimeFinder/FS on R2ATA

**symm\_ssd**

High performance uses in 3+1 or 7+1 Raid5 configurations [DMX4 5773/5.6.37.x], not supported with TimeFinder/FS or SRDF

**clar\_r1**

High performance & low cost volumes using Clariion CLSTD from RAID 1 mirrored-pair disk groups

**clar\_r6**

High availability at low cost using CLARiiON CLSTD disks from 4+2, 6+2, or 12+2 RAID 6 disk groups

**clar\_r5\_performance**

Medium performance at low cost using CLSTD disk volumes from 4+1 RAID 5 disk groups

**clar\_r5\_economy**

Medium performance lowest cost using CLSTD disk volumes from 8+1 RAID 5 disk groups

**clarata\_archive**

Archival performance lowest cost using CLATA drives in RAID 5 configuration

**clarata\_r3**

Archival performance lowest close using LCFC, SATA II, or CLATA disk drives in RAID 3 configurations

**clarata\_r6**

High availability at low cost using CLATA disk volumes from 4+2, 6+2, or 12+2 RAID 6 disk groups

**cm\_r1**

High performance & availability at low cost. Uses CLARiiON CMSTD disk volumes from R5 4+1 for MView/S

**cm\_r5\_performance**

Medium performance & availability low cost. Uses CLARiiON CMSTD disk volumes from R5 4+1 MView/S

**cm\_r5\_economy**

Medium performance & availability lowest cost. Uses CLARiiON CMSTD disk volumes from R5 8+1 MView/S.

**cm\_r6**

High availability low cost using CMSTD disk volumes from 4+2, 6+2, or 12+2 RAID 6 disk groups for MView

**cmata\_r6**

High availability low cost using CMATA disk volumes from 4+2, 6+2, or 12+2 RAID 6 disk groups for MView

**cmata\_archive**

Archival retrieval only, using CLARiiON ATA drives in R5 for MView/S

**cmata\_r3**

Archival retrieval only at lowest cost, using CLARiiON ATA drives in R3 for MView/S

**clar\_ssd\_r5**

High performance using RAID 5 4+1 or 8+1 with (2) luns

**cmssd\_r5**

High performance MView volumes using RAID 5 4+1 or 8+1

**User-Defined Storage Pools:**

Can create User-defined pools from Celerra Manager, but are based on single disk type

**DISK TYPES:**

CLSTD—standard CLARiiON disk volumes

CLATA—CLARiiON ATA volumes

STD—standard Symmetrix disk volumes

R1STD—Symmetrix FC disk volumes used for mirroring storage as in SRDF, etc.

R2STD—“

ATA—standard symmetrix disk volumes built on SATA drives

R1ATA—Symmetrix SATA disk volumes for mirroring storage as in SRDF, etc.

R2ATA—“

**TWO TYPES AVM PROFILES:**

Volume Profiles—defines how disk volumes are aggregated and placed into a pool, applies only to system-defined pools

Storage Profiles—description of disk volumes, used by a volume profile, matches disks to a certain expected disk type, system-defined pools

**AVM POOLS:**

- Containers for Volumes with similar characteristics [can consist of disks, stripes, slices, metavolumes]
- Association between pools and profiles
- A volume can only be a member of a single pool
- Pool members must be of the same device type

**System-defined Storage Pools vs. User-defined Storage Pools**

|                                     |                                                         |
|-------------------------------------|---------------------------------------------------------|
| Volume Profiles predefined          | No Volume Profile                                       |
| Dynamic, but can be disabled        | Not dynamic, user must create and populate storage pool |
| Storage added/removed automatically | Storage added or removed manually                       |

**Comment:** NAS 5.2.9.6 calls the “profile” a “pool”: pool=<pool> and the pool options are the same as with NAS 5.1. System-defined pools use default 8k stripe size

**ABOUT AVM:**

- Automatic creation and deletion of volumes during file system operations—rule set for defining a “pool of storage”
- Pools are made from profile disk volumes
- Requires creation of rule set called a “profile” that defines a “pool of storage” in order for WEB UI to be able to administer FS
- AVM is invoked for either Symmetrix or Clariion BackEnds by Web UI, by CheckPoints, and by CLI when creating FS using “size” and “profile” parameters
- Clariion uses disk drives in pairs for “profiles”—one for each SP
- Disk Volume profiles, RAID type, and spindle counts must match

**Note:** AVM automatically claims volumes—in order to keep a reserve of volumes, might need to create stripes/metis via CLI

**AVM BACKEND ENHANCEMENTS NAS 5.4:**

- More flexibility in creating Raid Groups and configurations
  - Setup\_clariion script for user-defined templates, used only for Integrated Systems
  - Mixed shelves of different RAID configurations [such as RAID1 for Logs and RAID5 for tablespace for Oracle solutions]
  - Script will prompt for template to use when adding new enclosure
  - New RAID 3 configuration for Backup-to-Disk (B2D) ATA solutions [clarata\_r3]
  - AVM to prevent creation of file system that spans multiple arrays
- Note:** GUI will warn, CLI does not
- Extend System pool by size
  - Extend User pool by volumes
  - No mix of RAID 3 & RAID 5 on same shelf

**CREATING FILE SYSTEM FROM WEBUI USING AVM PROFILE:**

\$ nas\_fs -n fs09 -c size=32 profile=clar\_r5\_economy -o slice=y, mover=server\_2 [32=32GB]

**Note:** Profiles are a set of rules to aggregate storage

# nas\_fs -name cdms -type uxfs -create size=50000M pool=clar\_r5\_performance storage=SINGLE  
worm=off -option slice=y,mover=server\_2 (NAS 5.4)

**CREATING FILE SYSTEM FROM CLI USING AVM PROFILE:**

\$ nas\_fs -n fs10 -c size=10G profile=symm\_std -o slice=y, mover=server\_2

**Note:** Can also create Checkpoints using the AVM rules set. Do not need to specify “slice=y”—this will create a file system by striping (4) d volumes into a meta. When using “slice=y”, AVM creates stripes first, then metas, then slices, metas again, then creates the File System.

# nas\_fs -name migrate -create size=1000M pool=clar\_r5\_performance -o slice=y

```
id      = 63
name    = migrate
acl     = 0
in_use  = False
type    = uxfs
worm   = off
volume  = v203
pool    = clar_r5_performance
member_of = root_avm_fs_group_3
rw_servers=
ro_servers=
rw_vdms =
ro_vdms =
stor_devs = APM00040303779-0011
disks   = d8
```

## # nas\_fs -s migrate

total = 1000 (sizes in MB) ( blockcount = 2048000 )

## WEB UI LIMITATIONS:

- cannot extend filesystems
- cannot setup 32-bit GIDs
- cannot setup Quotas
- cannot export with “anon=0” option
- when setting up default network route, must use 0.0.0.0 in “Destination” field!
- File Systems created from CLI cannot be managed with this interface [Requires AVM profile ]

## TROUBLESHOOTING HTTPD FOR WEB UI:

1. Grep for process: **#ps -awlx |grep httpd** [Shows complete path of service]
  2. Kill processes: #pkill -9 12543 [Should kill all httpd processes]
  3. Check to see if CS is listening on Port 8000: #netstat -alp
- | PID/Program Name          | State |
|---------------------------|-------|
| tcp 0 0 *:8000 *:* LISTEN |       |
4. Restarting HTTPD daemon: **#/nas/sbin/httpd -D HAVE\_PERL -D HAVE\_SSL -f /nas/http/conf/httpd.conf** [NAS 5.1.9.4]

## CELERRA SECURE NFS IN NAS 5.1:

**Overview:** Secure NFS provides Kerberos-based User and Data authorization & is designed to provide strong authentication using secret-key crypto. The service allows a Client process to prove its identity without sending User information across the network. It further assures the identity of sender and recipient. Clients must run Sun Solaris 5.8 or Hummingbird Version 7 to support Kerberos. Celerra uses RPCSEC\_GSS & Kerberos protocols and runs only with NFS over TCP.

## NFS CLIENT SUPPORT FOR SECURE NFS:

- Supported by SUN Solaris 8, 9, 10 using SEAM v1.01 [SUN Enterprise Authentication Mechanism]
- Supported by Hummingbird Maestro v7.2

## OTHER INFO:

- RPQ Only for NAS 5.1
- SecMap caching can be used with SecureNFS, beginning with NAS 5.2
- NFS User and data authentication via RPC calls using Kerberos 5 RPCSEC\_GSS framework and NFSv3 over TCP/IP
- Security services are AUTH\_SYS (UID/GID) & RPCSEC\_GSS (API)—sys and krb5 for SecureNFS
- Single Kerberos REALM only for Secure NFS
- KDC Server runs (2) Services and contains the encrypted database of principals and keys
- AUTH\_SYS or AUTH\_UNIX—authentication via UID/GID [Server assumes this info passed to it is correct]
- AUTH\_DH—DES key exchange
- AUTH\_KERB4—Kerberos version 4 DES key exchange
- RPCSEC\_GSS—Generic Security Services API—encryption of user credentials and data

## Keys:

- User Key is 1-way hashing of User password
- Service key from random or known password
- “Principal” is any User or Service that is using the KDC Service [username@t2dom2.com; nfs/server,t2dom2.com@t2dom2.com]

## How Does Secure NFS Session Work?

1. Client contacts KDC for session ticket
2. KDC replies with two messages encrypting first with User’s Key & second with NFS Server’s Key
3. Client decrypts and stores Session Key and replies to Server with new message verifying identity
4. Server stores Session Key and validates Client’s identity

## Security Options Available:

- sys [Default implementation--no authentication or encryption performed by Server—Client supplies credentials]
- krb5 [Server requires authentication through Kerberos—EMC’s implementation of SecureNFS]

## Unsupported:

- krb5i—RPC Data Checksum header ensures data integrity
- krb5p—Encrypting data before sending to Client to ensure data integrity
- Windows 2000 Kerberos Server NOT supported for SecureNFS

## CONFIGURING SOLARIS 2.8 FOR KDC SERVICES:

- Install SEAM v1.01 using custom install option
  - Install KRB5 encryption package [Solaris uses KRB4 by default]
  - Configure DNS & NTP
1. Setup the /etc/krb5/krb5.conf file with Principal Hosts & REALM name
    - /usr/krb5/sbin/kdb5\_util create -r HOSTS.PVT.DNS -s [libdefaults]

```
default_realm=HOSTS.PVT.DNS
[realms]
HOSTS.PVT.DNS = {
    kdc=sun1.hosts.pvt.dns
    kdc=sun1.hosts.pvt.dns
    admin_server=sun1.hosts.pvt.dns
    default_domain=hosts.pvt.dns  }
[domain_realm]
.hosts.pvt.dns=HOSTS.PVT.DNS
hosts.pvt.dns=HOSTS.PVT.DNS
```

### **Windows 2000 Note:**

SecureNFS requires setting up of Sun KDC Realm before setting up Windows 2000 CFS Server

2. Edit /etc/krb5/kadm5.acl file

**#\*/admin@HOSTS.PVT.DNS\*** [comment out so that all Admins do not have KDC privileges—first \* indicates any Admin]  
**szg30/admin@HOSTS.PVT.DNS\*** [Last \* indicates All Permissions]

3. Add Passwd for Kerberos Administrator to Keytab file: /usr/krb5/sbin/kadmin.local

4. Add Principals using “ktadd system1” or “ktrem system2”

(Use ‘kadmin’ utility to create keytab entries for all NFS servers)

#kadmin -k krb5.keytab nfs/dm3.pvt.dns

5. Start KDC daemon: /etc/init.d/kdc start

/etc/init.d/kdc.master start

6. Create gsscred\_db database for User Credentials: Maps UID/GID to Users

#gsscred -m kerberos\_v5 -a [creates db using all Users from /etc/passwd file]

#gsscred -m kerberos\_v5 -u 71 -r [Remove UIDs of System Users, etc from db]

#gsscred -m kerberos\_v5 -n root/yucca.pvt.nds -u 0 -a [Create gsscred for root of each host]

#gsscred -l

7. Reviewing NFS or ROOT Principals;

#kadmin: listprincs nfs\* llistprincs root\*

### **Key Directories & Files:**

/etc/krb5            /var/krb5

kpropd.acl [Key propagate ACLs for KDCs]

kdc.conf file: kdc\_ports = 88, 750

#kutil: read\_kt /etc/krb5/kadm5.keytab [Read Keytab files]

#kutil: read\_kt /etc/krb5/krb5.keytab [Principals with Keytab entries]

### **TroubleShooting SecureNFS:**

→Increase DM logging, Verify NTP service, Verify DNS service, Verify principals & keytab entries, Verify gsscred\_db, take snoop traces, Verify that Realm name matches KDC name

#kdestroy [destroys logged in User’s KDC ticket]

#kinit [regenerates new KDC ticket for user]

#klist [Ticket cache]

\$server\_config server\_3 -v “gsscred list” |grep quota3 or \$server\_config server\_3 -v “gsscred -l”

\$server\_config server\_3 -v “rpcgssctl statserv prog=100003 vers=3 all”

\$server\_config server\_3 -v “rpcgssctl showclnt prog=100003 vers=3 handle=2”

### **USING GSSCRED:**

**Note:** Creates mapping between security principal name and local unix User ID

**# gsscred -m kerberos\_v5 -a** [Creates credentials for all users located in /etc/passwd or NIS DB]

# gsscred -m kerberos\_v5 -n root/dm3.realm.com -u 0 -a [Adding credentials for root user of Client]

# gsscred -m kerberos\_v5 -n username -u 1400 -r [Removing credentials for a User]

### **CONFIGURING SECURENFS ON CELERRA:**

1. Data Mover name must match DNS Name

2. Setup NTP Service on DM

3. Setup NIS Service on DM [or use local Passwd/Group files]

4. Setup DNS Service on DM

5. Add Kerberos Realm to DM:

\$server\_kerberos server\_2 -add

realm=t2dom2.com,kdc=sun.t2dom2.com,kadmin=sun.t2dom2.com, domain=t2dom2.com, defaultrealm

6. Add Service Principal Names to Control Station:

```
$server_kerberos server_2 -kadmin -p root/admin@sun.t2dom2.com
7. Generate Keytab File on Sun Server: #ktadd nfs/server_3.t2dom2.com
8. Generate Kerberos Principal to UID Map: gsscred -a -m [Adds entries to NIS table]
$fncreate -t org -o org/
$vi /etc/gss/gsscred.conf [Add line: xfn_nis]
$gsscred -m kerberos-v5 -a
$gsscred -n krbusr1 -u 5000 -c "kerberos user" -m kerberos_v5 -a
9. Upload Keytab and Gsscred Map: $server_kerberos server_3 -p krb5.keytab krb5.keytab lgsscred_db gsscred_db
10. Export File System for SecureNFS: $server_export server_3 -o sec=krb5:root=clients,sec=sys:ro /fs211. Remote Mount to Solaris: #mount -f nfs -o sec=krb5 server_3:/fs2 /mnt
12. Access Filesystem as valid user $klist
Note: Minimum files on DM: ./etc/gsscred_db ./etc/krb5.keytab
```

### **KRB5 SECURITY OPTIONS FOR SERVER EXPORT:**

ro, rw=, ro=, root=, access=

### **TROUBLESHOOTING SECURE NFS ISSUES:**

- Increase Server Logging
- Verify NTP & DNS setup
- Verify principals, gsscred\_db, and keytab entries
- Verify realm names match KDC

#### **DNS Domain Configured Incorrectly:**

RPC: 3: RpcGssServer::acquireCred:gss\_import\_name ([name=nfs@dm2,type=13089288](#)) failed  
RPC: 3: GSS-API major error: An invalid name was supplied  
RPC: 3: GSS-API minor error: Configuration file does not specify default realm

#### **Wrong Principal in Request:**

RPC: 3: RpcGssClient::accept:gss\_accept\_sec\_context failed  
RPC: 3: GSS-API major error: Miscellaneous failure  
RPC: 3: GSS-API minor: Wrong principal in request

#### **Uname Problem:**

User authenticates to NFS Server but new files do not contain UID/GID

Solution: Update gsscred database or NIS/Passwd files

SECURITY: 3: Access\_GsscredDatabase::interpret: No uname found for uid 5000

#### **Permission Denied:**

Expired Kerberos credentials; NTP Time is off; DNS Entries not setup properly; Kerberos not setup correctly

#### **Kadmind Daemon Not Running:**

#/etc/init.d/kdc.master start

#### **SUN Tools:**

\$kutil

\$klist; kinit; kdestroy

\$/usr/krb5/sbin/kadmin

### **NAS 5.1 LIMITATIONS:**

- SRDF not supported for NS600 BackEnd
- TimeFinder/FS or R2 Backup not supported for NS600
- HighRoad enhancements for CAVA & Snapsure not supported for NS600

#### **LOG CHANGES & CALLHOMES:**

```
/nas/log/nas_rdf.log [New Log]
/nas/log/ERRSFILE.LOG & ERRSFILE.LOG.old [Call Home Files for NS600]
#cat /nas/log/CH*
/nas/var/log/log_config_unknown_021201040012.gz
```

### **NAS 5.1M BEST PRACTICES & PERFORMANCE TUNING FOR CLARIION BACKENDS:**

- When possible do not extend File Systems on same spindles
- Set Clariion stripe size to 8kb, Set Symmetrix NFS stripe size to 32kb and CIFS stripe size to 8kb, HighRoad to 256kb
- Do not stripe file systems across two LUNs from same RAID group
- Stripe multiple DAE2 file systems across LUNs of same RAID type and configuration
- Never build file systems directly on Symm metavolumes or stripes, always use Celerra Stripe volumes
- HighRoad and NFS workloads, use 16 volumes in each stripe set
- Ensure two LUNs are bound for each RAID group

--RAID 1 has better performance than RAID 5, though optimal RAID 5 performance is using 4+1 R5 LUNs

--Increase NFS threads in heavy workload environments from 192 to 512

#vi /nas/server/slot\_x/netd

### **nfs start openfiles=44032 nfsd=512**

--Write Intensive Environments, disable Level 2 Oblocks

### **param cifs capabilities=0xA379**

--Configure Read Cache after code upgrades using:

#/nas/sbin/setup\_backend & #nas\_raid cache configure [32-256MB]

### **2GB Memory per SP:**

Recommended Write Cache allocation—1465MB

Recommended Read Cache allocation—32MB

### **4GB Memory per SP:**

Recommended Write Cache allocation—3072MB

Recommended Read Cache allocation—146MB

--Bind LUNs with following parameters to maximize cache

-rc 1 [enables read cache on LUNs]

-wc 1 [enables write cache on LUNs] -wc 0 [disables write cache]

-aa [adjusts auto assignment value, used in failover; -aa 0 for NS600 & -aa 1 for Celerra/CX600]

--Tune CIFS threads if required

--Enable preallocation for CIFS to preallocate space before writing to new files [**param cifs prealloc=6**]

--Tune asynchronous I/O on Clarion

**param cfs closeDelay=30**

**param cfs deleteDelay=1**

**param cfs maxPendingClose=127000**

**param file secureReadSide=1**

--Solaris Client Mounting for NFS Operations using NFS v3 with TCP

**\$mount -o vers=3,proto=tcp,rsize=32768,wszie=32768 192.10.0.111:/fs01 /mnt**

--Solaris 2.7/2.8 Tuning [Add to /etc/system and reboot]

**set nfs:nfs3\_nra=8**

**set nfs:nfs3\_max\_threads=32**

--Adjust write flush parameters on Solaris

**\$echo "flush\_freq/Z 0" |adb -kw [Turns off flushing for better write performance]**

**\$echo "flush\_freq/Z 800000" |adb -kw [Optimal setting for most environments]**

**\$echo "flush\_freq/Z 1000000" |adb -kw [Sets flush frequency at 16M]**

--Linux Client Mounting for NFS v3 using TCP

**\$mount -o nfsvers=3,tcp,rsize=32768,wszie=32768 192.10.0.111:/fs01 /mnt**

--Linux Client Tuning for Read-Ahead threads

**\$echo 8> /proc/sys/vm/min-readahead**

**\$echo 256> /proc/sys/vm/max-readahead**

## **WINDOWS 2003 SUPPORT LIMITATIONS—see Primus emc77391:**

**SMB Signing:** Problem with Windows 2003 & SMB Signing involved with use of Kerberos tickets, frequently seen as failures to ‘Join’ the domain. Only NAS 5.1.18.8, with mods referenced here, can interoperate with Win2K3 DC’s for Windows 2003 domains.

### **NAS 5.2 provides native support for SMB Signing:**

→Disable GPO Settings [Security Settings>Security Options]

→Digitally sign communications (always) [disable]

→Digitally sign communications (if client agrees) [disable]

**Group Policy Objects:** Disable in Windows 2003 domains

→Add following param to data movers: **param cifs gpo=0**

**Dynamic DNS:** Authenticated Updates are not supported in Windows 2003

→Disable Dynamic DNS or Enable Non-Authenticated DNS Updates

**param dns updateMode=0** [If the choice is to disable Dynamic DNS]

DNS Zone>Properties>General Tab>Change “Allow Dynamic Updates?” to “Yes” for non-authenticated updates

### **DNS With Top Level Zones:**

Top Level zones are used if the Windows Domain is a single word domain, such as in “EMC.COM”. In Domains of this type, Celerra must have GPO enabled to allow for updates to the Top Level Domain Zones:

GPO Editor>Administrative Templates>Network>DNS Client>Update Top Level Domain Zones

## **NS600 PEER POWER CONTROL: NAS 5.1.10.0 +**

**Support:** NAS 5.1.4.0; Hidden CS utilities added 5.1.6.0; Complete CS reset commands added 5.1.10.0

### **Purpose:**

Cycle, shutdown, or restore power to panicked or hung DM via a peer datamover when serial or network connections won't work.

Allows for reset and powerdown of DM's connected to NS600 from CS

Allows Control Station to issue reset commands & obtain getreason for DMs over Serial path if network path not working

**Note:** Traditional Celerra Cabinets have more hardware controls built-in, so this will solve the problems for NS600. NS600 has only a single Network & Serial connection to DM

### **Prerequisites for Using Peer Power Control:**

NS600 DM boards that support this feature—Calandor2 boards [Peer Power Control is using additional hardware & SW to perform]

Peer DM must be at reason code 4 or 5

Requires use of either Serial [DART Console] or Network [XML] connection to DM

Underlying connection is made using Telnet, therefore make sure that DNS is correctly setup in /etc/resolv.conf

**Note:** HTTP XML MAC interface is replacing the traditional RPC Client-Server protocol

## **SERIAL LINE COMMUNICATION BETWEEN CS & DM:**

**\$ /nas/tools/.server\_tty -c 2 “peer\_powerctrl action=reset”**

**Note:** .server\_tty are an older set of commands, no longer supported with 5.5

**\$ /nbsnas/tools/.server\_peer\_powerctrl**

**Note:** Current method of running Peer Power Control Commands

**XML Command Interfaces:** Conducted over HTTP—don't know how to invoke this interface with NAS 5.5

checkPowerctrl [Verifies whether peer power control hardware is present]

isPeerDMInserted [DM inserted]

rebootPeer [Cycles power to peer data mover]

shutdownPeer [Shutdowns power to DM]

restorePeer [Restores power to DM]

### **Typical Peer Power Management Configuration Commands:**

**\$server\_cpu server\_x -reboot | -halt now**

**\$t2reset pwroff | pwrone | hldrst -s 2 | rlsrst**

recover\_slot

install scripts

**Note:** CS processes peer power control commands over XML network interface or serial DART Console. A reset command first performs a network shutdown over the mac\_shutdown interface, then issues CS code to shutdown hardware

## **USING PEER POWER CONTROL COMMANDS:**

**#/nbsnas/tools/.server\_peer\_powerctrl**

.server\_peer\_powerctrl <-chkhw | -chkins | -reboot | -shutdown | -restore> <slot>

**Note:** Commands are not useable on NSX systems

**/nas/tools/.server\_peer\_powerctrl -chkhw 2** [verifies that peer power control hardware is present in slot\_2]

**/nas/tools/.server\_peer\_powerctrl -reboot 2** [Reboots server\_3]

**/nas/tools/.server\_peer\_powerctrl -chkins** [checks to see if peer power control hardware is present]

**Note:** No output indicates that all is well

**# /nbsnas/tools/.server\_peer\_powerctrl -chkhw 4**

host 192.168.1.4 is not responding! Is it up??

.server\_peer\_powerctrl: Data Mover server\_4 is not responding

**Note:** There is no physical server in slot\_4 in the above example

**/nas/tools/.server\_peer\_powerctrl -chkins 2 | 3** [checks to see if peer DM is inserted]

**/nas/tools/.server\_peer\_powerctrl shutdown** [powers off DM]

**/nas/tools/.server\_peer\_powerctrl -restore** [restores DM power]

**Note:** Peer power control commands use HTTP/XML to perform tasks and telnet to create communications link. Be aware that if DNS configurations are incomplete or wrong, telnet, and therefore peer power control commands may fail—see example:

**# /nas/tools/.server\_peer\_powerctrl -chkins 3**

host server\_3 is not responding! Is it up??

.server\_peer\_powerctrl: Data Mover server\_3 is not responding

## **USING T2TTY COMMANDS—Serial or RPC communications between CS & DM:**

→The t2tty facility can be used to communicate to the Data Mover, from the Control Station, using either Serial communication, or Internal Network interface using RPC (RPC would be only facility available for NSX, NS40, or NS80 systems—no Serial connections)

→t2tty facility can be used to test Serial connections on system, and the IPMI connection between CS0 & CS1

### # /nasmcd/sbin/t2tty -n

2 →Indicates two active serial connections (i.e., Data Mover 2 and Data Mover 3)

Note: Used to count the active Serial connections for ttyS4 – ttyS9

### # /nasmcd/sbin/t2tty -t

ttyS4 on

ttyS5 on

ttyS6 off

ttyS7 off

Note: Used to check state of Serial connection for Serial ports

### # /nas/sbin/t2tty -s 3

Slot-3 (ttyS5) on

### # /nasmcd/sbin/t2tty -m 192.168.3.101

IPMI Ping to 192.168.3.101 Succeeded

Note: Use to check state of IPMI connection between CS0 & CS1

→t2tty facility can also be used to initiate a Flash upgrade of the Data Mover BIOS/POST

Flash Data Mover in slot (2-5) with image file(s) (BIOS and/or POST) -F forces overwrite, disregarding version numbers

### # t2tty -f 2 image\_file {image\_file}

→Use t2tty to force PXE boot of Data Mover

### # /nasmcd/sbin/t2tty -p 2

## EXAMPLES:

### RPC METHOD:

#### # /nasmcd/sbin/t2tty -C 2 "ifconfig" →Uses RPC to send & receive output from DART to Control Station

Note: For NSX Systems, the RPC interface allows upper or lowercase: -c “ifconfig” or -C “ifconfig”

### SERIAL PORT METHOD:

#### # /nasmcd/sbin/t2tty -c 2 "logsys add output console" →Uses Serial communication between DART & Control Station

#### # /nasmcd/sbin/t2tty -c 2 "ifconfig"

#### # /nasmcd/sbin/t2tty -c 2 "logsys delete output console"

Note: Make sure to change output to console or the “ifconfig” command will not produce expected output on screen. Make sure to delete the output to console after you are done using t2tty. May want to consider just using -C for the RPC method.

### /nas/sbin/t2tty or /nasmcd/sbin/t2tty

Celerra\IP Serial Connection Tester....

Usage:

Check serial connection signal on ttyS4 thru ttyS9

t2tty -t

Check serial connection signal to a given slot (2-5)

t2tty -s 2

Force Data Mover in slot (2-5) to PXE boot

t2tty -p 2

Send dart command "cmd" to data mover in slot (2-5)

t2tty -c # "cmd"

for example: t2tty -c 2 "ifconfig"

### # /nasmcd/sbin/t2tty -c 3 "camshowconfig"

camshowconfig

CAM Devices on scsi-32:

## **OUTPUTTING INFORMATION TO CONSOLE USING T2TTY COMMANDS:**

**Note:** Changing Server output to local console allows t2tty commands to output to screen.

**# /nasmcd/sbin/t2tty -c 2 "logsys add output console"**

**CONSOLE>**

**# /nasmcd/sbin/t2tty -c 2 "logsys delete output console"**

**Note:** Run this command after running t2tty commands to delete output to console

**# /nas/sbin/t2tty -c 2 "ifconfig" "ifconfig 192.168.1.2 down" "ifconfig 192.168.1.2 up"**

reason\_code=05

ifconfig

**# /nasmcd/sbin/t2tty -c 2 "logsys delete output console"**

## **CELERRA NAS 5.2:**

NAS 5.2.9.6 GA February 9, 2004; Supports the CNS-14, CFS-SE systems, Celerra NS family and Celerra NS-G (direct and switched connections) family products. Current revision 5.2.22.1. EOL announced as February 28, 2006 for this code family.

### **Caution:**

Be aware that NAS 5.2.15.3 conducts automatic conversion to MPD format on all file systems and changes directory last modified times. Also, this revision supports FLARE 14.

### **Requirements:**

--Symm microcode 5267.42/52.29 Symm 4.0/4.8; 5568.62.23 for Symm 5.0/5.5; 5669.48.25/5670.26.28/5670.66.62 for Symm 6.0

--Flare 8.50/8.51 for FC4700; 2.05.1.60.5.xxx or 2.06.400.5.xxx for CX400; 2.06.500.5.xxx for CX500; 2.05.0.60.5.xxx for

NS600/600S & 2.05.1.60.5.xxx for NS600G/700G & 2.06.600.5.xxx; Flare 2.06.700.5.xxx for CX700

### **Limitations:**

--Supports only Flare 12 & 13 for Clariion backends!

### **Features:**

--Internal Usrmapper

--Introduces Multiprotocol Directories (MPD—DIR3) that will replace the old Shadow file directory format

--Windows 2003 Domain support, SMB Signing, Dynamic DNS Updates, GPO Policies, Kerberos over TCP

--NDMP Version 4 support

--SYR support

--ADS support for directories

--GPO, NFS Security, UNIX ACL tool, CDMS, CIFS Replication, SnapSure, virtual DM for CIFS, enhancements

--Introduces NS630 with 3Ghz Pentium 4 and 533 Mhz Front Side Bus, 4GB RAM

--Supports Clariion with Flare 12 and 13 [Flare 11 or lower is not allowed]

### **NAS 5.2 SUPPORT:**

CFS-14; CFS-SE; NS600/G ; NS700/G and higher requires 5.2

## **NAS 5.2 BOOT OPTIONS FOR INSTALLS, UPGRADES**

--Ability to conduct ‘unattended’ installs and upgrades via the use of a ‘kickstart’ or ‘serialkickstart’ command and the “ksnas.cfg” file

### **BOOT OPTIONS:**

Install

Serialinstall

Kickstart [Run d:\setup -f ksnas.cfg for Golden Eagle from Service Laptop CD-ROM]

Serialkickstart [Use for NS600 unattended installs]

**Note:** CFS-14 Eagle, SE, NS600, NS600G, NS700, or NS700G will require editing of ‘ksnas.cfg’ file on the boot floppy, whereas the CNS-14 Golden Eagle requires editing of ‘ksnas.cfg’ file from the install CD-ROM onto a c:\Temp directory on the service laptop.

D:\NetworkInstall>setup -f ksnas.cfg

## **CONTROL VOLUME CHANGES:**

From NAS 5.2.7.0 and higher, all new installs will require a size change from 4G to 11G on the first two Control Volumes [Captive Clariion backend control luns will remain same until next release of 5.2 and then this will be auto calculated. Clariions on SAN will require manual configuration]. Purpose of this change was to allow for more room for the Internal Usrmapper database.

## **ASYNC DATA RECOVERY FOR CELERRA REPLICATOR:**

Allows use of replication between file systems for disaster recovery by allowing failover/failback with incremental resyncs and baseline checkpoint on SFS. CIFS is supported with Virtual Data Mover module to transfer Share ACLs, Usrmapper database, GPO, AV, local groups, and password file information. DR means that Primary site goes down, Secondary site is activated and SFS can be made Read/Write. Then, when Primary is back online a resync operation occurs without making full copies of filesystems necessary and replication can be re-established.

## **INTERNAL USRMAPPER:**

Usermapper automatically starts and runs on Server\_2 for new installations. No manual configuration required and other data movers will discover the Usrmapper service via broadcast over the internal IP network. External Usrmapper configurations can also be migrated, or imported, to an Internal Usrmapper configuration, and vice versa.

## **SNAPSURE ENHANCEMENTS:**

- Subfolders now contain hidden .ckpt directories
- Out of order deletion of checkpoints are now supported, persistent after DM reboots
- Supports 64 checkpoints per file system
- Checkpoints will automatically mount after being taken
- Can now rename a specific checkpoint

## **CELERRA MULTIPROTOCOL DIRECTORY (Celerra MPD—aka DIR3):**

**Note:** Introduced NAS 5.2.x. NAS 5.2.15.3 automatically converts all file systems to MPD format during Upgrade and last modified date on directories are updated to the date the conversion took place. NAS 5.5 will no longer allow old COMPAT Shadow structure. With DIR3, the Unix name, DOS m8.3 name, and Windows M256 long name, are all stored in the directory block for files. Hash algorithms are used to aid in searches & listings. Hash is built using file name, inode number, and file's position within the directory. With COMPAT, the traditional SHADOW file implementation is used, and only the Unix file names are stored in the directory block.

## **PREVENTING AUTOMATIC MPD CONVERSION:**

List all file systems to exclude from conversion in [\*\*# nas\\_fs -l | awk 'NR>1{print \\$6}' > /nas/site/fs\\_exclude\*\*](#), listing each file system name on a separate line

**Note 1:** To create a list of file systems for the EXCLUDE file, run:

**# nas\_fs -l | awk 'NR>1{print \$6}' > /nas/site/fs\_exclude**

**Note 2:** AR71786 describes a problem with NAS 5.4 Upgrades in which the fs\_exclude file is ignored because it is now looking for fs\_exclude file with the following format:

### **NEW FS EXCLUDE FORMAT 5.4:**

fs1:fs2:fs3 (now requires colon separation between file system names, all on a single line in the file!)

→ This behavior will be corrected in a future 5.4 release so as to accommodate the original fs\_exclude format, which was to have each file system listed separately on separate lines, without colons—see primus emc94312

### **ORIGINAL FS EXCLUDE FILE FORMAT:**

fs1

fs2

fs3

## **MANUAL MPD CONVERSION SYNTAX HAS CHANGED FOR NAS 5.4:**

**\$ nas\_fs -translate Shane\_mpd -mpd start** (original syntax nas\_fs –translate fs1 start)

→ Support for both Shadow File and new MPD FS [Enhanced FS Directory “DIR3”]

→ Ability to change from Shadow [COMPAT] to MPD [DIR3] Online

→ New installs and upgrades will create/convert File Systems to MPD, but at sites with known Shadow problems, this process can be stopped on designated file systems

→ Both NFS and CIFS directories will contain names within file system—current algorithm to translate between NFS and & CIFS names was dependent on order in which files were created, and Shadow rebuilds do not guarantee that the order will be saved.

**Note:** Main difference is that the CIFS FS metadata was stored outside of the file system with the “SHADOW” file [CIFS attributes, CIFS long & short names, UNIX name] whereas the MPD stores the metadata within the File System in a new three-name directory format composed of NFS Name, CIFS Long Name (M256), and CIFS Short Name (8.3)

#### **PATH CACHING PARAMETER:**

DIR3 file systems do not contain shadow files, yet still rely on legacy shadow routines such as name lookups and path checking to perform work. Enable or disable path caching using following:

**param cifs PathCache=0**

#### **MPD CONVERSION PROBLEMS:**

MPD conversion routine has had a bug since day one such that if the inlineValidate complains about a “.” Inode as not the same as a containerInumber, then the xlate process cannot fix because it does not have permission to read containers to validate this issue. So, MPD conversion fails with Mangled directory entry panic. See AR50292.

##### **1. MPD Conversion Fails to Complete on File Systems:**

###### **Solution:**

→FSCK/ACLCHK affected file systems, mount to Standby after converting to a Primary Server, complete MPD conversion, mount back to production Server.

**Comment:** This would not be the first course of action to take for failed MPD conversions—this would be a last resort step in conjunction with an Engineering recommendation!

##### **2. MPD Fails Because of Shadow File Corruption:**

--#nas\_fs -i xxx -o mpd shows Translation\_error\_code = 28

--Server Log shows ‘MPDTranslate of /test: failure on dir inode 679125, status = InternalError

**Solution:** see emc103638

##### **3. MPD Conversion Fails and Server Log Indicates Quota Issues:**

--Failover & fallback Server, have customer reconfigure affected User Quotas, stop and restart conversion, should succeed

--similarly for Tree Quotas issue, one case required customer extension of Hard Quota on Tree Quotas to complete conversion

##### **4. MPD Conversion Fails with I18N characters and Shadow File Translation Issues:** see AR48340

2004-11-13 05:52:03: SHADOW: 3: update: Unable to translate name: 5

2004-11-13 05:52:03: SHADOW: 3: aA39497a938582a918485A3KA3A7A3--

2004-11-13 05:52:05: UFS: 3: 6: MPDTranslate of /home: failure on dir inode 276314, status = InvalidArgument

**# nas\_fs -i vol1 -o mpdtail**

Multi-Protocol Directory Information

```
Default_directory_type = DIR3
Needs_translation      = True
Translation_state       = Not Requested
Percent_nodes_scanned  = 99%
Has_translation_error  = True
Translation_error_code  = 5
Translation_error_message = %InvalidArgument%
```

- a. Get the list of files or directories that failed during the Conversion from the Server Log
- b. Locate the path for each file/directory by running the following for the file name or the inode:

**# find -iname mail997715f00050099.mai**

./Backups/dan/tmp/mail997715f00050099.mai

**Note:** Command run from Control Station mounted to Server over External interface:

**# find /emcfind -inum 125228 -print >/inode1 &**

**# cat inode1**

/emcfind/home/Faculty/KHS/kgonzalez/ZSpeech/Introduction speech/INTRODUCTION SPEECH GRADE SHEET.doc

c. Conduct a Unix rename of the file or in the case of a directory, cd to the directory above the problem directory, move the offending directory to a temporary directory name.

d. Restart MPD Conversion:

**#nas\_fs -translate fs1 start**

**Note:** Pre-NAS 5.4 syntax to manually convert File Systems to MPD

**# nas\_fs -translate fs1 -mpd start**

**Note:** New syntax for manually converting File Systems to MPD with NAS 5.4

e. After the MPD Conversion completes, rename the directories and/or files back to their original names

##### **5. After MPD Conversion CIFS Clients cannot see all Directories:**

Problem where the root directory of a file system was hashed before the xlt tables were available. See AR50408. Fix would be to unmount and remount file system to rebuild hash table correctly. Also, running cifs update, shadow fix, etc., can help resolve Shadow problems that prevent successful translations.

**PROCEDURE FOR CORRECTING MOST FAILED MPD CONVERSIONS/TRANSLATIONS:**

**Note:** Use following procedure if MPD translation fails with InternalError, InvalidArgument, or NameTooLong errors

**1. Use Server Log to find the problem inode(s):**

```
2005-03-02 18:36:57: ADMIN: 4: Command succeeded: file MPDTranslate ufs filesys on 18
2005-03-02 18:36:58: UFS: 3:10: MPDTranslate of /fs1: shadow getAllNames of daily plans.doc failed in upgrade of ino 125246,
status = InternalError
2005-03-02 18:36:58: UFS: 3: 6: MPDTranslate of /fs1: failure on dir inode 125246, status = InternalError
2005-03-02 18:37:02: UFS: 3:10: MPDTranslate of /fs1: shadow getAllNames of ~WRL0516.tmp failed in upgrade of ino 738231,
status = InternalError
2005-03-02 18:37:02: UFS: 3: 6: MPDTranslate of /fs1: failure on dir inode 738231, status = InternalError
2005-03-02 18:42:50: UFS: 3: MPDTranslate of /fs1: completed translation of 0 of 101905 dir inodes without 100 percent success.
See log for errors
```

**Note:** In most cases, the problem Inode number is actually the directory for where the filename that is printed in the Server Log is located. See AR47080 for more details. Sometimes, during DIR3 MPD translation, the XLATE process queries each file system directories' SHADOW file structure, and in this case, when the SHADOW file is broken, returns an InternalError, preventing the translation from completing.

**2. Conduct XOR calculation of Inode number from Server Log:**

**Note:** From the Inode number provided in the Server Log, conduct XOR calculation to convert the Inode number to the 'correct value' when conducting a file system search from the rootfs of the data mover. For example, when conducting find from /nas/rootfs/slot\_2/fs01, or when mounting the root of the Server from the Control Station (#mount server\_2: /find), you would need to search by the XOR'ed value. If you had the permission to mount, from the Control Station, as server\_2:/fs1 /find, then the find operation would use the same inode value as listed in the Server Log, but in most cases, you will not have the permission to do so:

a.) Find fsid value of file system mounted to /fs1 using #nas\_fs -l

**Note:** Left column of nas\_fs -l output represents fsid value, in this case fsid=26

b.) Inode number from Server Log: 738231

c.) Enter value in calc as decimal, click on XOR function, enter fsid value of "26", and the click on enter: **738221 is the XOR value**

**Note:** XOR the FSID and INODE number from Server Log using AWK in script to get true Inode number

**\$ echo “44449 45” | awk '{print(xor(\$1,\$2)) }'**

44428

**3. Mount root file system of data mover from Control Station:**

**# mount server\_2:/ /find**

**4. Conduct Inode search based on XOR value, 738221, from "/" on Control Station, and print to file:**

**# find /find/fs1 -inum 738221 -print >xor\_inode &**

**Note:** The find operation can take many hours, depending on size and layout of file system.

**5. Check the output file once the find job has completed:**

```
# cat xor_inode
# /find/fs1/.ckpt_v0l_tue_ckpt/pliu/CCTemplate/0224-Wholesale-LNC_Success.doc
/find/fs1/.ckpt_v0l_mon_ckpt/pliu/CCTemplate/0231-Wholesale-OCRA_FailureNack.doc
# /find/fs1/pliu/CCTemplate/IC
```

**Note:** Ignore checkpoint paths and concentrate on the path that prints for the production file system.

**6. Verify that the inode found translates into the directory called "IC", by going to the directory above "IC" and running an ls -ail:**

```
#pwd
/find/fs1/pliu/CCTemplate
#ls -ail
738221 drwxr-xr-x 5 80172 wheel 3072 May 4 21:06 IC
```

**7. Conduct Shadow fix on the problem directory:**

**#.server\_config server\_2 "shadow fix \fs1\pliu\CCTemplate\IC"**

1115402638: ADMIN: 4: Command succeeded: shadow fix \fs1\pliu\CCTemplate\IC

**Note:** Shadow Fix zeroes out Shadow file completely, eliminating the conflict, subsequently allowing the MPD translation to run. Be aware that Shadow Fix will not succeed where there is no residual Shadow File, a key indicator.

**# .server\_config server\_2 -v "shadow fix '\PMC\_FS01\_E\$\Data\CO390\Users\JWKleparsk\My Docs'"**

1112312141: CFS: 3: shadow fix failed: NotFound

**Note:** Above output indicates that it could not find a Shadow File to fix!

**8. Restart MPD translation & Observe Successful Conversion:**

**# nas\_fs -translate fs1 start**

**# nas\_fs -translate fs1 -mpd start**

**Note:** NAS versions 5.3.14.0 & 5.4.6.0 contain syntax change for conducting manual MPD conversions. AR71461 submitted to doc.

### # nas\_fs -i fs1 -o mpd |tail

Multi-Protocol Directory Information

```
Default_directory_type = DIR3
Needs_translation = False
Translation_state = Completed
Has_translation_error = False
```

### **ALTERNATIVE FIND METHOD TO BYPASS NEED FOR XOR'ing INODE NUMBER:**

**Note:** If you can successfully export and mount the file system in question directly from the Control Station, then you do not need to run the XOR method outlined above, as the Server Log inode number will be the actual inode number used in the find

#### **1. Export file system with anon=0 rights:**

```
# server_export server_2 -o anon=0 /cifs1
```

server\_2 : done

```
# server_export server_2
```

server\_2 :

```
export "/cifs1" anon=0
```

#### **2. Make temporary mountpoint on Control Station and mount DM file system:**

```
# mkdir /mnt/cifs1
```

```
# mount server_2:/cifs1 /mnt/cifs1
```

```
# mount
```

server\_2:/cifs1 on /mnt/cifs1 type nfs (rw,addr=192.168.1.2)

#### **3. Run find using same inode number as seen in Server Log:**

```
# find /mnt/cifs1 -inum 163205 -print >cifs1_inode &
```

### **COMMON ERRORS AND CONDITIONS SEEN:**

#### **Server Log InternalError:**

2005-03-02 18:36:57: ADMIN: 4: Command succeeded: file MPDTranslate uxf5 filesys on 18

2005-03-02 18:36:58: UFS: 3:10: MPDTranslate of /fs1: shadow getAllNames of daily plans.doc failed in upgrade of ino 125246, status = InternalError

2005-03-02 18:36:58: UFS: 3: 6: MPDTranslate of /fs1: failure on dir inode 125246, status = InternalError

2005-03-02 18:37:02: UFS: 3:10: MPDTranslate of /fs1: shadow getAllNames of ~WRL0516.tmp failed in upgrade of ino 738231, status = InternalError

2005-03-02 18:37:02: UFS: 3: 6: MPDTranslate of /fs1: failure on dir inode 192485, status = InternalError

2005-03-02 18:42:50: UFS: 3: MPDTranslate of /fs1: completed translation of 0 of 101905 dir inodes without 100 percent success.

See log for errors

#### **Server Log InvalidArgument error:**

2005-05-04 21:06:17: UFS: 3:10: MPDTranslate of /fs1: shadow getAllNames of Image Caf addon\_welcome.doc failed in upgrade of ino 738231, status = InvalidArgument

2005-05-04 21:06:17: UFS: 3: 6: MPDTranslate of /fs1: failure on dir inode 738231, status = InvalidArgument

2005-05-04 21:20:53: UFS: 3: MPDTranslate of /fs1: completed translation of 0 of 306542 dir inodes without 100 percent success.

See log for errors

#### **NAS FS OUTPUT:**

errors during a running translation

```
# nas_fs -i fs1 -o mpd |tail
```

```
Needs_translation = True
Translation_state = Running
Percent_nodes_scanned = 2%
Has_translation_error = True

### **Server log server 3 -a -s**

2005-08-13 12:51:00: UFS: 3:10: MPDTranslate of /appsmp: direnter of rt.jarOrig failed for dir into 119253, status = NameTooLong

2005-08-13 12:51:00: UFS: 3: 6: MPDTranslate of /appsmp: failure on dir inode 1 19253, status = NameTooLong

### **SERVER LOG ERRORS FOR ADS PROBLEM:**

UFS: 3: 7: MPDTranslate of /filesystem: Dir corruption in inode 21: Corrupted inode number 20 found for ".", status = InternalError

UFS: 3: 6: MPDTranslate of /filesystem: failure on dir inode 21, status = InternalError

UFS: 3: MPDTranslate of /filesystem: completed translation of 0 of 7 dir inodes without 100 percent success. See log for errors

**Note:** Alternate Data Streams translation issues resolved in AR49041, NAS 5.2.17.1, 5.3.12.0, 5.4.2.0

### **COMMENTS ABOUT XOR:**

When accessing DM file system over internal IP network or from by mounting its root, you will need to XOR the inode value printed in the Server Log to find the actual problem directory (s) where the Shadow File is corrupt. Both examples below are mounting rootfs of Data Mover over Internal IP network:

```
#cd /nas/rootfs/quota/slot_x/fs1
```

```
#mount server_2:/ /find
```

### **IMPORTANT COMMENTS ABOUT SHADOW REaddir & SHADOW FIX:**

```
# .server_config server_2 -v "shadow readdir"
```

```
\PMC_FS01_E$\Data\H0060\Users\MAWeed\AppData\Microsoft\Office\Recent"
```

1113219816: CFS: 5: start scavenging

1113219816: CFS: 5: scavenged 101 forks to free 208 maps in 12553511 ticks

**Note:** Shadow Readdir fails because of a problem with the Shadow File in this directory. Shadow Readdir command succeeds even for DIR3 style directories, this is normal.

```
# .server_config server_2 -v "shadow fix '\PMC_FS01_E$\Data\C0390\Users\JWKleparsk\My Docs'"
```

1112312141: CFS: 3: shadow fix failed: NotFound

**Note:** Shadow Fix command will log above results if the directory has already been converted to DIR3 & does not contain a residual Shadow File. You know you have the correct directory found when the command does succeed, as in following output:

```
# .server_config server_2 -v "shadow fix"
```

```
\PMC_FS01_E$\Data\H0060\Users\MAWeed\AppData\Microsoft\Office\Recent"
```

1113219869: ADMIN: 4: Command succeeded: shadow fix

\PMC\_FS01\_E\$\Data\H0060\Users\MAWeed\AppData\Microsoft\Office\Recent

**Note:** In some cases, the command will not run because of spaces or other peculiarities in the path—when all else fails, try to determine DOS 8.3 name for the next directory in the path and substitute that name:

```
# .server_config server_7 -v "shadow readdir '\data\userdata\SFISHE3\Sandy's files\Action Plans'"
```

1131570657: CFS: 3: shadow fix: getAlternateName failed: NotFound

```
# .server_config server_7 -v "shadow readdir \data\userdata\SFISHE3\SANDY'~1\ACTION~1"
```

### **MPD BENEFITS:**

-- MPD is expected to improve file system performance & maintain more consistent metadata

--No Shadow file rebuilds

### **MPD ERRATA:**

With NAS 5.3, Upgrades will automatically convert file systems to DIR3 format. Use the “-no\_shadow” switch when translating pure NFS file systems so as not to incur space and inode usage with the building of a Shadow directory. MPD directory format contains UNIX Name, CIFS Long & DOS 8.3 Short Names. NAS 5.5 will not allow file systems to remain as COMPAT.

### **VERIFYING DIR3 FILESYSTEMS WITH NAS 5.5:**

```
# /nas/sbin/rootnas_fs -i root_fs_common
```

Multi-Protocol Directory Information: not available

**Note:** NAS 5.5 does not properly return the DIR3 value using nas\_fs -i or the XML query. Output below from NAS 5.4:

```
# nas_fs -query:"name=root_fs_common" -format:"%s %s\n" -fields:Name,DirectoryType
root_fs_common DIR3
```

### **DETERMINING FS FORMAT—‘COMPAT’ SHADOW vs. ‘DIR3’ MPD FORMAT:**

1. Turn on NAS FS Option for MPD:

```
#export NAS_DB_DEBUG=1
```

2. #nas\_fs -info fs1 –option mpd

#### Multi-Protocol Directory Information

|                       |                 |                                                                                       |
|-----------------------|-----------------|---------------------------------------------------------------------------------------|
| <b>directory_type</b> | <b>= DIR3</b>   | [DIR3 means that FS is using MPD format]                                              |
| needs_translation     | = False         | [Means all directories are of the same type; ‘True’ means some of each DIR3 & COMPAT] |
| translation_state     | = not requested | [Means a translation has never been requested on this FS]                             |
| has_translation_error | = False         |                                                                                       |

#### **EXAMPLES:**

**# nas\_fs -i vol1 -o mpd|tail**

Multi-Protocol Directory Information

|                           |                     |
|---------------------------|---------------------|
| Default_directory_type    | = DIR3              |
| Needs_translation         | = True              |
| Translation_state         | = Not Requested     |
| Percent_nodes_scanned     | = 99%               |
| Has_translation_error     | = True              |
| Translation_error_code    | = 5                 |
| Translation_error_message | = %InvalidArgument% |

**\$ nas\_fs -i fs1 -o mpd |tail**

Multi-Protocol Directory Information

|                        |             |
|------------------------|-------------|
| Default_directory_type | = DIR3      |
| Needs_translation      | = False     |
| Translation_state      | = Completed |
| Has_translation_error  | = False     |

### **CONVERTING “COMPAT” SHADOW FORMAT TO MPD “DIR3” FORMAT:**

1. Verify Current File System Directory Format & Obtain Inode and File System Space Info:

**\$ nas\_fs -i fs94 -o mpd**

|        |         |
|--------|---------|
| id     | = 21    |
| name   | = fs94  |
| acl    | = 0     |
| in_use | = True  |
| type   | = uxfss |
| volume | = mtv04 |
| pool   | =       |

```
rw_servers= server_2
ro_servers=
rw_vdms =
ro_vdms =
symm_devs = 002806000123-0010
disks = d12
disk=d12 symm_dev=002806000123-0010 addr=c0t119-16-1 server=server_2
```

#### **Multi-Protocol Directory Information**

```
Default_directory_type = COMPAT
Needs_translation = False
Translation_state = Completed
Has_translation_error = False
```

**\$ server\_df server\_2 -i |grep fs94**

```
fs94 10325744 9546816 778928 92% /mp04
```

**Note:** Do not proceed with conversion unless you have at least 10% Inodes and Space available

2. Change Directory Format Type with Following Command:

**#nas\_fs -modify fs94 directory\_type=DIR3 | directory\_type=COMPAT**

3. Start File System Format Conversion:

**#nas\_fs -translate fs94 start | -no\_shadow** [Will not create a Shadow directory when translating from COMPAT]

4. Monitor Conversion Process:

**\$ nas\_fs -i fs94 -o mpd**

#### **Multi-Protocol Directory Information**

```
Default_directory_type = DIR3
Needs_translation = True
Translation_state = Running
Percent_nodes_scanned = 4%
Has_translation_error = False
Skipped_dir_inodes = 0
Current_inode = 50720
Entries_in_current_dir = 0
```

5. Verify in Server Log:

**\$ server\_log server\_2 |grep -i mpd**

```
2004-05-07 14:11:29: ADMIN: 4: Command succeeded: file MPDTranslate uxfss filesys on 21
```

```
2004-05-07 14:11:48: UFS: 3: 6: MPDTranslate of /fs94: Successfully completed translation of 0 of 2349 dir inodes
```

**Caution:** You can actually convert back to COMPAT format but it is not supported at this time and should not be done

### **CONVERTING DIR3 FILE SYSTEM TO COMPAT WITH NAS 5.5:**

**#.server\_config server\_4 -v "file dirType uxfss filesys DIR\_COMPAT 266"**

### **TROUBLESHOOTING DIR3 CONVERSIONS:**

**Note:** By default, a translation will “pause” at 99% capacity of the file system or inode value. To resume translation, do following:

1. Extend File System or delete data to reach 90% [Translation is supposed to resume if the 90% threshold is reached]

2. If translation does not resume, permanently unmount and then remount File System

**Note:** Possible translation states: running; not requested; never; pending; queued; paused; completed; failed

3. Do not run MPD conversions with Quotas turned on—disable quotas first, then do the conversion

4. Directory Translation Error with multiple stream attributes—code is unaware of streams & fails with following:

```
2004-08-18 02:40:28: UFS: 3: 7: MPDTranslate of /volumes-mnt: Dir corruption in inode 64828183: Corrupted inode number
```

```
64828181 found for ".", status = InternalError
```

```
2004-08-18 02:40:28: UFS: 3: 6: MPDTranslate of /volumes-mnt: failure on dir inode 64828183, status = InternalError
```

**Note:** Primus emc94552, AR49041, to be corrected in NAS 5.2.17.x, 5.3.12.x and higher

### **MPD PARAMETERS:**

**\$ .server\_config server\_2 -v "param ufs" |grep -i xlate**

```
ufs.xlateMinThreads 0x01170074 0x0000000a 0x0000000a [Default = 10 threads minimum]
```

```
ufs.xlateMaxThreads 0x01170070 0x0000000a 0x0000000a [Default = 10 threads]
```

```
ufs.xlateSpaceLowCeiling 0x01170088 0x000003e8 0x000003e8
```

[Default = 1000 = 10% free space before resuming]

```
ufs.xlateSpaceHighCeiling 0x01170084 0x00000064 0x00000064
```

[Default Value=100 dec. = 99% Full]

## **GPO ENHANCEMENTS:**

Max lifetime for kerberos user tickets

Domain audit account logon events, account management, directory service access, user rights, etc.

## **UNIX ACL TOOL:**

Allows for NFS User to view & modify CIFS ACLs for files [emcgetsd and emcsetsd] from a Unix Host [HPUX, Linux, Solaris] or the Control Station. Obtain ‘emcgetsd’ and ‘emcsetsd’ from Applications & Tools CD>CifsTools>unixacltools/linux. Must set param cifs acl.extacl=32 in order for the “emcsetsd” tool to work.

## **CELERRA VDM:**

### **NAS 5.2 VIRTUAL DATA MOVER (VDM):**

#### **Purpose:**

--Separates CIFS Services and File Systems into virtual containers to allow for administration of separate groups of CIFS Servers and

to enable replication of CIFS environments between physical Data Movers [NAS 5.3]

--VDM will be logically connected between network interfaces and the file system as a separate CIFS instance that can be transferred from DM to DM.

--VDM will contain the audit log, local groups, and shares database within the .etc directory of each file system. A VDM server can only export a directory on its own file system or nested file system. Default root filesystem size of VDM will be 128MB, same as current root file systems. VDM relationship to rootfs will be saved on CS.

--Internal Usermapper required for VDM.

--Can have a group of VDM's per file system.

--VDM container can have more than one CIFS Services

## **LISTING VDMs ON CELERRA:**

**# nas\_server -a -i -vdm**

```
id      = 3
name    = vdm_houfsrv0
acl     = 0
type    = vdm
server  = houons7041dm2
rootfs  = root_fs_vdm_houfsrv0
I18N mode = UNICODE
mountedfs = houfsrv0,ckpt_daily_houfsrv0_001
member_of =
status   :
defined = enabled
actual = loaded, active
```

Interfaces to services mapping:

```
interface=10_30_161_228 :cifs
interface=10_30_161_61 :cifs
```

**# nas\_server -l -vdm**

```
id      acl server mountedfs rootfs name
3       0      1       165,166,238,240 225  vdm_source
```

## **ISSUE WHEN VDM NAMES ARE ALL UPPERCASE:**

**# nas\_server -i -a -vdm**

```
id      = 1
name    = CLKPTDM04
acl     = 0
type    = vdm
server  = server_4
rootfs  = root_fs_vdm_CLKPTDM04
```

**# server\_export CLKPTDM04**

**Note:** In this particular example, had to use all Uppercase characters when retrieving VDM information from CLI. AR74879

## **CONTENTS OF VDM DATABASE:**

--local groups database  
--shares database for file systems dedicated to the VDM  
--CIFS server configuration [compnames, interface names, etc]  
--Home directory information  
--Auditing and Event log information  
--Kerberos information for Servers in VDM  
--Secmap cache—secure cache

**Unsupported VDM Features:**

No individual NTP configuration—must use single NTP for data mover globally  
FTP to VDM not supported  
Failover between VDMs not supported  
CDMS with CIFS supported, but not CDMS with NFS  
NFS exports are not supported  
Server\_uptime, cpu, standby commands are not supported on individual VDMs

**SETTING UP A VDM CIFS SERVER CONTAINER ON THE DATA MOVER:**

**1. CREATE VDM CONTAINER:**

# **nas\_server -n vdm\_tm -type vdm -create server\_2**

```
id      = 1
name    = vdm_tm
acl     = 0
type    = vdm
server  = server_2
rootfs  = root_fs_vdm_1
I18N mode = UNICODE
mountedfs =
member_of =
status   :
defined = enabled
actual = loaded, ready
```

Interfaces to services mapping:

**Note:** For VDM creation, only two “states” are allowed, setstate “loaded” or “mounted”. When the –setstate switch is not specified, the default behavior is to create the VDM in a loaded state. The “-fs” switch is used when the rootfs for the VDM has already been manually created for use with a VDM.

# **nas\_server -a -i -vdm**

```
id      = 1
name    = vdm_dest
acl     = 0
type    = vdm
server  = server_2
rootfs  = root_fs_vdm_vdm_dest
I18N mode = UNICODE
mountedfs =
member_of =
status   :
defined = enabled
actual = temporarily unloaded → This is normal condition of target VDM Server running rootfs as rawfs—changes to “actual=mounted” when replication is running and rootfs changes to uxfss
```

**2. VERIFY NEW VDM:**

# **nas\_server -vdm -l**

```
id    acl server mountedfs  rootfs name
1     0    1          25    vdm_tm
```

# **nas\_fs -l**

```
25    y  1  0  155  root_fs_vdm_1  1
#/nas/sbin/rootnas_fs -i root_fs_vdm_1
```

```
id      = 25
name    = root_fs_vdm_1
acl     = 0
in_use  = True
type    = uxfss
```

volume = v15

### # /nas/sbin/rootnas\_volume -i v155

id = 155

name = v155

acl = 0

in\_use = True

type = meta

volume\_set = s87

disks = d9

clnt\_filesys= root\_fs\_vdm\_1

### # /nas/sbin/rootnas\_slice -i s87

id = 87

name = s87

acl = 0

in\_use = True

slice\_of = v135

**offset(MB)= 128** →Default size VDM rootfs also 128MB, as is data mover rootfs

size (MB)= 128

volume\_name = s87

### # server\_cifs server\_2 [output abridged]

---

CIFS service of VDM vdm\_tm (state=loaded)

Home Directory Shares DISABLED

## **3. CREATE MOUNTPOINT AND MOUNT FILE SYSTEM TO VDM:**

### # server\_mountpoint vdm\_tm -c /fs1

vdm\_tm : done

### # server\_mount vdm\_tm fs1 /fs1

vdm\_tm : done

### # server\_mount vdm\_tm

vdm\_tm :

fs1 on /fs1 ufs,perm,rw

## **4. CREATING CIFS SERVERS WITHIN A VDM CONTAINER:**

### # server\_cifs vdm\_tm -add compname=virtuous, domain=mouse.com, interface=47

vdm\_tm : done

**Note:** Default CIFS server is not compatible with VDMs. Each CIFS server of a VDM must have its own interface defined.

#### **SERVER LOG:**

2004-06-07 15:56:21: SMB: 4:[vdm\_tm] CIFS Server VIRTUOUS[] created (0)

2004-06-07 15:56:21: SMB: 4:[vdm\_tm] Full computer name virtuous.mouse.com, Realm MOUSE.COM

2004-06-07 15:56:22: ADMIN: 4:[vdm\_tm] Command succeeded: :1 cifs add compname=VIRTUOUS domain=MOUSE.COM interface=47

## **5. JOINING CIFS SERVERS TO DOMAIN WITH VDM CONTAINER:**

### # server\_cifs vdm\_tm -Join compname=virtuous, domain=mouse.com, admin=administrator

vdm\_tm : Enter Password:\*\*\*\*\*

done

#### **SERVER LOG:**

2004-06-07 15:59:13: KERBEROS: 4:[vdm\_tm] Upgading file krb5.conf from version 0 to verion 2

```

CIFS Server VDM\_1[W2K] RC=2

Full computer name=vdm\_1.w2k.pvt.dns realm=W2K.PVT.DNS

Comment='hello vdm'

if=vdm l=192.1.4.223 b=192.1.4.255 mac=0:60:16:c:51:46

FQDN=vdm\_1.w2k.pvt.dns (Updated to DNS)

Password change interval: 0 minutes

Last password change: Tue Jun 10 12:40:15 2008 GMT

Password versions: 2

**# cat /nas/server/vdm/vdm\_1/export.shares**

```
# 1213101225
```

share "vdm\_share" "/vd़m1" umask=022 maxusr=4294967295

share "vdm\_comments" "/vd़m1" umask=022 maxusr=4294967295 comment="Sample comments for CIFS VDM Server"

**# cat /nas/server/vdm/vdm\_1/vdm.cfg**

```
cifs add compname=VDM_1 domain=W2K.PVT.DNS interface=vdm comment="hello vdm"
```

### **CREATING VDM ON SPECIFICALLY CONFIGURED FILE SYSTEM:**

**1. \$ nas\_slice -n svdm2 -c d7 512** [Default size of VDM root is 128MB when configured by system]

**2. \$ nas\_fs -n fsvdm2 -c mvdm2**

**3. \$ nas\_server -name vdm2 -type vdm -create server\_2 -setstate loaded -fs fsvdm2**

**Note:** Must create a VDM root file system with this method for Clariion backends

### **VDM STATES:**

**\$ nas\_server -i -v vdm2**

```
id      = 6  
name    = vdm1  
acl     = 0  
type    = vdm  
server  = server_2  
rootfs  = root_fs_vdm_6  
I18N mode = UNICODE  
mountedfs =  
member_of =  
status   :  
  defined = enabled  
  actual = loaded, ready
```

Interfaces to services mapping:

### **MOVING VDM FROM ONE DM TO ANOTHER:**

**\$ nas\_server -vdm vdm02 -move server\_4**

### **CREATING VDM IN LOADED STATE:**

**1.) \$ nas\_server -name vdm01 -type vdm -create server\_2 -setstate loaded -fs vdm\_root\_fs1**

**Note:** Loaded state means a normally running CIFS server with configuration mounted Read-Write with Cifs Service running. In this example, the VDM root filesystem is created on the file system specified.

2.) Create mountpoint and mount file system

```
$server_mountpoint vdm01 -create /vdmfs01           $server_mount vdm01 vdmfs01 /vdmfs01
```

3.) Create CIFS service and Join to Domain:

```
$ server_cifs vdm01 -add compname=vdm01, domain=vdm01.network.com, interface=ace0  
$ server_cifs vdm01 -Join compname=vdm01, domain=vdm01.network.com, admin=administrator
```

4.) Create Shares:

```
$ server_export vdm01 -P cifs -n vdm01 /vdmfs01
```

#### **VDM IN UNLOADED STATE(temp unmount of vdm root & permanent unmount of vdm root):**

```
1.) $ nas_server -vdm vdm01 -unload
```

```
2.) $ server_umount vdm01 -all
```

**Note:** Root filesystem is unmounted and CIFS Service is not running

#### **CHANGING VDM STATE FROM LOADED TO MOUNTED:**

```
# nas_server -vdm vdm_tm -setstate mounted
```

```
id      = 1  
name    = vdm_tm  
acl     = 0  
type    = vdm  
server  = server_2  
rootfs  = root_fs_vdm_1  
I18N mode = UNICODE  
mountedfs = fs1  
member_of =  
status   :  
    defined = enabled  
    actual  = mounted
```

Interfaces to services mapping:

#### **LOADING VDM SERVER ON SERVER\_2:**

```
# nas_server -vdm vdm_1 -setstate loaded server_2
```

```
id      = 1  
name    = vdm_tm  
acl     = 0  
type    = vdm  
server  = server_2  
rootfs  = root_fs_vdm_1  
I18N mode = UNICODE  
mountedfs = fs1  
member_of =  
status   :  
    defined = enabled  
    actual  = loaded, active
```

Interfaces to services mapping:

#### **VDM IN MOUNTED STATE:**

```
$nas_server -name vdm01 -type vdm -create server_2 -setstate mounted -fs vdm_root_fs1
```

**Note:** Use this mode when CIFS services do not need to be running, such as for Celerra Replication on Secondary side.

Configuration file system is mounted read-only. Default config file system size is 128MB, but can be created larger. CIFS Services are not running.

#### **DELETING VDM SERVER:**

```
$ nas_server -vdm vdm01 -setstate loaded | tempunloaded | permunloaded server_2
```

```
# server_umount vdm1 -p -all
```

```
# nas_server -vdm vdm1 -setstate permunloaded server_2
```

```
id      = 6  
name    = vdm1  
acl     = 0  
type    = vdm  
server  =  
rootfs  = root_fs_vdm_6  
I18N mode = ASCII  
mountedfs =  
member_of =  
status   :
```

defined = enabled  
actual = permanently unloaded

Interfaces to services mapping:

**Note:** This operation will delete the VDM Server and associated vdm\_rootfs

### **DELETING & CHECKING STATUS OF VDM:**

# nas\_server -info -vdm vdm1

# nas\_server -list -vdm

```
id    acl  server  mountedfs   rootfs  name
1     0    1        37       vdm1
2     0    1        43       vdm2
```

# nas\_server -delete vdm1

### **VERIFYING SIZE OF VDM ROOTFS:**

# /nas/sbin/rootnas\_fs -s root\_fs\_vdm\_6

total = 128 (sizes in MB)

### **DELETING VDM ROOTFS:**

# /nas/sbin/rootnas\_fs -d root\_fs\_vdm\_6

```
id      = 35
name    = root_fs_vdm_6
acl     = 0
in_use  = False
type    = uxf
volume  = v137
rw_servers=
ro_servers=
rw_vdms =
ro_vdms =
symm_devs = APM00040303779-0012
disks   = d9gg
```

### **RENAMING & MOVING VDM:**

\$nas\_server -rename vdm01 vdm001

\$nas\_server -vdm vdm01 -move server\_3

### **NDMP BACKUP SUPPORT:**

NDMP version 4 support introduced

Multi-threaded PAX (Portable Archive Xchange) enhancements made to increase BackUp/Restore performance

**Note:** Goal is to meet NetApps 104GB/hour backup with (2) tape drives

### **WINDOWS 2003 SUPPORT:**

Support for SMB Signing for both Kerberos and NTLMSSP

Kerberos over TCP

Joining Windows 2003 Domains as member servers [Windows Server 2003, Windows Server 2003 family interims, Windows Server 2003 .NET]

### **REDUCED PERMISSION JOIN:**

Prior to 5.2, only a person who was a member of the Domain Admins group in the domain to be Joined could Join a DM At 5.2.14.100 and higher, anyone with the appropriately delegated rights to Join a Server can Join the DM to the Domain

#server\_cifs server\_2 -Join compname=dm1, domain=domain.com, admin=delegateduser@domain.com

### **PRE-CREATED COMPUTER ACCOUNT JOINS:**

Authority to Join a ‘pre-created’ computer account can now be allowed to a User or Group from different domains in the same forest

#server\_cifs server\_2 -Join compname=dm1, domain=domain.com, admin=admin -option reuse

### **JOINING WHEN DNS AND WINDOWS DOMAIN NAMES ARE DIFFERENT (Disjointed Namespace)**

**Note:** Original 4.0 code used a “dns” switch to allow for a ‘dis-jointed’ DNS to AD Domain—later revisions removed this switch NAS 5.2 re-introduces the option as follows to allow for successful Joins when DNS and AD Kerberos Realm names are different

\$server\_cifs server\_2 -add compname=dm1, domain=domain.com, interface=cge0, dns=bigcompany.com

\$server\_cifs server\_2 -Join compname=dm1, domain=domain.com, admin=administrator

**Note:** Delegated users must still belong to an Admin Group to use this feature

## **EXAMPLE SYNTAX FOR DISJOINED NAMESPACE JOIN:**

**\$ server\_cifs server\_2 -Join**

**compname=schnas01.rmd.navistar.com, domain=ad.navistar.com, admin=yytxg**

## **CREATING CIFS SERVICE WITH DNS DOMAIN AND KERBEROS ONLY AUTH:**

**\$ server\_cifs server\_2 -add compname=BYCFS1DM2A03839,**

**domain=IUSER.IROOT.ADIDOM.COM, interface=DM2\_fsn0\_if1, dns=nat.bt.com, authentication=Kerbeos**

### **NAS 5.2.14 JOIN OPTIONS:**

**param cifs djAddAdminToLg=0** [Set this value to 1 to enable]

**Note:** Use this parameter if you want the user performing the Join to be added to default local Administrator's group on DM. You would want to use this switch if the User is not a Domain Admins account [i.e., is a reduced permission user] and needs to be able to "manage" the compname after the Join.

**param cifs djUseKpasswd=1** [Code default is 1 for using Kerberos kpasswd protocol to set/change server passwd; Setting this value to 0 will enable Joins to succeed for Reduce Permission Users by using the SAMR authentication for setting machine password]

**param cifs djEnforceDhn=1** [Set this value to 0 to prevent DNS updates to Windows domain]

### **EXPANDED NOTE ON JOIN FAILURES WITH REDUCED PERMISSION ACCOUNTS:**

Normal Join process with W2K/W2K3 & CIFS servers is to set the machine account password with the DC at the end of the JOIN using the KPASSWD utility. Any operation using the "server\_cifs -J" process uses the same JOIN function, and will require KPASSWD to be executed at the end of the JOIN. In this situation, the KPASSWD operation is being attempted over UDP which has a datagram size limit of 2K. The security information for the user exceeds this 2K limit due to the number of groups of which the user is a member, causing the user authentication to fail. DART does not currently support the use of TCP for the KPASSWD protocol and therefore cannot recover from an oversized KPASSWD UDP packet. To correct this, modify the djUseKpasswd param to enable SAMR over TCP instead of KPASSWD.

#### **Example of Error Seen for Failed Join:**

Error Code / Message: krb5\_set\_password: krb5\_rd\_setpw\_rep returned

## **DISJOINED NAMESPACE/REDUCED PERMISSIONS JOIN/MANAGE PROCEDURE:**

Step 1. Ensure data movers are running NAS 5.2.14.100 or higher

Step 2. Ensure data movers have the following parameters set and have been rebooted:

**param cifs djAddAdminToLg=1**

**Note:** Adds User account used in Join to local Administrators group on Data Mover for delegated management for non-Domain Admin users--required for delegated management of Compname.

**param cifs djUseKpasswd=0**

**Note:** By setting value to 0, use of Kpasswd protocol to set CIFS server password is disabled, and SAMR authentication (MS\_RPC) is used instead, which allows a User with Reduced Permissions, to Join the compname and set the machine's password.

**param cifs djEnforceDhn=0**

**Note:** When set to 0 prevents DNS updates to Windows domain during Join process

Step 3. Add the DNS and NTP Services to the Data Mover

**\$server\_dns server\_2 -p tcp foobar.world.com 10.241.169.16**

**\$server\_date server\_2 timesvc start ntp 10.241.169.16**

Step 4. Add the NIS or Usermapper client service to the Data Mover, but not both (NIS & Usermapper combined is not allowed)

**\$server\_cifs server\_2 -add usermapper=10.241.169.43**

**\$server\_nis server\_2 hosts.pvt.dns 10.241.168.21**

Step 5. Created two Windows Users called "Reduced" & "Reduced2" and added to a new Domain Local Group called "Reduced Manage"

Step 6. Created Celerra OU's called GCM & Servers

Step 7. Rightclicked on each new OU from within ADUC Interface and selected "Delegate Control" wizard to grant manage rights to the Domain Local Group "Reduced Manage", and repeated for each of the two Users "Reduced" and "Reduced2" as well.

---

Delegate Control>Next>Add>add Users and Groups>Tasks to Delegate, selected 'Custom...'>Selected 'Delegate control of This folder, existing objects in this folder, and creation of new objects in this folder'>Permissions, selected all three checkboxes and granted 'Full Control' to complete delegated control.

Step 8. Manually created CIFS Compnames "Mini" and "Mini2" in OU GCM>Servers and granted the following right to the "Reduced Manage" group via the wizard:

"The following user or group can join this computer to a domain. User or group: Reduced Manage"

Step 9. Manually created Forward and Reverse Lookup Zone entries for Host and PTR records respectively, for ‘Mini’ & ‘Mini2’

Step 10. Created CIFS Service for each compname:

**\$server\_cifs server\_2 –add compname=mini, domain=mouse.com,interface=cge0,dns=foobar.world.com**

**Note:** Use “dns=” syntax only when the FQDN of the Windows domain is different from the DNS domain

**\$server\_cifs server\_2 –add compname=mini2, domain=mouse.com,interface=cge0,dns=foobar.world.com**

Step 11. Started CIFS Service on Data Mover

Step 12. Joined each Compname to the Domain (Joins do not map a User’s Group SIDs, only their User SID):

**\$server\_cifs server\_2 –Join**

**compname=mini.foobar.world.com, domain=mouse.com, admin=reduced, ou=”ou=Servers:ou=GCM”**

**\$server\_cifs server\_2 –Join**

**compname=mini2.foobar.world.com, domain=mouse.com, admin=reduced2, ou=”ou=Servers:ou=GCM”**

**Note:** Join command adds the User to the Administrators localgroup for the Compname—only a single User can be added during the Join. Manually add additional Users to Administrators localgroup file from a privileged account such as Domain Admins, or logged in as the User already added to the group. Above syntax for ‘compname=’ is required to denote the different DNS domain, while the ‘domain=’ entry denotes the Windows Fully Qualified domain name. Also note that CIFS output shows “Update of “A” record failed during update...”—this is normal message since the DNS entries were added manually to the FWD and Reverse Lookup Zones.

Step 13. Verify access and management rights to new Compnames

- a.) Log into AD Domain as user ‘Reduced’, open Computer Management>Connect to another Computer>\\\mini
- b.) Add additional users as required to local Administrators group and save

**Caution:** Users and Groups found in AD can be successfully added to the local Administrators group, but keep in mind that unless the Users and respective Groups are mapped via Usermapper or NIS, they will not have the ability to ‘manage’ the compname. In otherwords, Users and Groups can be added to the data mover’s localgroups file without being mapped with a UID/GID. This is why a delegated user might be able to Join a compname to the domain successfully but might not be able to ‘manage’ the compname after the Join—the User’s Group memberships are not mapped until attempting to ‘manage’ the compname for the first time. In otherwords, a Join never maps a User’s Group memberships.

### **TEARING CIFS DOWN BETWEEN TESTS:**

1. Stop CIFS service
2. Delete CIFS configuration: \$server\_setup server\_2 –P cifs –o delete
3. Delete computer accounts from AD (if repeating tests immediately, then use new Compnames for testing)
4. Delete DNS entries from Forward and Reverse Lookup Zones for compnames
5. If Usermapper running, stop, disable, delete records if required, remove pointer to Usermapper from CIFS, if required
6. Delete SecMap cache directory: #rm –Rf secmap
7. Delete all krb5\* files from /.etc directory on Data Mover
8. Delete all .db.localgroups, .db.localgroups.bak, localgroups.db files from /.etc directory
9. Go to /nas/server/slot\_2 directory and delete all krb5\* and .db.localgroups files
10. Reboot data mover and verify that no entries exist in the /.etc/secmap or /.etc/usrmapper directories or in any of the above-mentioned files in /nas/server/slot\_2
11. Build new configuration for next series of tests

### **SMB SIGNING CONFIGURATIONS:**

1. **param cifs smbsigning=1** 10 disables [with parameter set, enables DM Server & Client signing and overrides GPOs]

**Note:** Enabled by default with NAS 5.2. Disable this parameter if joining a Windows 2000 domain that does not have SMB Signing enabled.

2. GPO Settings apply to all machines in domain, controlling both Server & Client signing

Default Domain Security Settings>Security Settings>Local Policies>Security Options

--Microsoft network client: Digitally sign communications (always) →Disabled by default

--Microsoft network client: Digitally sign communications (if server agrees) →Enabled by default

--Microsoft network server: Digitally sign communications (always) (Server requires signing)→Disabled by default

--Microsoft network server: Digitally sign communications (if client agrees) →Disabled by default

3. In lieu of GPO settings, Windows systems use Server/Client-side signing with Registry entries

### **SERVER-SIDE SIGNING:**

HKLM>System>CurrentControlSet>Services>lanmanserver>parameters:

enablesecuritysignature 1 [Enables]

requiresecuritysignature 1 [Requires that SMB signing be used]

### **CLIENT-SIDE SIGNING:**

HKLM>System>CurrentControlSet>Services>lanmanworkstation>parameters:

enablesecuritysignature 1 [Enables]

requiresecuritysignature 1 [Requires that SMB signing be used]

## **TERMINOLOGY:**

Disabled—Client or Server does not support SMB signing

Enabled—Client or Server supports SMB signing but is not required for all transactions

Required—Client or Server requires SMB signing for all transactions

## **NAS 5.3 BORDEAUX:**

--NAS 5.3.10.4 GA Aug 4, 2004, supporting CNS-14, CFS-SE, Celerra NS, and Celerra NSG systems

--Support for NAS High and midrange CNS, CFS, NS600/G, NS700/G, using NAS 5.2 as base code

--Current release 5.3.24.200, compatible with Flare 16 & 19

**Restrictions:** NS500, NS500G, & NS704G requires use of NAS 5.3 as minimum NAS code, while 506 CM/CS Models and below cannot be used with 5.3

## **Features:**

Snapsure enhancements, VSS Integration; Replicator enhancements, Replication Silvering, etc.; Home Dir enhancement; Quotas, ACL Tools; On Demand AV; CSV Reporting, etc.; New TFTP protocol to be included; Variable length subnet masks; NSB-4 Support, Exterminator, CNS TOE support [TCP Offload Engines on NIC cards]; ILM Data Protection; iSCSI Exchange; LDAP iPlanet; iSCSI Target; Celerra Manager to have enhanced statistical displays, as well as capability to export the stats

## **MICROSOFT SHADOW COPY FOR SHARED FOLDERS (SCSF):**

→Support for Windows 2003/XP Clients to list, view, copy, restore files from SnapSure Checkpoints

→Requires installation of SCSF software on XP Client, not Win2k3

→Celerra support enabled by default

→No support for Windows 2000 Clients

→Not the same thing as MS VSS

## **ISSUES:**

XP/Win2k client stations hang when trying to access CVFS checkpoints on 5.4.19.5, when traversing NMFS structure—AR74087

## **iSCI SUPPORT:**

--iSCSI is a transport protocol for sending SCSI packets over TCP/IP networks

--iSCSI requires iSCI Host Initiator to encapsulate SCSI commands, data, status and send to iSCSI Target (storage device)

--Two topologies are Native iSCSI (Celerra is a native iSCSI solution—uses no Fibre Channel) and Bridging iSCSI (uses Ethernet & Fibre Channel—Servers attach to network using Ethernet and Storage devices connect via Fibre Channel)

--iSCSI targets can be configured on DM using either CLI or Celerra Manager

## **Celerra supports following iSCSI Components:**

--stopping & starting of iSCSI service on DM

--Creation of iSCSI targets to include portal groups & LUN masking

--Creation & management of iSCSI LUNs—each LUN emulates a SCSI disk device

--Support for IP Naming Service (iSNS) Client on Data Mover, a service that includes Naming, Discover, Login

--Support for CHAP authentication by iSCSI Initiators when challenged by iSCSI targets before access is granted to LUNs

**Note:** `param iscsi RequireChap=0` (Chap is off by default=0)

## **Support for iSCSI Host-based Solutions:**

(Solutions that use Celerra iSCSI targets that add iSCSI snap capabilities for backing up and restoring data stored on iSCSI LUNs)

**iSCSI SnapSure Manager for Exchange 2000** (stores Exchange system/log files & storage groups on separate iSCSI LUNs)

**Note:** Functionality includes ability to restore or delete Storage Groups/log/system files, promote storage groups for mailbox restores, demote storage groups, schedule group snaps

**SnapSure Manager for iSCSI**—point-in-time iSCSI snaps of iSCSI LUNs using Windows GUI

**Note:** Functionality includes creation, deletion, restoration of iSCSI luns, promotion or demotion of iSCSI snaps, displaying snaps of iSCSI luns

## **FILE SYSTEM LINKING:**

--Ability to access several file systems from Single share using UNIX absolute symbolic links created by 'Root'

**param shadow followabsolutpath=1** [Set this param to enable file system linking and reboot DM]

## **SETTING UP FILE SYSTEM LINKING TO SOLARIS:**

1. Create & Mount file systems

2. Export each fs using "root=192.168.25.140"

3. Set param and reboot Server

4. On Solaris, mkdir /fs1 and /fs2

5. From Solaris, #mount 192.168.25.122:/fs1 /fs1 and /fs2

6. From Solaris, #mkdir /fs1/subdir1 /fs2/subdir2 and copy data to /fs2/subdir2

7. Create Symbolic link from /fs1/subdir1 to /fs2/subdir2

**#cd /fs1/subdir1;ln -s /fs2/subdir2 subdir2**

8. Verify link in /fs1/subdir1:

**#ls -l [subdir2 → /fs2/subdir2]**

10. Test access to Link in Windows using Explorer [\dm2\fs1\ subdir2\kernel]

#### **ERROR CONDITIONS:**

- If target does not exist, or param is not set, directories are seen as files
- If target is a link and we enter a loop, the link is seen as a file
- If symbolic link has not been created by ‘root’, link might be seen as a file

#### **TFTP PROTOCOL SUPPORT:**

Text or binary transfers using get or put commands via UDP Port 69, up to 33MB total for any single file transfer

TFTP uses UGO ‘Other’ permissions for Read or Write

Secure TFTP drops Client into specific toplevel directory without cd capability

#### **CONFIGURING CELERRA TFTP:**

**\$server\_tftp server\_2 -service -start | -stop**

**\$server\_tftp server\_2 -set -path /fs1 -readaccess all -writeaccess -all** [Define access to directories]

**\$server\_tftp server\_2 -service -status | -stats**

**\$ server\_tftp server\_2 -service -status**

server\_2 :

Tftp Running

**\$ server\_tftp server\_2 -service -stats**

server\_2 :

Attempted Transfers:5363

Successful Transfers:1890

createdthrds:5363

deletedthrds:5363

timedoutthrds:20

TotalBinds:5363

TotalUnbinds:5185

BindFailures:416

InvalidAttempts:3258

AttemptedReadTransfers:5363

SuccessfulReadTransfers:1890

AttemptedWriteTransfers:0

SuccessfulWriteTransfers:0

**\$server\_tftp server\_2 -info | -clear**

Export filesystem for remote access

Create temporary /tftp directory on Unix host

**Note:** Only one path can be defined by default—use **param tftp pathno=10** to increase number of paths from 1 to 10. TFTP supports up to 16 concurrent connections.

#### **Transferring From Unix Client:**

#tftp –i 192.168.25.122 [Use –i for binary files]

tftp> bin

tftp> get filename

tftp>quit

#### **Transferring From Windows Client:**

C:>tftp 192.168.25.122 get passwd

### **CELERRA FILEMOVER/CELERRA DHSM (Distributed Hierarchical Storage Management):**

NAS 5.3 API version 1.0

NAS 5.4 API version 1.1

NAS 5.5 API version 1.2 with HTTP v.1.1 XML digest authentication, and BAR (Bulk Attribute Retrieval)

NAS 5.6 turns on Digest authentication by default

#### **SUPPORTED POLICY/MIGRATION ENGINES:**

##### **ARKIVIO auto-stor v4.3:**

→NAS 5.4.18 and above; ONTAP 7.0.6 or higher; Windows NT, 2000, 2003, 2008; Solaris 2.6, 7, 8, 9, 10; HP-UX 19, 11, 11i; IBM AIX 4.3.3, 5.x; Linux; Apple; VMWare

→Secondary File Servers running most versions of Centera, Celerra, NetApps, etc.

##### **ATEMPO Digital Archive 2.3:**

→NAS 5.6.43 or higher; see support matrix

##### **CENTERA FileArchiver v3.5:**

Centera is a data storage platform that uses a data access mechanism called CAS (Content Addressable Storage), which creates unique handles for each object stored—no directories, no pathnames, no URLs

→Centera Gen3/Gen4 or Dell 2850 as Policy Engine runs on Linux as CUA (Centera Universal Access)

→Supports NFS or CIFS

→Secondary storage Centera-only

→Does not support digest authentication for DHSM API

#### **CENTERA v4.0 CFS/CUA SUPPORT:**

Minimum NAS versions are 5.4.24.8 & 5.5.27.5.

**Note:** v4.0 Support information is not posted on the Celerra Matrix, only in the Centera PSB.

#### **DISKXTENDER FOR NAS v3.1:**

→Policy engine running on Windows 2003, Solaris 9 & 10, Redhat Enterprise 4.0

→NAS 5.5 or 5.6 required

#### **SYMANTEC ENTERPRISE VAULT v7.0 FSA:**

→NAS 5.5 or 5.6, refer to Symantec.com for information

#### **SMARTMOVE v.2.3 Enigma Data Systems (SmartMover 2.3.2):**

→NAS 5.2 + Windows 2003; Solaris 8, 9, 10; Linux RedHat 3.x or 4.x; SUSE Linux 8 or 9; Supports FLR

#### **RAINFINITY FILE MANAGEMENT APPLIANCE (FMA) VERSION 7.2 (& 7.3):**

→IP-based File level archiving solution

→Offerings are FMA, FMA-HA (High Availability), and GFV (Global File Virtualization)

→Data Movers communicate using HTTP and resolving FQDNs via DNS. Celerra can directly recall data from storage using CIFS or NFS protocols. If on Centera storage, the EMC Centera SDK is called.

#### **DHSM FILEMOVER INFORMATION:**

→NAS 5.3.12.0 supports primary & secondary DHSM file systems on same Data Mover using external interface

→Recommended NAS 5.3.21.2 for 5.3 and 5.4.18.3 for 5.4

→DHSM is a feature that uses an external Policy Engine (Windows Enigma Server or FMA) to migrate infrequently used files from primary storage (Celerra) to less-expensive hierarchical secondary storage, and then set the file ‘offline’, meaning that it becomes a stub file, with the absolute path to the Secondary Storage defined in the stub inode

**Note:** Enigma Server reads files from Celerra & transfers to secondary storage, leaving “stub” file on Celerra. Stub files contain attributes & metadata. Clients access “stub” files and Celerra will read file from secondary server.

--DHSM migrates files based on type, size & access times, migrates only regular files, and only data, not metadata

--Migrated files are converted to stub files, held on the Primary storage in order to recall or read from secondary storage when requested from NFS, CIFS, or FTP clients

--DHSM is part of ILM (Information Life-Cycle Management) for Migration of data

--another DHSM product is Arkivio Auto-Stor

#### **CELLERRA FILEMOVER/DHSM RULES:**

→Must use Celerra as primary storage in order to have a Celerra as part of a secondary storage solution

→FileMover can support a two hop configuration, but Policy Engines may not yet support

→FileMover requires I18N Data Mover

→Port 5080 must be opened on network between DM and Policy Engine

→Default HTTP threads = 20, with 15 threads dedicated to FileMover API (up to 15 simultaneous FileMover API requests from Policy Engine)

→HTTP protocol is used to communicate between Policy Engine and Celerra FileMover API, for both NFS or CIFS connections, when converting file to stub file after the migration

→\$ server\_http\_server\_2 –modify dhsm –threads 30 (max number threads is 30)

→Every file that gets migrated requires the Policy Engine to initiate the migration

→But, files that are recalled do not involve the use of the Policy Engine, just the rules that have been setup on the storage systems

**Note:** The exception is if secondary storage is on Centera, which would require a Policy Engine to recall the file, since Celerra has no concept of the clip ID which Centera uses to store files. Celerra would provide the inode stub info to the Policy Engine, which would recall the file and deliver to Celerra.

→ There can be multiple FileMover connections for a primary file system, but each connection must go to a Secondary storage target

→If using offline folders, set –read\_policy\_override option to prevent files from being migrated back to primary storage

#### **DHSM ATTRIBUTES:**

--File migration most commonly based on size and access times

--File migration and management using Open standards to other Celerra Servers or File Servers

--Only regular files are migrated, not links or directories

#### **Stub Files:**

Files become stubs after migration—stub file resides locally on DM & contains metadata & attributes. Stub files store modification times (mtime) of files, name, permissions, timestamps, size in 8k, offline path, file size, user data string, Policy engine ID string, and Read recall policy. Orphan files are those files on Secondary storage that do not have Stub file data on Celerra.

- Uses CDMS building blocks for files offline
- HTTP uses 20 threads by default for DHSM API requests
- Uses distributed data but accessible from single point on Celerra [transparent data recall]
- File attributes and metadata are stored on Primary Store as a “stub” file, which uses 1 inode and consumes an 8k block (mtime)
- Policy-Based defined by Administrators
- Celerra VDMs can be used as Primary and Secondary Stores [use UNC paths]
- AntiVirus options can skip Offline file scanning or use Scan on First Read using pass-through mode
- HighRoad Clients use NFS or CIFS protocol for Offline files
- Quotas uses additional inode for offline and uses pass-through reads when reaching Quota Limits
- SnapSure defaults to pass-through reads
- Do not allow quotas or file system to become full as Server will revert back to ‘Passthrough Read’

**Note:** For migrated data, select migration policy to ‘Recall Data’ if the desire is to bring files ‘online’ or read data in ‘pass-through’ mode to leave offline

### **STUB FILE ATTRIBUTES:**

- Stub files reside on the Primary storage file system
- Contains offline path to Secondary storage for recall or pass-through
- Contains mtime of file and original file size, though stub file itself is only an 8k block
- Contains file name and permissions
- Contains Recall Policy and policy engine ID
- Contains User data string
- Windows Clients see offline file with clock graphic icon, and file sizes bracketed in DOS directory output [ ]
- CIFS Redirector timeout increases for Stub files from 45 secs to 1000 seconds

**Note:** Stub and Secondary file MTIME & File Size must be the same, or else the file will become orphaned

### **FILEMOVER API FUNCTION CALLS:**

- FMOpenSession: open a session with a FileMover server
- FMCloseSession: close a session
- FMGetApiAttrs: retrieve version and attributes
- FMGetFileAttributes: retrieve online and offline attributes
- FMSetOfflineAttributes: get secondary connection information
- FMGetErrorString: get string related to FileMover API error code

### **DHSM API CALLS:**

- DHSM\_GET\_API\_ATTRS →Query version and capabilities of API  
./get\_api\_attrs -user -password 10.241.169.13 /
- DHSM\_GET\_ATTRS →Get attributes of a file  
./get\_attributes 10.241.169.13 /dm2fs1/dir1/pax.tar
- DHSM\_SET\_ATTRS →Convert online file to stub file after copying to secondary storage  
.set\_attributes -user dhsm\_user -p dhsm -v 1004503452 10.241.169.13 /dm2fs1/dir1/pax.tar nfs://192.168.10.30/nfsv3\_fs/pax.tar
- DHSM\_GET\_CONNECTION\_LIST →List of secondary connections (new with 5.4)  
.get\_connection\_list -u dhsm -p dhsmdhsm 10.241.16.13 cifs://cifs7dm2.w2003.celerra.com
- DHSM\_GET\_BULK\_ATTRIBUTES →Attributes of files/directories in a tree (NAS 5.5)—filter by Size, Timestamps, Type, State
- DHSM\_QUERY\_BULK\_RETRIEVAL →status of running BAR (Bulk Attribute Retrieval) job, up to 4 per DM
- DHSM\_ABORT\_BULK\_RETRIEVAL →abort running BAR job

```

## **DHSM ARCHITECTURE:**

Primary Server Store = Celerra

NAS Clients access data via Celerra

Secondary Server Store = data migrated to a File Server

Policy Engine runs on CIFS or NFS Client, has access to both Primary and Secondary Server Stores

DHSM API's run XML over HTTP Port 5080 [DHSM\_SET\_OFFLINE\_ATTRS & DHSM\_GET\_ATTRS]

## **POLICY ENGINE:**

Searches Primary Store for files that match defined policies (rules) and transfers files to Secondary Storage and marks files offline [absolute path, attributes, and metadata info is stored in offline inode (Opaque Inode) on Primary Store--called stub files]

**Note:** CIFS default for accessing offline files is 1000 secs.

## **DHSM FILE READ RECALL POLICIES:**

**Passthrough:** Client accesses stubfile on Primary storage, Celerra recalls data from Secondary storage as a Read operation and passes to Client. Stub file is preserved and data is not recalled to Primary Storage. Read-Only file systems, such as checkpoints, use Passthrough Reads automatically.

**Full Recall:** Client access file on Primary storage, Celerra recalls entire file and writes back to Primary Storage, then passes to Client, and stub file is converted back to a normal file.

**Partial Recall:** Recalls only data needed by client, but moves data to Primary Storage. If whole file is Read, stub file reverts to a normal file.

**Note:** DHSM Policies are specified when the CIFS or NFS Connection is established. File System Read policies take precedence over Connection or Stub file policy settings, while Connection Read policies take precedence only over Stub file policies.

## **File Retrieval Process:**

- 1) Client request made to Celerra
- 2) Celerra reads stub file attributes
- 3) Celerra retrieves info on file from Secondary storage and compares mtime and file data size to verify the correct file
- 4) File is read back using Full, Partial, or Passthrough

**Note:** Default behavior is to recall all files to primary storage if the DHSM connection is deleted

## **DHSM WRITE MODIFY POLICY:**

**Modify Recall:** Complete file recalled from Secondary to Primary, Client modifies file on Primary.

→CIFS, NFS, FTP clients that try writing to an offline, or secondary storage file (modify), must first have the entire contents of the file recalled to local storage before the modification can be made

## **DHSM MIGRATION POLICIES:**

These policies are handled by the Policy Engine

## **ANTIVIRUS APPLICATIONS & DHSM BEHAVIOR:**

→Be aware that some Virus applications may update last access times on files, which may defeat purpose of DHSM policies in that files that are always updated will not migrate properly (Symantec with option ‘Skip offline files’ will skip stub files; McAfee has an option to scan migrated files, but does not work & will not scan such files)

→CAVA will skip offline stub files and not scan, therefore not change last access times

→McAfee automatic scan will preserve last access times—a manual scan, however, will update last access times, but not for stub files

→Symantec versions cause file recalls because of read behavior & requires special settings to address

    Disable Realtime Protection or Auto-Protect; clear the Opened for backup option; select Skip offline files option, etc.

→Write operations proceed normally

→With “Scan-on-Read” mode set, data is read in passthrough mode from AV Server—this setting is recommended or else the AV application may change the last access times on files

→Using “-fsscan” option, Stub files are not scanned by default. However, if ‘-fsscan –create offline’ option is used, CAVA will allow scanning of Stub Files from the AV Server in ‘readthrough’ mode.

**Note:** Stub File attributes are stored as an SMB Offline file attribute, which is set on all migrated files by default. If full file system scans are anticipated, EMC recommendation would be to set –read\_policy\_override to passthrough option for fs\_dhsm options.

## **BACKUP APPLICATIONS & DHSM BEHAVIOR:**

→CIFS performs backups by default using –backup passthrough as offline options, which backs up stub files as 0-byte files with extended acls, and does not recall the whole file from Secondary storage

→Be aware that some Backup applications can change the last access time, which may defeat the purpose of DHSM policies in that the file access times will always be updated [Veritas NetBackup & Legato NetWorker do not change last access times for stub files]

→General Unix backups would recall all files

### **CONFIGURING BACKUP OPTION ‘PASSTHROUGH’:**

**# fs\_dhsm -modify <fsid> -backup passthrough**

## **SPECIAL CONSIDERATIONS FOR NFS APPLICATIONS & DHSM:**

CIFS works with DHSM using DOS attributes called OFFLINE, or FILE\_ATTRIBUTE\_OFFLINE, for zero-byte stub files. NFS is not DOS aware and the following settings are recommended in order to ensure that stub files are not recalled inadvertently:

1. Change –read\_policy\_override option to passthrough, at filesystem or connection level, and stub files will not be recalled
2. Alternatively, create a Checkpoint and backup files from a Read-Only file system (reading of stub files defaults to passthrough)
3. Use NDMP backups, which handles stub files properly

→NDMP can perform offline backups of attributes or data using Variables [EMC\_OFFLINE\_DATA=Y or EMC\_OFFLINE\_DATA=N]

## **OTHER APPLICATIONS TO CONSIDER WHEN USING DHSM POLICIES:**

→By their nature, Web applications will recall files read—avoid use of web bots that scan websites—will cause large file recalls!

→Microsoft Utilities, CACLS & ATTRIB will not recall files—reads metadata; Robocopy requires /B switch to prevent file recall

→Unix find and touch Utilities do not recall files, but grep, head, tail will cause files to be recalled

→IP Replication would recall data if stub files are copied

## **VIEWING OFFLINE ATTRIBUTES FROM CIFS CLIENT:**

**# fs\_dhsm -modify cifs\_common**

cifs\_common:

state = enabled  
offline attr = on →EMC recommends keeping this enabled, otherwise Windows explorer can inadvertently recall files  
popup timeout = 0  
backup = passthrough  
read policy override = none  
log file = on  
max log size = 10MB

**# fs\_dhsm -modify cifs\_common -offline\_attr off** (turns off capability of viewing offline attributes for files)

cifs\_common:

state = enabled  
offline attr = off

## **FS DHSM COMMAND & TOOLS:**

**Note:** fs\_dhsm is used to create, delete, or modify NFS, CIFS, or HTTP connections to remote hosts. It also displays and configures DHSM properties on Celerra file systems.

**# fs\_dhsm** (DHSM management, status)

**# server\_http** (API security access)

**# /nas/sbin/server\_user** (user id to access policy engine)

### **\$/nas/tools/dhsm/get\_attributes**

**Note:** get\_attributes retrieves information on file attributes using the Data Mover DHSM API

### **\$ /nas/tools/dhsm/set\_attributes**

**Note:** set\_attributes can set a file offline using Data Mover DHSM API or change Retention State

**\$ ./set\_attributes -u rsadmin -p Stud3nt123 -w "0" server\_2 '/podE/LICENCE.TXT'**

## **DHSM COMMANDS:**

**# fs\_dhsm -list**

|    |            |
|----|------------|
| id | name       |
| 29 | fs01       |
| 30 | fs03       |
| 83 | fs01_snap1 |

**# fs\_dhsm -i fs01**

```
fs01:
state      = enabled
offline attr = on
popup timeout = 0
backup      = passthrough
read policy override = none
log file    = on
max log size = 10MB
```

**\$ fs\_dhsm -connection <file\_systemname> -info**

```
podE:
state      = enabled

**# .server\_config server\_x -v “disconnect fsid=65 cid=1”**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
**# fs\_dhsm -c id=65 -type cifs -admin “gabp.bsch\\\admin” –secondary \\\\nasarch\_oeste.san.corp\\VFS0030\_ARCH –local\_server “vnasfs0012.gabp.bsch” –password exchange1**

## **OFFLINE MTIME IN STUBFILE DOES NOT MATCH REMOTEMTIME:**

The offline Mtime no longer matches the remoteMtime for many files and customer has users that cannot access certain files.  
Turn off Mtime verification via following:

**# fs\_dhsm -modify <<fs\_name>> -verify off**

## **CONFIGURING FILEMOVER/DHSM ON CELERRA:**

1. Create Primary and Secondary file systems of same size on different Servers & Export for CIFS

**# nas\_fs -n fs1 -c size=512M pool=symm\_std -o slice=y**

2. Create MD5 User Accounts on Server if Digest Access Authentication is going to be used for FileMover:

**# /nas/sbin/server\_user server\_2 -add -md5 -passwd dhsm\_user**

**Note:** Use unique UID/GID and min. password length 7 characters—password must be stored locally on DM for access

3. Configure access to FileMover API on Data Mover for Policy Engine IP Address:

**# server\_http server\_2 -append dhsm -hosts 192.168.25.45**

4. Configure digest access authentication to HTTP Server:

**# server\_http server\_2 -append dhsm -users valid -hosts 192.168.25.45,192.168.25.122,192.168.25.123**

**Note:** valid option allows all Users in passwd file to digest authenticate. If no Users are specified, digest authentication is turned off.  
Specify users via comma separated list for specific digest authentication.

5. Enable the Primary Storage file system for DHSM:

**# fs\_dhsm -modify fs1 -state enabled**

6. If not already done, setup CIFS on Primary and Secondary Servers

7. Create (CIFS/NFS) DHSM connection from the Primary File System to the Secondary File System:

### **CIFS CONNECTION:**

**# fs\_dhsm -connection fs1 -create -type cifs -admin ‘nas2000.lab\Administrator’ –secondary \\sec.celerra5.emc.com\\sec’ –local\_server dm2 –password nasadmin**

**Note:** If Primary & Secondary storage systems are in different Windows domains, then the –admin switch must be used. Do not use DFS share to create CIFS connection.

### **NFS CONNECTIONS:**

**# fs\_dhsm -connection fs1 -create -type nfsv3 –secondary 10.241.169.13:/nfsv3\_fs -proto UDP -useRootCred true | false**

**Note:** The default credentials used when accessing Secondary Storage via Stubfiles using NFS, are to use the credentials presented by the owner of the file when retrieving the files. When set to “true”, the credentials used are as “root” user.

8. Modify & Verify DHSM Connections:

**# fs\_dhsm -connection fs1 -modify 0 -read\_policy\_override partial**

**Note:** Implications here are that the –modify needs to be run after creating the connection if you need to specify Read & Write Recall policies

9. Configure HTTP server on DM to accept Celerra FileMover API connections from Host:

**\$ server\_http server\_2 -append dhsm -users <user\_name> -hosts <ip\_addr\_policy\_engine>**

**# fs\_dhsm -connection fs01 -info**

fs01:

```
state          = enabled
offline attr   = on
popup timeout  = 0
backup         = passthrough
read policy override = none
log file       = on
max log size   = 10MB
cid            = 0
type           = CIFS
secondary      = \\fei0018a030.hq.ferg.com\\DMC\
state          = enabled
read policy override = none
write policy    = full
local_server    = FEI0018S009.DS.FERG.COM
```

```
admin      = ds.ferg.com\backup
wins      =
cid       = 1
type      = CIFS
secondary = \\\fei0018s012.hq.ferg.com\ArchiveHome$\_
state     = enabled
read policy override = none
write policy = full
local_server = fei0018s009.ds.ferg.com
admin     = ds.ferg.com\backup
wins     =
```

**# fs\_dhsm -connection -info sec id=0**

**# server\_http server\_3 -info dhsm**

server\_3 :

DHSM:

users: <all valid users>  
allowed IPs: 172.16.105.180

threads: 20

9. DHSM Logging:

**# fs\_dhsm -modify fs1 -log on | off**

**CREATING CONNECTION FOR NFS:**

**# fs\_dhsm -connection fs01 -create -type nfsv3 -secondary nfs\_server:/dest\_path**

**MODIFYING CONNECTIONS:**

**# fs\_dhsm -connection fs1 -modify 0 -read\_policy\_override partial**

**DELETE CONNECTION:**

**# fs\_dhsm -connection fs1 -delete -recall\_policy check | no | yes** (yes will recall files before deleting connection)

**BACKING UP FILES:**

**# fs\_dhsm -modify fs1 -backup offline | passthrough** [backs up stub files, CIFS only]

**# fs\_dhsm -modify fs1 -read\_policy\_override full | partial | passthrough | none** [backs up files using NFS]

**MODIFYING HTTP THREADS:**

**# server\_http server\_2 -modify dhsm -threads 40**

**DISABLING DHSM:**

**# fs\_dhsm -modify fs1 -state enabled | disabled**

**MODIFYING DHSM WITH DISKXTENDER FOR VDMs:**

**Source Celerra:**

CIFS Server = vdma, Share = vdm\_source, IP = 10.32.22.34, File System = vdm\_fs\_1 on vdm\_1, FQDN path

[\\vdma.nas2000.lab\\vdm\\_source](\\vdma.nas2000.lab\\vdm_source)

**Target Windows 2000 Server:**

Nasdc2000, domain = nas2000.lab, IP = 10.32.22.240, admin=administrator, target directory = c:\vdmdest, target share = <\\vdmdest>,  
FQDN path to target share = <\\nasdc2000.nas2000.lab\\vdmdest>

**Modifying Celerra:**

**# server\_http server\_4 -modify dhsm -users valid -hosts 10.32.22.240**

**# /nas/sbin/server\_user server\_4 -a -md5 -passwd dhsmuser**

**# fs\_dhsm -modify vdm\_1\_fs1 -state enabled**

**# fs\_dhsm -connection vdm\_1\_fs1 -create -type cifs -admin 'nas2000.lab\administrator' -secondary '\\\nasdc2000.nas.lab\\vdmdest' -local\_server vdma**

**Setting up DiskXtender:**

--Setup all DX Data Manager services to run using Log On As NAS2000\Administrator account

--Using Data Manager for Celerra>Source dirs: setup Source path ([\\vdma.nas2000.lab\\vdm\\_source](\\vdma.nas2000.lab\\vdm_source)) & Host Name  
(vdma.nas2000.lab)

--Using Data Manager for Celerra>Destination dirs: setup Destination path (<\\nasdc2000.nas2000.lab\\vdmdest>), Path to primary storage (/vdmdest/), & Host Name (nasdc2000.nas2000.lab)

--Rules>setup Rule criteria as "-name \*.txt"

--Migration methods>setup Readback method (full), Migration Mode (DHSM), & Username (dhsmuser)

--Jobs>setup Rule (vdmtext), Migration method (vdmmigrate), Destination (vdmtarget), Time Limit (minutes) (0), Source (vdmsource)

**SMARTMOVE ENIGMA DATA SYSTEMS DHSM POLICY HOST:**

1. Open Enigma Management Console and add ‘DHSM Hosts’ by compname and port 5080, selecting ‘Enable secure HTTP, and testing with ‘Test Connection’ button
2. Configure>Destinations>Add: add remote Secondary Server by name and define secondary file system path using UNC
3. On Primary Store ‘Share’, create folders and migrate data for testing to these folders
4. Add Container to Enigma: Configure>Containers>Add: Container name, UNC path to container [\dm2\prim\container1], select ‘Migrate Celerra’ radial button
5. Select ‘Update>Projects>Update All’ and verify that files are added
6. Create Filters: Migration>Filters [Use Exclude if selecting file types such as \*.pdf for a filter or Include for all files]
7. Add Rule to Filter: Migration>Rules>Add
8. Add a Job: Migration>Jobs>Add
9. Execute the Job and check Secondary Store Share for migrated files [View Primary Store for Offline Inodes for migrated files]

### **FILEMOVER UTILITIES (developed by IST group):**

--fmexport (bulk file exporter, copies data to Secondary & converts regular files to offline stubs; scriptable, works with Policy Engine)  
--fmimport (bulk file importer, copies stub files from one location to Celerra—NFS or CIFS; scans existing directory tree to get file attributes, creates 0-length file, transfers permissions, then replaces 0-length file with stub file pointing to Secondary source)  
Issues: links, namespace of files; can use xfrperms to transfer Windows permissions  
--fmxfer (Unix copy that is stub file aware). Retrieves attributes of files from Source, creates zero-length file on Primary and transfers permissions from Source, then converts file to Stub while pointing to same Secondary storage. Preserves hard & soft links.  
--fmlist (Unix ls that displays stub files and offline attributes)

### **PROBLEMS RECALLING FILES FROM SECONDARY STORAGE:**

→There is an issue where Rainfinity FMA preserves file permissions when copying to Secondary Storage. This means that if files are Read-Only, Celerra will not be able to recall them unless the FileMover connection account has backup privileges [e.g., member of local Backup Operators group, or member of Domain Admins], and also has the “backupintent” flag set.

→AR135811 introduced hard-coded BackupIntent flag, and NAS 5.6.46 introduced a param that can be changed

**# .server\_config server\_2 -v "param mgfs useBackupIntentMode"**

mgfs.useBackupIntentMode INT 0x03534f5c 1 1 (0,1) FALSE NONE 'The parameter decides whether DHSM connection should use backupIntentMode or not.'

### **TROUBLESHOOTING COMMANDS:**

fs\_dhsm →DHSM management on Celerra

server\_http →Security management on Celerra

server\_user →DHSM User creation on Celerra

get\_attributes →DHSM API query call to get state of files and return attributes

set\_attributes →DHSM API call to convert online files to Stub or update offline attributes of stub files (# ./set\_attributes -u dhsm\_user -p dhsm\_user -v 1063404534 (mtime of file) 192.168.4.53 /path/file.tar nfs://10.241.168.78/path/file.tar)

get\_api\_attrs →DHSM API queries to check API access and functionality (# ./get\_api\_attrs -u dhsm -p dhsmdhsm 10.64.200.53 /PATH...PATH="/")

get\_connection\_list →DHSM API query for list of connections configured on Data Mover (# ./get\_connection\_list -u dhsm -p dhsmdhsm 10.64.200.172 cifs://celdm2.w2k.celerra.com/fs1)

### **TROUBLESHOOTING FILEMOVER/DHSM:**

Check Server Log and DHSM logs (pfs/.etc), increase logging levels, verify Policy Engine, Data Mover configuration and connections, use get\_attributes commands, etc.

#### **1. Set following debug logging levels:**

**\$ .server\_config server\_2 "logsys set severity DHSM=LOG\_DBG3"**

**\$ .server\_config server\_2 "logsys set severity MGFS=LOG\_DBG3"**

**\$ .server\_config server\_2 "logsys set severity HTTPD=LOG\_DBG3"**

**Note:** Use the following syntax to turn off debug logging when completed with log collection and troubleshooting

**\$ .server\_config server\_2 "logsys set severity DHSM=LOG\_PRINTF"**

**# .server\_config server\_2 -v "printstats dhsm"**

SetOfflineAttrs : 0

GetAttrs : 0

GetAttrsFail : 0

SetOfflineAttrsFail : 0

GetApiAttrs : 0

GetApiAttrsFail : 0

```
GetConnectionList      : 0
GetConnectionListFail : 0
GetBulkAttrs          : 0
GetBulkAttrsFail      : 0
QueryBulkRetreival   : 0
QueryBulkRetreivalFail: 0
AbortBulkRetreival   : 0
AbortBulkRetreivalFail: 0
```

## **2. Check DHSM Log on the Primary Storage File System in the hidden .etc directory:**

```
.etc]# ls -la
-r--r--r-- 1 root bin 7144638 Sep 22 09:06 dhsm.log
```

**Note:** (5) generations of the 10MB log are kept. Increase log size:

**\$ fs\_dhsm -modify fs01 -max\_log\_size 20 [20MB]**

→SET\_OFFLINE indicates that migrated file was replaced by stub

→REMOVE indicates that stub file was deleted

→GET\_ONLINE indicates that stub file on primary was recalled from secondary

**# head dhsm.log**

```
91760*: SET_OFFLINE: 1.1d.1d198e.4296ec2f, pe_id: NONE, offline_path:
```

```
\\\fei0018a030.hq.ferg.com\DMC\fei0018s009.hq.ferg.com\home\HQ\epuckett\My Documents\Vendor Queries\Queries for Thom Riley\4294967325-1907086-1117187119 ... Sun Sep 4 13:14:05 2005
```

## **3. Check Primus & AR's before escalating issues**

## **4. Check Policy engine, Server and DHSM file system logs**

## **5. Verify NFS or CIFS exports**

## **6. Verify connections from DM to Secondary using fs\_dhsm -c <fs01> -i**

## **7. Use get\_api attrs script to check connectivity to API**

## **8. Use get\_attributes script to check files**

## **9. User server http to verify various parts of DHSM configuration that relate to HTTP**

**Note:** With NAS 5.6, the default Authentication for DHSM is set to “Digest”. You may need to modify the security access settings as the following example shows:

**# server\_http server\_2 -info**

```
server_2 : done
DHSM FACILITY CONFIGURATION
Service name      : EMC File Mover service
Comment          : Service facility for getting DHSM attributes
Active           : False
Port             : 5080
Threads          : 16
Max requests     : 300
Timeout          : 60 seconds
ACCESS CONTROL
Allowed IPs      : any
Authentication   : digest ,Realm : DHSM_Authorization
Allowed user     : nobody
```

**# server\_http server\_2 -modify dhsm -authentication none**

```
server_2 :
DHSM FACILITY CONFIGURATION
Service name      : EMC File Mover service
Comment          : Service facility for getting DHSM attributes
Active           : False
Port             : 5080
Threads          : 16
Max requests     : 300
Timeout          : 60 seconds
ACCESS CONTROL
Allowed IPs      : any
Authentication   : none ,Realm : DHSM_Authorization
Allowed user     : everybody
```

## **MS EXCEL FILES & DHSM BEHAVIOR:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Excel files have a tendency to be recalled when a stub file is accessed by a Windows client. Workaround to correct this behavior--  
modify Excel files as ReadOnly.

## **VERIFIER MISMATCH OFFLINE FAILURE:**

### **Server Log:**

DHSM: 6: API failed: VERIFIER\_MISMATCH

→See AR78669, but basically, DiskXtender will fail to complete setting files offline if DART returns more than 40  
VERIFIER\_MISMATCH errors, which can occur when DM updates file attributes after DX has cached previous values. DART  
returns the mismatch error because the file attributes are different than DX. Setting mappingErrorAction=1 may allow offline  
operation to succeed in the face of many unknown SIDs.

## **NETGROUP ACCESS WITH NFS EXPORTS:**

**Purpose:** Netgroups are groups of Hosts and/or Users used to restrict access to shared NFS exports

--Hosts and Subnet groups have preference over Netgroups

--When two or more netgroups are defined, the first matching entry is used for granting access

--Negation can be used to specify hosts to be excluded from access

**Note:** Negated entries should be at beginning of list and do not negate other netgroup lists

**#server\_export server\_2 -o rw=-netgroup1:netgroup2 /fs1**

**#server\_export server\_2 -o rw=-host1:netgroup1 /fs1**

--If both RW and RO are used in Export, result depends on following params:

**param nfs secureExportMode=0** [Provides RW access in case of conflict]

**param nfs secureExportMode=1** [Provides RO access in case of conflict]

### **EXAMPLES:**

rw=host1 ro=netgroup1 [If host1 is a member of netgroup1, then host1 will have RW access due to host preference]

rw=netgroup1 ro=subnet1 [host1 is a member of both groups, host1 will have only RO access due to subnet preference]

rw=-netgroup1:netgroup2 [host1 is member of both groups, then host1 will not have RW access]

rw=netgroup2:-netgroup1 [host1 is member of both groups, then host1 will have RW access]

## **FILE EXTENSION FILTERING (Celerra File Filtering):**

**Intro:** Can now filter what file extension types are allowed to be saved to a network Share on Data Mover

### **FILE FILTERING CIFS PARAM:**

**# server\_param server\_2 -facility cifs -info enableFileFiltering**

server\_2 :

```
name      = enableFileFiltering
facility_name = cifs
default_value = 0x00000007
current_value = 0x00000007
configured_value =
user_action = none
change_effective = immediate
range     = (0x00000000,0xffffffff)
description = Bit vector to enable various forms of file filtering
```

**param cifs enableFileFiltering=7**

**Note:** File Filtering, with PopUps and Auditing, is enabled by default. 0=disabled; 1=filtering enabled; 3=filtering + Popups;

5=Filtering & Auditing; 7=Filtering, Auditing, & Popups

### **File Extension Filtering Requirements/Limitations:**

→works only with CIFS protocol (NFS Users cannot be controlled with this feature)

→requires security NT policy

→File Filtering uses combination of file extension and ACLs to work

→File Filtering done at DM or Share level, not subfolder level

→filters are created in the /nasmcd/quota/slot\_2/.filefilter directory on the DM

# pwd

**/nasmcd/quota/slot\_2**

[root@nyip1 slot\_2]# ls -la

**drwxr-xr-x 2 root bin 80 Sep 25 14:10 .filefilter**

### **CREATING FILTER FILES IN .FILEFILTERING FOLDER:**

--You must create the 'filter' file from a Windows client

--As Administrator, connect to [\\datamover\c\\$](\\datamover\c$) share and go to the .filefilter folder and create the filter file inside this folder

**Note:** The actual “filter” file is a zero byte file with the chosen extension identified as the name of the file itself.

--As Administrator, set ACL permissions on the actual “filter” file itself to further control behavior

#### **FILTER FILE EXAMPLES:**

**Note:** The name after the first @ sign indicates the Sharename—if a 2<sup>nd</sup> @ sign is used, the name that follows is the Compname  
**/slot\_2/.filefilter/jpg@isaac | exe@isaac | allfiles@isaac lhtm@isaac@isaac**

**htm@isaac@compname →htm=extension to filter on | @isaac=sharename | @compname=compname**

1. Create a filter file to prevent any .jpg files from being saved on a share called “Isaac” on Server\_2 by using notepad to create an empty file with a name “jpg@isaac”. Do not allow notepad to save the file with the .txt extension. The actual file is on the extension called “jpg” for the share called “isaac”. With this setting, and file filtering params in effect, the only persons allowed to copy files with the ‘.jpg’ extension to this Share will be the actual Owner of the filter file, in this case an Administrator. To further refine access, you can then define ACL’s on the filter file to allow or disallow Windows Users or Groups from being able to copy .jpg files to the share. For example, if you grant a user called “NAS1” a specific ACL to allow RW privileges to “jpg@isaac”, that User will be able to copy jpg files to this Share, and so on.

2. Create a filter file to prevent copying of any files to a Share called ‘isaac’: allfiles@isaac. Only the Owner of the filter file will be able to copy files to this Share. You could then set permissions to allow specific Users or Groups to be able to copy files to the Share. Add specific file filters with ACE entries to allow for specific file types to be copied to a Share for specified Users/Groups, etc.

3. To allow all files to be copied to a share called ‘isaac’ on a Server called ‘compname’:

allfiles@isaac@compname

4. To allow only a specific extension to be copied:

exe@isaac@compname

**Note:** Multiple filter files should be tested to ensure the desired effect. For example, creating a filter ‘allfiles@isaac’ to deny all files, then creating an allow filter for ‘exe@isaac’ will not result in exe files to be copied

5. To allow only xls files to be copied to a share, create following filter files:

allfiles@isaac

xls@isaac [Set ACL on this file to all Everyone Full Control—will allow copy or creation of xls files to this share]

noext@isaac [Set ACL on this file to Everyone Full Control—file needed because of temp files used by excel process]

#### **RESERVING A SHARE FOR SPECIFIC FILE TYPES:**

a.) Create the Filter Filename called allfiles@sharename@compname (restricts all file types from Share)

b.) Prevent files without extensions from being added to share: noext@sharename@compname

c.) Specify the actual file type for each extension that will be allowed on the Share: extension\_name@sharename@compname and then make sure to set ACLs on the filter files

#### **SPECIAL FILE FILTER NAMES REQUIRED TO SUPPORT MS WORD, EXCEL, PPT, etc:**

allfiles@sharename →No ACL assigned

noext@sharename →No ACL assigned

doc@sharename →Assign ACE for User/Group access

tmp@sharename “ “

asd@sharename “ “

wmf@sharename “ “

rtf@sharename “ “

xls@sharename →Assign ACE for User/Group access for Excel files

ppt@sharename →Assign ACE for User/Group access for Powerpoint—also requires the tmp entry as shown above for Word

#### **FILE FILTERING BEHAVIOR TESTING:**

→allfiles@isaac@compname allows any user to copy any file type to Isaac Share on compname ‘Compname’

→allfiles@isaac denies any user except owner, or someone added to the ACL on the filter file with RW perms, the ability to copy files to Isaac Share

**Note:** This file filter is restrictive--other filter files added to allow extensions to be copied will be denied [allfiles@issac + exe@isaac or exe@isaac@compname]

→allfiles@isaac denies all Users, except for a user called “NAS1”, who has been granted Full Control permissions on the filter file called “allfiles@isaac” in the .filefilter directory

→jpg@isaac allows User to copy all files to Share except for jpg files

→jpg@isaac@compname allows users to copy all files, including jpg’s, to the Isaac Share on ‘Compname’

#### **FILE FILTERING PARAMETERS & OBSERVED BEHAVIOR:**

0: filtering disabled—No Filtering, No PopUps, No Event Logging

1: file filtering enabled—Filtering enabled, No PopUps, and No Event Logging on Client system

3: file filtering + popups enabled—Filtering enabled, PopUps enabled, and Event Logging on Client system occurs

5: file filtering + auditing enabled, no popups—Filtering enabled, No PopUps, and No Event Logging on Client system

7: file filtering + popups + auditing enabled [Default Celerra setting]—Filtering enabled, PopUps enabled, and Event Logging on Client occurs

**Note:** Messenger Service is required in order for Clients to be able to receive a PopUp message—runs by default on Win2k, does not on Win2k3. Must reboot Server if changing file filter param policy.

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
**FILE FILTERING CLIENT ERROR MESSAGE** [Not a PopUp message—message results when Filter policy is in force]:

Error Copying File or Folder

Cannot copy JUNKMAIL: Access is denied

Make sure the disk is not full or write-protected and that the file is not currently in use.

**FILE FILTERING POPUP MESSAGE FROM MESSENGER SERVICE:**

Message from Iprep2 to Sneezy on 3/29/2005 3:12:30PM

File Extension not allowed

Share Isaac

File \JUNKMAIL.LKO

Operation create

## **USING CIFSMSG.TXT FILE TO CREATE CUSTOM POPUP NOTIFICATION MESSAGES:**

→cifsmsg.txt file can be used to customize PopUp messages for File Filtering, CAVA, Quotas, DHSM [CIFS only]

→In order to use PopUp messages, the Windows client must run the Messenger service

→The cifsmsg.txt file is meant only to customize the actual popup message generated by the feature

→Last line for the Warning or Error should have a period

### **CUSTOMIZING POPUP MESSAGES FOR QUOTAS:**

1.) Create and/or edit a file called “cifsmsg.txt” to create the custom popup.

#

# Warnings for status NoSpace, QuotaExceeded and

# GroupQuotaExceeded

#

#

\$warning.NoSpace=

You're about to run out of space on your home share

Please initiate cleanup of unwanted and old files now to

prevent future disruption

.

\$warning.QuotaExceeded=\$warning.NoSpace

\$warning.GroupQuotaExceeded=\$warning.NoSpace

#

#

# Errors for status NoSpace, QuotaExceeded and GroupQuotaExceeded

#

#

\$error.NoSpace=

Your home share has reached the allotted quota limit

Please initiate cleanup of unwanted and old files now

Contact the ANR help desk @ ext 5800 for any needed assistance

.

\$error.QuotaExceeded=\$error.NoSpace

\$error.GroupQuotaExceeded=\$error.NoSpace

2.) Push file out to /.etc of DM using server\_file -put

3.) Stop and Start CIFS service

## **TOE TCP OFFLOAD ENGINES ON NIC CARDS:**

NAS 5.3 introduces TOE (TCP Offload Engines) with Alacritech Accelerator 10/100/1000 Base-T or 1000Base-SX NICs, introduced with 514 DM's and designed to offload NFS, CIFS, and FTP connections

**Note:** Drawback of TOE is that network captures from DART do not see TOE traffic—must use other sniffing equipment. Disable TOE with following parameter. Additionally, TOE devices can panic, causing a SLIC dump to logfile called “/slicdump” ~16MB.

**param TOE StdNicMode=1**

**Note:** Current recommendation is to disable TOE offload engine for TOE cards by setting value to 1—see AR44627

**\$ .server\_config server\_2 -v "param TOE"**

| Name | Location | Current | Default |
|------|----------|---------|---------|
|------|----------|---------|---------|

|                |            |            |            |
|----------------|------------|------------|------------|
| TOE.StdNicMode | 0x011f9654 | 0x00000000 | 0x00000000 |
|----------------|------------|------------|------------|

|                    |            |            |            |
|--------------------|------------|------------|------------|
| TOE.framechk.hiwat | 0x011f97d4 | 0x00020000 | 0x00020000 |
|--------------------|------------|------------|------------|

|                    |            |            |            |
|--------------------|------------|------------|------------|
| TOE.framechk.lowat | 0x011f97d8 | 0x00008000 | 0x00008000 |
|--------------------|------------|------------|------------|

## **ESCALATING TOE ISSUES :**

**1. Server Log will indicate when a TOE dump has been produced :**

2005-07-05 09:28:25: DRIVERS: 3: slicNicDevice: TOE (ace0) panic detected. Saving TOE core image to '/slicdump'  
2005-07-05 09:28:25: DRIVERS: 3: 6: slicNicDevice: TOE (ace0) panic detected. Saving TOE core image to '/slicdump'  
2005-07-05 09:28:25: DRIVERS: 4: slicDumpManager: Dump requested for ace0  
2005-07-05 09:28:25: DRIVERS: 4: slicDump: HALT Receive Processor  
2005-07-05 09:28:26: DRIVERS: 4: slicNicDevice: output(): CARD\_DOWN! Packet dropped!  
2005-07-05 09:28:26: DRIVERS: 4: last message repeated 20 times  
2005-07-05 09:28:26: DRIVERS: 4: slicDump: halt receive sequencer failed  
2005-07-05 09:28:26: DRIVERS: 4: slicDump: Write CoreHeader len[168] offset[0]  
2005-07-05 09:28:26: DRIVERS: 4: slicNicDevice: Dump complete

2. When escalating to EE, run the following script—collects information from sys\_log, server\_log, server\_sysconfig, server\_netstat, etc., and retrieves TOE dumps, and bundles tarred gzip file in /tmp/Toe\_Materials\_050718\_1507

**#/nas/tools/toe\_support\_materials server\_2**

/tmp/Toe\_Materials\_050717\_2057.tar.gz

/tmp/slicdump.gz

3. Debugging TOE Firmware Issues :

**param slic diagFW=1**

4. Disabling TOE Card :

**param TOE StdNicMode=1**

**COMMANDS USED TO DERIVE TOE INFORMATION :**

**\$ .server\_config server\_2 -v "slic ace0 showlist"** →Shows connections on TOE card

**\$ .server\_config server\_2 -v "slic ace0 showatkt"**

**\$ .server\_config server\_2 -v "slic ace0 showadapter"**

**\$ .server\_config server\_2 -v "slic ace0 showcard"**

**\$ .server\_config server\_2 -v "slic ace0 showoffload"**

**\$ .server\_config server\_2 -v "slic ace0 showints"**

**BROADCOM BCM GIGE DEVICES:**

Currently, Broadcom NICs are used in NS600/NS700 & have (6) copper ports

New ‘Ajaguar’ card to have (6) copper, (2) optical 1GB fibre, and (1) copper management port for NS700 uses 5704 chipset

**Note:** When a port is set to (1) GB, duplexing must always be set to full. Txflow & Rxflow are only used at 1Gbps. Linkneg is on by default and must be disabled on switches that do not support linkneg. Support for MAC flow control added.

**NETWORKING STATISTICAL LOAD BALANCING USING TCP OR IP ADDRESSES:**

--TCP and IP Statistical load balancing [TCP uses source and dest. IP address and tcp port number; IP uses source & dest. IP address]

--Configure load balancing via param file or server\_sysconfig command

**param trunk perTrunkLB=0** [Sets default stat. load balancing based on IP addr., vs. MAC addresses in previous versions]

**\$server\_sysconfig server\_2 -v -n trk1 -create trk -option “device=cge0,cge1 lb=tcp”** [Load balancing TCP]

**\$server\_sysconfig server\_2 -v -info trk1**

**\$server\_sysconfig server\_2 -v -n link1 -create trk -option “device=cge0,cge1 protocol=lacp lb=tcp”** [Load balancing LACP]

**\$server\_sysconfig server\_2 -v -info link1**

**VLSM—VARIABLE LENGTH SUBNET MASKS:**

--support for optional subnet mask lengths [DART now supports VLSM in the Routing Table]

--new Broadcom NIC driver support for flow control

**#server\_sysconfig server\_x rxflowctl=enable | disable      txflowctl=enable | disable**

**TCP CONNECTION HASHING:**

New default maxStreams=65536 [16k to 64k increase]

NAS 5.3 caches the ‘last connection’ in cache

**CELLERRA MONITOR 5.3:**

HomePage Statistics tab

CIFS Shares, Data Movers, NFS Exports, Network, File Systems, Volumes, Control Station, Network Storage systems

Capability of exporting “lists” & “graphs” into .csv files by rightclicking>Export Data [comma-separated]

Graphical displays of past and current status of DM’s, FS’s, Storage Systems, Networks

Notifications of DM resource issues can be done using email or SNMP traps [High Memory & CPU Usage] via Polling

Notifications of FS issues are done using email/SNMP traps [File System Usage & File System Projection]

## **NEW NAS SERVER -QUERY INTERFACE WITH CELERRA MANAGER:**

**\$ /nas/bin/nas\_server -query:name=server\_2 -fields:MemoryUsage -format:"%s\n"**

62

**Note:** Use above format to make queries for quotas, file system info, etc.

## **USING SERVER CIFS TO MIGRATE SIDs FROM ONE DOMAIN TO ANOTHER:**

**\$server\_cifs server\_x -Migrate fs1 -acl Disney:nb=walt:if=ana0 mouse:nb=Minnie:if=fsn0**  
**\$server\_cifs server\_x -Migrate walt -localgroup disney:nb=walt:if=ana0 mouse:nb=Minnie:if=fsn0**  
**\$server\_cifs server\_x -Replace fs1 -acl Disney:nb=walt:if=ana0**  
**\$server\_cifs server\_x -Replace walt -localgroup Disney:nb=walt:if=fsn0**

**Note:** -Migrate updates SIDs from a Source domain to SIDs of a target domain by matching User and Group account names. – Replace updates all SIDs on a file system with target SIDs and localgroups information.

## **SNAPSURE ENHANCEMENTS:**

--more than one schedule per PFS is now supported, and schedules can be modified

**Note:** 5.1 and 5.2 will convert old Schedules to new format automatically on upgrades, 4.2 will require manual conversion

--New ‘PAE’ feature to provide for memory blockmaps if RAM greater than 4GB [Physical Address Extension], to be handled by the VSM [Virtual Space Manager]

**Note:** This requires special PAE Data Movers and will support up to 64 Checkpoints per PFS

--New ‘VSS’ [Virtual Shadow-Copy Service] support—based on Microsoft’s VSS feature found in NetWin products

## **FS REPLICATE/IP REPPLICATION ENHANCEMENTS:**

→Replication of CIFS environments from (1) DM to another [VDM root file system and PFS are replicated at same time to SFS, mounted RW by User, becomes a replicated VDM]

**Note:** Rules are that mounts must be identical on PFS and SFS; Source & Target VDMs must be in same Windows Domain; Interfaces must also be identical & use same IP Address

→Ability to change DART TCP Window Size to support replication and fs\_copy

→nas\_fs supports “cloning” through use of ‘samesize=’ syntax to create PFS and SFS of same size

→Full copy on a failed resync

→Initial Copy Support for Disk or Tape transport to startup Remote IP Replication Sites

→ -suspend and -restart commands to allow for changes in SavVol, unmount filesystems and move, change IPs on interfaces, etc.

**New commands:** fs\_replicate -suspend | -restart | -reverse (replaces the ‘failback’ command) | -modify | -refresh | -resync

### **fs\_replicate -suspend:**

The –suspend command is run on the PFS side and creates a checkpoint newer than the SFS, causing Replication and Playback to shut down and stops replication processes—leaves SFS as rawfs. Command allows for changes to SavVol size, change of mountpoints, or change of IP Addresses.

### **fs\_replicate -restart:**

Also run on PFS side. Checks to see if a Suspend has occurred and if so, will use the suspend checkpoint to initiate an incremental restart of replication. Data from point of suspend on PFS side will be copied to remote side. Checks to see if PFS and SFS are in a restartable condition. Verifies that SFS is same size as PFS and that SFS is rawfs.

### **fs\_replicate -modify:**

Does not create a deltabset or attempt playback. Makes changes to HWM, Timeouts, autorotate or autofreeze immediate.

### **fs\_replicate -refresh:**

Takes new deltabset and sets new timeout, HWM policies

### **fs\_replicate -resync:**

Allows for full copy of fs to be sent back to primary side if incremental resync failed.

## **INITIAL COPY SUPPORT (aka, Disk & Tape Silvering):**

### **TAPE LEVEL COPY:**

→Special NDMP backup and restore using Volume Level Copy (VLC) using NDMP Variable VLC=y

→Volume level backup only of RO filesystems such as Checkpoints

→Restore from tape is made to rawfs file systems only

→File system limited to 2TB in size for this variable

### **DISK LEVEL COPY:**

→Transporting CX300 array to site

**Note:** Concept here is that a bulk copy of a PFS to the SFS can be done via Tape or Disk images, then synced up using IP Replication. For example, a 1TB file system could take 50 days to replicate over a T-1 line.

## **NDMP ENHANCEMENTS:**

--Increased Restore and Backup performance using multi-threading for PAX

--Better directory traversal and large file handling

### **Remote NDMP Support with Veritas:**

Heterogeneous 3-way backup over network. Data Mover is not connected to Tape Server and acts as Data Server.

### **THREE NEW THREAD GROUPS:**

NASA—Thread responsible for writing file header information, reading file data, and writing to buffer. Sends metadata to backup software and activates multiple threads, puts buffer in stat buffer pool. Allows multiple NASA threads for large file support. Pre-NAS 5.3 allowed only single NASA thread per file.

NASS—Threads responsible for traversing file system and providing metadata for each file and directory--returns metadata to stat buffer pool for each file and directory. Directory Traversal bottlenecks could occur with many small CIFS files or highly fragmented file system.

NASW—Threads gather data from buffer pool, write to tape or send to remote NDMP system.

### **New PAX Tuning Commands & GUI Interface:**

**#server\_param server\_x -facility <name> -list <paramname> | -modify <paramname> <value>**

[paxStatBuff; paxWriteBuff; paxWriteToTape; paxWriteToArch; paxnPrefetch; paxnThread; paxnFTSThreads; paxReadBuff]

**#server\_pax server\_x -stats | -reset | -verbose**

--New PAX param added to configure PAX block size: PAX.readWriteBLockSizeInKB (64 kb default—256 maximum value)

**Note:** Issue with EDM in which this value needs to be set specifically to 128

### **PARAMETER TUNING INTERFACE:**

**\$server\_param server\_x -facility PAX -info paxWriteBuff**

**Note:** Outputs current, configured, and maximum values for a param

**\$server\_param server\_x -facility PAX -modify nThread -value 8** [Sets PAX threads to 8]

**\$server\_param ALL -facility PAX -modify nThread -v 8**

**\$ server\_param server\_2 -f PAX -l**

server\_2 :

| name         | facility | default | current | configured |
|--------------|----------|---------|---------|------------|
| paxWriteBuff | PAX      | 64      | 64      |            |
| paxStatBuff  | PAX      | 128     | 128     |            |
| nFTSThreads  | PAX      | 8       | 8       |            |
| nThread      | PAX      | 64      | 64      |            |
| nPrefetch    | PAX      | 8       | 8       |            |
| nRestore     | PAX      | 16      | 16      |            |

**Note:** New default values for PAX in 5.3

### **AVM ENHANCEMENTS:**

#### **AVM Profiles:**

→Storage Pools—containers used for storage management [User-defined and System-defined]

→Profiles—set of rules to aggregate storage

→Striping only occurs in the building of a pool, never in the contents of a pool

#### **User-Defined Pools:**

--Create manually with specialized volume striping, etc, aggregate into pools

--Volume Profiles do not apply to ‘user-defined’ pools

--Cannot be dynamically extended or shrunk

--Storage must be explicitly added or removed

#### **System-Defined Pools:**

--Uses Volume Profile and Storage Profile

--Aggregates disk volumes into Pools automatically

--Volume profile that allows disks to be added and released automatically

**Note:** Storage profiles match disks to certain profile and compares to template to see if they match. Volume profiles define how new disk volumes are added to a system-defined storage pool.

#### **Volume Profile:**

--system-defined pools only

--defines how disks are aggregated and placed into pools

--only (1) volume profile per system-defined pool

#### **Storage Profile:**

--system-defined pools only

--description of disk volumes

--only Symm STD disks, not BCV's

#### **STORAGE POOL:**

--A container used to aggregate disk volumes into pools

--can consist of disks, stripes, slices, metavolumes

--A volume can only be a member of one pool

--Volumes must be of the same type as other members

### **MANAGING AVM STORAGE POOLS:**

--CLI

--Celerra Manager GUI

### **AVM GUIDELINES:**

--File Systems can be extended from only one storage pool

--Use multiple disk volumes from one Backend and not multiple backends at the same time

--Create user-defined pools if there are different Storage systems [System-defined might span different storage Backends]

### **STORAGE POOLS:**

**#nas\_pool -create pool\_1 | -delete pool\_1**

**#nas\_pool -list**

**#nas\_pool -size pool\_1 #nas\_pool -i pool\_1**

**#nas\_pool -modify id=11 -default\_slice\_flag y**

**Note:** CLI behavior is to have the default\_slice\_flag on by default—set to “n” if not desired—used to control whether volumes can be sliced or not. For example, if member volumes have already been built on slices, you might want to use “n” to disable.

**#nas\_pool -modify symm\_std -is\_dynamic y**

**Note:** -is\_dynamic indicates whether pool is allowed to automatically Add or Remove member volumes. Applies only to system-defined pools. Setting the value to no will prevent QoS mechanism from grabbing additional storage luns for use. An Error 3024: No free disks are available would be indicated.

**# nas\_pool -modify symm\_std -is\_greedy y**

**Note:** System-defined pools where volumes will be created from new space before using space from existing member volumes. A pool that is not greedy will first use up all space from existing pool member volumes before using other volumes.

**# nas\_pool -append pool\_1 -volumes d40 | -remove** [to remove a volume from a pool]

**Note:** Adds a volume to the pool indicated

### **USING AVM TO CREATE SYSTEM-DEFINED POOL FOR FILE SYSTEM:**

**# nas\_fs -name fs\_system -create size=100G pool=symm\_std**

### **USING AVM TO CREATE USER-DEFINED POOL:**

**# nas\_pool -create -name user\_pool -volumes d40,d41,d42,d43**

### **USING AVM TO CREATE FS FROM USER-DEFINED POOL:**

**# nas\_fs -name fs\_system -create size=100G pool=user\_pool -o slice=y**

**Note:** Must create the user-defined pool first!

### **EXTENDING FILE SYSTEM USING AVM:**

**nas\_fs -xtend fs1 size=50G**

**Note:** NAS 5.3 is NOT backend aware, meaning that AVM may or may not choose to extend a file system across different Storage systems! Recommendation would be to create user-defined storage pools that are built on specific systems. To be doubly certain, create a temp meta that uses all free disks on the backends you do not want to extend to! Then conduct the extension and delete the temp meta.

### **CREATING NEW FILE SYSTEM FROM EXISTING POOL:**

**# nas\_pool -list**

```
id    inuse  acl   name
1     n      421   symm_std
2     n      421   clar_r1
3     n      421   clar_r5_performance
4     y      421   clar_r5_economy  [Pool exists]
8     n      421   symm_std_rdf_src
10    n      421   clarata_archive
```

**# nas\_pool -i clar\_r5\_economy**

```
id          = 4
name        = clar_r5_economy
description = CLARiiON RAID5 8plus1
acl         = 421
in_use     = True
clients    = IPrep_src,vpfs24,pfs,vpfs30,vpfs32,boeing
members    = v110,v114,v121,v124,v128,v131,v139
default_slice_flag = True
```

```
is_user_defined = False [Pool is a system-defined pool]
disk_type = CLSTD
server_visibility = server_3,server_2
volume_profile = clar_r5_economy_vp
is_dynamic = True
is_greedy = True
# nas_pool -size clar_r5_economy
id = 4
name = clar_r5_economy
used_mb = 303736
avail_mb = 462512 [Pool shows room available to create file systems]
total_mb = 766248
potential_mb = 218928
```

### **# nas\_pool -size id=3 -slice y**

**Note:** Use this to see pool size information based on Slice information

```
# /nas/sbin/rootnas_fs -n new_group -create size=2G pool=clar_r5_economy -o slice=y
```

```
id = 47
name = new_group
acl = 0
in_use = False
type = uxf
volume = v152
pool = clar_r5_economy
member_of = root_avm_fs_group_4
rw_servers=
ro_servers=
rw_vdms =
ro_vdms =
stor_devs = APM00042103183-0018
disks = d11
```

### **NOT ALLOWED TO EXTEND FILE SYSTEM FROM POOL:**

S: nas\_fs -xtend fs1 size=29000M pool=symm\_Std

E: nas\_fs -xtend fs1 size=29000M pool=symm\_std: : volume(s) are not available

**Note:** Though message may be legitimate, in many cases, it may only mean that an entire disk is not available to perform the extension. Check the output of nas\_pool to determine if there really is any space left and then use the slice=yes option:

### **\$ nas\_pool -s symm\_std -slice y**

```
id = 1
name = symm_std
used_mb = 315040
avail_mb = 30200 →Total space left in pool
total_mb = 345240
potential_mb = 0
```

```
# nas_fs -xtend fs1 size=29000M pool=symm_std -o slice=y
```

### **SRDF FILE SYSTEM:**

If a file system is to be mirrored for SRDF, must use symm\_std\_rdf\_src storage pool. AVM will allocate space from other volumes for the remotely mirrored file system.

### **HIGHROAD ENHANCEMENTS:**

--Highroad now supports all Clariion Backend configurations (prior to this only Symmetrix)

--As before, Highroad functions with large file transfers only—metadata and small files go over production network using normal NFS or CIFS protocols

--New AVM now supports use of 256k stripes created from CLI by using Celerra Manager to combine stripes into metavolumes for filesystem creation or storage pools (prior GUI only supported stripe sizes of 8k & 32k)

### **Required Components for Clariion Support:**

--Access Logix for Array, HighRoad and PowerPath software for clients

### **CONFIGURING MPFS WINDOWS CLIENT:**

1. Connect Client to Storage, configure AccessLogix and StorageGroups (create StorageGroups, rightclick, add LUNs)
2. From Windows Client, open Computer Management>Disk Management>Rescan Disks, but DO NOT write disk signature!

3. Install PowerPath and enable Failover Policy on array (1)
4. Install HighRoad for Windows Client
5. Reboot Windows Client, open DOS prompt and run cmd: c:\mpfsinq
6. Create file system from Clariion Luns that are presented, after building meta(s) manually

**# nas\_volume –name hrstripe –create –Stripe 262144 d7,d8,d13,d14** (Use stripe in meta or Volume Pool)

7. Create Share or Export
8. Enable MPFS on Data Mover using server\_setup command

**# server-setup server\_2 –P mpfsf –o start=16**

9. Enable MPFS on Share via Properties tab (Enable MPFS) or Export for NFS using mount option for MPFS

**# mount –F mpfs 192.168.25.143:/hrfs2 /mpfs**

**# mpfslabel /dev/rdsk/emcpower1c** [run for Sun Solaris Clients]

**# server\_mpfs server\_2 –mountstatus**

**# server\_mpfsstat server\_2**

**# server\_mpfs server\_2 -Stats**

#### **HIGHROAD LIMITATIONS:**

- NFS v2 not supported
- Unicode for Share names not supported
- CIFS mandatory locks are not supported
- Per Seat licenses for Windows restricts access to shares on only a single CIFS server per data mover

### **CELERRA NAS 5.4 CHAMPAGNE:**

Introduction of Celerra NSX platform at this code version. NAS 5.4.14.3 GA 11 April 2005, latest version 5.4.31.2. Supports CNS-14, CFS-SE, NS, NSG platforms. Last maintenance version 5.4.31.2 for Flare 26 support, except for Raid 6, which is not supported. Also, 5.4.31.2 does not support DMX-4. Upgrade path is from NAS 5.1 & higher only. Sites should be running Flare 16 or Flare 19, but the latter requires a minimum 5.4.18.3 NAS. NAS 5.4.26 introduces support for Flare 24. Only 5.4 and higher will support DMX3 Symm7 hardware. Supports Symm microcode 5567.52.29, 5566.46.31, 5267.42.29, 5266.43.30, & 5568.56.22, DMX code 5669.47.25 & 5670.27.29.

### **NAS 5.4 IMPROVED GATEWAY INSTALLATIONS:**

- Manual installation required public IP addresses, PXE booting DM's to obtain WWN's, creating Storage Groups, Raid Groups, Binding LUNs, Registering Initiators/Hosts, Mapping LUNs to Storage Group, Configuring Zoning, etc.
- Automatic installation requires IP addresses, switch username and password, but when script runs, Data Movers are PXE booted to acquire WWNs, Storage Groups, Raid Groups, LUNs WWN Registration, LUN Mappings, and Switch zoning [DM auto-senses switch speeds while SP's must be set manually] are done automatically via script and user replies

**Note:** Must use WWN Zoning, have all (4) paths cabled for both DMs, and available storage for Control Luns (Raid5 4+1) from 5 disks. For each DM, BE-0 port will be connected to SPA & SPB, and BE-1 will be connected to a port on SPA & SPB. Switches are zoned per E-Lab rules, DM's WWNs cannot be part of any pre-existing Zones. AccessLogix must be installed and enabled on Clariion before install can succeed:

“Rechecking for existing System RG/Lun: Invalid system raid group detected. Recovery must be performed. Type ‘C’ to continue”

**Note:** Open NaviSphere, connect to SP, rightclick “Storage Systems”>properties>Storage Access \_\_Access Control Enabled

### **INTEGRATED (aka captive) NS INSTALLS:**

→ Installation script automatically configures disks 0-5, creates Control LUNs, creates two data LUNs (16 & 17 decimal HLU), and runs nas\_diskmark to discover and add the new devices to the Celerra database

**Note:** The use of the User Defined template does not work from Celerra Manager, but does from the CLI, as shown below

→ The use of setup\_clariion to configure additional storage, does so on a shelf-by-shelf basis

→ The setup\_clariion command cannot be used on FC-enabled models, only Navi tools

### **ADDING SPECIFIC DAE SHELF TO CELERRA SYSTEM:**

**# /nas/sbin/setup\_backend/setup\_clariion2 -S setup -e 0\_1 SL7E1081700022**

**Note:** If one of the attached DAE's is missing all their disks, the setup\_clariion2 command may fail and require the use of a specific DAE Enclosure identity to add the shelf. See emc200483.

#### **Example of Adding Disks to existing configuration:**

**# /nas/sbin/setup\_clariion -init**

The system displays:

Found CLARIION(s) APM00044604xxx

Setup CLARIION APM00044604xxx storage device...

System 192.168.1.200 is up

System 192.168.1.201 is up

Clariion Array: APM00044604xxx Model: CX700 Memory: 3967

**Enclosure(s) 0\_0,1\_0,0\_1,1\_1 are installed in the system.**

-----output abridged-----

**Continue to configure APM00044604xxx as User\_Defined [yes or no]?:** yes

The system displays:

The following 3 template(s) available:

1. ATA\_RAID5\_HS\_6+1\_6+1

2. ATA\_RAID3\_HS\_4+1\_8+1

3. None

### **Enclosure 1\_1**

Please select a template in the range of 1-3 or 'q' to quit: 1

Enclosure info:

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14

1\_1: 320 320 320 320 320 320 320 320 320 320 320 320 320 320 320

**ATA \*HS \*14 \*14 \*14 \*14 \*14 \*14 \*15 \*15 \*15 \*15 \*15 \*15 R5**

"\*" indicates a diskgroup/spare which will be configured

Template: User\_Defined

Summary:

**2 disk group(s) are created. 14,15**

**1 spare(s) are created. 202**

-----output abridged-----

Do you want to continue and configure as shown [yes or no]?: yes

Enclosure 0\_0.

Enclosure 1\_0.

Enclosure 0\_1.

### **Enclosure 1\_1.**

**Created spare 202**

**Created disk group 14, luns 31,33**

**Created disk group 15, luns 30,32**

Binding complete.

All luns are created successfully!

## **Use WebUI or CLI to add additional LUNs:**

**#/nas/sbin/setup\_clariion -init**

## **NAS 5.4 FEATURES:**

iSCSI NBS support for MS Exchange, etc.

File Level Snaps

Asynchronous Disaster Recovery for Celerra Replicator—Allows Secondary Side to sync with Primary after restore

Multiprotocol Directory Structure (Unified Unix/Windows Directory—no more Shadow file?)

Virtual DM [CIFS]

Linux Upgrades; Modularized NAS Code; Parameter Tuning Tool

Unlimited DNS domains can be specified (lifts the 3 DNS domain limitation)

## **NFS Cluster:**

DMs export same FS Read-Write multiple times, with (1) Server controlling the Metadata & Data, all others control data only  
Bulk Archiving (HSM-lite)

## **NBS Block Services:**

Block access over IP; Celerra Local Disk (CLD); Support for Snapshots; Exchange 2000 Email Support

NS600G Phase 2—Gateway Server for both NAS & SAN environments; uses CX600 Back-End

Level II Oblock Support

NDMP v4 Support

Internal Usrmapper running on DM

Connect Home Support—similar to Symmetrix model

Out of Order Checkpoints can be deleted

## **DFS ( System) ROOT (standalone only):**

**Note:** There are two types of DFS Servers: Domain Root DFS, stores DFS hierarchy in AD, & StandAlone Root DFS, stores DFS hierarchy locally on the Server. DFS provides mapping and uniform naming convention for collections of servers, shares, and files within a single directory tree—idea is to group shared folders from different physical servers into the same logical DFS namespace. A

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
DFS Root is the DFS service containing DFS links pointing to Shared folders, or DFS targets, on the network. Celerra provides DFS Targets when hosting a DFS Standalone Root, using DFS links to point to the Shared folders (aka targets).

- DFS Root can be stored on local Server as Standalone DFS Root or within Active Directory as Domain DFS Root.
- Celerra only supports Stand-alone DFS root as either single DFS Root with W2K or multiple DFS Roots with W2K3 Servers
- DFS Root on a global share [XP or Win2k3 only] can be viewed from any CIFS server on the Data Mover
- use Windows tools dfsutil.exe (use to create DFS root) and dfscmd.exe (use to manage DFS tree)

**Note** NAS does not currently support dfs query for siteinfo with Win2k version of dfsutil--Win2k3 version of dfsutil does not have this issue—AR70360:

**Failure:**

**C:>dfsutil /sitename:cel23cge0**

Above syntax works for Win2k3 version of dfsutil and Celerra, but not Win2k version--client connects to the svrsvc pipe and issues a "NetrDfsManager ReportSiteInfo" command. We return a DCE RPC Fault of 0x1c010002, or "Range Error".

**Success:**

**C:>dfsutil /sitename:cdms-source**

Microsoft(R) Windows(TM) Dfs Utility Version 4.0

Copyright (C) Microsoft Corporation 1991-2001. All Rights Reserved.

Site for cdms-source is Default-First-Site-Name

- Disable DFS on DART via registry: HKLM>SW>EMC>DFS>Enable=0
- Normal DFS Management should be done from MMC Console
- Celerra DFS does not support FRS (File Replication Service)
- Do not create DFS root when access-checking policy is UNIX or SECURE—DFS links cannot be created with UNIX rights
- dfscmd.exe tool can be used to administer DFS root content, creating & deleting links, but not to delete the DFS tree

**Note:** Default DFS cache value 1800 secs for TTL (time that Client will cache list from DFS Root Server)

**Debug:**

**\$server\_config server\_x -v “dfs audit” | “dfs check” | “dfs repair”** (repairs share attribute information)

**CREATING DFS ROOT ON CELERRA USING MMC or CLI TOOL:**

1. Open MMC DFS gui (Welcome to the New Root Wizard) and select next
2. Enter Host Server server name information as fully qualified name of CIFS server
3. Enter Root Type as \*Stand-alone root
4. Enter unique DFS Root Name and any comments
5. If Root Share is not already created, enter the path for the new DFS Root Share: C:\dfs\_root

**CLI EXAMPLE:**

**C:>dfsutil /AddStdRoot /Server:DM2\_cge0 /Share:dfs\_root**

**Note:** Both dfscmd.exe and dfsutil.exe tools are found in Win2k/Win2k3 Support Tools.

**CELERRA WIDE LINKS (Widelink) NAS 5.4:**

**What are Wide Links?**

Combined with the functionality provided by DFS, Celerra CIFS Servers can allow Clients to resolve UNIX absolute paths via symbolic links stored on the Celerra using a DFS Root service that maps the UNIX mountpoint path to the Server:\share\path. Allows CIFS to follow Symbolic Links between file systems on different Servers using DFS redirector (DM sends redirect to Clients)

- Wide Links is enabled by default on the Celerra when CIFS is running
- To disable Wide Links, enter 0 for following Data Mover Registry entry using Regedit.exe from Windows Client:  
HKLM>Software>EMC>DFS>Enable: 0
- A feature that works in conjunction with a DFS share. When a link contains absolute path, we return a DFS Referral to CIFS client with path of the target. Purpose of Widelink is to allow CIFS Clients to resolve absolute symbolic links using DFS <\\name\\share> paths, similar to way Unix clients can resolve absolute links normally via mountpoints. DFS only redirects directories, so DFS link must consist of a directory pathname.

→Widelink Server and Share specified in Registry: Set WideLink Share in Registry, Stop & Restart CIFS Service  
HKLM>SW>EMC>WideLink>Share <\\server\\sharename>

→Feature works with File System Linking when param shadow followabsolutepath=1 is set

**NAS 5.5.26.0 and higher extends param to allow CIFS Users to follow non-root owned symbolic links:**

**# server\_param server\_3 -facility shadow -info followabsolutepath -v**

```
server_3 :  
name      = followabsolutepath  
facility_name = shadow  
default_value = 0  
current_value = 0  
configured_value =  
user_action = none  
change_effective = immediate
```

range = (0,3)

description = Whether to follow the absolute path in symlinks

**param shadow followabsolutpath=0**

→Neither bit 0 or 1 is set and CIFS cannot follow Unix symbolic link paths

**param shadow followabsolutpath=1**

→=1 means that bit 0 is set & symbolic links are enabled--root-owned absolute path symlinks can be followed by CIFS Users

**param shadow followabsolutpath=3**

→=3 means that bit 0 & 1 are set, symbolic links are enabled, and CIFS Users can follow any absolute path symlink (See AR84916)

**CONFIGURING WIDE LINKS:**

1. Create Shares to be used for Wide Link

2. Configure Data Mover for DFS Standalone Root using MMC DFS Utility

DFS>Action>Show Root>enter compname of DM>Select & rightclick DFS root to be used>New Link>Enter Link name & Path to target

3. Create a second New Link for the Remote Server, specifying Link Name and Path to target

4. Make sure that Wide Link shares are listed in registry:

**HKLM>Software>EMC>WideLink>Share: \\server\sharename**

5. Stop and restart CIFS Service

**Requirements/Limitations:**

→Must have DFS Standalone Root shares configured on the Data Mover

→Symbolic links with absolute paths are seen as directories from Explorer

→Use WideLink only on directories

→Pathname in link must be the same between CIFS and UNIX names

→Supports CIFS VDM's

**CELERRA LOCAL USER SUPPORT**

**“Local Users Supported” or “Standalone” modes for CIFS (Beginning with NAS 5.4):**

**Purpose:** Allows for the creation of Local User accounts on a CIFS Data Mover, either on a CIFS Server joined to a Windows Domain (Local Users Supported mode), or as a completely Standalone CIFS server operating within a Workgroup environment (i.e., no Domain authentication).

**Benefits/Restrictions of Local User Support on CIFS Servers:**

→Administrators could access the CIFS Server if Domain authentication is not available, as long as you log into the local CIFS server using its Administrator account.

→No need for Domain structure when using Local Users created on DM, similar to Workgroup

→Encrypted passwd NTLM authentication

→Use ACLs with Local Groups and Local Users (up to 128 Users can be created)

→Can also use Domain structure and mix Local Users, just as in native Windows Servers

→Designed to replace Share and Unix Security modes

→Can only be used for CIFS access, not Unix access

→Local User UIDs are automatically assigned from a pre-determined range

→Unicode must be turned on for this feature to work

→Data Mover authentication must be NT

→Local Users Support does not support Kerberos authentication, so attempts to do so from hard-coded Clients, will fail—Celerra will use NTLM V1/V2

→Default Local User accounts are Administrator and Guest and are automatically generated when setting up Local Users Support (Up to 128 other local Users can be created—Guest is disabled by default)

→Once enabled, Local Users Support cannot be disabled (it would need to be completely broken down)

**PopUp Message if trying to create the 129<sup>th</sup> Local User:**

*Local Users and Groups*

*X The following error occurred while attempting to create the user bottste on computer 10.217.214.9:*

*Not enough server storage is available to process this command.*

**Two Modes of Local User CIFS Server Support**

1. Local Users Supported mode whereby existing domain CIFS Server is configured with Local User support/accounts

**CIFS Output for this mode:**

CIFS Server CIFS\_SERVER1[W2K] RC=4 (**local users supported**)

2. Local Users Supported mode (Standalone mode) completely outside any Domain authentication

**CIFS Output for this mode:**

CIFS Server(**standalone**) SERVE\_ALONE[EMC] RC=2

## **SETTING UP STANDALONE CIFS SERVER USING CLI:**

### **1. Create Standalone CIFS Server:**

```
# server_cifs server_2 -add standalone=serve_alone,workgroup=EMC,interface=192-1-10-22,local_users
```

server\_2 : Enter Password:\*\*\*\*\*

Enter Password Again:\*\*\*\*\*

Done

### **2. Verifying Standalone server:**

```
# server_log server_2 -s |tail
```

2009-01-29 15:38:32: SMB: 6: CIFS Server SERVE\_ALONE[EMC] created (0)

2009-01-29 15:38:32: LGDB: 6: {Administrator} password must change (C=0x1c982518c9f9400 LS=0x0

MA=0x8000000000000000)

2009-01-29 15:38:32: ADMIN: 6: Command succeeded: cifs add standalone=SERVE\_ALONE workgroup=EMC

localAdminPassword=\*\*\*\*\* interface=192-1-10-22

2009-01-29 15:39:49: LGDB: 6: Database consolidated

```
# server_cifs server_2
```

CIFS Server(standalone) SERVE\_ALONE[EMC] RC=2

### **3. Use Windows client to “Change Password” from above temporary password to a permanent password**

#### **a. Log into Windows client**

#### **b. Use ctrl + alt + delete sequence and select “Change Password”**

#### **c. Enter IP address of standalone CIFS server in “Log on to” box**

#### **d. Enter temporary password in “Old Password” box and then enter a new password**

### **4. Managing Local User accounts on the Standalone CIFS Server:**

**a. Enter the CIFS name in the local Windows system’s Host file:** c:\WINNT>System32>Drivers>etc>hosts file (Add to lmhosts file if Browsing is required on a network or if netbios Name Resolution is required and WINS is not established on the subnet)

**b. Issue the Net Use command to provide the security context for the Windows logon session:**

```
C:>net use \\serve_alone /user:serve_alone\administrator <password>
```

The command completed successfully.

**c. Open Computer Management>Connect to another computer: Name [Must enter CIFS server name, not IP address]**

**Note:** You will not be prompted for username and password. Console will open and local groups database will be manageable on the Server. Please note that the security credentials are only valid for the existing logon session. The net use step would have to be reissued to any system from which access is desired, and each time the Windows system is logged in to.

## **SETTING UP STANDALONE CIFS SERVER USING CELERRA MGR:**

Celerra Manager>Data Movers>server\_2>CIFS>CIFS Servers>New

→Select Standalone option, specify NetBIOS name and Workgroup, Set Local Admin Password, assign interface

→Start CIFS Service on separate screen or via CLI

```
# server_cifs server_2
```

CIFS Server(standalone) LONER[LONER] RC=2

Comment='EMC-SNAS:T5.6.37.6'

if=cge0 l=192.1.4.222 b=192.1.4.255 mac=0:60:16:c:51:3e

Password change interval: 0 minutes

```
/nasmed/quota/slot_2/.etc
```

-rw-r--r-- 1 root bin 1270 May 8 10:02 .db.5.localgroups

```
# cat .db.5.localgroups
```

# Localgroups database

#

\$RELEASE:5\$

@LONER:1:1000:AdMcAdMcAdMcIdAdAdAdAdAdAdAdAdAdAdAdAdAdAdAdAdAdMcAdMcAdMcBdMcAdMcIdAdAdAdAdAdAdA

%Guest|117|0#546|=KdCiIdDjNkKpCnNmGkBoEkEbDpLoPnIfHpKdAkBoAfHmKfHbAaOiKkDnElFdFlEbEaOoKd|

LONER:Administrators:0x220:0x1007f:\

Members can fully administer the machine:\

User name: Administrator

Log on to: <Compname or IP address of CIFS server>

Old Password: <enter passwd used in Step 1>

New Password: <new\_passwd>

Confirm New Password: <new\_passwd>

[PopUp window] “Your password has been changed.”

**Note:** In some cases, only the Compname will work in the “Log on to” box, not IP Address.

#### **4. Results of passwd change are not logged in Server Log but are seen in the Local Users group db:**

%Administrator|1|16|0|#544|=KdMnOgPhFpMgMfAkPpAfOfIiLcMjNiJpInKdOhGoOkHbApNaMjDoFdMeCmOoDgPaPeHIKd|21c  
9824baccc54801

#### **5. Managing Local User accounts for existing domain CIFS Server where Local Users support has been enabled:**

##### **Using Computer Management Snapin to access from a computer within the Domain:**

a. Open the Computer Management MMC snapin on any computer within the same Domain as the CIFS server>rightclick Computer Management>Connect to another computer>Name: <enter CIFS server name or IP address> and manage local users and groups

**Note:** As long as the CIFS name or IP is resolvable with DNS (generally would be since its also a member of the Domain), there is no need to add the CIFS server name and IP address to the local \winnt\system32\drivers\etc\hosts file.

##### **Using Computer Management Snapin to access from a computer outside the Domain:**

- a. Add the CIFS server name and IP address to the Windows local \winnt\system32\drivers\etc\hosts file
- b. Use the following command to establish the security context from the Windows management station:

**C:\>net use \\cifs\_server1 /user:cifs\_server1\administrator <password>**

The command completed successfully.

- c. Open Computer Management>Connect to another computer>Name: <enter Name or IP address>

**Note:** No username and password prompt will appear. Local groups can be accessed and modified.

#### **DELETING STAND-ALONE CIFS SERVER:**

**# server\_cifs server\_x –delete standalone=dm2\_local**

#### **DELETING CIFS SERVER ENABLED FOR LOCAL USERS SUPPORT:**

**# server\_cifs server\_x –delete compname=cifs\_server1 –remove\_localgroup**

**Note:** Use the –remove\_localgroup option only if you want to delete the CIFS instance from the .db.5.localgroups database.

#### **RESETTING THE LOCAL USERS/STANDALONE CIFS SERVER PASSWORD:**

**# .server\_config server\_2 -v "lg admin passwd=<temp\_passwd> vs=<standalone\_CIFS>"**

**Note:** This resets the temporary password to a known password, useful for staring over when logging in from a Windows client to change the temporary to a permanent password.

#### **LOCAL USERS/STANDALONE CIFS SERVER USES NEW LOCALGROUPS DB FILE:**

-rw-r--r-- 1 root bin 1361 Jan 29 2009 /nasmcdb/quota/slot\_2/.etc/.db.5.localgroups

#### **MOVING STANDALONE NETBIOS SERVER TO VDM CONTAINER:**

##### **1. Setup standalone netbios CIFS server:**

**# server\_cifs server\_2 -add standalone=squib,workgroup=emc,interface=squib,local\_users**

server\_2 : Enter Password:\*\*\*\*\*

Enter Password Again:\*\*\*\*\*

done

##### **2. Move standalone server to VDM container:**

**# server\_cifs server\_2 -move netbios=squib vdm1**

server\_2 : done

##### **3. Verify:**

**# server\_cifs vdm1**

CIFS Server(standalone) SQUIB[EMC] RC=2

Comment='EMC-SNAS:T5.6.43.4'

if=squib l=192.1.10.24 b=192.1.10.255 mac=0:60:16:1f:ad:ca

Password change interval: 0 minutes

#### **CELLERRA NT CREDENTIALS FOR UNIX ACCESS:**

When specifying the “ntcredential” option in the file system mount, NT Credentials will be built when NFS users access file system objects. The “ntcredential” is built from matching UID & GIDs to SIDs, merging Unix and Windows groups together. Main difference from pure Windows credential is that this credential does not contain local groups information.

## **PURPOSE OF NT CREDENTIALS FEATURE:**

- More consistent permissions on file system objects, regardless of access protocol
- Cache to store credentials, reducing access-checking times
- Unix access rights managed by ACL
- Eliminates 16-group limitation for Unix secondary groups

## **SETTING UP NT CREDENTIALS:**

**\$ server\_mount server\_2 -o accesspolicy=NT,ntcredential fs1 /fs1**

fs01 on /fs1 uxt,perm,rw,accesspolicy=NT,ntcredential

## **STEPS REQUIRED TO BUILD AN NT CREDENTIAL FOR NEW USER:**

1. Applies only to NFS access
2. DART checks UID of incoming User against existing NT Credential Cache
3. If UID is not in the cache, tries mapping UID to Windows SID
4. If UID-to-SID match fails, will try UID-to-Name match from local passwd file or NIS. If name is found, retrieves SID from DC.
5. If name found, but SID cannot be matched up, then a failed mapping entry gets put into cache, and file access reverts back to traditional Unix credentials
6. If name to sid match is found, retrieves group list for User from DC
7. Builds new Windows NT credential for NFS user and places credential into cache
8. Performs access checking

## **NT CREDENTIAL CACHE:**

→default ttl 20 minutes **param nfs NTcred.TTL=20**

**# server\_param server\_2 -facility nfs -i NTcred.TTL**

server\_2 :

```
name          = NTcred.TTL
facility_name = nfs
default_value = 20
current_value = 20
configured_value =
user_action   = none
change_effective = immediate
range         = (0,4294967295)
description   = NT credential TTL (in minutes) for NFS connections before renewing it
```

→default size 1009 entries: **param nfs NTcred.size=1009**

**# server\_param server\_2 -facility nfs -i NTcred.size**

server\_2 :

```
name          = NTcred.size
facility_name = nfs
default_value = 1009
current_value = 1009
configured_value =
user_action   = reboot DataMover
change_effective = reboot DataMover
range         = (0,4294967295)
description   = Global NT credential cache size for NFS connections
```

**\$ .server\_config server\_2 -v "ntcredcache list"**

List of the nt credential cache entries

**param cifs acl.extendExtraGid=0** →disables mapping Secondary UNIX groups to NT users

**param cifs acl.extendExtraGid=1** →Enables NT User to add Unix secondary groups to their credential, from NIS or ./etc

#### STORED ACL INFORMATION:

SIDs, GIDs, UIDs

#### **BENEFITS:**

- Consistent permissions on file system object
- Cache that stores NT Credentials, performance
- Management of UNIX access rights from Windows ACLs
- Lifts 16-group UNIX limitation for Users

#### TRADITIONAL CIFS BEHAVIOR FOR USERS:

- SIDs are only thing checked from ACLs

#### TRADITIONAL NFS BEHAVIOR FOR USERS:

- UID & GIDs are only thing checked for Unix credentials

#### NEW NT CREDENTIAL FOR UNIX PURPOSE:

→NT Credentials built for Unix User based on UID/GID-to-SID match of User/Groups in order to allow NFS access based on ACL checking (and to lift the 16-group UNIX limitation). NT Credential replaces the Unix credential for NFS access checking.

**Note:** NT & SECURE access policies means that ACLs are checked using UID/GID mappings as stored in the ACL

→With NT for Unix Access, the credentials are built from the UID and SID equivalent, plus the SIDs of all groups that the User is a member of, then added to cache with ttl of 20 minutes to reduce access-checking times & increase performance

→Purpose to manage UNIX access rights using Windows ACL

→NT Credential is built where possible, negative lookups cached, failures will result in Unix credential (old style)

**param nfs NTcred.winDomain=emc.com**

**Note:** Use of this param is required if there are multiple CIFS Servers on a Data Mover and defines the default Windows domain to be used in the environment. Param allows DM to use name from UID/GID to retrieve SIDs from DC. Failure to build an NT credential will revert to normal UNIX credentials.

**param nfs NTcred.size=1009**

**Note:** This cache contains a default value of up to 1009 NT Credentials, and/or negative UID/GID entries that could not be mapped to SIDs. This value is configurable. Cache entries TTL is 20 minutes by default. Oldest, ‘unused’ entries expire first.

**param nfs NTcred.TTL=20**

**Note:** Default value is 20 minutes for caching of NT Credentials.

**param cifs acl.extendExtraGid=0**

**Note:** When disabled (default), the built NT credential for the User is based only on Windows groups, not Unix.

**param cifs acl.extendExtraGid=1**

**Note:** When enabled, NT Credentials are built using both Active Directory Groups and Unix Secondary Groups, using either NIS, local passwd/group files, or LDAP.

#### HOW SID LOOKUPS ARE CONDUCTED:

1. The Unix UID is received & matched to SID using Secmap Cache directly, or using Passwd/Group files, or NIS by using “user.domain” or “user” name query to DC’s

2. Once User SID is determined, DM queries DC’s for list of Group SIDs, if not found in SecMap cache

#### **Misc:**

Accesspolicy=MIXED | MIXED\_COMPAT

param nfs NTcred.winDomain=name\_of\_domain

param nfs NTcred.size=1009 (default entry)

param nfs NTcred.TTL=20 (default = 20 minutes)

“ntcredcache status” →Statistics on cache access

| reset →Flushes cache | list →Lists UID/SIDs in cache and negative mappings | fulldump →UID/SIDs & GID/SIDs

| dump=uid →List credentials for particular UID | remove=uid →remove from cache

#### CELLERRA MIXED & MIXED COMPAT ACCESSPOLICIES (new with NAS 5.4):

- Original Access Policy models had Unix Mode bits and CIFS ACLs managed and checked independent of each other, with no synchronization between the two
- New Access Policy called “Mixed” in which UNIX ownership mode bits are translated into ACE’s “Owner, Group, & Everyone”,
- MIXED Policy synchronizes UNIX & Windows permission as closely as possible using algorithm to translate UNIX rights (mode bits) into ACLs and Windows ACLs into UNIX rights.

### **MIXED ACCESSPOLICY:**

- Works with either Compat or DIR3 file systems
- UNIX ownership mode bits are translated into (3) ACEs: Owner, Group, Everyone (MIXED\_COMPAT does not translate Group)
- ACL and UNIX mode bits are synchronized to create a single ‘merged’ list of attributes
- Mixed Access policy information is stored within the File System, not on the Control Station, but controlled by CS not DART?
- a Chmod will overwrite the equivalent ACL setting
- a SetACL will try to create equivalent UNIX Mode bits
- When determining access rights, DART will always use ACLs, for both NFS & CIFS clients, but only for MIXED
- Last protocol that modifies a file system object’s security is used to generate the new ACL, and that ACL will be used when granting or denying access to both NFS or CIFS clients
- Mixed Access Policy designed to be used with NFSv4
- Slightly modified “Mixed\_Compat” access policy is to be used when displacing NetApp systems. Mixed\_Compat does not translate UNIX groups into Group ACEs, and instead creates an Everyone ACE for the UNIX group information
- File Systems must go through a translation process when changing to “Mixed” or “Mixed\_Compat”
- Once translated to Mixed accesspolicy, cannot properly revert to the original accesspolicy

### **MIXED TRANSLATION OF UNIX MODE BITS INTO ACLS:**

- (3) ACL entries are created based on the UNIX mode bits of Owner, Group, Other: File Owner, Group, Everyone
- Delete/Change permissions & Take Ownership are set for the Owner but not for Everyone or other Groups

### **MIXED TRANSLATION OF ACLS INTO UNIX MODE BITS:**

- Windows ACL Deny option is not translated, but the Allow ACL option is (same for both MIXED & MIXED\_COMPAT)
- UNIX Owner mode bits are built from Owner entry, the ACE of the file/directory Owner, and the Everyone Group ACE
- UNIX Group mode bits are built from Group entry, the ACE of the primary group Owner, and the Everyone Group ACE
- UNIX Other mode bits are built from Other ACE, all ACE’s different from User/Group, and the Owner/Group ACE

### **MIXED COMPAT ACCESSPOLICY:**

- When determining access rights, DART will use the ACL when checking NFS or CIFS access, but only when there is an EXPLICIT ACL, meaning that the file or directory perms were last set or changed from a CIFS Client
- When a file or directory permission was last modified by an NFS client, access checking for both NFS and CIFS is done against the UNIX mode bit permissions—an ACL gets created based on the Mode bits, but is not enforced
- Access checking is therefore independent of protocol
- The last protocol used to set permissions or ownership on a FS object is used to recreate the ACL for that object, but only when the ACL is created or modified from CIFS does it become EXPLICIT, meaning that access checking is done against the ACL and not UNIX mode bits
- Celerra synchronizes and merges Unix and Windows permissions by translating UNIX rights to ACLs, and WINDOWS rights to Unix mode bits

#### **EXAMPLE:**

If a CIFS User1 is given RWX permissions to a file, an ACL is created, and UNIX mode bits would read –RWX for Other, but in reality, only User1 would have RWX from NFS, and nobody else in the Other category would

→For MIXED or MIXED\_COMPAT, the default group should be set for Windows users, as this group will become the primary UNIX group when file system objects are created from CIFS

- NetApps does not map group SIDs to UNIX GIDs
- UNIX Mode bits are only translated into ACLs as Owner and for the Everyone group
- Since UNIX groups are not translated into a Group ACE, the Everyone group ACE is generated for the ACL
- Delete/Change permission and Take Ownership always set for File Owner and never for Everyone

### **MIXED COMPAT TRANSLATION OF ACLS INTO UNIX MODE BITS:**

- Windows ACL Deny option is not translated, but the Allow ACL option is (same for both MIXED & MIXED\_COMPAT)
- Builds None, Owner, and granted ACEs into Group and Other UNIX mode bits (different than MIXED policy)

### **MIXED COMPAT TRANSLATION OF UNIX MODE BITS INTO ACLS:**

- Only two entries are created in the ACL: Owner & Everyone (MIXED policy builds (3) entries in ACL)
- An Everyone Group ACE is created from Group mode bits, since other groups are not translated with this policy
- The Other mode bits are ignored and not used when building the ACL
- Delete/Change permissions and Take Ownership are set for the File Owner but not for the Everyone group

## **CHANGING EXISTING FILE SYSTEM ACCESSPOLICY TO MIXED:**

1. Set Accesspolicy:

**#server\_mount server\_x -o accesspolicy=MIXED | MIXED\_COMPAT fs1 /fs1**

2. Conduct Translation:

**#nas\_fs -translate fs01 -access\_policy start -to MIXED -from NATIVE | NT | UNIX | SECURE**

3. Verify Translation:

**# nas\_fs -translate fs01 -access\_policy status**

1145387101: CFS: 7: conversion in progress : 829/830 inodes done 99 % done

status=In progress

percent\_inode\_scanned=99

**# nas\_fs -translate fs01 -access\_policy status**

1145387319: UFS: 6: inc ino blk cache count: nInoAllocs 2: inoBlk d5a73584

status=Completed

## **SERVER LOG ENTRY:**

2006-04-18 15:04:49: ADMIN: 4: Command succeeded: acl database=/fs01 convertAccessPolicy start old\_policy=NATIVE

2006-04-18 15:05:01: SVFS: 4: D304131\_0: allocDataBlock: transition index state

2006-04-18 15:06:17: CFS: 4: conversion done status 0 : 829/830 inodes done 99% done

## **MIXED or MIXED COMPAT ACLDUMP INFORMATION:**

**# server\_mount server\_2**

fs01 on /1 uxf,perm,rw,accesspolicy=MIXED\_COMPAT | MIXED

**# ls -la lhead**

drwxrwxrwx 5 32773 32773 1024 Apr 17 10:27 copy

**# chmod 755 copy**

**# .server\_config server\_2 -v "acl dump=/fs01/copy"**

1145388087: SMB: 3: Dump with no ThreadCtx

Dump of rights of /fs01/copy

===== UNIX =====

USER 0x8005 GROUP 0x8005 mode=rwxr-xr-x

===== NT =====

aclId=0xd

controlSummary = 0x8004

**Owner=+USER 0x8005 S-1-5-12-1-8005 →+USER shows directory permissions created or modified by NFS Client**

**Owner=USER 0x8005 S-1-5-12-1-8005 →USER shows directory permissions created or modified by CIFS client**

Group=GROUP GID=0x8005 S-1-5-12-2-8005

**Note:** MIXED & MIXED\_COMPAT are special accesspolicies in which the last protocol that modifies permissions on files or folders, is what is used to generate the resultant ACL. But, a big difference with MIXED is that ACLs are always used for access-checking, whether NFS or CIFS client. MIXED\_COMPAT access-checking is dictated by the last protocol that modified the permissions.

## **CELERRA KERBEROS CREDENTIAL MANAGEMENT:**

### **Dump Cache:**

**#server\_kerberos server\_2 -ccache**

server\_2 :

Dumping credential cache

Names:

Client: WBCROOT\$@STJOSEPHSWB.COM

Service: WBC-DC.STJOSEPHSWB.COM

Target: HOST/WBC-DC.STJOSEPHSWB.COM@STJOSEPHSWB.COM

Times:

Auth: 04/07/2006 04:38:12 GMT

Start: 04/07/2006 04:38:12 GMT

End: 04/07/2006 14:37:53 GMT

Flags: PRE\_AUTH,OK\_AS\_DELEGATE

Encryption Types:

Key: rc4-hmac-md5

Ticket: rc4-hmac-md5

-----abridged-----

### **Flush Cache:**

**#server\_kerberos server\_x –ccache –flush**

krb5.account → File contains Computer account information

krb5.keytab → File contains keys for encryption/decryption of Kerberos Service Tickets

### **CELERRA PARAM TUNING:**

Objective is to be able to view and tune Server parameters from either CLI or GUI

**#server\_param server\_2 –facility cifs –info acl.extendExtraGid -verbose**

**#server\_param server\_2 –facility NFS –modify acl.checkacl –value 0**

### **CELERRA NDMP B2D (Backup-to-Disk):**

→ Built on dedicated “cartridge” ufs file systems using VTLU [Virtual Tape Library Unit]

→ NDMP2D can be employed as two-way or three-way solution using Data Management Application (DMA) to control backup and recovery of an NDMP host, which is accomplished in NAS 5.4 through use of VTLU for Data Mover

→ Both Legato Networker and Veritas Netbackup are ISV backup software solutions

### **TWO-WAY NDMP B2D SOLUTION:**

DMA NDMP Backup Server uses NDMP to tell Data Mover to backup local VTLU file system—indexing information is sent to DMA Host over network. DMA Host never touches actual data. Optionally, data mover could have physical tape drives attached and backup to tape.

### **THREE-WAY NDMP B2D SOLUTION:**

DMA Host instructs source DM to begin backup, which sends data over network to DM containing the VTLU. Indexing information sent over network to DMA host. Optionally, DM with VTLU could have physical tape drives attached for writing backups to tape.

### **B2D (BackUp-to-Disk):**

Growing trend to use server-based arrays using cheap large capacity ATA drives for backups

Backups generally faster and more reliable

### **CONFIGURING VTLU FOR B2D ON CELERRA USING CELERRA MANAGER:**

1. VTLU properties, set Chain desired for Servers [Default chain is 0]
2. Create File System for use by Tape Storage
3. Create VTLU on Server using VTLU>new>Server\_2>accept defaults and record target & lun info for Robot Device
4. Create virtual Tape Media Storage on VTLU file system: VTLU>properties>create Tape Media Storage

**Note:** Select VTLU file system, create Media Tapes, specify size, specify ‘vault’ for location if you intend to move from Celerra Mgr to Import/Export, use Barcode Prefix (2GBtapes). Backup SW alone moves tapes from or to the ‘slot’ location.

5. VTLU>Properties>Tapes: Record Target & Luns for each Media Tape created

6. Move Media from Vault to Import/Export Slots using “Insert” (so that backup software can utilize)

**Note:** Move back to Vault using “Eject” button.

### **CONFIGURING VTLU FOR B2D ON CELERRA USING CLI:**

**1. Create file system for use as VTLU Storage**

**2. Set Chain for Server if desired & Verify:**

**# server\_vtlu server\_2 –service –set –chain 2**

**# server\_vtlu server\_2 –service -info**

**3. Create VTLU with default settings & Verify:**

**# server\_vtlu server\_2 –tlu -new**

**# server\_vtlu server\_2 –list**

server\_2 :

|    |        |          |          |               |             |
|----|--------|----------|----------|---------------|-------------|
| id | vendor | product  | revision | serial_number | device_name |
| 2  | ADIC   | Scalar24 | 1.0      | gkzp9492k5    | c9000t010   |

**4. Create Tape/Media & Verify:**

**# server\_vtlu server\_2 –storage –new vtlu\_fs3 –tlu 3 –tapesize 2G –tapes 4 –barcodeprefix 2GBTapes – destination vault**

**\$ server\_vtlu server\_2 -storage -list 2**

server\_2 :

|        |            |                |
|--------|------------|----------------|
| tlu_id | filesystem | barcode_prefix |
| 2      | NDMP_VTLU  | 0022           |

**5. List out Tape Drives and record Target & Luns for Backup SW Configuration:**

**# server\_vtlu server\_3 -tape -list 3**

server\_3 :

|          |            |              |          |             |
|----------|------------|--------------|----------|-------------|
| barcode  | filesystem | capacity(GB) | location | source_slot |
| 00220000 | NDMP_VTLU  | 400          | drive:1  | 0           |

```
00220002 NDMP_VTLU 396 slot:2 2
00220003 NDMP_VTLU 396 slot:3 3
00220004 NDMP_VTLU 396 slot:4 4
```

### # server\_vtlu server\_2 –drive –list 3

```
server_3 :
drive_id device_name serial_number status tape_barcode
0 c9000t011 h9SJIC000 empty
1 c9000t012 xFgSmIC000 in_use 00220000
```

#### EXTENDING TAPE STORAGE:

1. Extend File System first:

```
# nas_fs –xtend vtlu_fs3 size=4G pool=symm_std –o slice=y
```

2. Extend Tape Storage:

```
# server_vtlu server_2 –storage –extend vtlu_fs3 –tlu 3 tapesize 1G –tapes 4
```

#### CONFIGURING CELERRA FOR B2D BACKUPS:

1. Verify that NDMP & PAX params are set correctly

```
# server_param server_2 –facility NDMP –info –all
```

```
# server_param server_2 –facility PAX –info –all
```

**Note:** Modify param if required using –modify paxWriteBuff –value 128 syntax

2. Create NDMP account on DM

```
# server_user server_2 –add –md5 –password ndmp
```

#### VTLU PRINCIPLES:

(4) Parts of a VTLU Tape Library: Vault, Import/Export Slots (0-12); Regular Slots (0-500); (4) Tape Drives

--Tapes move from the Vault through the Import/Export Slots to the Regular Slots. The best situation is to load up to (12) tapes in the Regular Slots, as this is the only location that the Backup software can manage them—Backup sw cannot touch tapes in the Vault.

--File Systems are created for each VTLlibrary using the VTLU GUI

--An “svtl” database is created on the root of each data mover, consisting of a tables directory that holds VTLU configuration information in the following directories in the form of links: connections, drives, elements, inquiry, libraries, servers

→connections directory holds information on robots & drives

→drives directory holds compression information, which is off by default for VTLU configs

**Note:** SW compression only gains 1:1.75 compression ratio—can only be set using .server\_config, not GUI

→elements directory holds element info on each Library

→inquiry directory holds EMC and svtlRobot information

→libraries directory shows configuration: 1 4 32 8 0 1603737314040820 (robots, drives, slots, Import/Exp slots, vault slots, and timestamp)

```
$ .server_config server_2 –v "svtl"
```

```
$ server_param server_2 -f svtl -l
```

server\_2 :

| name            | facility | default | current | configured |
|-----------------|----------|---------|---------|------------|
| discardTapeData | svtl     | 0       | 0       |            |
| dbLocation      | svtl     | '/svtl' | '/svtl' |            |

#### Checking Robot Configuration:

```
$ .server_config server_2 -v "svtl tlusInfo tluld=1"
```

```
$ .server_config server_2 -v "svtl probeAll devType drive details=yes" (query each device)
```

```
$ .server_config server_2 -v "svtl probe device svtl0001 details=yes"
```

#### Checking VTLU Tape Configuration:

```
$ .server_config server_2 -v "svtl showDrvParams tluld=1"
```

```
$ .server_config server_2 -v "svtl setDrvParams tluld=1 drive=0 compression=zlib maxRate=10"
```

```
$ .server_config server_2 -v "svtl configChains startChain=50"
```

#### Checking for Free Space on Tapes:

```
$ .server_config server_2 -v "svtl storageInfo path=/vtlu_3"
```

**Note:** Shows all tapes for the VTLU file system—this info cannot be seen from GUI—Backup sw can see free space if tapes are in “slots”

#### VTLU BEST PRACTICES:

→Always configure as many “slots” as there are tapes and load all tapes to slots, because Backup SW can see tapes only in the “slots”

→After configuration, all operations should normally be done from the Backup sw side

**NAS 5.4 CELERRA CWORM (Write Once Read Many):** Compliance & Enterprise Levels

**FILE LEVEL RETENTION CAPABILITY:** New marketing name for this feature

File Systems that can be committed to a CWORM state with retention period—default Celerra Retention Period is indefinite

**Note:** Files show default infinity with “December 31, 1969” timestamp. Current release does not require CWORM License. CWORM file system must be created on a new ufs file system, and is applied on a per-file basis only

CWORM can be used on NFS or CIFS implementations

CWORM cannot be converted back from committed state, or otherwise reverted, but can be deleted by an administrator

**CWORM FILE SYSTEM STATES:**

WORM\_CLEAN: CWORM file state is CLEAN (files can be modified, etc)—initial state of newly created fs before files committed

WORM\_OK: (cannot be modified or renamed--committed) Files are RO, cannot be modified, moved, extended, renamed.

WORM\_EXPIRED: (Commit interval expires (Retention), files still cannot be modified/renamed--can be deleted by Owner/Admin)

**DETERMINING CWORM STATE OF FILES:**

**\$ .server\_config server\_2 -v "file query worm\_state /fs1/cworm/file.txt"**

1112722242: CFS: 4: cworm\_state of file /fs1/cworm/file.txt = WORM\_OK

**CREATING CWORM FILE SYSTEM & COMMITTING FILES:**

1. Create Cwom File System Type:

**# nas\_license -create cworm=<key\_code>**

**# nas\_fs -n worm\_fs -create v132 worm=enterprise**

**# nas\_fs -n worm\_fs -create size=500M pool=<pool> worm=enterprise -o slice=y**

2. Set Retention period using Unix Utime Utility (if specific expir. Time desired other than default ‘infinite’):

**# touch -at 201011200510 filename**

3. Commit file to CWORM by changing to R-Only or R-X-Only in Unix, or setting file attributes to RO in Windows:

**# chmod 444 filename** [If file is an executable, set to 555]

**# chmod 555 filename**

**Note:** If you forget to specify the retention period, the default will be ‘indefinite’, however, user can set new retention period

4. Verify using following:

**# nas\_fs -i cworm\_fs1**

**# ls -ul**

**Verifying Whether File System CWORM or not:**

**# grep file5 /nas/volume/filesys**

28:file5::0:1::y:1,c:97:1::::0::24::0:0:-1,-1: →Blue highlight fields indicate CWORM properties

**# nas\_fs -i file5**

id = 28

name = file5

acl = 0

in\_use = True

type = ufs

worm = compliance with no protected files

worm\_clock= Fri Nov 13 10:55:26 EST 2009

worm Max Retention Date= No protected files created

**# .server\_config server\_2 -v "file query 28"** (28 = fsid from nas\_fs -l)

1258127987: CFS: 6: isWorm = 1

**CWORM COMMIT:** Clearing Write bits!

→You cannot delete or modify (write), or overwrite a committed file. Unix will say permission denied, Windows will say “Cannot create the....file” and will prompt you to save file as a new file. If you try to change attributes on Windows file, you will get ‘Access is denied’ message. Please note that a copied CWORM file can be written to, and therefore is not in a committed state.

**Note:** CWORM enforces DOS RO bit mode for Windows (param cifs ReadOnly.Comp) and R-W Mode for UNIX

**CWORM & WINDOWS:**

1. Use Windows setTime Utility to set Retention period via CIFS

2. Commit file to CWORM by changing to RO using Windows property tab

**CWORM INTEROPERABILITY/SUPPORT:**

SnapSure and Replicator can be restored to a cworm fs after confirmation message answered

CDMS Migrations can be done to CWORM file system

Backup restores are not allowed to overwrite existing files

HighRoad supported

CAVA (scan files prior to committing)

NFS Clusters/Nested Mounts (but root of nested mounts cannot be CWORM file system)

**NOT SUPPORTED CWORM:**

DHSM, NFSv4

**CELERRA NMFS (NESTED MOUNT FILE SYSTEM):**

- Intro:** New file system type 102 that contains the nested root file system (RO) and its component file systems underneath, with purpose to provide ability to manage a collection of file systems under a single mountpoint.
- Creation of nested mountpoints only at the data mover root. Underneath the mountpoints are the component, or real file systems
  - Feature allows Celerra to present a single virtual filesystem with multiple diff. fs underneath (nested)
  - Clients will see component file systems as an Export for NFS or Share for CIFS
  - Server\_df will show total size of NMFS (combines file system sizes that are nested)
  - File System Export permissions are inherited from NMFS root level, but if permissions are exported on individual file systems, they override nested mountpoint export permissions when there is a conflict (Enforced at local file system level)
  - Cannot create mountpoints on the NMFS root (RO Root)
  - CIFS will be RO unless component file systems are properly Shared
  - No HardLinks or renaming across nested file systems
  - NFSv3 or higher only

**NMFS OPERATION:**

- Space is managed by each component file system, but will display at NMFS
- Quotas managed only at component file system
- Cannot have hard links, renaming, or copying of files between component file systems
- Component file systems must be ‘Shared’ for CIFS RW—otherwise, component file systems will inherit RO of NMFS root
- Server\_df should show total aggregated file system space, and individual file system components

**NESTING UXFS FILE SYSTEMS UNDER ANOTHER UXFS FILE SYSTEM:**

- Evidently, our earlier NAS versions (prior to 5.5.27) allowed the nesting of one filesystem underneath another, but this is not encouraged or really supported
- NMFS is not the same thing as nesting one file system under another. Rather, it is the nesting of multiple ufs file systems under a common /nmfs file system object and mountpoint, with each ufs file system having its own mountpoint defined under the toplevel NMFS mountpoint

/nmfs  
/nmfs/fs1  
/nmfs/fs2, etc.

**Hidden Option to Nest One File System under Another:**

**# server\_mount vdm2 -nested vdm\_fs9 /nmfs\_vdm2/test/vdm\_fs8/vdm\_fs9**

vdm2 : done

**FAST MOUNT ISSUE WITH NMFS & NESTED FILE SYSTEMS:** NAS 5.6.47 & emc233009

vdm\_fs9 on /root\_vdm\_2/nmfs\_vdm2/test/vdm\_fs8/vdm\_fs9 ufs,perm,rw,<unmounted>

**server\_log:**

2010-02-05 14:31:25: NMFS: 3: getNodeByName: thr 0x22ff08b0 findNode vdm\_fs8 NULL, status 5 - InvalidArgument  
2010-02-05 14:31:25: CFS: 3: file mount ufs rw /root\_vdm\_2/nmfs\_vdm2/test/vdm\_fs8/vdm\_fs9 123=42 rw: failed. Error NotFound

2010-02-05 14:31:25: UFS: 4: 48: The file system 42 mount failed during failover because the file system was corrupt.

**Sys log:**

Feb 5 14:31:25 2010:DART:UFS:WARNING:48:Slot 2:::1265398285:The file system 42 mount failed during failover because the file system was corrupt.

**Workaround—Disable the maxParallelMount parameter and reboot:**

# vi /nas/server/slot\_2/param  
param cfs maxParallelMount=0

→ Or, if already at 5.6.47, simply reissue the mount command using the –nested option, then add the param, and reboot

**SETTING UP CELERRA NMFS FOR NFS:**

1. Create the ‘User’ file systems using Celerra Manager, then permanently unmount the file systems
2. Create the NMFS object:

**# nas\_fs -name nmfs -type nmfs -create**

```
id      = 36
name    = nmfs
acl     = 0
in_use  = False
type    = nmfs
worm   = off
volume  = 0
```

```
pool      =
rw_servers=
ro_servers=
rw_vdms   =
ro_vdms   =
auto_ext = no,virtual_provision=no
deduplication = unavailable
stor_devs =
disks     =
```

**Note:** No actual volumes are used when creating the NMFS object

3. Create the NMFS object mountpoint:

**# server\_mountpoint server\_2 -create /nmfs**

server\_2 : done

4. Mount the NMFS object to the NMFS mountpoint as “Read-Only”:

**# server\_mount server\_2 -o ro nmfs /nmfs**

server\_2 : done

5. Export the NMFS object for NFS:

**# server\_export server\_2 -P nfs /nmfs**

server\_2 : done

6. Create mountpoints for the component file systems that will be nested under the NMFS ‘file system’:

**# server\_mountpoint server\_2 -create /nmfs/nmfs1**

server\_2 : done

**# server\_mountpoint server\_2 -create /nmfs/nmfs2**

server\_2 : done

7. Mount the component file systems to the NMFS

**# server\_mount server\_2 nmfs1 /nmfs/nmfs1**

server\_2 : done

**# server\_mount server\_2 nmfs2 /nmfs/nmfs2**

server\_2 : done

8. Verify:

**# server\_mount server\_2**

-----abridged-----

```
nmfs on /nmfs nmfs,perm,ro
nmfs1 on /nmfs/nmfs1 udfs,perm,rw
nmfs2 on /nmfs/nmfs2 udfs,perm,rw
```

## **SETTING UP NMFS FOR CIFS VDM:**

1. Create CIFS VDM container:

**# nas\_server -name vdm1 -type vdm -create server\_2**

2. Create NMFS object:

**# nas\_fs -name nmfs\_vdm -type nmfs -create**

3. Create NMFS object mountpoint on the VDM:

**# server\_mountpoint vdm1 -create /nmfs\_vdm**

4. Mount the NMFS object to the NMFS mountpoint RO on the VDM:

**# server\_mount vdm1 -o ro nmfs\_vdm /nmfs\_vdm**

5. Export the NMFS object for CIFS on the VDM:

**# server\_export vdm1 -P cifs -name nmfs\_vdm /nmfs\_vdm**

6. Create mountpoints for the component file systems on the VDM:

**# server\_mountpoint vdm1 -create /nmfs\_vdm/vdm\_fs1**

**# server\_mountpoint vdm1 -create /nmfs\_vdm/vdm\_fs2**

7. Mount the component file systems on the VDM:

**# server\_mount vdm1 vdm\_fs1 /nmfs\_vdm/vdm\_fs1**

**# server\_mount vdm1 vdm\_fs2 /nmfs\_vdm/vdm\_fs2**

8. Verify:

**# server\_mount vdm1**

vdm1 :

```
nmfs_vdm on /nmfs_vdm nmfs,perm,ro
```

vdm\_fs1 on /nmfs\_vdm/vdm\_fs1 ufs,perm,rw

vdm\_fs2 on /nmfs\_vdm/vdm\_fs2 ufs,perm,rw

## **DETERMINING NMFS OBJECTS:**

**\$ nas\_fs -l**

```
141  y  102 0  0      nas_nmfs2      1 →NMFS filesystems are type "102"  
144  y  102 0  0      home2        1
```

**\$ nas\_fs -i nas\_nmfs3**

```
id      = 146  
name    = nas_nmfs3  
acl     = 0  
in_use  = True  
type    = nmfs
```

**\$ .server\_config server\_2 -v "file mountdisplay"**

Current Mounted File Systems are:

uxfs rw /nmfs/nmfs2 113=35 rw →Shows that this ufs file system is mounted to the NMFS object 'nmfs'

uxfs rw /nmfs/nmfs1 111=34 rw

nmfs ro /nmfs 0=36 ro

## **DATA MOVER CAPACITY & FSCK SUPPORT:**

→NAS 5.4 will support up to 16TB file size on NS700 & Hammerhead DM's [but limited by SCSI to 2TB metavolumes]

→507 DM models or lower, are not supported

→Uses Intelligent Caching Scheme

→iSCSI LUNs will increase from 1TB max to 2TB max size

→FSCK will run integrated ACLCHK at the same time

→Up to two concurrent nas\_fsck's can be run per DM

# nas\_fsck -aclchkonly [Option for running aclcheck only—cannot be run with fs exported]

→Server may initiate an autofsck if corruption is detected—system will panic and run autofsck

**# nas\_fsck -fsckonly** [Option for running fsck only]

**param ufs skipFsck=1** [Set value to 1 to disable auto-fsck for corrupted file systems on reboots—corrupted file system will remain unmounted while all other file systems are mounted and needs manual fsck and remounting]

**param ufs corrupt=0** [disabling auto-fsck]

## **CELLERA SNAPSURE ENHANCEMENTS NAS 5.4:**

→Support for up to 64 checkpoints per fs, checkpoint Version V2.5

→Memory limitations of checkpoints have been lifted, now only restricted by SavVol size. Prior to V2.5, BlockMaps resided in DM memory. Now BlockMaps are paged to and from the SavVol.

→NAS Upgrades will convert Checkpoints to V2.5

→Checkpoint & Replicator are limited to 1GB memory—Deltasets for Replicator are limited to 8GB in size

→High Capacity Mode for >2TB file systems once systems running NAS 5.4 and all Checkpoints converted to V2.5

→V1 Checkpoints [i.e., NAS 4.2] will not convert—upgrade will fail

**#server\_sysstat ALL -blockmap** [page in rate page out rate →average pages into & out of SavVol for last 3 minutes]

**\$ server\_sysstat server\_2 -blockmap** (enhanced memory for checkpoints--25% physical RAM reserved for blockmap)

server\_2 :

```
total paged in      = 0  
total paged out     = 17416  
page in rate        = 0  
page out rate       = 0  
block map memory quota = 1048576(KB)  
block map memory consumed = 16272(KB)
```

**file systems greater than 2TB = disallowed**

**Note:** Above 'disallowed' message indicates that all checkpoints and replication delta sets have not yet been converted to high capacity version 2.5 format after a NAS 5.4 upgrade, meaning that the Control Station is still in low capacity mode and file systems cannot be extended past 2TB in size

## **VERIFYING DART HIGH CAPACITY MODE:**

**\$ .server\_config server\_5 -v "param SVFS useBtree"**

SVFS.useBtree INT 0x018f66b8 1 1 (0,4294967295) FALSE REBOOT 'NA'

**\$ .server\_config server\_5 -v "param blockmap conversion"**

blockmap.conversion INT 0x018f69d8 1 1 (0,4294967295) FALSE REBOOT 'NA'

## **CELLERRA MANAGER/MONITOR ENHANCEMENTS:**

- Navigation Tree enhancements with blinking status icon for new events; Tooltip text with number of alerts, hardware issues; Acknowledge Status of events to turn off blinking
- Status Monitor is a standalone version of navigation tree that can be launched—no expansion nodes, use as Monitoring window
- Alert Enhancements for CS, VC, FS Full & Usage predictions, Control LUNs [launch Navisphere]
- Default Monitor polling is 5 minutes, default polling for File System space and inode usage is 10 minutes

## **NAS 5.4 IP REPLICATION ENHANCEMENTS:**

- Introduction of GUI to setup and manage replication [CLI management uses fs\_replicate, fs\_copy, fs\_ckpt]
- Source/Destination timeout values at minimum of 600 secs—Timeout value is interval that Replication Svc uses between delta set creation and/or playbacks
- Source/Destination HWM represents Delta Set size in MB in which Replication Svc will be triggered to replay a delta set on SavVol. Default value is 600
- Source & Destination requires use of “rdfadmin” passphrase
- SavVol size for replication is 1-500GB, but VDM replication defaults to 1GB
- Must first establish connections between replication sites using shared passphrase
- GUI can setup file systems and VDMs
- Replication can be setup in two basic modes:

Immediate Method → Baseline source copied to destination, replication then started, and differential copy completed

Physical Transport → Requires creation of checkpoint backed up to media which is shipped to destination site and then loaded to the destination file system—when loaded, replication will then create the differential copy and start replication [data file systems only]

→ Destination VDMs & Filesystems are created under Destinations tab

→ Failover always initiated from Destination side

### **TERMS:**

#### **Delta Set:**

Source file system block updates [or changes] that are used to update destination file system. Minimum size of delta set is 128MB and max size is 8GB

#### **SavVol:**

Volume used to store copied data blocks from source fs locally and a remote SavVol for storing changes until Playback commits changes to remote file system

#### **VDM:**

Ability to administer and replicate a CIFS server from one location to another

#### **Replication Policies on Source:**

- Continue fs access even if replication will become out-of-sync [for whatever reason]
- Upon exceeding SavVol size and buffer changes, stop writes to buffer but allow reads [AutoRO]
- Upon exceeding SavVol size and buffer changes, stop all reads and writes to buffer [AutoFreeze]

**Note:** After changing timeout, hwm, or policy, changes will show as ‘pending’ until an update occurs

#### **IP REPLICATION COMMANDS/OPTIONS:**

Refresh → creates new delta set on demand, same as what replication svc will do when reaching timeout or HWM, starts playback of delta set on destination side

Suspend → Stops delta set playback and the replication service, but leaves in restartable state, starts playback of delta set on dest.

Restart → Restarts a suspended replication or resyncs a failed over or out-of-sync replication—source & destination will be resynced

**Note:** Run on Source side, but failed-over replication restart is done on Destination side.

Reverse → Reverses direction of Replication, run on Destination side [can also reset local timeout, hwm, bandwidth, & source policy]

Failover → fails over replication from Source to Destination only, but always issued from Destination side

**Note:** Restarting replication may require that Source & Destination timeouts, HWM, Interfaces, Bandwidth, SavVol name & size, and Source Policy be redefined. In otherwords, a Suspend of Failover does not maintain replication attributes. With a Reverse, local timeout and HWM and Source Policy can be specified.

#### **OUT OF SYNC REPLICATION RESTART [RESTARTABLE CHECKPOINTS]:**

CS script runs at 25 minutes past the hour to guarantee a restart point for out-of-sync replication restart

1. Manually create src\_fs\_repl\_restart\_1 and src\_fs\_repl\_restart\_2 checkpoints on each Production File System
2. Cron job takes over and refreshes the oldest checkpoint every hour

#### **Runs as Cron job /nas/sbin/refresh\_ckpt:**

```
# cat /etc/cron.d/nas_sysgrep refresh  
25 * * * * root /nas/sbin/refresh_ckpt >/dev/null 2>&1
```

**Note:** refresh\_ckpt script checks to see if replication source file systems have two restart checkpoints. If two already exist by name [\_repl\_restart\_1 and \_repl\_restart\_2], then refreshes the oldest checkpoint

Check sys\_log to verify that script refreshes are succeeding

#### **MOUNT ATTRIBUTES—CELLERRA MANAGER:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Path; Data Mover; File System; Read Only; Multi-Protocol Access Policy; Virus Checking status; CIFS Oplocks in use; NT Credential; Direct Writes Enabled (writes to disk without caching); Prefetch Enabled; Multi-Protocol Locking Policy; CIFS Sync Writes Enabled (Yes means synchronous writes); CIFS Notify Enabled;  
Requires use of IE or Netscape in order to login

### **USER/GROUP QUOTAS:**

- Can manage User and Group Quotas from Celerra Manager
- Separate User/Group quotas can be applied per Tree quota [in addition to User/Group quotas at FS level]
- Tree quotas can have User/Group defaults; Soft quota grace periods; Deny Disk Space option; Flags to control errors/events
- Note:** If File System and Tree User quotas are enabled, the most restrictive Quota will be applied at FS level. For example, if a User has a User Tree quota of 100MB, but a file system User Quota of 50MB, then total allowable quota for the User will be 50MB  
\$nas\_quotas –on –fs fs01 –path /tree2 [Turns on User Quota for Tree Quotas]
- Still can only set User & Group quotas on a file system with TreeQuotas set, but empty!
- Also, if QuotaPolicy is set to Blocks, you cannot change to FileSize

### **CELERRA VSS FOR iSCSI (Volume Shadow Copy):**

Runs as a Windows 2003 service, providing interface between Volume Shadow Copy Service (VSS) and Celerra iSCSI snapshot iSCSI target & LUN snapshot. Provides ability of VSS aware applications to create shadow copies of iSCSI Luns using Celerra iSCSI snapshot technology

- Point-in-time RO copy of single or multiple volumes
- VSS are RO by default and limited to 512 copies per volume and 1000 snapshots per LUN
- Requires use of Windows 2003 as Volume Shadow Copy Service with Celerra VSS Provider Service
- Purpose is for Backups and Rapid Recoveries
- Celerra supports two VSS Usage Models: Backups & Data Transport
- Benefits are consistent copies of application data without impact, and can backup open files
- One strategy would be to create the VSC copy, backup to tape, then delete VSC
- Another strategy would be to transport VSC to other servers for testing, etc.
- Celerra iSCSI target provides data protection, snapshot file versioning, for iSCSI storage devices

### **VSS COMPONENTS:**

VSS Volume Shadow Copy Service → Windows 2003 [EMCVSSPack.exe]—coordinates actions of Requestors, Providers, Writers  
VSS Requestors → Backup Applications, such as Legato Networker 7.1 or Veritas BackupExec 9.0 that invoke a Shadow Copy

VSS Writers → Applications such as Exchange or SQL that store persistent information, and participate in Shadow Copy sync

VSS Providers → Hardware & Software Providers initiate Shadow Copies & own the Shadow Copy data

Celerra VSS Hardware Provider → NBS Server & iSCSI Targets, Storage Backend does work of creating Shadow Copy using LUNs

**Note:** CBMAPI.DLL (Celerra Block Management API) used to create, promote, delete iSCSI LUNs exported by DART, between iSCSI initiator and NBS server and Win2k3 Server

Software VSS Provider → Owns Shadow Copy data & initiates shadow copies of volumes--Intercepts & processes I/O requests in software layer between filesystem & volume manager

Celerra Provider & MS iSCSI Software Initiator & SnapAPI DLL

### **HOW SHADOW COPIES WORK FOR CELERRA:**

- Requester makes request and Celerra Provider determines if iSCSI LUNs are supported
- VSS Service tells Provider to prepare snapshot sets for LUNs
- VSS Service asks Provider to commit snapshot sets & CBMAPI works with backend to create snapshots
- VSS Provider provides snapshot device info and VSS Service saves information to XML file
- VSS Provider software for EMC is “EMC\_ISCSI\_UTILS\_1\_6\_2”

### **VSS LOGS & TROUBLESHOOTING:**

Event Logs

DebugView utility

C:\...\VssPrvOut.log

Debug info with CelerraVssProvider /debug | nodebug

Restart Volume Shadow Copy Service and Celerra VSS Provider Service on Windows 2003 system

### **VSS BACKUP LIMITATIONS:**

Veritas NetBackup & Backup Exec iSCSI LUNs become RO after Shadow copy → Resolved with VSP 1.04

Legato NetWorker cannot select individual SQL db's or Exchange info Stores for backups [whole only]

### **VSS REQUESTORS:**

EMC Legato NetWorker 7.1

EMC Snapview Integration MS Exchange

### **VSS WRITERS:**

Exchange 2003 & SQL Server 2000

### **VSS PROVIDERS:**

EMC Clariion & Symmetrix

## **NAS 5.4 NDMP2D ‘Backup-to-Disk’ ENHANCEMENTS:**

Purpose of NDMP is to provide a protocol for controlling Backup & Recovery of data, as well as low-level control of tape devices and SCSI media changers.

#### **TLU (TAPE LIBRARY UNIT):**

→ TLU has four elements: Robot, Drive, Slot, & Import/Export Elements

#### **VTLU COMPONENTS:**

**VTLU:** A software-based Virtual Tape Library Unit that resides on a DM filesystem & emulates the physical TLU [aka, SVTL]

Purpose of VTLU is to allow for compatibility between NDSMP and Disk-based storage [as opposed to tape-based storage]

**Barcode Prefix:** User-defined string to identify virtual tapes

**Slots:** Virtual tapes in the VTLU (move virtual tapes from virtual slots to virtual drives)

**Vault:** Holds virtual tapes, not visible from Backup software

**Import/Export Slots:** Slots that hold virtual tapes, using CLI or Celerra Mgr, move to & from Vault, or to & from tape slots

#### **VTLU Limitations:**

Limited to 65536 elements and tapes per TLU

#server\_vtlu server\_x -tlu -new -robot -slots [Configuring new VTLU]

#server\_vtlu server\_x -storage -new fs01 -tlu tlu\_id [Add storage to existing VTLU]

#server\_vtlu server\_x -storage -import fs01 -tlu tlu\_id -destination [import configured file system to a VTLU]

#server\_vtlu server\_x -storage -export fs01 -tlu tlu\_id [Export storage from a VTLU]

#server\_vtlu server\_x -tape -insert | -eject -tlu tlu\_id [Insert or Eject a tape]

#server\_vtlu server\_x -drive -unmount -tlu tlu\_id -id drive\_id [Unmounting a drive]

#server\_vtlu server\_x -service -info | -tlu -list | -tlu -info tlu\_id

#server\_vtlu server\_x -storage -list tlu\_id

#server\_vtlu server\_x -tape -list tlu\_id | -tape -info [Querying VTLU tapes]

#server\_vtlu server\_x -drive -list tlu\_id [list VTLU drives] -drive -info drive\_id -tlu tlu\_id [information on a drive]

#### **Recommendations:**

→ Use dedicated file systems for VTLU storage

→ Create virtual tapes to use up all available space

→ Use RAID-3 LUNs for ATA drives

→ Do not use 2 LUNs from same RAID group when making virtual tape storage

→ Do not use LUNs of different RAID types when making virtual tape storage [cartridge file system]

→ Best restore performance is with 64k striping

## **SUN JAVA SYSTEM DIRECTORY SERVER:** (aka; Sun One Directory Server, iPlanet, Java System Directory Server)

#### **INTRO:**

Purpose of iPlanet is to allow for LDAP-based entity lookup based on Directory schema outlined in RFC 2307(DIT—Directory Information Tree), and implemented with the Sun ONE Directory Server. iPlanet LDAP Directory Services would be a good way to integrate the Naming Services for environments that have both Windows and Unix systems. LDAP provides common language for Clients & Servers to communicate. LDAP applications can authenticate, search, add, delete, and modify directory entries. LDAP searches are in accordance with RFC 2254.

**Note:** Traditional entity queries use NIS, NIS+, DNS, local passwd/group files for Naming Services

#### **SUN ONE DIRECTORY SERVER COMPONENTS:**

→ Sun One Directory Server 5.1 was originally called iPlanet

→ Sun One Directory Server 5.2 replaces iPlanet

→ Backend LDBM database; LDAP Server protocol; authentication & access control; administrative interfaces

→ dse.ldif file describes LDAP configuration, entries, & attributes in LDAP Data Interchange Format (LDIF)

#### **SUPPORTED SERVER PLATFORMS:**

→ UNIX systems, Windows NT/2000

#### **CELERRA CLIENT PLATFORM:**

→ DART must be configured to use an iPlanet domain name and at least (1) iPlanet Server Host for the iPlanet domain

→ Celerra makes LDAP queries to Sun ONE Directory Server via LDAPv3 per RFC 2251 using ‘gethostbyname’ query. SunOne Is meant to complement or replace the existing Naming Services: NIS, DNS, Local Files, AD

→ Celerra will connect to Sun ONE using ‘client profile’ to obtain LDAP info, schema, list of preferred Servers

→ Requires use of configuration for Domain, Server Location, Client Profile, and NSSWITCH file

→ Ability to use LDAP v3 Server Controls (latter resides on Sun ONE Server):

**Server Side Sorting Request:** Ability to ask LDAP server to sort the reply

**Virtual List View Request:** Ability to return only a set number of entries from sorted list

→ Celerra can control order and use of various Naming Services via the nsswitch.conf file (Current entity queries are passwd, group, hosts, netgroup, usermapper), and now add LDAP as a Naming Service

→ Celerra, as an LDAP client, does NOT listen to TCP/UDP ports, but opens connections using TCP to the Sun ONE Server

→ Specific LDAP queries will be for Username [getpwnam()]; UID [getpwuid()]; Groupname [getgrnam()]; GID [getgrgid()]; Hostname or IP [gethostbyname() or gethostbyaddr()]; Netgroup name [using NIS YP Match calls]

→Configure DM as iPlanet Client using \$ server\_ldap server\_x –set –domain domain.com –servers xxxx.xxxx.xxxx.xxxx, which also starts the LDAP Service on the DM

→Manage DM as iPlanet Client using \$ server\_ldap

## **USE OF NSSWITCH.CONF FILE FOR DATA MOVERS AND USER/GROUP MAPPINGS:**

**\$ cat nsswitch.conf**

passwd: files ldap nis

group: files ldap nis

### **iPLANET STRUCTURE:**

→Objects stored as directory entry

→Each entry has multiple attributes & are stored in hierachical tree form

## **CELERRA iPLANET (SUN ONE DIRECTORY SERVICE) GENERAL OVERVIEW:**

→Version 5.2 LDAP Directory Service

→Sun ONE supports use of SASL, GSS-API, TLS, simple password, and anonymous authentication methods (Celerra supports only the Simple ‘Proxy’ Authentication & Anonymous Authentication methods)

→Supports CIFS & NFS/FTP

→Celerra uses iPlanet as NIS replacement [passwd, group, hosts, netgroup databases] using Simple Password & Anonymous authentication

→If NIS is in use, LDAP domain will be used as Sun ONE Directory Domain

→DART limited to single LDAP domain & single NIS domain per physical Server [NIS objects passwd, group, hosts, netgroup]

→Recommended use of DNS for host records

→NSSwitch.conf file must be configured and copied to /.etc directory on DM or iPlanet LDAP queries will not occur

→Sun ONE Directory Server DOES NOT register with DNS

## **USE OF CLIENT CONFIGURATION PROFILE:**

Client profiles reside on the iPlanet server and can be specified using the –profile option to include additional configuration attributes

**\$ server\_ldap server\_2 –set –domain pvt.emc.com –servers 172.16.21.10 -profile celerra\_profile**

Client Profiles contain schema mapping, authentication info, list of servers, preferred server

### **CLIENT PROFILE ATTRIBUTES:**

→Client attributes are preferred and alternate servers

→Search path

→Profile TTL

→Object class and attribute mapping

→Authentication method

→Order of Servers is Preferred, Alternate, and Configuration

## **CELERRA PROFILE ISSUE WITH BASE DNs:**

→Celerra establishes a default base DN based on the default domain to which it is configured

→Celerra does not know how to set a specific profile for a base DN or to search for available base DNs [AR76154 77525]

## **Appendix A Configuring Celerra Naming Services:**

preferredServerList—List of Server Addresses & Port numbers in the order the DM should contact

defaultServerList—if preferredServerList fails or is not configured, establish connection with same Server as used in ldap config.

defaultSearchBase—defines the base for directory searches

defaultSearchScope—default is one for one-level search, and sub for whole sub-tree searches

authenticationMethod—LDAP bind method to use when contacting DSA (Directory Server Agent)—Celerra supports Simple only

credentialLevel—what type of credentials DUA (Directory User Agent—DM) should use—Celerra supports Anonymous & Proxy

profileTTL—defines time interval before DUA should reload and reconfigure itself—set to zero does not reload

-----many other attributes that Celerra does not yet support-----

## **LDAP iPLANET AUTHENTICATION SUPPORT:**

→Data Mover uses Anonymous Logon by default if a Bind Distinguished Name was not specified during server\_ldap configuration

→Data Mover uses Simple Proxy Authentication if –binddn option is used during server\_ldap configuration. Use of –binddn allows user to specify the DN of the identity used to bind the service, which otherwise defaults to the Domain Manager. Use of –p will prompt User for the directory bind password during initialization.

**\$ server\_ldap server\_2 –set –p –domain pvt.emc.com –servers 172.16.21.10 -binddn**

**“uid=admin,ou=Administrators,ou=TopologyManagement,o=NetscapeRoot”**

## **SPECIFYING NIS DOMAIN:**

If the NIS domain name is different from the iPLANET domain name, use the following syntax to specify the NIS domain name

**\$ server\_ldap server\_2 –set –domain pvt.emc.com –servers 172.16.21.10 -nisdomain nsg**

## **CONFIGURING iPLANET FOR CELERRA:**

1. Recommended that DNS be configured for Host Name resolution on Control Station

2. Configure nsswitch.conf file for Celerra with ldap switch and put on /.etc directory

4. Export file system for NFS [specify netgroups if appropriate]

5. Configure Data Mover for LDAP:

**# server\_ldap server\_2 -set -p -domain hosts.pvt.dns -servers 192.1.4.209,192.1.4.201 -profile celerra1**

**-binddn "uid=admin,ou=Administrators,ou=TopologyManagement,o=NetscapeRoot"**

**#server\_ldap server\_2 -set -domain firstlogic.net -servers 172.16.5.148,172.16.5.149 -binddn**

**"cn=proxyagent,ou=profile,dc=firstlogic,dc=net"**

Password “nasadmin”

6. Verify LDAP setup:

**# server\_ldap server\_2 -info -v**

server\_2 :

LDAP domain: hosts.pvt.dns

State: Configured - Connected

NIS domain: hosts.pvt.dns

Proxy (Bind) DN: uid=admin,ou=Administrators,ou=TopologyManagement,o=NetscapeRoot

Profile Name: celerra1 -----output abridged-----

→Need minimum of domain name and configuration server address

**#server\_ldap server\_2 -set -domain nfs.lab -servers 10.241.169.150 -profile Celerra\_profile**

**#server\_ldap server\_2 -info -v | -clear (stops & deletes config) | -service -start | -stop | -status**

**#server\_ldap server\_2 -lookup -user user1 | -uid | -group | -gid | -hostbyname host1 | -netgroup netgroup1**

**# server\_export server\_2 -P nfs -n ldap\_fs1 -o root=clients /ldap\_fs1** [Example of exporting to Netgroup]

→Use /etc/nsswitch.conf file to configure precedence of naming services

passwd: files ldap

group: files ldap

hosts: dns ldap files

netgroup: ldap

## **MANAGING DM AS iPLANET CLIENT:**

**\$ server\_ldap server\_2 -service -status | -stop | -start | -clear** (permanently stops LDAP iPlanet service)

**\$ server\_ldap server\_2 --set** (use to make configuration changes on existing service)

## **MIGRATING FROM NIS DOMAIN TO SUN ONE:**

1. Migrate passwd, group, hosts, netgroup tables from NIS to Sun ONE Directory Server

2. Delete NIS Client service on Data Mover

3. Configure Sun ONE Directory service for Celerra

4. Test

## **TROUBLESHOOTING SUN ONE DIRECTORY SERVICES:**

**\$ server\_ldap server\_2**

Error 2100: usage: server\_ldap { <movername> | ALL }

**-set [-p] -domain <FQDN>**

**[ -servers <ip\_addr>[:<port>][,<ip\_addr>[:<port>]...]]**

**[ -profile <profile\_name> ]**

**[ -nisdomain <NIS\_domain> ]**

**[ -binddn <bind\_DN> ]**

**| -clear**

**| -info [-verbose]**

**| -service { -start | -stop | -status }**

**| -lookup { -user <username>**

**| -group <groupname>**

**| -uid <uid>**

**| -gid <gid>**

**| -hostbyname <hostname>**

**| -netgroup <groupname> }**

where 'profile' is Sun ONE Directory Server Client Profile

'binddn' is DN of the identity used to bind to the service

**\$ server\_ldap server\_2 -lookup -user ndmp**

server\_2 :

user: ndmp, uid: 999, gid: 101

**\$ server\_ldap server\_2 -lookup -group facilities**

server\_2 :

Group name: facilities, gid: 2010

**\$ server\_ldap server\_2 -lookup -uid 3019**

server\_2 :

user: stevez, uid: 3019, gid: 1010

**\$ server\_ldap server\_2 -lookup -gid 1010**

server\_2 :

Group name: domain users, gid: 1010

**\$ cat /nasmcd/quota/slot\_2/.etc/passwd**

ndmp:34M8hLCSxDGLY:999:101:ndmp backup user:/userdata/users/ndmp:

**\$ server\_ldap server\_2 -service -status**

server\_2 :

LDAP service active

**Note:** Not 100% sure, but secmap cache does not appear to store any entries as originating from “ldap”, just “nis”, even though customer was not using NIS client or NIS in the options for the nsswitch.conf file.

**\$ server\_ldap server\_2 -info**

server\_2 :

LDAP domain: firstlogic.net

State: Configured - Connected

NIS domain: firstlogic.net

Proxy (Bind) DN: cn=proxyagent,ou=profile,dc=firstlogic,dc=net

Profile Name: default

Profile TTL: 43200 seconds

Next Profile update in 27974 seconds

user=b275(fde8)

Name=2K3\W2kU45685

## **RPM INSTALL & UPGRADE FOR STORAGE API:**

New RPM install and upgrade program to address need for new storage API's between NAS release cycles

EMC Solutions Enabler = SymAPI, aka Widesky

NaviCli/Agent = Clariion

Primary and Standby Control Station packages

Compatible with NAS 5.4 and higher releases only

Disable NAS Services prior to running

## **REPLACING NAS STORAGE API ON 5.5 SYSTEM:**

1. Copy the desired nasStorage API rpm version to the /tmp directory from the NAS CD-ROM:

**# cp /mnt/cdrom/EMC/nas/emcnas-5.5.31-1.i386.rpm /tmp**

**Note:** Or find the correct nasStorageAPI rpm file from the /nas/sys/apis directory

2. Extract the NAS rpm package:

**# cd /tmp & extract the NAS rpm package**

**# rpm2cpio emcnas-5.5.31-1.i386.rpm | cpio --extract --make-directories \*nasStorageAPI\*.i686.rpm &**

3. Unzip & untar the nasStorageAPI:

**# cd /tmp/nas/sys/apis**

**# tar -zxfv nasStorageAPI-6.0-3.tar.gz**

**# cd /tmp/nas/sys/rpms;ls**

nasStorageAPI-6.0-3.i686.rpm

3. Erase the old API:

**# rpm --erase nasStorageAPI**

4. Install the new nasStorageAPI:

**# rpm --install nasStorageAPI-6.0-3.i686.rpm**

5. Run PAHC to ensure that the storage api check passes

**# /nas/bin/nas\_checkup**

Checking if NBS devices are accessible..... Pass

**Note:** The nasStorageAPI provides Navicli/Naviagent and Solutions Enabler functionality when the Control Station interfaces with Symmetrix or Clariion backend storage systems. Alternatively, use the /var/sadm/pkg/nasStorageAPI\_mgr to erase, install, or upgrade the StorageAPI rather than using rpm.

## **INSTALLING, UPGRADING, ERASING STORAGE API NAS 5.6 SYSTEMS:**

**# /var/sadm/pkg/nasStorageAPI\_mgr/nasStorageAPI\_mgr**

**Note:** BASH script for Upgrading, Installing, or Erasing the nasStorageAPI on the system

## **UPGRADING STORAGE API WITH NAS RUNNING NORMALLY—Single CS:**

1. Copy the appropriate nasStorageAPI-7.1-8.tar.gz update to /tmp and make /nsa subdirectory

**# cd /tmp;mkdir nsa;cd nsa**

2. Untar the StorageAPI file in the nsa sub-directory

**# tar zxvf ..../nasStorageAPI-7.1-8.tar.gz**

**# ls -la**

-rwxr-xr-x 1 root root 8859 Jan 27 14:12 nasStorageAPI\_mgr

drwxr-xr-x 2 root root 4096 Jan 27 14:12 rpms

drwxr-xr-x 2 root root 4096 Jan 27 14:12 scriptlets

drwxr-xr-x 2 root root 4096 Jan 27 14:12 symcli

3. Run the storage api manager script

**# ./nasStorageAPI\_mgr -u**

Checking Backend Storage System(s) Version(s)

Backend Storage System(s) Version(s) OK

Stopping NAS Services...

rmdir: `/nas/etc/Navisphere/backup': Directory not empty

Did not delete /nas/etc/Navisphere/backup due to the presence of generated files.

If these files are no longer necessary, please delete manually.

Starting EMC Solutions Enabler install. This may take several minutes.

Removed EMC Solutions Enabler semaphores 0

EMC Solutions Enabler install complete

Re-starting NAS Services.....

### **LISTING OUT CONTENTS OF RPM PACKAGE:**

# rpm -ql nasStorageAPI

/etc/Navisphere

/nas/etc/Navisphere

/nas/etc/Navisphere/Navimon.cfg

/nas/etc/Navisphere/SupportedFlareRevisions

/nas/etc/Navisphere/agent.config

/nas/opt/Navisphere/bin

/nas/opt/Navisphere/bin/classic\_navicli

/nas/opt/Navisphere/bin/nas\_navi

/nasmcd/sbin/classic\_navicli

/nasmcd/sbin/nas\_navi

/nasmcd/sbin/navicli

/nasmcd/sbin/naviseccli

/opt/Navisphere

### **LOCATION OF NAS STORAGE API ON CS:**

**#** /nas/sys/apis

# ls

nasStorageAPI-6.0-3.tar.gz

# cat /nas/sys/apis/nasStorageAPI.env | head -8

#Primary NAS Storage API RPM Environment Variables:

NAS\_STORAGE\_API\_NAME=nasStorageAPI

NAS\_STORAGE\_API\_VERSION=7.0

NAS\_STORAGE\_API\_RELEASE=12

NAS\_STORAGE\_API\_TARGET=i686

NAS\_STORAGE\_API\_RPM=nasStorageAPI-7.0-12.i686.rpm

NAS\_STORAGE\_API\_TAR=nasStorageAPI-7.0-12.tar.gz

NAS\_STORAGE\_API\_REQUIREMENTS="#nasStorageAPI-7.0-12

# rpm -qa nasStorageAPI

nasStorageAPI-6.0-3

### **UPGRADING NAS STORAGE API AFTER UPGRADE FAILURE:**

**Note:** If NAS 5.4 upgrade fails with following message, download the latest nasStorageAPI and install Backend Storage Requirements Check Failed:

INSTRUCTIONS: Upgrade NAS Storage API

1. Download nasStorageAPI from TS2 website (An API required for primary CS and also one for Standby CS)
2. Upgrade RPM: # rpm --upgrade nasStorageAPI-0.0-6.i386.rpm
3. Query to verify: **# rpm --query --info nasStorageAPI**

#### **StorageAPI Install & Upgrade:**

#rpm --install nasStorageAPI-0.0-3.i386.rpm [Primary CS]

#rpm --install nasStorageAPI-sby-0.0-3.i386.rpm [Standby CS]

#rpm --upgrade nasStorageAPI-0.4.i386.rpm [Primary CS]

#rpm --upgrade nasStorageAPI-sby-0.4.i386.rpm [Standby CS]

**StorageAPI Erase:** Run only in emergency if needed to uninstall

**# rpm --erase nasStorageAPI**

#### **StorageAPI Query:**

**# rpm --query -info nasStorageAPI**

```
Name      : nasStorageAPI          Relocations: (not relocateable)
Version   : 6.0                  Vendor: EMC
Release   : 3                   Build Date: Mon 06 Aug 2007 06:03:03 PM EDT
Install date: Tue 21 Aug 2007 12:01:08 PM EDT  Build Host: NasBuild5
Group     : System Environment/Base  Source RPM: nasStorageAPI-6.0-3.src.
rpm
Size      : 83359399            License: EMC
Packager  : EMC
URL       : http://www.celerra.isus.emc.com/top_level/top_docs.htm
Summary   : API used to interface with Celerra backend storage systems.
Description: API used to interface with Celerra backend storage systems. The API provides NaviCli/Agent and EMC Solutions
Enabler functionality.
```

**# rpm --query -provides nasStorageAPI** [From NAS 5.5.31.1 system]

```
NaviCli_Agent = 6.26.0.2.14-1
EMC_Solutions_Enabler = V640
FC4700_Software_Support >= 8.51
FC4700_Software_Support < 8.53
CXx00_Software_Support >= 2.19
CXx00_Software_Support <= 2.26
CX3-x0_Software_Support >= 2.24
CX3-x0_Software_Support <= 2.26
Symm5267_Software_Support > 17
Symm5567_Software_Support > 31
Symm5568_Software_Support > 23
Symm5669_Software_Support > 36
Symm5670_Software_Support > 23
Symm5671_Software_Support > 31
Symm5771_Software_Support > 68
Symm5772_Software_Support > 55
nasStorageAPI = 6.0-3
```

#### **SOLUTIONS ENABLER:**

→A host-based API used to manage & monitor Symm, CLARiiON, and Celerra storage devices

→SE 7.1 is expected to be IPv6 capable, Q4 2009

→ECC and SYMAPI are host-based applications built on the SE

→SYMAPI used by Celerra to monitor Symmetrix and Clariion storage

#### **CAVA ENHANCEMENTS:**

→Automatic recognition of AV software updates

→Popup notifications of infected files and action taken by AV engine

#### **CELERRA NAS 5.5 BURGUNDY:**

5.5.19-4 GA March 17, 2006; Current release 5.5.42

#### **NAS 5.5 BURGUNDY RELEASE:**

#### **UNSUPPORTED ITEMS:**

→SCSI connections to backends no longer supported, though is still provided to Tapes

- 507 DM or below
- FDDI/ATM connections not supported
- FC4700 no longer supported
- Symm 5 FC

### **NS350 ENTRY LEVEL LOW-END NAS PLATFORM:**

- Ease of Use/Installation initiative designed with Placemat and Configuration Wizard—No fresh install required!
- NAS 5.5.19 and Flare 19 minimum using CX300 array
- Introduced with Single or dual-Data Mover configurations, but Single Control Station only
- Sold as Integrated model only, but upgradeable to Gateway NS500G
- Old model NS350-AUX-FD has been discontinued—no more “fresh install” platforms
- Factory-install models are all that are available now

### **NS350FC:**

You may encounter the term “NS350 FC”, which is a misnomer. What is meant is that an NS350 Integrated can be manually upgraded to become a Fibre Channel enabled NS500G. There is no additional software charge for this option. This is the “origin” of the so-called “All-in-one” models that are really being introduced in a public way starting with the NS20. The big marketing spiel is that one platform will support FC Hosts, iSCSI Hosts, and NAS Hosts. The “Celerra NS350...Series Hardware Upgrade Procedures Guide” contains the complete process for upgrading an NS350 to an NS500G—the use of the EMCNAS Software CD and upgrade script is required: [/mnt/cdrom/EMC/nas/setup\\_hw\\_upgr\\_aux2fc](/mnt/cdrom/EMC/nas/setup_hw_upgr_aux2fc).

### **Data Mover Specs (same hardware as NS500 DM):**

Processor = Intel Pentium 4  
Processor speed (MHz) = 1600  
Total main memory (MB) = 4031  
Mother board = Exterminator XP  
Bus speed (MHz) = 533  
Bios Version = 3.62  
Post Version = Rev. 02.25

### **RSA/ENVISION SOLUTION:**

→The special RSA/enVision solution used to ship on the NS350 platform, and in 2008 changed over to the NS20 Integrated platform. It will soon be shipping on the NS-120 Integrated. The current issue is that the NS20 system is being implemented without Proxy ARP (No CSA applied) or public IP address assignments for the SPs, which is contrary to the productline itself. Product will move over to the NX4 platform at some point(?).

→RSA enVision is a security information and event management solution (SIEM)

### **RSA enVision LS Series NS20 Solutions:**

RSA NAS 3500 →NS20 with 15 disks 3.5TB capacity; Dual Blades; CIFS-based  
RSA NAS 7000 →NS20 with 30 disks 7TB capacity; Dual Blades; CIFS-based

### **LINUX KERNEL UPDATE:**

→Kernel 2.4.9-34 will be replaced by 2.4.20-28.7 (Still RedHat 7.2) as a drop-in update, i.e., no recompiling of kernel is required (main purpose of update are to address security updates, bug fixes, and provide more hardware support, such as USB ports, and also to be at same kernel version as Blackbird project). Incidentally, will add hyper-threading capability, though code is still uniprocessor.

#### **\$ uname -r**

2.4.20-28.5504.EMC

→KLMs (Kernel Loadable Modules) will be supported at runtime, and supports standard insmod, lsmod, modprobe, and rmmod commands (other KLMs are ctap (serial), nd (network drivers), and SNARE audit (System iNtrusion Analysis & Reporting Environ.)

→Control Station considered an appliance with an embedded Linux kernel

→USB port support on Control Station—do NOT reboot CS while USB port is in use

SimpleTech STI-USB2FD/1GB USB 2.0 Flash Drive

### **USING LINUX USB PORTS WITH CELERRA CONTROL STATIONS:**

1. Plug flash drive into Control Station USB port
2. Run /sbin/fdisk -l to identify the dynamic sda number that was assigned.

**Note:** For NS Models, the sda device will most likely be the only such local SCSI device seen, as in the following output from an NS700 system:

```
# /sbin/fdisk -l
```

Disk /dev/sda: 32 heads, 63 sectors, 993 cylinders

Units = cylinders of 2016 \* 512 bytes

| Device    | Boot | Start | End | Blocks  | Id | System |
|-----------|------|-------|-----|---------|----|--------|
| /dev/sda1 |      | 1     | 992 | 999813+ | 6  | FAT16  |

3. Create mountpoint for usb device and mount:

```
# mkdir /usb
```

```
# mount /dev/sda1 /usb
# df -T
Filesystem Type 1k-blocks Used Available Use% Mounted on
/dev/sda1 vfat 999552 14160 985392 2% /usb
# mount
usbdevfs on /proc/bus/usb type usbdevfs (rw)
# cd /usb
# ls -la
drwxr-xr-x 2 root root 16384 Dec 1 2004 CruzerLock 2
drwxr-xr-x 2 root root 16384 Mar 22 13:12 my files
4. Copy files, etc.
5. Umount usb device from Control Station and Verify!
# umount /usb
# df -T
Filesystem Type 1k-blocks Used Available Use% Mounted on
/dev/hda3 ext3 2063536 889600 1069112 46% /
/dev/hda1 ext3 31079 2751 26724 10% /boot
none tmpfs 257448 0 257448 0% /dev/shm
/dev/nde1 ext3 1818352 787776 938204 46% /nbsnas
/dev/nda1 msdos 136368 36212 100156 27% /nas/dos
/dev/ndf1 ext3 1818352 121500 1604480 8% /nas/var
/dev/hda5 ext3 2063504 673660 1285024 35% /nas
```

**WARNING:** Never reboot the Control Station while the USB drive is engaged and mounted as it could corrupt the USB drive and cause the Control Station not to boot properly. Also, before removing the USB Drive, make sure you manually unmount from the Control Station.

**Note:** The only “supported” thumbdrive at this time is the SimpleTech STI-USB 2FD/1GB USB 2.0 Flash Drive, with EMC 053-001-348 USB part number. Other drives may work, such as the ‘SanDisk Cruzer mini’ 1GB USB 2.0 Flash Drive with an NS700 Control Station, but are not supported.

#### **CONTROL STATION USB PORTS:**

CFS, CNS, & NS600 Control Stations have version USB 1.1 ports that have transfer rates of 1.5MB/sec  
NS500/700 & NSX Control Stations (Falcon and Chivas CS, respectively) use USB 2.0 ports with transfer rates of 40MB/sec. Falcon CS has (3) USB ports on back of system to far left. Chivas CS has (2) USB port in back of system to the middle of the unit, and (2) ports in the front of the system to the far right. NS600 Control Station has (2) ports in the center rear of the unit, but buried behind the Allied Telesyn Ethernet switch.

#### **NTFS DRIVER SUPPORT FOR 5.5:**

→NTFS RO file system driver for use in special cases for iSCSI recovery

1. Loading NTFS driver

**#/sbin/modprobe ntfs**

**#mount -t ntfs -o ro /dev/xxx /mnt/zzz**

#### **NAS STORAGE API:**

# pwd

**/nas/sys/apis**

# ls -la

```
-rwxrwxr-x 1 nasadmin nasadmin 46887850 Nov 9 15:33 nasStorageAPI-0.0-18.i686.rpm
-rwxrwxr-x 1 nasadmin nasadmin 728 Nov 9 15:33 nasStorageAPI.env
-rwxrwxr-x 1 nasadmin nasadmin 21 Nov 15 16:13 nasStorageAPI.ok
```

**Note:** API interfaces with backend storage and enables NaviCli Agent and EMC Solutions Enabler functionality

#### **NAS PRE UPGRADE HEALTH CHECK TOOL (PUHC):**

**# /nas/tools/check\_nas\_upgrade -pre | -up | -debug | -version**

**Note:** Errors will result in the upgrade NOT being allowed to proceed until corrected. Pre-Upgrade check tool can be used as stand-alone healthcheck tool.

**# /nas/bin/nas\_storage -check -all**

```
/nas/log/nas_log.al
2006-01-26 12:46:44.260 db:0:7000:S: /nas/bin/nas_storage -check -all
2006-01-26 12:47:26.404 db:0:7000:E: /nas/bin/nas_storage -check -all
```

**# /nas/tools/check\_nas\_upgrade -up** →Triggered by NAS upgrade script

**# /nas/tools/check\_nas\_upgrade -pre** →More checks than -up, run as part of CCA process

Check Version: 5.5.19.1

Check Command: /nas/tools/check\_nas\_upgrade

Check Log : /nas/log/check\_nas\_upgrade.Mar-17-09:41:54.log

-----Checks-----

Control Station: Checking if standby is down..... Pass

---

/nas/log: -rw-r--r-- 1 root root 3636 Mar 17 09:43 check\_nas\_upgrade.Mar-17-09:41:54.log

Overall status code is 0

## **TO RUN PUHC HEALTHCHECK:**

**[/nas/tools/nas\\_checkup](#)**

### **CONTROL STATION CHANGES:**

- nasStorageAPI upgrade capability on Control Station (/nas/sys/apis)
- USB 2.0 thumb drive support, NTFS file system driver support
- Intended as a recovery tool for iSCSI
- Plug in thumb drive, mount the drive

**# mkdir -p /mnt/usb**

**# mount /dev/sdx1 /mnt/usb**

**# umount /mnt/usb**

**Note:** Always unmount USB drive before rebooting or unplugging the USB drive

→ Load NTFS driver to kernel separately for RO purposes only

#/sbin/modprobe ntfs

#mount -t ntfs -o ro /dev/xxx /mnt/zzz

### **GSS-API ERROR DECODING:**

- Creation of a GSS-API interface to decode internal error codes related to GSS-API, and its components, such as Kerberos
- Provides for a NULL-terminated decoded error string when returning error codes
- Subsystems CIFS, DNS, LDAP, RPCGSS will be modified to use gss\_error\_decode for Kerberos error decoding
- convertGssError and logGssError are modified

## **LDAP SIGNING SUPPORT:**

- LDAP Integrity Checking requires that messages are signed using Kerberos authentication
- LDAP Client & Server authentication is conducted via Kerberos and SASL (Simple Authentication and Security Layer) protocol, which describes how data is carried, and allows Security Layer to be negotiated (Integrity, Privacy, or None)
- Note:** The Integrity & Encryption Provider is Kerberos, which uses the GSS-API. Kerberos will check signatures and decrypt messages, as required. An algorithm is used for Signing and Encryption, from Kerberos, using krb5.conf file algorithms, such as DES, RC4, etc.
- LDAP Privacy Protection requires that messages are signed and encrypted using Kerberos
- LDAP Signing, or Integrity Checking, is requested by all Win2k/2k3 Servers, and DART 5.5 when using LDAP sessions, but not enforced on Clients
- Dart will use LDAP Integrity checking if DC uses & clients request—param value is 2
- Dart can only perform message encryption if param value of 4 is set
- Win2k/2k3 does not perform Message encryption by default
- LDAP used for Joins, Unjoins, Server Passwd Changes, GPO Updates, ADMapping LDAP Queries, IPsec policies, adding Services to a CIFS Server, iPlanet LDAP Services and queries

### **Win2k registry to enforce LDAP message signing:**

HKLM>System>CurrentControlSet>Services>NTDS>parameters>LdapServerIntegrity: [0 for no signing; 2 for signing]

→ Win2k3 contains Domain Policy & Domain Controller Policy

**None:** Data Signing not required to bind to Server, but if Client requests, Server will support signing

**Require signing:** LDAP signing must be used between Client & Server, unless Transport Layer Security/SSL is used (TLS/SSL)

**Not defined:** setting not enabled or disabled

## **DART LDAP PARAMETERS:**

CIFS Stop & Restart will put param change in place

param ldap SecurityLayer=0 → Signing & Encryption disabled—if DC or Servers require LDAP Security, LDAP bind will be rejected with LdapErr: DSID-OC090169

param ldap SecurityLayer=1 → Negotiate whatever Security layer the Server/DC is proposing

param ldap SecurityLayer=2 → Default Celerra value, Server enforces Signing with Clients

**param ldap SecurityLayer=4** → Enforces LDAP Encryption (Privacy)

**# server\_param server\_2 -facility ldap -info SecurityLayer -v**

server\_2 :

```
name      = SecurityLayer
facility_name = ldap
default_value = 2
current_value = 2
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range     = (0,4)
description = 0=No security layer, 1=Server proposes, 2=Integrity (default), 4=Privacy
```

## **AUTOMATED SAN INSTALL PART II:**

→ Automated zoning & Storage Group setup will be done for hardware upgrades, supporting all NS Celerras & NSX Hammerhead, Gateway direct-connect or fabric-connect (Does not support CNS or CFS cabinets)

→ If NS Celerras boot from a Symm, script can be used to add a Clariion backend

→ Direct-connect will support only 2Gbs/sec speeds for CX500/600/700, while fabric-connect will support CX300/500/600/700

→ Up to (4) fabric switches supported, using models Brocade, Cisco, or McData

→ Does healthcheck first of Array, as it will not succeed if there are faults (requires Write Cache enabled, Access Logix, etc):

**# /nas/sbin/check\_requirements**

→ Single data mover can be added:

**Note:** Script will not work if Zones or WWN Initiator Records or StorageGroup already exists!

## **AUTOMATED SAN INSTALL FUNCTIONALITY:**

### **ADDING DATA MOVER TO CABINET:**

**Note:** Script is invoked during setup\_slot to automatically add fibre DM fibre ports to existing Storage Group

**# /nas/sbin/setup\_slot -init -gateway\_auto\_config <slot#>**

Starting PXE Service....done

1<sup>st</sup> Reboot ....0000000333333314

Stopping PXE Service...done

2<sup>nd</sup> Reboot....000000033333344

Asks for Switch info and login prompt

Configures Zones and Storage Group records

3<sup>rd</sup> Reboot....discoveries disks

4<sup>th</sup> Reboot--Stops PXE Service

#### **ADDING ADDITIONAL CLARIION ARRAY & LUNS TO CELERRA:**

##### **# /nas/sbin/add\_clariion -init**

→New array must have AccessLogix enabled, write cache, two ports per SP for Celerra, and Root user

→Script prompts addition of SPA & SPB IP addresses for array, fibre switch information, creates new Storage Group and adds all Data Movers to the new SG.

##### **# /nas/sbin/setup\_clariion -init <serial\_no>**

**Note:** Run this after the add\_clariion to add new Storage Luns to Celerra database

#### **TROUBLESHOOTING LOGS:**

/nas/log/nas\_raid.log

/nas/log/zone.log

#### **SYMANTEC SAVSE ANTIVIRUS SUPPORT NAS 5.5—see Celerra Antivirus section:**

#### **FSDB CHECK TOOL:**

Tool to allow for inspection of on-disk structures for problem troubleshooting. For example, if a checkpoint fs is corrupt, the tool can show if the corruption exists on the PFS or the SavVol. Tool will obtain volume layer info from DM—which presumes that this info is correct. Tool will be a fs\_db executable on the CS using RPC to communicate to DART, and require linking to work (similar to mac\_db tool).

##### **Using the fs\_db Tool:**

→Inspect superblock:

##### **# fs\_db server\_2 readsb 120 16 (metavolume id=120, fsid=16)**

→Inspect cylinder group headers:

##### **# fs\_db server\_2 readcg 120 1**

→Inspect inode for given file:

##### **# fs\_db server\_2 readi 120 14 (metavolume id=120, inode=14)**

→Inspect metadata or data block:

##### **# fs\_db server\_2 readfsb 120 4479 /tmp/block.out (reads block 4479 & outputs to file)**

#### **EXAMPLE—VERIFYING STATE OF SUPERBLOCKS ON A FILESYSTEM:**

\$ server\_mount server\_2 -v <fs\_name>

\_fs\_db server\_2 readsb <volid> psb (PSB is located on Sector 16 of the file system)

\_fs\_db server\_2 readsb volid asb (ASB is located on Sector 32 of the file system)

\_fs\_db server\_2 readsb volid 8194

\_fs\_db server\_2 readsb volid 16386

#### **USING FS\_DB TOOL:**

1. While in the /nas/tools directory, create following link:

##### **# ln -s fs\_db \_fs\_db**

lrwxrwxrwx 1 root root 5 Feb 13 12:08 \_fs\_db -> fs\_db

2. Finding volume ID for file system “file4” (or use nas\_fs –list to see volume ID associated with the file system)

##### **# grep file4 /nas/volume/filesys**

26:file4::0:4::y:1:**93:1**::0::24::0:: (vol ID and Server\_ID, respectively)

3. Run fs\_db tool to obtain superblock information:

##### **# /nas/tools/\_fs\_db server\_2 readsb 93 psb →93 is the Volume ID of the file system “file4”**

About to read superblock from volume 93 and sector 16

ncyl=250

magic=0xdabadface →This magic value indicates file system is not a FLR Compliant file system [0xdcbaabc = FLR Compliant]

version=2

ncg=16

size=128000

bsize=8192

nbfree=108108

nifree=12589

4. Remove link when done with activity

#### **CAM MEMORY REDUCTION:**

→Reducing memory used by CAM subsystem

→Most memory used for caching inquiry data from target-lun addresses on backend (up to 256 connections)

→scsi\_dev object will hold INQUIRY data, and backend can be queried for updates

→I/O queue implemented at volume layer (starting with 5.4)

## **CELERRA MANAGER INDICATIONS MANAGER ENHANCEMENT:**

**Note:** Whole purpose is to increase WebUI and API performance via new caching mechanism

→Indication Mgr subsystem will provide clients (JServer, Celerra Mgr, API) with more objects to track persistent state changes

→JServer receives indications via core schema (Port 8887, use telnet to verify port)

→API & Celerra Mgr will receive indications via APL schema (Port 8886, use telnet to local CS to verify port)

### **Logs:**

/nas/log/apl\_log.al.indication (Indication Mgr service on CS)

/nas/log/webui/apl\_ind.log (apl\_ind\_mgr service on CS)

### **Troubleshooting:**

→Telnet to ports 8886 or 8887 to verify ports

→Set NAS\_DB\_DEBUG=1 and restart apl\_indication\_mgr and core\_indication\_mgr

## **CHECKPOINTS/SNAPSURE:**

→max number checkpoints increased to 96/file system, 64/fs for 510 DM—fs cyl group caching redesigned

→max number file systems per DM/Celerra 2048, except NSX, which has 2048 fs/DM and 4096/NSX

→max number replication sessions 64 for NSX and 32 for all other cabinets, from 16 previously

### **Cylinder Group Cache Statistics:**

**\$server\_config server\_2 -v "printstats cgcache"**

## **CELERRA CCMD--COMMON MESSAGE DEFINITION:**

**\$ nas\_message -info <msg\_id>**

**# nas\_message -info 13421904928**

id = 13421904928

severity = ERROR

component = CS\_CORE

facility = cabinetdr

baseid = 1056

brief description = Operation not permitted. Command must be run from remote administration account.

full description = This error message may be reported when the /nas/sbin/nas\_mview command to manage the remote environment is run from the local NAS administration account.

recommended action = Rerun the command from remote administration account.

→Message IDs can range from 1 – 68719476735 (1-65534)

## **CCMD PURPOSE:**

Purpose to provide common framework for storing and presenting messages. Post-Burgundy, messages will be stored as raw message data. Currently, all error messages are embedded in DART as strings, which are called by logmsg to create logEvents, and from Control Station sys\_log as strings. Goal is to convert sys\_log and many DART logmsg formats to CCMD format. Burgundy is creating a CCMD framework and CCDM message compiler, though enhancing and converting message definitions will be ongoing in further code releases. CCMD messages are 64-bit.

### **Four Major Components:**

**WebUI:** Browser-based interface using TCP and XML

**API:** Gets messages from CS via SAL and transmits to WebUI (JServer is part of this). Interface between WebUI presentation layer and core CS code.

**CS CORE:** Messages from DART; transmits some messages from DART to API via SAL.

**DART:** CS requests are sent via MAC/RPC or MAC/XML interfaces. DART also uses MMC to send messages to hosts.

**Note:** Feature limited to those messages translated into this framework

## **CONCEPTUAL CCMD FRAMEWORK:**

DART Cmd → HTTP → XML Dispatcher → MAC Handler → XML\_CMD\_Handler → Cmd (logmsg debug) → logmsg (CCMD) → Server Log

DART Facility → logmsg will output any debug messages to Server Log, just as it does now—current design is to not format debug messages into CCMD

DART Facility → logevents will be generated in CCMD format, which go into a DART memory buffer

The Control Station Facility will use MAC/XML to collect messages from memory buffer and puts into the ‘NAS Event Collector’ → then reports events to ‘NAS\_Eventlog’ → which then get recorded to sys\_log. Sys\_log will be viewable by a CCMD tool to read the new format (currently uses .server\_config MAC/RPC interface to retrieve DART messages)

DART Facility → if Server Log messages become CCMD cataloged, then DART will generate logmsg and record to Server Log

### **NAS EVENTLOG DAEMON:**

→Daemon receives messages from DART via “nas\_eventcollector”

→Daemon receives messages from CS via ReportEvent and PostEvent

## **WHEN ARE CCMD MESSAGES LOGGED AND WHEN ARE THEY NOT LOGGED?**

There are CCMD messages generated by User or System activity that would display to console only [Query-based non-state change actions], which would not be logged anywhere on the Celerra, and then there are Transaction-based actions [Transaction-based actions are “state” change actions that take locks to make system changes] that would log CCMD Error messages in sys\_log or server\_log when they occur. It’s not clear whether Warning messages would ever be logged.

**EXAMPLES OF MESSAGES NOT LOGGED in SYS LOG (even with nas logviewer -v switch):**

# **nas\_diskmark -m -a**

Discovering storage (may take several minutes)

done

**Warning 1771681587:** tid/lun= 1/4 type= disk sz= 0 val= -99 info= DGC RAID 5 03241400140014NI: invalid LUN size

**Note:** Even though a nas\_diskmark would be a transaction-based command, in this case, the diskmarking portion of the code still executed, but the invalid LUN itself would not be diskmarked, which is considered a Warning and not an event that would be logged.

# **nas\_diskmark -m -a**

Discovering storage (may take several minutes)

**Warning: 17716815787:** server\_2 c0t0l7 skipping reserved LUN id,

APM00073801838 stor\_dev=0x0007 (7 decimal), maps to a reserved host LUN id 0x7.

**VIEWING CCMD RECORDS IN SERVER LOG:** NAS 5.6

**\$server\_log server\_2 -v >slog2.ccmd**

Then used nas\_logviewer to view the contents of the file

**\$server\_log server\_2 -i**

**Note:** A hidden option that outputs server log entries in Unix epoch time

**VIEWING CCMD FORMATED SYS LOG ENTRIES:** NAS 5.6

**# /nas/bin/nas\_logviewer -v /nas/log/sys\_log >system.log |more** (CCMD events from sys\_log to file or screen)

facility = Callhome

baseid = 206

type = EVENT

argument name = arg0

**Debug Logging for MMC Issues:**

Set registry: HKLM>Software>Emc>Celerra>MMC>Configuration>Debug: Set value 0x4

Configure DebugView on system and run in capture mode while reproducing problem

**CIFS EMC TOOLS:**

→New tool fstoolbox.exe to list, remove, move, take ownership of files and directories for specific User and manage Quotas

**NAS 5.5 COMPUTER ACCOUNT PASSWORD CHANGE & HISTORY FEATURE:**

**How the Computer Account Password Feature works:**

DART generates a computer account password during the initial Join process, and is renewed as scheduled (Windows default every 30 days), or manually using –Join resetserverpasswd command. The computer’s password is transferred to the KDC and stored in AD & on the DM, using either Kerberos Set Password protocol [KPASSWD] or MSRPC SAMR Set Password protocol. NAS 5.5 introduces ability to keep password history of last (2) passwords, which will be stored under version numbers that match Kerberos key version information. The DM produces encryption/decryption Kerberos keys based on its computer account password—these keys are regenerated during Join process, during password renewal, or when restarting CIFS service. Clients will be able to connect to DM

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
using Kerberos service tickets generated from a KDC using either the current or previous password version. When decrypting Client Kerberos Service Tickets, the DM will use its computer account password, newest, then oldest, to decrypt the ticket. Whenever a Kerberos key is generated, DM cache will be searched for principal name and key version—if that fails, then all passwords will be searched to generate new keys for Kerberos principal.

### **NAS 5.5 PASSWD CHANGE FEATURE IS DISABLED BY DEFAULT:**

**# server\_param server\_2 -facility cifs -info srwpwd.updtMinutes**

```
server_2 :  
name      = srwpwd.updtMinutes  
facility_name = cifs  
default_value = 0  
current_value = 0  
configured_value =  
user_action = reboot DataMover  
change_effective = reboot DataMover  
range      = (0,4294967295)  
description = Time interval between password changes
```

**NAS 5.5 PASSWD HISTORY ENABLED BY DEFAULT** (requires updtMinutes param set to become functional):

**# server\_param server\_2 -facility cifs -info srwpwd.maxHistory**

```
server_2 :  
name      = srwpwd.maxHistory  
facility_name = cifs  
default_value = 2  
current_value = 2  
configured_value =  
user_action = none  
change_effective = immediate  
range      = (1,10)  
description = Number of password kept when password changes
```

#### **Pre-NAS 5.5 Method:**

→ Password stored in krb5.keytab file, which were looked up as needed by DM Kerberos client

→ Enforce legacy keytab file behavior and disable password history:

**param cifs srwpwd maxHistory=0**

**Note:** Default setting is 2, to keep newest and previous passwd in krb5.account file. Change value to store up to 10 passwords.

#### **KEY FEATURES:**

#### **PASSWORD HISTORY & KERBEROS KEY CACHE**

→ Data Mover will keep two passwords in a new Kerberos key cache, oldest will be destroyed after each password renewal—passwords are stored in krb5.account file for NAS 5.5

→ NAS 5.5 will support Windows 2003 GPO Policies:

Domain Member: Maximum machine account password age

Domain Member: Disable machine account password changes

→ Pre NAS 5.5, passwords were stored in the krb5.keytab file and read every time a Kerberos key needed to be generated

→ Key cache will be populated during Join, whenever CIFS is started, or when password is changed, and from keytab file if authenticating NFS Users

→ Kerberos Keys are generated on the fly and cached in memory, deleted when Unjoined, when CIFS service is stopped, etc.

→ Domain policy default is to renew password every 30 days

→ cifs srwpwd.updtMinutes, default changes every 30 days, though passwd change is disabled by default

→ server\_cifs server\_2 –Join –o resetserverpasswd (use to change machine password)

→ For UNIX systems, computers do not have accounts, and keys generated by KDC will be stored in DM's keytab file using 'kadmin'

#### **NEW CIFS OUTPUT FOR PASSWORD HISTORY FEATURE:**

CIFS Server LAIP1\_DM2A[2K3] RC=2

Full computer name=laip1\_dm2a.2k3.pvt.dns realm=2K3.PVT.DNS

Comment='EMC-SNAS:T5.5.18.2'

if=laip1-2a l=192.1.6.202 b=192.1.6.255 mac=8:0:1b:42:15:9e

FQDN=laip1\_dm2a.2k3.pvt.dns (Updated to DNS)

Password change interval: 0 minutes

Last password change: Mon Feb 6 17:35:46 2006 GMT

Password versions: 3, 2

**Note:** During the Join, a temporary machine account password based on the machinename is used, but never actually saved, hence the minimum password version starts at 2, not 1.

### **SETTING UP PASSWD CHANGE FREQUENCY & PASSWORD HISTORY:**

**Note:** Passwd change feature is disabled by default with NAS 5.5. To enable Passwd Change History, run following command to specify value, in minutes. Command also updates server param file & requires Data Mover reboot.

**\$ server\_param server\_2 -facility cifs -modify srpwd.updtMinutes -value 120**

server\_2 : done

Warning 17716815750: server\_2 : You must reboot server\_2 for srpwd.updtMinutes changes to take effect.

\$ cat /nas/server/slot\_2/param

**param cifs srpwd.updtMinutes=120**

**# server\_param server\_2 -facility cifs -modify srpwd.maxHistory -value 5**

server\_2 : done

**# server\_param server\_2 -facility cifs -info srpwd.maxHistory**

server\_2 :

name = srpwd.maxHistory

facility\_name = cifs

default\_value = 2

current\_value = 5

configured\_value = 5

user\_action = none

change\_effective = immediate

range = (1,10)

description = Number of password kept when password changes

### **WINDOWS 2003 ACCESS-BASED ENUMERATION SUPPORT (ABE):**

Windows 2003 SP1 provides a new properties tab called “Access-based Enumeration” which, when enabled (“Enable access-based enumeration on this shared folder” or all Shared folders on a computer), allows administrators to set ACLs on folders and files so that the right to view and access the subfolders or files under the Share can be restricted—minimum of Read access required. Win2k3 provides a GUI, CLI, or API to utilize this feature—ABEUI.msi. Celerra provides a Windows executable called “emcabe.exe” version 1.03 which can be downloaded from the Applications & Tools CD—its function is similar to Windows “abecmd” tool.

**C:\emcabe tool>emcabe.exe**

EMCABE 01.03

emcabe [/E [/D [/G] [/T <servername>] [/A] [/S <sharename>] [/H]

/E Enables ABE on specified shares

/D Disables ABE on specified shares

/G Get ABE status on specified shares

/T <servername> Target server name

/S <sharename> Specifies the name of the shared folder on which to run the command

/A run the command on all shares of the target server

/? display this usage message

### **ENABLING ABE ON CELERRA FILE SHARE:**

**C:\emcabe tool>emcabe /E /T \\mview\_dm3 /S nyip2**

EMCABE 01.03

ABE is now enabled on share nyip2

### **STATUS OF ABE SHARES ON COMPNAME:**

**C:\emcabe tool>emcabe /G /T \\mview\_dm3 /A**

### **CELLERRA MIRRORVIEW/SYNCHRONOUS DR(MView/S):**

**Note:** Introduced with NAPA\_3 NAS 5.5.23.2, RPQ only. With the release of NAS 5.6.47, MView is now considered a “GA” product, no RPQ required.

#### **What is MirrorView/S DR for Celerra?**

A Celerra implementation that uses the new CLARiiON MirrorView functionality (Flare 16/19) to maintain synchronous copies of LUNs mirrored from a Source Celerra/CLARiiON system to a Target Celerra/CLARiiON system, and used as a Disaster Recovery (DR) solution, though the solution can also be used as a way to perform planned or unplanned maintenance by failing over to the DR location, or for testing, etc. The Source LUN is called the Primary Image and the Destination LUN is the Secondary Image. Together, the Primary and Secondary form a mirrored relationship. MirrorView can be setup in an Active/Passive or Active/Active configuration, providing full-copy synchronous remote mirroring of LUNs between arrays. Delta set technology tracks changes between transfer cycles.

#### **MIRRORVIEW SPECIFICS:**

→CLARiiON backend DR solution for Celerra, similar to SRDF, though MView consists of binaries built into NAS, vs. shell scripts (possible framework for SRDF in future)

- Synchronous mirroring of Control & Data Luns between Primary Images (mirrors) on Source array & Secondary Images on Target array
- Disaster Recovery Campus solution up to 60km distance
- MirrorView is Clariion licensed software used to copy data between Local & Remote LUNs using delta set technology to maintain synchronous mirrors
- Active/Active and Active/Passive configurations allowed (former just means each Celerra has an Active MView configuration with its own Primary LUNs mirrored to a CG with corresponding Secondary LUNs onTarget/Passive side)
- Only Gateway NS, NS40, & NSX Celerra platforms in any combination using only CX/CX3 Clariion arrays [no integrated Celerras for MirrorView]
- Multi Storage Systems allowed (if qualified CLARiiONs), but all LUNs must reside on (1) Backend—other backends used only if there is local storage & other DM's available

→Write Intent Log (WIL) LUNs are used to facilitate sync between arrays & to prevent need for full sync if a link goes down or SP crashes—tracks in-flight writes and stores ondisk. WIL LUNs are not referenced during normal operations—WILs are Private LUNs, not in Storage Group, not visible to Celerra—(1) set of WIL LUNs for Source & Dest Arrays

- (1) 128MB WIL private Lun required for each SP dedicated for MirrorView software on both Source & Target CLARiiON arrays
- WIL LUNs are Bitmaps that indicate which portions of the primary image are different from the secondary image, and assists in resyncing after link interruptions or SP crash and recovery [Recovery is either automatic or manual]

**Note:** Changes in the bitmaps are transferred during the resync vs. the entire LUN

→Fracture Log is a bitmap of 64kb chunks that is only put into use if the link between Primary & Secondary goes down for over 10 seconds, which is the heartbeat interval—changes are automatically tracked in this bitmap once a ‘fracture’ occurs—as a Best Practice, when configuring the Backend for MirrorView, provision the MView link to automatically recover when the link is restored, as opposed to a manual resync using nas\_mview –resume. Fracture Log stores differences between images in SP memory.

→Synchronous means that a Host writes to a local storage LUN, and the data is then copied via MView fibre link to Secondary storage before local storage acknowledges write back to Host—all this needs to happen before next write can occur

## **MIRRORVIEW INFORMATION:**

- New synchronous mirroring solution used for DR to remote Celerra in Active/Passive or Active/Active configurations
- Similar to traditional Celerra SRDF DR solution using Symmetrix backend
- This feature will be limited to NS & NSX “gateway” configurations only with CX arrays
- One difference from Symm SRDF is that remote devices (Secondary LUN images) are not visible to Data Movers on Destination side until after failover has occurred (i.e, Secondary LUNS are offline)
- nas\_mview commands are built into DART to Initialize, Activate, & Restore MirrorView DR (nas\_rdf is composed of scripts)
- DR solution up to 60km
- NAS 5.5.27 will support Secure NaviCLI and requires that nas\_mview –init be run to update the security file since the format has changed with this version
- Synchronous mirroring on storage array to replicate control and user data
- Storage and DM failover/failback

→Only a single Consistency Group (devicegroup) per Active side is allowed for Celerra solution with dedicated FC link between Primary & Secondary arrays

**Note:** Consistency Groups are required since there is a possibility that an SP could fail, and Flare 19 supports Consistency Groups to allow LUNs to fracture if heartbeat communications are lost between Primary & Secondary image (heartbeat every 10 seconds)

## **HOW DATA WRITES ARE HANDLED WITH MIRRORVIEW:**

1. Data is written to the Source array by a Host
2. MirrorView copies data to Remote array cache
3. Remote array performs CRC check on data in cache and sends acknowledgement to source array
4. Write-acknowledgement is returned to Host from Source array before next write is allowed

## **MIRRORVIEW REQUIREMENTS:**

- Required NAS SW=NAPA\_3 NAS 5.5.23.2 release, or higher, RPQ until NAS 5.6.47
- Required SW=MirrorView, Navisphere Mgr, & Access Logix on Arrays
- Minimum EMC Solutions Enabler V6.0.1 [/nas/symcli/bin/symcli], but NAS 5.5.23.2 comes with SYMAPI Version V6.2.1.0
- FLARE 19 Patch 034 CLARiiON array support with MirrorView license on each array
- Celerra MirrorView/S solution is somewhat different than native CLARiiON MirrorView [e.g., Celerra only supports single CG, fewer LUNs for mirroring, and Synchronous mode, etc.]
- A Single CLARiiON Consistency Group (CG) contains all the Primary & Secondary LUN images for the Celerra MView configuration

**Note:** True for Active/Passive, but there could be two CG's if using Active/Active setup

- From Celerra perspective, CG is called a ‘devicegroup’ [synonymous]
- LUNs on source must be in single Storage Group on Source array
- LUNs on destination must be in single Storage Group on Target array
- A single CLARiiON security domain is required between arrays

- Source & Target LUNs must be of same RG Type, Same size, owned by same SP, use same Disk Types, same AVM type, for each respective side's Mirrored LUNs
- Best Practice recommends single LUN per Raid Group
- Depending on array type, max of (13) Data LUNs & (3) Control LUNs allowed in the Consistency Group
- New installs preferred, but upgrading a platform for MView is allowed
- For dual-CS Celerras, CS1 must be powered off during Activate and Restore operations, and never run nas\_mview or nas\_devicegroup commands on CS1
- IP communications are used CS-to-CS and CS-to-SPs
- Control Station clock times must be within 10 minutes of each other
- MirrorView links between SPs must be on the highest numbered SP port [Either port 1 on CX500 or port 3 on CX700]
- Each SP must have a separate zone between the source & target SP ports for SPA, and same for SPB for the “mirror” ports [SP A mirror source → SP A mirror destination]
- Management of MirrorView is done via CLI only, no WebUI support
- IP comm ports 80/8000 for HTTP, port 6839 for NaviCLI, and port 443 for Naviseclli
- Each SP is zoned to remote SPA and SPB ports, and vice versa—array-to-array communications are via dedicated Fibre Channel links, usually configured on highest SP port
- Local file systems are allowed only if there are non-MirrorView Data Movers available [i.e., Celerra does not have to be pure MView; could have NS704 with (2) local DMs and (2) DMs doing MView, for example, but keep in mind that the configuration between local backend Storage and MirrorView Backend Storage must be kept separate]
- Replication, SnapSure, MPFS, autofs extend features are not Supported with MView
- Source & Destination Data Movers must have same network interfaces--there is a special procedure to mask extra NIC devices on one side vs. the other side (e.g., NSX has more interfaces than NS series)
- Rule-of-thumb; run nas\_mvview –init after any Backend or MView configuration changes are made after initial setup (do not make config changes while in failed over state—will present problems)
- Support for NS/NS, NSX/NSX, NS/NSX, with Clariion CX/CX3 backends only (no mixed backends such as NS + Symmetrix,etc)
- Only SAN-attached NS platforms, no integrated NS platform support
- Active/Passive and Active/Active configurations
- Data Movers must boot from the CLARiiON which is also used for the MirrorView devicegroup (i.e., a MView Celerra must boot from an eligible Clariion array), no Symmetrix storage allowed
- Consistency groups can only have LUNs from single Storage Group
- Requires MirrorView license on each array & single MirrorView/Sync Consistency Group for Active/Passive, two CG for Active/Active configurations
- Only the Global User account is available for MirrorView/S commands (local accounts are not allowed)
- Only single consistency group allowed for Active/Passive, consisting of all data volumes and (3) Control Luns [0, 1, 4, root\_disk, root\_ldisk, and /nas, respectively]
- Max. (13) User Luns for CX600/700 & (5) User Luns for CX400/500
- Preferred setup is for new installations, but upgrading to MirrorView/S can be accomplished if LUN requirements allow (cannot have mixed local and MirrorView storage on the same Celerra)
- MirrorView/Sync -activate or -restore commands can only be issued when CS1 is powered off, for sites with dual CS
- Requires NAS 5.5, Flare 19 (Saturn) for introduction of Consistency Groups, Solutions Enabler v6.0.1 or higher, MirrorView license & SW, Navisphere Manager, Access Logix on each array
- Max distance 60km between sites—Campus solution
- Requires IP communication between Control Stations and between Control Stations & Clariion SPs
- Clariion uses FC port 3 on CX600/CX700 on each SP for MirrorView & port 1 for CX400/500 (highest SP port on the array)
- Clariions also must communicate between sites using IP
- Standby Data Movers must have same or superset of Primary Data Mover's network configuration (use hidden\_interfaces param to mask any interfaces that should not be seen by each side)
- Required ports for IP communications are Port 80 & 8000 for HTTP, Port 6389 for NaviCLI, Port 443 for Navicli.jar (Naviseclli)

## **MIRRORVIEW RESTRICTIONS:**

- If first failover or restore fails to complete all operations, rerun –activate or –restore again (this is critical information to know!)
- Auto File System extension not support
- Celerra Replication, Celerra Replicator for iSCSI, & MPFS are not supported with MirrorView
- SnapSure is supported only if the SavVol is built on MirrorView LUNs, but Schedules will not work in failed over state
- Checkpoints can be used, but SavVol should be built on MirrorView luns
- Synchronous MirrorView may impact write operations, but should not impact Reads
- Only single CG per Active setup, and only max. of 13 Data LUNs supported (as opposed to CLARiiON itself, which does more)
- Keep CS1 out of the picture when doing MView operations!
- MAN pages are missing for nas\_mvview & nas\_devicegroup in NAS 5.5.23.2
- Requires MirrorView/S license on Clariion backend, not on Celerra side

→Celerras can run with dual control stations, but must be on CS0 when invoking Failover or Failback, and is recommended that CS1 be powered off before running nas\_mview commands

→Basic iSCSI LUNs are not supported until NAS 5.5.24.x release

### **NAS 5.5.24.x iSCSI LUN SUPPORT WITH MVIEW:**

→Destination LUN copy cannot be accessed by iSCSI host until after activating and failing over to the destination side

→Same or different iSCSI host can be used to access the LUN after failover, but during failover, lun is not available

→If performing a failover with iSCSI LUNs, stop all Windows applications on the iSCSI Client that are using the Celerra; Clear the Session information to logoff the iSCSI initiator session under target properties; Failover; Run fsck or chkdsk before accessing the iSCSI LUN after failover

### **COMMUNICATION CHANNELS USED:**

→Array-to-Array uses dedicated Fibre Channel link

→Celerra CS-to-CS, and Celerra-to-SP communications will be IP over LAN or WAN links to either local or remote Array

### **DISK TYPES FOR MIRRORVIEW:**

CMSTD—Clarion mirrored standard device (nas\_mview –init will change from CLSTD to CMSTD)

CMATA—Clarion mirrored ATA device

**Note:** Setup via Navisphere Manager interface or navicli

### **MIRRORVIEW AVM STORAGE POOLS:**

cm\_r5\_economy (8+1 mirrored RAID5)

cm\_r5\_performance (4+1 mirrored RAID5)

cm\_r1 (mirrored RAID1)

cmata\_archive (6+1 mirrored RAID5)

cmata\_r3 (4+1 or 8+1 mirrored RAID3)

**Note:** Different pool types allowed provided LUNs are configured with same AVM pool type between sites

### **RAID Types:**

RAID 1, 4+1 RAID5, 8+1 RAID5 for FC, 6+1 RAID5, RAID3 4+1or 8+1 for ATA, SATA II, LCFC

→Max. fibre channel storage depends on disk size, from 1.7 – 13.9 TB on CX700 4+1 RAID5, 3.4 – 26.0TB on CX600 8+1 RAID5, to .6 – 5.4 TB on CX500 4+1, to 1.3 – 10TB on CX500 Raid5 8+1.

→ATA storage 6+1 RAID5 6.3-8.3TB for CX500 & 16.5-21.6TB for CX700

### **DEVICEGROUP vs. CONSISTENCY GROUP:**

→When referring to MirrorView devices from the Celerra database perspective, we refer to devices in a “devicegroup”

→When referring to MirrorView devices from Clarion perspective, we are talking about the same devices in a “Consistency Group”

### **CELERRA MIRRORVIEW CLI COMMANDS (no Celerra Manager support):**

#### **# nas\_cel**

**# /nas/bin/nas\_devicegroup** (Run as nasadmin/root or DRAdmin/root, depends if system is failed over or not; Never run on CS1)

**Note:** Will not see mirrored devices unless logged in as DR account when failed over

**# /nas/sbin/nas\_mview** (Run –init nasadmin/root but –active/-restore as DRadmin/root; Never run on CS1)

**Note:** Run –info as nasadmin/root unless failed over, then use DR account/root to run -info

\$ java -jar /nas/opt/Navisphere/bin/navicli.jar -AddUserSecurity -password nasadmin -scope 0

\$ /nas/sbin/navicli -h 10.241.168.52 mirrorview (Use for info only, not configuration; must be nasadmin, not root to run)

# export NAS\_DB\_DEBUG=1 (use for troubleshooting & special command usages)

# export CLARAPI\_DEBUG=1 (use for troubleshooting MirrorView CG operations)

---

#### **# nas\_cel –create**

→Used to establish communication paths & passphrase trust between Control Stations—run on both Local and Remote systems

**# nas\_devicegroup -list** (list devicegroups) | **-info -all** (summary info) | **-acl** (NAS\_DB access control for device group) | **-suspend** (suspend mirroring, Secondary consistent but no updating) | **-resume** (resumes mirroring state and synchronizes Secondary with Primary)

**Note:** nas\_devicegroup used to manage MirrorView devices (equivalent to the Clarion Consistency Group) from Celerra db

→Run as nasadmin/root or DRaccount/root, depending on whether system is failed over or not

#### **# nas\_devicegroup -list**

| ID | name            | owner | storage ID     | acl | type  |
|----|-----------------|-------|----------------|-----|-------|
| 2  | 872_MViewCGroup | 0     | APM00030600872 | 0   | MVIEW |
| 3  | 172_AP_MView    | 500   | APM00030600872 | 0   | MVIEW |

**# nas\_devicegroup -info id=3 -sync no**

```

name      = 172_AP_MView
description = Active Passive MirrorView Consistency Group
uid       = 50:6:1:60:90:60:7:BB:0:0:0:0:0:0:0
state     = Consistent
role      = Primary
condition = Active
recovery policy = Automatic
number of mirrors = 9
mode      = SYNC
owner     = 500

```

### **mirrored disks = root\_disk,root\_ldisk,d5,d7,d8,d9,d10,d11,d12,**

```

local clarid = APM00030600872
remote clarid = APM00023700172
mirror direction = local -> remote

```

# **nas\_devicegroup** with special usage options after setting #export NAS\_DB\_DEBUG=1

special usage:

```

| -list [-backend]
| -info {<name>}lid=<id>|-all} [-backend] [-sync [yes|no]]
| -suspend {<name>}lid=<id>} [-backend]
| -resume {<name>}lid=<id>} [-backend]
| -add <name>
| -delete {<name>}lid=<id>}
| -failover {<name>}lid=<id>} [-backend] [-Force]
| -failback {<name>}lid=<id>} [-backend]

```

### **# nas\_devicegroup -list -backend**

| ID | name            | owner | storage ID     | acl | type  |
|----|-----------------|-------|----------------|-----|-------|
| 1  | 172_AP_MView    | 0     | APM00030600872 | 0   | MVIEW |
| 2  | 872_MViewCGroup | 0     | APM00030600872 | 0   | MVIEW |
| 3  | 872_MViewCGroup | 0     | APM00023700172 | 0   | MVIEW |
| 4  | 172_AP_MView    | 0     | APM00023700172 | 0   | MVIEW |

# **/nas/sbin/nas\_mview -init <cel\_name> | -info | -activate | -restore** (built into CLI—converts CLSTD to CMSTD during init)

special usage: | mcdrestore

**Note:** -init prepares source and destination Celerras for MirrorView DR & configures Data Mover standby relationships. Rerun the -init command anytime the configuration of the Celerra has been changed. Run command as root on the SOURCE Control Station.

→Run -init as nasadmin/root, run -activate/-restore as DRaccount/root, and -info depends on whether failed over or not

### **[root@nyip2 mvadmin]# /nas/sbin/nas\_mview -info**

**# export NAS\_DB\_DEBUG=1** (troubleshooting & special command usages)

**# export CLARAPI\_DEBUG=1** (troubleshooting MirrorView CG operations)

**\$ java -jar /nas/opt/Navisphere/bin/navicli.jar -AddUserSecurity -password nasadmin -scope 0**

**\$ /nas/sbin/navicli -h 10.241.168.52 mirrorview** (Info only & not to configure; must be nasadmin—root account will not work)

**# /nas/sbin/nas\_mview –activate:** Used to failover from primary lun images to secondary lun images on remote CLARiiON, shuts down local data movers & fails over NASDB to RDF Data Movers on remote Celerra, always run from the Passive Celerra [all LUNs in devicegroup (Consistency Group) failover together]

**# /nas/sbin/nas\_mview –restore:** Used to fallback to Source CLARiiON & Active Celerra--run from Passive Celerra (on occasion, may need to complete restore by running /nasmcd/sbin/nas\_mview –restore on source side if previous restore was incomplete)

**# ls -la /nas/sbin |grep nas\_mview** (Link to nas\_cmd, issued only from Destination side for –activate or –restore operations)

lrwxrwxrwx 1 nasadmin nasadmin 14 Sep 5 14:32 nas\_mview -> ../bin/nas\_cmd

**# ls -la /nasmcd/sbin |grep nas\_mview** (Special executable for /nasmcd/sbin restore on Source)

-rwxr-x--- 1 root nasadmin 9492 Sep 5 14:09 nas\_mview

**Rule of Thumb:** If first –restore fails, run a 2nd time from Destination side. However, as last resort, or as directed by Error message, run the –restore from Source side using special executable /nasmcd/sbin/nas\_mview –restore

### **RUNNING NAVICLI MIRRORVIEW COMMANDS FROM CONTROL STATION:**

**Note:** Setup the security context first, then run navicli commands as nasadmin

**\$ java -jar /nas/opt/Navisphere/bin/navicli.jar -AddUserSecurity -password nasadmin -scope 0**

**\$ /nas/sbin/navicli -h 10.241.168.52 mirrorview -listlog**

Storage Processor: SP A

Lun Number: 150

Storage Processor: SP B

Lun Number: 151

### **SOME USER ACCOUNTS THAT ARE REQUIRED FOR MVIEW OPERATIONS:** (know when to use)

→Global CLARiiON domain account (needed for MView init; single Domain concept—see Backend Setup Guide—setup using Navisphere)

→nasadmin & root account passwords are still used at proper times

→DRadmin (special MView admin account) account is required—can be given any name [e.g., mvadmin, dradmin, etc.]

nasadmin & root accounts used on Source MView Celerra for normal management of Celerra

**Note:** DR admin account does not exist on Source unless you have an Active/Active MirrorView configuration

→nasadmin & su root used on Target Celerra for nas\_mview -init

→DRadmin account is used on Target Celerra to perform –activate, failover or –restore failback operation, & to administer/manage the Celerra when in a failed over state (dradmin account is set for NASDB at /nas/rdf/500, the location of NASDB after failover)

# env

USER=mvadmin

PATH=/bin:/usr/bin:/usr/local/bin:/usr/bin/X11:/usr/X11R6/bin:/home/mvadmin/bin:

**Note:** Do not use nasadmin account to reboot or perform any changes while in failed over state (may present problems during restore)

## **OVERVIEW OF MVIEW INITIALIZATION:**

- Prompts for global Clariion user account info
- Runs diskmark on Source & Destination Celerras
- Validates MirrorView/S storage configuration
- Prompts for Source & Destination Data Mover configuraiton
- Prompts for DR Admin account
- Configures Source & Destination systems

**Note:** See MirrorView Troubleshooting section for information on navicli and naviseccli MirrorView commands

## **Basic MirrorView Configuration Overview—Parts I, II, III**

- I. MirrorView Backend Setup: Configuring Arrays for MView (aka Engineering Backend Setup Guide)
- II. MirrorView Celerra Setup: Initializing & configuring Celerra for either Active/Passive, or Active/Active (aka MirrorView Tech Module)
- III. Conducting MirrorView Failover, Restore, Suspend Operations

## **PART I. MIRRORVIEW BACKEND SETUP:**

### **SUMMARY OF STEPS:**

1. Create CLARiiON Global domain account on either array
2. Establish MirrorView comms links between arrays
3. Create & allocate WIL LUNs on both arrays
4. Prepare Source LUNs (aka Primary LUN images)
5. Prepare Target LUNs from Source side (aka Secondary LUN images)
6. Create ‘Remote Mirrors’ on Primary Source LUNs
7. Add Secondary Mirror Images to respective Source Remote Mirror Images
8. Wait for LUNs to synchronize before continuing...
9. Add Source LUNs & Target LUNs to respective Storage Groups
10. Create CG on Source (Active side) & add Source Remote Mirrors to CG

### **I. CONFIGURE ARRAYS FOR MIRRORVIEW DR—ACTIVE/PASSIVE:**

#### **1. Create Clariion Global Administrative Domain:**

**Note:** Both Clariions must be in same Global Administrative Domain (Use nasadmin user and nasadmin as default password; can select Systems via IP Address or scan a Subnet for IPs; assign one storage system as domain master, & other storage system to domain—can perform these steps from either Storage system, doesn’t matter)

**Navisphere>File>Setup Domain>Configure Domain>IP Address of System>Selected Systems>o.k.**

**Navisphere>File>Setup Domain>Select Master>enter IP address of Clariion system to change Domain Master** (One array is assigned the Domain Master role)

#### **From Naviseccli:**

```
# /nas/opt/Navisphere/bin/naviseccli -h mview_source -user nasadmin -password nasadmin -scope 0 domain -setmaster  
10.241.168.57  
# /nas/opt/Navisphere/bin/naviseccli -h mview_source -user nasadmin -password nasadmin -scope 0 domain -add  
10.241.168.52
```

#### **2. Establish MirrorView communication links between arrays:**

- a) (2) fibre channel zones required, SPA-to-SPA, SPB-to-SPB point-to-point or fabric on highest numbered SP port
- b) Then, the logical communication path between storage systems via Navisphere must be created

**Navisphere>rightclick array>MirrorView>Manage Mirror Connections>Unconnected/Unknown Systems>select>Enable**

**Note:** Highest numbered port is Port 3 on CX600/700 and Port 1 on CX400/500. This procedure can be conducted on either Source or Target system and it automatically creates the logical link path between Source & Target SP’s in each direction.

**# /nas/opt/Navisphere/bin/naviseccli -h 10.241.168.57 (Source--SPA) -user nasadmin -password nasadmin -scope 0 mirror -enablepath 10.241.168.52 (Target—SPA)**

**Note:** Command activates all the necessary paths between all SPs: SPA local to SPA remote; SPA remote to SPA local; SPB local to SPB remote; SPB remote to SPB local

#### **3. Create & allocate 128MB WIL (Write Intent Log) LUNs (aka Private LUNs) on Source & Target arrays—(1) each for SPA & SPB on each side:**

**a.) Create two RAID GROUPs for Source & Destination Arrays:**

**Navisphere>Rightclick array>Create Raid Group>select (5) disks>Initiate create RAID Group operation? yes**

**b.) Create two WIL LUNs and bind each WIL into a separate RAID GROUP for Source & Destination Arrays:**

**Raid Groups>RAID Group 30 [Unbound] >Bind LUN** >Ensure RAID Type is set to RAID 5, assign LUN ID number (150), keep Number of LUNs to bind as 1, select the desired SPA, enter 128 for LUN Size and select \*MB for megabytes, apply

**Raid Groups>RAID Group 31 [Unbound] >Bind LUN** >Assign LUN ID (151), Select desired SPB, enter LUN Size 128MB, apply

**Note:** Select each new RAID Group & bind one WIL Private LUN into each respective RAID Group—one for SPA and one for SPB.

**Binding WIL Luns via CLI:**

\$ navicli -h spa bind r5 100 -rg 2 -rc 1 -wc 1 -sp a -sq mb -cap 128

\$ navicli -h spb bind r5 101 -rg 3 -rc 1 -wc 1 -sp b -sq mb -cap 128

**c.) Allocate WIL LUNs for Source and Destination Arrays:**

Source Navisphere>rightclick array>MirrorView>Allocate Write Intent Log>select Available LUNs 100 & 101 and move to Selected LUNs>o.k.

Destination Navisphere>rightclick array>MirrorView>Allocate Write Intent Log>select Available LUNs 150 & 151 and move to Selected LUNs>o.k.

**Allocating WIL Luns via CLI:**

\$ /nas/opt/Navisphere/bin/naviseccli -h spa\_source -user nasadmin -password nasadmin -scope 0 mirror -sync -allocatelog -spa 100 -spb 101

\$ /nas/opt/Navisphere/bin/naviseccli -h spa\_destination -user nasadmin -password nasadmin -scope 0 mirror -sync -allocatelog -spa 150 -spb 151

**Note:** Move luns 100 & 101 to “Selected LUNS” and click o.k., Confirm Allocate Intent Log—Yes. WIL records which areas of primary image differ from secondary image and assists in resynchronization after failure. WIL LUNs are not part of the mirrored configuration and should not be created from the same RAID group as the Control LUNs. Create WIL LUNs in separate RAID Groups (SPA WIL LUN & SPB WIL LUN)—note that WIL LUNs are NOT added to the Storage Group & are therefore not directly visible to Celerra—used only in the background as “Private LUNs” for MirrorView functionality. Repeat for Destination array.

**d.) Repeat a-c steps on DESTINATION Array**

**4. Prepare Primary LUN Images on Source (Control Luns HLU 0, 1, 4, & up to (13) user LUN images):**

**Note:** Create Data LUNs if required, and add to Celerra Storage Group on Source. Must bind at least one Data lun using HLU 16 or higher.

**Example:** Created new RAID Group and 5 disks. Rightclicked new RAID Group and selected BIND LUN, created ALU lun numbers 90-95, choose “Default Owner Auto” for LUN Owner assignments.

**a.) Create RAID GROUP for Data Luns:**

Navisphere>Create Raid Groups and Bind User LUNs

**b.) Bind LUNs, select LUNS, select Default Owner Auto**

Navisphere>rightclick on new RAID GROUP>Bind LUN>Set number of LUNs, Default Owner Auto, LUN Size, o.k.

**c.) Add User LUNs to Storage Group:**

Navisphere>Storage Groups>Celerra\_NYIP1>rightclick and “Select Luns”, making sure to assign correct HLU numbers

**Note:** Assign correct HLU numbers to Data LUNs (> than HLU 16)—at this point, you could still remove from Storage Group and re-add with correct HLU assignments. All Control & Data LUNs should be in the correct Storage Group on the Source at this time. This procedure assumes that Control Luns have already been added to the Storage Group as part of the initial NAS installation.

**Binding and Assigning Data LUNs to Storagegroup via CLI:**

\$ navicli -h spa bind r5 16 -rg 4 -rc 1 -wc 1 -sp a -sq gb -cap 10 (capacity 10Gb)

\$ navicli -h spa storagegroup --addhlu -gname Celerra\_Mirrorview -hlu 16 -alu 16

**Note:** Created single Data LUN 16—repeat above steps to create additional Data Luns

**5. Create Secondary Image LUNs using Source Navisphere for Control & Data Luns:**

**Note:** As with Steps 1-4, this is done from Navisphere on the SOURCE Clarion system, but the Secondary Image LUNs themselves will be created on the Destination array. This ensures that all Secondary images will match with same size, the same SP, and be of the same RAID type as the Source.

**a.) Create Secondary Image Luns for Control Luns:**

Navisphere>expand SPA>rightclick LUN 0 (choose correct LUN number in display)>MirrorView>Create Secondary Image

LUN [Secondary Storage system is displayed] >Select an ALU LUN number “Secondary Image LUN” box >Select existing RAID Group or New RAID Group, ensuring that the RAID Group type is identical to Source. Repeat process for Source Control Luns 1 & 4. Could also create LUN directly from the Raid Group section of Navisphere. Please keep in mind that the LUN numbers seen in Navisphere are ALU numbers—therefore, LUN 0 could be a different number entirely from that displayed in Navisphere.

**Note:** Later, when adding the Secondary Control Luns and Data Luns to the Remote system’s Storage Group, the HLU numbers will become Secondary Image LUN number 6, 7, 9, respectively—data HLU numbers must be >than 16)

**Using CLI to create Secondary Image LUN 0:**

\$ navicli -h spa bind r5 17 -rg 3 -rc 1 -wc 1 -sp a -sq gb -cap 11

**Note:** Creates ALU 17 same size as source control lun 0

**b. Create Secondary Image Luns for Data Luns:**

Navisphere>expand SPA>rightclick data LUN 91, 93, 95 >MirrorView>Create Secondary Image LUN>Secondary Image

LUN: 91 | 93 | 95 >Existing or New RAID Group

**Navisphere>expand SPB>rightclick data LUN 90, 92, 94 >MirrorView>Create Secondary Image LUN>Secondary Image LUN: 90 | 92 | 94 >Existing or New RAID Group**

**Note:** The option to select ‘Use Write Intent Log’ seems to be only available when creating the Remote Mirrors and not when creating the Secondary LUN Images—but, the system by default will select “Use Write Intent Log” so it doesn’t seem to matter.

**Using CLI to create Secondary Image for Data Luns:**

**\$ navicli -h spa bind r5 20 -rg 3 -rc 1 -wc 1 -sp a -sq gb -cap 10**

**Note:** Select Raid Group ID and number of disks, then apply. After RAID Group is created, go back and add Data Lun 91 as Secondary Image LUN, select correct Raid Group that was just created, make sure RAID 5 is selected in Select RAID Type, click o.k. to bind LUN 91. Repeat process for each Data Lun to be added to the Raid Group.

## **6. Create Remote Mirrors for each Primary Image for Control (0, 1, 4) & Data LUNs (Source side):**

**Navisphere>SPA>rightclick each primary image LUN>MirrorView>Create Remote Mirror>Mirror Type:**

**Synchronous>Enter a Name: Lun 0 Primary>Select ‘Use Write Intent Log’>Select LUN 0>Apply**

**Note:** Remote Mirrors hold changes made to primary data blocks for each lun, stored either in SP memory or WIL. Perhaps an easier way to ensure that correct LUNs are being used, go to **RAID Group>LUN X>MirrorView>Create Remote Mirror>**check the **Use Write Intent Log box, assign Name ‘Lun 0 Primary’**, apply. Repeat for all LUNs to be mirrored

**Creating Remote Mirror of Source LUN using CLI:**

**\$ /nas/opt/Navisphere/bin/naviseclli -h spa -user nasadmin -password nasadmin -scope 0 mirror -sync -create -name spa\_m0 -lun 0 -description "mirror for src LUN 0" -usewriteintentlog**

## **7. Add Secondary Image LUNs to their respective Source Remote Mirrors:**

**Navisphere>Array>Remote Mirrors>rightclick LUN 0>Add Secondary Image>Select appropriate matching LUN 6>**Set recovery policy to Automatic & Initial Sync Required—LUN will go FAULTED, then to TRANSITIONING state, as LUNs synchronize. We are adding the remote lun that matches up with lun 0, and so on, in this step.

**Note:** Each Source Image LUN, aka Remote Mirror, will need to have an equivalent Secondary image LUN matched up with it. Repeat steps and match Source Data Lun number to corresponding Secondary Image Lun number. This is the step where the Source & Destination LUNs become ‘paired’. Each LUN pair must go through a synchronization process before the destination luns can be added to the Remote Storage Group. For this step, the chosen ALU numbers for each of the Secondary Image Control & Data Luns does not matter—might be useful to label the Luns in Navisphere, however, to keep track of ALU, System, HLU numbers.

**Adding Destination LUN Image to Mirror from CLI:**

**\$ /nas/opt/Navisphere/bin/naviseclli -h spa -user nasadmin -password nasadmin -scope 0 mirror -sync -addimage -name spa\_m0 -arrayhost 10.6.1.112 -lun 17**

**Note:** The option to select ‘Use Write Intent Log’ seems to be only available when creating the Remote Mirrors and not when creating the Secondary LUN Images—but, the system by default will select “Use Write Intent Log” so it doesn’t seem to matter.

## **8. Wait for Synchronization of Secondary Images to Remote Mirrors to complete before proceeding:**

**Expand Remote Mirrors>select LUN & properties>Secondary Image tab>monitor State and %Synchronized**

**Checking progress from Celerra CLI:**

```
# nas_devicegroup -info id=3 -sync no
name      = 172_AP_MView
state     = Synchronizing
```

When completed, Data Luns show up as State: Synchronized with %Synchronized: 100

Control Luns show up as State: Consistent with %Synchronized: Not Applicable or 100

## **9. Add Remote Array LUNs to Remote Storage Group & assign correct HLU numbers:**

After synchronization has completed, add Control Luns and Data Luns from Remote array to the Secondary Array Storage Group on the Remote Secondary Side using Navisphere. Make sure to assign the correct HLU numbers at this time—Control LUN HLU assignments are 6, 7, 9. Data HLU Lun numbers must be >than decimal 16.

**Navisphere>Storage Groups>Celerra\_nyip2>highlight & Select LUNs>Add LUNs to Storage Group>**Assign correct HLU numbers for Control LUNs 6, 7, & 9 before applying—all data HLU numbers must be >than decimal 16

**→Source Control Luns HLU 0, 1, 4 must be matched up with Secondary Image Luns HLU 6, 7, 9, respectively [DOS, UFSLOG, NBSNAS, respectively]**

**Adding Control Luns to Destination Storage Group from CLI:**

**\$ navicli -h element-spa storagegroup -addhlu -gname Celerra\_element -hlu 6 -alu 17**

**Note:** Assigns destination LUN 0, hlu 6, to destination Storagegroup as alu 17

## **10. Create MirrorView/S Consistency Group on Source Array & Add Remote Mirrors to Group:**

**Navisphere>Array>Consistency Group>Create Group>Mirror Type:Synchronous >Name: SVT MirrorView>Select all the Available Remote Mirrors>Recovery Policy automatic**

**Note:** Limited to (16) total Remote Mirror luns for NS600/700 and (8) total Remote Mirror luns for NS400/500. Can also create the Consistency Group from **Navisphere>Array>rightclick>MirrorView>Create Group**

**Create Consistency Group on Source & Add Remote Mirrors using CLI:**

**\$ /nas/opt/Navisphere/bin/naviseclli -h spa -user nasadmin -password nasadmin -scope 0 mirror -sync -creategroup -name cg\_source -description "consistency group from src to dst"**

\$ /nas/opt/Navisphere/bin/navisecl -h spa -user nasadmin -password nasadmin -scope 0 mirror -sync -addtogroup -name cg\_source -mirrorno cg\_m17

**Note:** Repeat above command to add Remote Mirrors for all System & Data LUNs to the Consistency Group

## **CONFIGURING MIRRORVIEW DR ON CLARIION SYSTEMS—ACTIVE/ACTIVE:**

### **ACTIVE/ACTIVE MIRRORVIEW SETUP:**

#### **ACTIVE/ACTIVE BACKEND CONFIGURATION:**

→There will be (1) Consistency Group (Celerra devicegroup) for each active side—make sure the CG names are unique

**Note:** See emc138372 if a Consistency Group has been renamed in Navisphere after MirrorView has been configured and initialized

→Do steps 1-11 above for Backend configuration to one Celerra/Clariion combination, then repeat steps 4-11 for the other Celerra/Clariion combination—each side will have a Consistency Group—an Active/Active setup really means that you have an Active/Passive relationship on each Celerra

**Note:** A recommendation would be to carefully name all Luns in Navisphere and map out the ALU/HLU Lun assignments for each MirrorView configuration and its respective Storage system

## **CONFIGURATION OF CONTROL LUNS BETWEEN SOURCE & DESTINATION:**

LUN 0 11GB Primary Image LUN maps to 11GB Secondary Image LUN 6

LUN 1 11GB Primary Image LUN maps to 11GB Secondary Image LUN 7

LUN 4 2GB Primary Image LUN maps to 2GB Secondary Image LUN 9

## **PART II. MIRRORVIEW CELERRA SETUP:**

### **OVERVIEW**

1. Register CS's with each other using nas\_cel
2. Initialize config on Target Celerra (Passive side) using nas\_mview -init (nasadmin/root account) and configure RDF Server relationships when prompted

### **INITIALIZING MIRRORVIEW/S CONFIG BETWEEN SOURCE & DESTINATION CELERRAS FOR ACTIVE/PASSIVE MVIEW:**

#### **Preparatory Information and Best Practices:**

→As Best Practice, run primary Internal Usermapper on Source server\_2—db and complete functionality will follow when conducting failover to Destination side

→Know IP Addresses of both Control Stations, management accounts and passwords, passphrase account and passwords, and create a new DR Admin account for MirrorView

→Must know Clarrion management authentication, Consistency Group, Mirrors (Primary & Secondary Images), and Storage Groups (Source and Destination)

→Celerra times must be within 10 minutes of each other

→Use nas\_cel -create to identify each Celerra to the other

→Passphrase used, and must be same on both Sides (6-15 characters)

→Configure remote communication

→Rerun -init on Destination Side after any config or DM relationship changes

→Run **nas\_mview -init** from destination control station (Prompts for Global User account, runs diskmarks on both source & destination, validates MirrorView/S configuration, prompts for DM configuration, prompts for DR admin account, configures source & destination systems)

**Note:** -init prepares source and destination Celerras for Mirror/View DR, but is run on the Destination side

#### **1. Register Control Stations for Remote Communications:**

##### **a.) Register Source CS to Remote CS:**

# **nas\_cel -name nyip2 -create 10.241.168.48 -passphrase mvadmin**

operation in progress (not interruptible)...

```
id      = 1
name    = nyip2
owner   = 0
device  =
channel =
net_path = 10.241.168.48
celerra_id = APM00030600872000F
passphrase = mvadmin
```

##### **b.) Register Destination CS to Source CS:**

# **nas\_cel -name nyip1 -create 10.241.168.50 -passphrase mvadmin**

operation in progress (not interruptible)...

```
id      = 1
name    = nyip1
owner   = 0
device  =
channel =
net_path = 10.241.168.50
celerra_id = APM000237001720000
passphrase = mvadmin
```

**Note:** Leaving the –name option off gives default name of “Dom1”. To rename, using –modify command:

**#nas\_cel -modify dom1 -passphrase mvadmin -name dom2**

**c. Verify results of Registration process:**

**# nas\_cel -l**

```
id  name      owner mount_dev channel net_path      CMU
0   nyip1     0          10.241.168.50 APM000237001720000
1   nyip2     0          10.241.168.48 APM00030600872000F
```

**Note:** Run on each Celerra to verify that the one is registered with the other

**# nas\_cel -info id=1**

```
id      = 1
name    = nyip2
owner   = 0
device  =
channel =
net_path = 10.241.168.48
celerra_id = APM00030600872000F
passphrase = mvadmin
```

**Note:** Both Source & Destination Control Stations should have the following passphrase files and contents

**/nas/httpreplication/inbound**

**/nas/httpreplication/outbound**

```
# cat APM000237001720000
```

```
mvadmin
```

```
/nas/httpreplication/inbound
```

```
/nas/httpreplication/outbound
```

```
# cat APM00030600872000F
```

```
mvadmin
```

**2. Initialize the MirrorView Configuration—Run from Destination Celerra:**

**# /nas/sbin/nas\_mview -init nyip1**

Celerra with MirrorView/Synchronous Disaster Recovery

Initializing nyip1 --> nyip2

Contacting nyip1 for remote storage info

Local storage system: APM00030600872

Remote storage system: APM00023700172

Enter the Global CLARiiON account information →Global Administrator account created in Setup of MirrorView Clariion security

**Username: nasadmin**

Setting up server\_2 on nyip1

Rebooting server\_2 on nyip2 as standby ... done

Creating user account mvadmin

Setting acl for server\_3 on nyip2

Setting acl for server\_2 on nyip2

Updating the Celerra domain information

Creating device group SVT MirrorView DR on nyip2

Creating device group SVT MirrorView DR on nyip1

done

**Note 1:** When prompted, configure the appropriate Servers on Source & Target sides, then type “c” to continue initialization, and setup the special User Account and Password to be used for MirrorView Operations. Notice that the ACLs for servers are set to 2000, a device group is created on each Celerra based on the Consistency Group name used earlier, and the Servers rebooted. Use the –v to verify the Standby Server configuration after the Servers have been selected.

**Note 2:** Keep in mind that Data Mover relationships and hardware compatibility will be enforced during initialization sequence.

Check MirrorView Tech Module for more information.

**Using Dissimilar Platforms with Different Network Interface Hardware—Source NS702G vs. Destination NSX:**

NS702G has (6) copper cge ports, NSX has only (5) copper cge ports. To logically hide the cge6 port on NS702G, enter following line on Source side /nas/site/nas\_param file:

**hidden\_interfaces:cge6:**

**3. Verify MirrorView Initialization on Destination (Passive Side):**

**Note:** nas\_devicegroup and nas\_mview commands may not output anything on the Destination side, unless the destination is running as the DR site. The –activate is initiated from the Destination side, and after failover, the following commands would be used to verify the state of MirrorView on Celerra.

### # cat /etc/passwd |grep mvadmin

```
mvadmin:x:50001:201::/home/mvadmin:/bin/bash
```

**Note:** This account is only created on the Destination side of an Active/Passive MirrorView configuration

### # nas\_devicegroup -list

```
ID name          owner storage ID    acl type
1  SVT MirrorView DR  50001  APM00030600872 0  MVVIEW
```

### # /nas/sbin/nas\_mview -info

### # nas\_devicegroup -info id=1

Sync with CLARiiON backend ..... done

```

```

**Note:** Data Movers should be set to 100FullDuplex while CS interface should be set to Auto. By default, after the initialization, a new cm\_r5\_performance Storage Pool is created to combine all the data luns used in MirrorView.

**# cat /nas/server/server\_setup**

```
2:0:1:1:3,1000,0,:  
1:2:1:3:2,1000,0,:  
Note: Shows local Standby Server relationship on Source & MView RDF Standby relationship on Destination side
```

## **INITIALIZING MIRRORVIEW/S CONFIG BETWEEN SOURCE & DESTINATION CELERRAS FOR ACTIVE/ACTIVE MVVIEW:**

**ACTIVE/ACTIVE SETUP PRECAUTION:** mvadmin UID numbers need to be different on each Celerra. The DR Admin account UID needs to be different on each Celerra CS that has been assigned the Active MView role—use following procedure to check and/or make sure account UIDs are different. Or, just follow the Active/Active steps in succeeding slides—let UID assignment default to UID 500 for first Active side setup, then create dummy account on other Control Station using same UID so that the –init process will choose the next higher UID value for the 2nd Active side (e.g., UID 501).

**Note:** If running NIS on Control Station, the default UID will be 50001, otherwise, the default UID assigned by the –init script is 500. The purpose for the separate UIDs ensures that the correct DR Admin account administers each side correctly when performing –active or –restore commands.

1. Check UID for DR Admin account on first Control Station setup as Active side
2. Make sure remote Active side uses the same UID account as a “dummy user account”—this will ensure that the ‘other’ side does not use the same UID value when creating the DR Account, which is the whole point of this procedure.

# /usr/sbin/useradd -u 500 drdummy (this will ensure that –init script will use next UID, 501, on remote side)

# tail /etc/passwd

drdummy:x:500:500::/home/drdummy:/bin/bash

3. Run –init on the remote Active side and the next UID to be assigned to the DR Admin account would be 501

### **ACTIVE/ACTIVE INITIALIZATION STEPS:**

- 1. Check to see if UID 500, 501, or 5001 have been used on either Linux Control Station:**

# tail /etc/passwd

nasadmin:x:201:201::/home/nasadmin:/bin/bash

emailhome:x:300:99::/:/bin/sh →Last UID assigned was 300

- 2. Register each Control Station with the other using the same Passphrase:**

[root@nyip1 rdf]# nas\_cel -name nyip2 -create 10.241.168.48 -passphrase mvadmin

operation in progress (not interruptible)...

```
id      = 2
name    = nyip2
owner   = 0
device  =
channel =
net_path = 10.241.168.48
celerra_id = APM00030600872001D
passphrase = mvadmin
```

[root@nyip2 outbound]# nas\_cel -n nyip1 -create 10.241.168.50 -passphrase mvadmin

operation in progress (not interruptible)...

```
id      = 1
name    = nyip1
owner   = 0
device  =
channel =
net_path = 10.241.168.50
celerra_id = APM000237001720000
passphrase = mvadmin
```

- 3. Verify Passphrase and Control Station-to-Control Station Registration:**

[root@nyip1 site]# nas\_cel -list

| id | name  | owner | mount_dev | channel | net_path      | CMU                |
|----|-------|-------|-----------|---------|---------------|--------------------|
| 0  | nyip1 | 0     |           |         | 10.241.168.50 | APM000237001720000 |
| 2  | nyip2 | 0     |           |         | 10.241.168.48 | APM00030600872001D |

[root@nyip2 site]# nas\_cel -list

| id | name  | owner | mount_dev | channel | net_path      | CMU                |
|----|-------|-------|-----------|---------|---------------|--------------------|
| 0  | nyip2 | 0     |           |         | 10.241.168.48 | APM00030600872001D |
| 1  | nyip1 | 0     |           |         | 10.241.168.50 | APM000237001720000 |

# cat /nas/httpreplication/inbound/APM00030600872001D (From Source system)

mvadmin

# cat /nas/httpreplication/outbound/APM000237001720000 (From Remote system)

mvadmin

**Note:** When the CS registers the remote Celerra, a file containing the passphrase is named after the Remote Clariion serial number and stored in both the /nas/httpreplication/inbound and outbound directories. As a troubleshooting note, if a prior DR setup had been in place at one time, there might be multiple passphrase files.

/nas/httpreplication/inbound | outbound

# cat /nas/site/cshosts (From Source system)

2:nyip2:0:10.241.168.48:::APM00030600872001D:

0:nyip1:0:10.241.168.50:::APM000237001720000:

# cat /nas/site/cshosts (From Remote System)

1:nyip1:0:10.241.168.50:::APM000237001720000:

0:nyip2.localdomain:0:10.241.168.48:::APM00030600872001D:

- 4. Run MirrorView Initialization on First Side for Active/Active Setup:**

**Note:** Example shows -init from Remote Celerra “NYIP2” to establish the MirrorView relationship with Local Celerra “NYIP1” as the Primary, with Server\_2 local and Server\_2 remote as the RDFStandby server

[root@nyip2 outbound]# /nas/sbin/nas\_mview -init nyip1

Celerra with MirrorView/Synchronous Disaster Recovery

```

#### **7. Create Dummy User Account on Local Control Station using Following procedure:**

**Note:** For an Active/Active MirrorView/S configuration, each DR Admin account should have a unique UID. This ensures that the correct configuration is displayed when logged into either Control Station as the DR Admin account.

##### **a. Remote CS UID for MirrorView is 500**

```
[nasadmin@nyip2 slot_2]$ tail -1 /etc/passwd
mvadmin:x:500:201::/home/mvadmin:/bin/bash
```

##### **b. Create dummy account on Source side**

[root@nyip1 slot\_2]# /usr/sbin/useradd dradmin\_ghost -u 500

[root@nyip1 slot\_2]# tail -1 /etc/passwd

```
dradmin_ghost:x:500:500::/home/dradmin_ghost:/bin/bash
```

**Note:** After –init of the other side of the Active Active MView setup, this is the UID that was assigned:

```
dradmin_ghost:x:500:500::/home/dradmin_ghost:/bin/bash → Dummy account, same UID as used on first Active MView setup
```

```
mvadmin:x:501:201::/home/mvadmin:/bin/bash → MVAdmin account on other Active MView Setup
```

#### **8. Run MirrorView Initialization on Remote Side for other half of the Active/Active Setup:**

[root@nyip1 /]# /nas/sbin/nas\_mview -init nyip2

### **III. CONDUCTING MIRRORVIEW FAILOVER, RESTORE, SUSPEND OPERATIONS:**

#### **ACTIVATING MIRRORVIEW DR FAILOVER ACTIVE/PASSIVE:**

##### **OVERVIEW**

1. Run –init from Target side after any backend changes
2. Run –activate or –restore operations as DR account/root
3. Run nas\_devicegroup –suspend or –resume when needing to stop or restart Devicegroup Mirroring (maintenance purposes, etc.)

##### **Testing Graceful DR Failover--activate:**

- Ensure MirrorView links and IP connections are up between Control Stations
- Verify devicegroup is Active & Synchronized or Consistent using nas\_devicegroup –info
- Target Servers should be plugged into same Network as Source Servers
- Target side needs to support DNS, Usermapper, & any other CIFS environmentals

##### **MirrorView Failover:**

- Use when disaster on Source side, or maintenance to be done, or to test DR
- Log in as “dradmin” account on Destination Control Station, then root to initiate failover or restore

##### **What happens during a MirrorView Activate (Failover):**

###### **#/nas/sbin/nas\_mvview –activate**

**Note:** During actual –activate, backends are sync'd, User prompted for Source shutdown, Source CS & DM's are shutdown, storage devices are failed over to Secondary Image & promoted to Primary status RW, Servers NBS environment reconfigured (cs.nbs.rw for RDF7 & RDF10), Target environment activated, Servers taken offline and failover completed as replace procedure is done. If the actual CLARiiON backend remains connected and available during the failover, changes will continue to be sync back to the original Source, making it easier to run the restore process later

- a. Destination CS shuts down Source CS & DM's gracefully, if possible
- b. Mirrored devices are failed over to their respective Secondary Images, then promoted as RW Primary images, becoming visible to Destination RDF Servers
- c. Primary Image Source LUNs are taken offline and no longer available on Source side(if source mirrors still available, synchronization will continue in reverse direction)
- d. The remote LUN 9 NAS\_DB is mounted RW on the destination Control Station (mirrored copy of Source LUN 4 NASDB). Configuration information is read from /nas/rdf/500/server/slot\_x to the local RDF Standbys using build\_config, and a compiled boot.cfg is copied to the local /nas/dos/slot\_x directory since the Data Mover must boot from a local LUN 0.
- e. After replaying the NASDB configuration information to the RDF Standbys, the Servers are rebooted and come up as the DR replacement Server for the original Source system

**Note:** During –activate, build\_config produces a new boot.cfg file based on the contents of LUN 9 (NBSNAS) and is copied to local DOS LUN 0 so that if a destination server is rebooted it will be able to boot. This file is copied to the local CS LUN 0, or /nas/dos/slot\_2 directory, NOT the /nas/rdf/500 directory. After failover is completed, there are (2) NAS databases on the Destination side; (1) for nasadmin for any local storage, & (1) DB for DR Admin for MirrorView management

##### **AMPLIFYING NOTE ON CONTROL LUNS:**

It may be useful to remember that during normal ‘Steady-state’ operation, Source LUNs 0, 1, 4 [DOS, ufslog, NBSNAS] are mirrored to Target LUNs 6, 7, & 9, but that after failover, only LUNs 7 & 9 remain mounted, taking on the role of ufslog and NBSNAS, respectively.

With DOS, during failover a new boot.cfg file is created from NBSNAS (LUN 9) using build\_config, and then copied to the local system's /nas/dos partition, which is LUN 0—this anomaly occurs because the Server must boot from a LUN 0. Hence, after failover is completed, LUN 6 is not actively used. In any case, no NASDB changes should be made while in a failed over state.

\$ ls –la /nas/rdf/500 → DOS is a link to local /nas/dos

lrwxrwxrwx 1 root root 8 Jul 19 10:23 dos -&gt; /nas/dos

**CONDUCTING MIRRORVIEW FAILOVER:****1. On Secondary Celerra, login with mvadmin account, then root user and initiate failover:****\$su – mvadmin****Note:** Once logged in as mvadmin, su to root user**#su**

&lt;root passwd&gt;

**#/nas/sbin/nas\_mview –activate**

Sync with CLARiiON backend ..... done

Is source site ns1 ready for complete shut down (power OFF)? [yes or no] yes

## **OVERVIEW OF MIRRORVIEW RESTORE:**

Backends sync'ed, mirror configuration validated, prompted for Source side shutdown, prompted for network restoration, destination Data Movers rebooted as RDF Standbys, backend sync'ed again, MV Resume is performed to make LUNs consistent & devicegroup updated, NBS access shifted back to cs.nbs.ro on failed over side, Failback operation completes, and original Source Data Movers are brought back online with NASDB

## **CONDUCTING MIRRORVIEW RESTORE:**

### **1. Login as mvadmin account and conduct –restore operation:**

**\$ su – mvadmin (login as mvadmin)**

**# su (login as root)**

**# nas\_storage –sync –all** (run prior to restore to sync up storage db with Celerra)

**# /nas/sbin/nas\_mview –restore** (Initiate restore on Destination side)

Sync with CLARiiON backend ..... done

Validating mirror group configuration ..... done

Contacting source site nyip1, please wait... done

Running restore requires shutting down source site nyip1.

Do you wish to continue? [yes or no] yes

Shutting down remote site nyip1 ..... done

Is source site nyip1 ready for storage restoration ? [yes or no] yes

Sync with CLARiiON backend ..... done

STARTING an MV 'RESUME' operation.

Device group: SVT MirrorView DR ..... done

The MV 'RESUME' operation SUCCEEDED.

Synchronized: 100% (\*\*\*\*\*)

**Note:** Once devices become consistent, IO access is stopped

Updating device group ... done  
Is source site ready for network restoration ? [yes or no] yes  
Restoring servers ..... done  
Waiting for servers to reboot ..... done  
Removing NBS access for server\_2 .. done  
Removing NBS access for server\_3 .. done  
Waiting for device group ready to failback ... done  
Sync with CLARiiON backend ..... done  
STARTING an MV 'FAILBACK' operation.  
Device group: SVT MirrorView DR ..... done  
The MV 'FAILBACK' operation SUCCEEDED.  
Restoring remote site nyip1, please wait... done (this action can take 10 minutes or more to complete)  
done

**Note:** For Warning 5026....Please run restore on primary side

**2. If restore fails, complete by running on Source side as local nasadmin/root User and specifying /nasmcd/sbin/nas\_mview -restore:**

# **/nasmcd/sbin/nas\_mview -restore** (do not use /nas/sbin/nas\_mview for restore)  
Powering on servers ( please wait ) ..... done  
Sync with CLARiiON backend ..... done  
STARTING an MV 'SUSPEND' operation.  
Device group: SVT MirrorView DR ..... done  
The MV 'SUSPEND' operation SUCCEEDED.  
server\_2 : going standby  
rdf : going active  
replace in progress ...done  
failover activity complete  
server\_3 : going standby  
rdf : going active  
replace in progress ...done  
failover activity complete  
commit in progress (not interruptible)...done  
commit in progress (not interruptible)...done  
Sync with CLARiiON backend ..... done  
STARTING an MV 'RESUME' operation.  
Device group: SVT MirrorView DR ..... done  
The MV 'RESUME' operation SUCCEEDED.  
commit in progress (not interruptible)...done  
commit in progress (not interruptible)...done

**Note:** Reboots CS after the restore succeeds. Make sure to use the /nasmcd/sbin path and not the /nas/sbin path, or else NAS may not properly restart and a lock will be left on the Control Station: /nasmcd/lock/dr.lck. Clearing the lock file manually will result in an automatic reboot of the CS, which will also resolve the issue.

→Synchronizes source devices to 99%, then I/O shutoff to Servers, remote Servers rebooted as remote standbys, mirrored devices are failed back, source Servers restored

→/nas is synchronized with changes from /nas/rdf/500 side, and servers are rebooted and brought up on Source, NAS Services started

**3. Verify that failback was successful:**

# **nas\_devicegroup -list | -info <id= >**

# **df -h**

# **nas\_disk -l**

# **server\_mount server\_export server\_devconfig**

**Note:** From Navisphere, verify that Primary side luns say 'Mirrored' and Secondary luns say 'Secondary Copy'

**SUSPENDING MIRRORVIEW SYNCHRONIZATION ON DEVICEGROUP:**

Used to temp halt mirroring from Source to Destination, as for maintenance purposes, etc.

# **nas\_devicegroup -suspend "SVT MirrorView DR"**

Sync with CLARiiON backend ..... done  
STARTING an MV 'SUSPEND' operation.  
Device group: SVT MirrorView DR ..... done  
The MV 'SUSPEND' operation SUCCEEDED.  
Done

**Navisphere Display:**

On Source side, Remote Mirrors will display as “F” for faulted, and then “AdminFractured” for each Secondary Image

**Note:** Use to administratively fracture and halt operation of consistency group by halting the mirroring between Source & Destination—same net effect as in suspending the MirrorView link. If there are spaces in the Consistency Group name, must use “ “ as in above example. A –suspend must be followed by a –resume to restart mirroring & synchronizing destination LUNs with source LUNs. Both –suspend and –resume commands are run from the Active side.

**PERFORMING RESTART & RESYNC OF MIRROR PAIRS:**

When would this command be used?

1. After issuing manual Administrative fracture of devicegroups via -suspend
2. Recovering from a destination-side failure, link down, or SP failure, if the devicegroup recovery policy is set to manual
3. Documentation says this is only used on Source side, but later states that if this command is run on destination side after failing over to the destination side, then a full synchronization is performed to reconstruct devicegroups and mirrors (on source), i.e., after a disaster has occurred on the Source.

**# nas\_devicegroup -resume "SVT MirrorView DR"**

Sync with CLARIION backend ..... done  
 STARTING an MV 'RESUME' operation.  
 Device group: SVT MirrorView DR ..... done  
 The MV 'RESUME' operation SUCCEEDED.

Done

**Note:** Used to resume after a suspend of the Consistency Group. Or, if recovery policy of a MirrorView Consistency Group is set to manual and the mirror fractures, then the nas\_devicegroup –resume command would be needed to recover.

**/nas/log/cmd\_log or nas\_log.al**

2006-05-03 20:01:02.021 db:0:18228:S: nas\_devicegroup -suspend SVT MirrorView DR  
 2006-05-03 20:02:29.255 db:0:18228:E: nas\_devicegroup -suspend SVT MirrorView DR

**SYSTEM vs. ADMIN FRACTURE OF SECONDARY MIRROR IMAGE/DEVICEGROUP:**

A fracture is when the Primary Image on the Source can no longer access the Secondary Image on the Destination. A system fracture can occur when a single SP is down (or bad cable) on either the Source or Destination sides, or when the MirrorView link between the two systems is down. The Recovery Policy in place determines if the Primary will begin resynchronizing with the Secondary Image automatically, or manually. An Admin Fracture is performed using nas\_mvview –suspend to suspend the synchronization between Primary & Secondary Images.

**OUTPUT FROM RUNNING –INIT FROM DESTINATION SIDE:**

**Note:** Must run the init as the local nasadmin and root account, not the DR account

**# /nas/sbin/nas\_mvview -init id=1**

### **CLARIION COMPONENTS:**

Clariion Management authentication using Global user with username/password

Consistency Group for remote mirrors, Control & User luns

Mirrors—primary and secondary image

Storage Groups—source and destination image

### **(5) MIRROR DATA STATES:**

Out of Sync—full sync needed

Synchronized (In Sync)—Primary & Secondary LUNs are in full sync, normal state for luns receiving I/O

Consistent—actual state of most systems. If write does not occur on Primary LUN for 60 secs, system declares an ‘In Sync’ status  
Synchronizing—mirror sync in progress

Rolling Back—Only applies to MirrorView/A operations, which is rolling Secondary Image back to a known good state

#### **MIRRORVIEW/A (Asynchronous):**

→Not supported with Celerra

→Much greater distances involved

→Uses SnapCache LUNs on Primary & Secondary images to maintain Tracking Log and Transfer Log

**Note:** Changes are tracked with Tracking Log until update interval occurs, when role of Transfer Log and Tracking Log are reversed so that tracking log becomes the transfer log for the marked Session

#### **MIRRORVIEW/S (SYNC):**

→Maintains synchronous copies of primary images at secondary site

→Changes on primary side are synchronously made to secondary

→Host writes to local storage LUN, then sends to secondary storage before local storage acknowledges write back to Host

→(1) 128MB private Lun for each SP dedicated for MirrorView software

→Bitmap indicating portions of primary image that may be different from secondary image

→Write Intent Log (WIL) on Primary array is used to facilitate sync between arrays and to prevent need for full sync if a crash occurs, otherwise, is not referenced during normal operations

→Fracture Log is a bitmap of 64kb chunks that is only put into use if the link between Primary & Secondary goes down for over 10 seconds, which is the heartbeat interval—changes are automatically tracked in this bitmap once a ‘fracture’ occurs—generally, you would provision the MirrorView link to automatically recover when link is restored, as opposed to a manual resync

#### **MIRRORVIEW/S CONSISTENCY GROUP:**

→Serves as a collection of synchronous mirrors that keeps all mirrored Control Lun & Data Lun members consistent (i.e. synchronized)

→All LUNs in the CG must be from a single Storage system, and also needs to be the boot CLARiiON for the Celerra involved

→Each device group member [aka mirror image LUN] must have a corresponding mirrored destination LUN (mirror pair)

→MView cannot be failed over (promoted) if in “synchronizing” or “out-of-sync” state

→Failover is an all or nothing state for devicegroup members (no partial or individual mirror failovers)

→Ufslog LUN 1/7 is one reason for need to include Control Luns in the Consistency Group—another is the NASDB, LUNs 4/9

→Max. of (16) mirrors in CX600/700 Consistency Group [3 Control Luns (Luns 0, 1, 4) + 13 Data Luns]

→(3) System LUNs and (13) Data LUNs for CX600/700 and (3) System & (5) Data LUNs for CX400/500

→Celerra manages MirrorView via the Devicegroup (nas\_devicegroup)

→Cannot be failed over (promoted) if in “synchronizing” or “out-of-sync” state

→Ufslog is one reason for need to include Control Luns in the consistency group

→Max. of (16) mirrors in CX600/700 Consistency Group [3 Control Luns (Luns 0, 1, 4) + 13 Data Luns]

→(3) System LUNs and (13) Data LUNs for CX600/700 and (3) System & (5) Data LUNs for CX400/500

#### **CONSISTENCY GROUP CONDITIONS:**

Active—normal state

Inactive—not accepting IO

Admin Fractured—admin or media failure fracture, must be manually synchronized

System Fractured—Link down, SP is down, etc. (will recover if policy for devicegroup recovery is set to Auto)

Waiting on Sync—automatic recovery occurring, or waiting for manual recovery of group by Administrator

Unknown—transient state where group is partially fractured

Image Recovery Policy for Fractured Mirrors:

Auto—restart synchronization automatically on recovery

Manual—User must start resync using –resume

Waiting on admin—waiting for Admin to resync

Invalid

#### **CONSISTENCY GROUP STATES:**

Synchronized—all Secondary images synchronized with primary images (-activate, -restore, -suspend can occur)

Consistent—all Secondary images in Synchronized or Consistent state (-activate, -restore, -suspend can occur), I/O occurring (transitions to synchronized if no I/O in 60 sec)

Synchronizing—at least one mirror in group synchronizing (cannot activate, restore, or suspend in this state)

Out-of-Sync—some or all mirrors out-of-sync; group fractured, waiting for synchronization (cannot activate, restore, or suspend)

Scrambled—mix. of primary & secondary images

Local Only—primary images only

Incomplete—some members have only primary images after failed promote

Empty—no mirror members

#### **SECONDARY IMAGE STATES:**

In Sync—Primary & Secondary images have byte-for-byte copy

Consistent—IO's occurring, but system consistent (normal state)

Synchronizing—Secondary Image in process of sync with Primary

Out of Sync—loss of sync, must do full synchronization between mirrors

### **VERIFYING STATE OF CONSISTENCY GROUP FROM NAVISPHERE:**

Expand 'Consistency Groups' section under the Array, rightclick and view properties of Consistency Group:

**State:** Consistent (Consistent, Synchronizing, Synchronized, Out-of-Sync, etc)

**Condition:** Active (Admin Fractured, System Fractured, Waiting on Admin, Inactive)

**Role:** Primary

**Note:** Above example shows normal operational state of Consistency Group

### **VERIFYING STATE FROM CLI:**

#### **# nas\_devicegroup -list**

```
ID name      owner storage ID  acl type  
1 SVT MirrorView DR 0  APM00023700172 0  MVVIEW
```

#### **# nas\_devicegroup -info id=1 | -all**

```
Sync with CLARiiON backend ..... done  
name          = SVT MirrorView DR  
description   =  
uid           = 50:6:1:60:80:60:5:35:0:0:0:0:0:0:0:0  
state         = Consistent  
role          = Primary  
condition     = Active  
recovery policy = Automatic  
number of mirrors = 9  
mode          = SYNC  
owner         = 0  
mirrored disks = root_disk,root_ldisk,d5,d7,d8,d9,d10,d11,d12,  
local clarid   = APM00023700172  
remote clarid  = APM00030600872  
mirror direction = local -> remote
```

#### **# nas\_devicegroup -info id=1 -sync no**

**Note:** Info without a full sync

### **TROUBLESHOOTING MIRRORVIEW FROM CLI:**

#### **USING NAS DEVICEGROUP SPECIAL USAGE COMMANDS:**

##### **# export NAS\_DB\_DEBUG=1**

```
# env  
NAS_DB_DEBUG=1
```

##### **# nas\_devicegroup**

###### **special usage:**

```
| -list [-backend]  
| -info {<name>} lid=<id> | -all } [-backend] [-sync [yes|no]]  
| -suspend {<name>} lid=<id> } [-backend]  
| -resume {<name>} lid=<id> } [-backend]  
| -add <name>  
| -delete {<name>} lid=<id> }  
| -failover {<name>} lid=<id> } [-backend] [-Force]  
| -fallback {<name>} lid=<id> } [-backend]
```

#### **USING NAVICLI MIRRORVIEW, NAVICLI.JAR, or NAVISECCLI COMMANDS:**

**Note:** In order to run the navicli mirrorview commandset, must first setup security for the user in the Control Station shell context to which you are logged into. Alternatively, run the navisecccli commands and specify –password and –user for each command.

##### **1. Create Security Context for Nasadmin User in order to run MirrorView commands (root is not privileged to run cmds):**

```
$ java -jar /nas/opt/Navisphere/bin/navicli.jar -AddUserSecurity -password nasadmin -scope 0
```

##### **2. MirrorView commands:**

```
$ /nas/sbin/navicli -h 10.241.168.57 mirrorview
```

usage: mirrorview

```
-info  <-cancreate> <-mirroredluns> <-mirrorableluns>  
      <-logs> <-systems> <-maxmirrors>
```

```

### \$ /nas/sbin/navicli -h 10.241.168.57 mirrorview -list -lun -state

MirrorView Name: Lun 93 Primary  
 Logical Unit Numbers: 93  
 Remote Mirror Status: Mirrored  
 MirrorView State: Active

### \$ /nas/sbin/navicli -h 10.241.168.57 mirrorview -list -lun -faulted

MirrorView Name: Lun 93 Primary  
 Logical Unit Numbers: 93  
 Remote Mirror Status: Mirrored  
 MirrorView Faulted: YES

**\$ /nas/sbin/navicli -h 10.241.168.57 mirrorview –listlog** (displays Write Intent Log LUNs)

Storage Processor: SP A

Lun Number: 100

Storage Processor: SP B

Lun Number: 101

**\$ /nas/sbin/navicli -h 10.241.168.57 mirrorview –listsyncprogress** (shows % sync progress of each mirrored lun)

MirrorView Name: Lun 93 Primary

Has Secondary Images: YES

Image UID: 50:06:01:60:90:60:07:BB

Image State: Synchronized

Synchronizing Progress(%): 100

MirrorView Name: Lun 0 Primary

Has Secondary Images: YES

Image UID: 50:06:01:60:90:60:07:BB

Image State: Consistent

Synchronizing Progress(%): N/A

**Note:** By definition, if an I/O has not occurred for 60 seconds or more, the Image State will be “Synchronized”. If an I/O has occurred within the 60 sec. window, then the Image State will be “Consistent”. These are the two desired LUN states.

**\$ java -jar /nas/opt/Navisphere/bin/navicli.jar -h 10.241.168.57 mirror -sync -listgroups**

Maximum Number of Groups Allowed: 16

Maximum Number of Mirrors per Group: 16

Group Name: SVT MirrorView DR

Group ID: 50:06:01:60:80:60:05:35:00:00:00:00

Description:

State: Consistent

Role: Primary

Condition: Active

Recovery Policy: Automatic

Mirror Name: Lun 91 Primary

**Note:** The –list commands show information about the remote mirrors

## **TROUBLESHOOTING MIRRORVIEW USING NAVISECCLI:**

**Note:** If a security file does not already exist for nasadmin, create one using the following—same file works for Navicli or Naviseccli

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 -AddUserSecurity -password mypass -scope 0 -user nasadmin**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -info** (info on mirror installation)

**Note:** This command is equivalent to the navicli -h <spa> mirrorview –info

## **OTHER NAVISECCLI COMMANDS:**

***Caution:*** Do not use any of the following commands unless instructed to do so by Engineering

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -enablepath <sp>**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -disablepath <sp>**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -allocatelog -spA 101 -spB 102**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -deallocatecatalog**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -destroy** (destroy mirror & images)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -create** (create new mirror)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -creategroup** (create Consist. Group)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -destroygroup <CG\_name>**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -addtogroup | -removefromgroup**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -changegroup | -syncgroup | -fracturegroup | -promotegroup**

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -addimage** (add sec. lun to mirror)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -removeimage** (remove second. from mirror)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -syncimage** (starts sync of secondary)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -promoteimage** (promote secondary)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -change** (change mirror properties)

**\$ /nas/opt/Navisphere/bin/navisecccli -h 10.241.168.57 mirror -sync -changeimage** (change second. image)

**\$ /nas/opt/Navisphere/bin/naviseccli -h 10.241.168.57 mirror –sync –fractureimage** (fracture image from mirror)

## **TROUBLESHOOTING MIRRORVIEW/S:**

- An expectation that NAS folks learn the CLARiiON platform & Navisphere to resolve backend configuration issues
- Identify Error messages, review Logs, set debug logging, search Primus
- For True DR situations, must escalate to EE when customer ready to rebuild Source side for Restoration [EE & Development must sponsor this activity]

### **After failover, the active NASDB on Destination side will be located:**

**/nas/rdf/500/** [Control Station mounts as /dev/ndj1—mirrored LUN 9]

→ For ‘True Disaster’ event where Source Celerra & CLARiiON arrays are down, the –activate will indicate that a full resync will be required to perform a restore, & promotes the Secondary LUN images to ‘Local-Only’ Primary mirrors so that failover can occur even without the Source online

→ NAS Upgrades require no special preparation or ‘downed’ links—following normal practice for ‘paired’ Celerras, Upgrade Target side first, then the Source

→ FLARE Upgrades should follow COLU NDU where applicable, and pay special attention to the CLARiiON Procedure Generator, as there are some special conditions around MirrorView fixes with FLARE. In general, Flare 19 Patch 034 and above will be o.k. and has been successfully tested

## **MIRRORVIEW LOGS:**

**/nas/log/dr\_log.al** → Normal location of DR logs after –activate, -init, or –restore has completed; located in local /nas/dos of the local Celerra system

**/tmp/dr\_log.al** → Logs are temporarily written to this directory on the system when –init, –activate, or –restore operations are in progress—logs are moved to /nas/log after the MirrorView threads are done running. It should be noted that even after failures, the logs are moved to this location.

→ Point of this information is that the applicable DR logs do not reside in /nas/rdf/500/log with respect to –init, -activate, or –restore

**\$ ls -la /nas/log |grep dr\***

**-rwxrwxr-x 1 nasadmin nasadmin 38860 May 18 13:54 dr\_log.al** [Main MView log of interest]

```
-rw-r--r-- 1 root root 1329 May 11 07:26 dr_log.al.err
-rw-r--r-- 1 root root 16821 May 10 15:14 dr_log.al.trace
```

**/nas/var/messages** [Good source of information for NBS issues]

**/nas/log/symapi.log** [some info may be found here related to backend issues]

**/nas/tools/collect\_support\_materials** script used for escalations, also contains dr\_logs

**/nas/rdf/500/log** [or UID in the path could be 501, 50001, etc.]

**Note:** After –activate is complete, this is where NBSNAS is located and where logs pertaining to the Servers while operating in a failed over state, are stored.

## **DEBUG LOGGING AND ERROR MESSAGES:**

Set SYMAPI or NASDB Debug Logging if needed:

**# export CLARAPI\_DEBUG=1** (Clariion API debug logging—outputs to screen & dumps to /nas/log/symapi.log)

**# export NAS\_DB\_DEBUG=1** (NAS debug logging--/nas/log)

### **New CCMD format MirrorView Error Messages:**

Many error messages will be in new CCMD format and documented, either in MView engineering documentation, or Primus (Check these sources first)

**Error 13421904897 : The device group is System Fractured.**

(seen during nas\_mvview –activate → refer to emc136398)

Other error messages are still generic, such as Error 5008, and may be seen across different features and for different situations

## **GENERIC ERROR MESSAGES STILL SEEN WITH NAS 5.5:**

Error 5008: 139:cmd failed: /bin/umount /dev/ndj1 2>&1: (# /nas/sbin/nas\_mvview –restore)

Error 5008: -1:Cannot restore nyip1. Please run restore on site nyip1. (# /nas/sbin/nas\_mvview –restore)

Error 5023: APM00023700172 unable to connect to storage (# /nas/sbin/setup\_slot -i 2

Error 5005: failed to complete command (# /nas/sbin/setup\_slot -i 2)

Validating mirror group configuration ..... Error 2237: Execution failed: Segmentation violation: Operating system signal.  
(# /nas/sbin/nas\_mvview –activate)

Error 2221: Operation not permitted (# /nas/sbin/nas\_mvview –activate)

Error 2237: server\_2 : Execution failed: Read-only file system: Routine failure. [RAW\_FILE.file\_open] (# server\_mount server\_2)

# /nas/sbin/nas\_mvview -activate fails: Error 5017: storage health check failed (APM00023700172 SPA is failed over)

Error 2237: Execution failed: No such file or directory: Routine failure. (# nas\_server -l)

Error 2237: Execution failed: is\_commitable: Precondition violated. [NAS\_DB.commit]

## **IMPORTANT RULE-of-THUMB ON ACTIVATE OR RESTORE FAILURES:**

**Try to determine point of failure before proceeding:**

From lab testing, errors will either prevent you from performing an action (figure out issue and carryon), or will generally allow the MirrorView devices to failover or failback—most problems seem to surface at the end of the process, where the Servers are not completely failed over or failed back, leaving NAS in a state of limbo and Servers in an inconsistent state

**Retry the –activate or –restore if first attempt fails:**

Check for obvious issues, then retry the –activate or –restore command—in the case of restores, if the 2nd attempt fails, then try to complete the restore on the Source side logged in as nasadmin, then root, using /nasmd/sbin/nas\_mview –restore directory only!

**ADVANCED MIRRORVIEW TROUBLESHOOTING:**

**MIRRORVIEW REFERENCES:**

**CLARiiON backend setup guide:**

Celerra MirrorView/Synchronous Setup on CLARiiON Backends NAS 5.5 (NAPA III release 5.5.23.x)

See sections for setting up Active/Passive & Active/Active MView

MirrorView not intended for customer setup

Most config & setup calls will come from PS

**Celerra Configuration and Troubleshooting Guide:**

Using MirrorView/Synchronous with Celerra for Disaster Recovery NAS 5.5 (NAPA III release 5.5.23.x)

Concepts, System requirements, Initializing, activating failover, conducting restore, Managing, Troubleshooting, Error messages

No real Celerra CLI for configuring MirrorView Backend

CLARiiON migrating to new navisecli command set

**RUNNING MIRRORVIEW COMMANDS FROM CONTROL STATION:**

**Note:** Setup the security context, then run navicli cmd as nasadmin

a.) \$ java -jar /nas/opt/Navisphere/bin/navicli.jar -AddUserSecurity -password nasadmin -scope 0

b.) \$ /nas/sbin/navicli -h 10.241.168.52 mirrorview –info | -list

Or

a.) \$ /nas/opt/Navisphere/bin/navisecli -h 10.241.168.57 -AddUserSecurity -password mypass -scope 0 -user nasadmin

b.) \$ /nas/opt/Navisphere/bin/navisecli -h 10.241.168.57 mirror -sync -info (info on MirrorView installation)

**Note:** Navisecli will replace navicli in the near future

**USING SERVER STANDBY TO RESTORE or ACTIVATE SERVERS:**

→Using server\_standby to complete activate or restore for an operation that completes everything but leaves Server in faulted state

In certain situations, if the –activate succeeds in failing over MirrorView devices on CLARiiON backend, and NASDB is mounted on /nas/500/rdf, but the destination Server is in a faulted status, may need to run following to complete failover

**# nas\_server -l**

```
id    type acl slot groupID state name
1     4   0   2       2   server_2.faulted.server_3
2     1   0   3       0   server_2
```

**# server\_standby server\_2.faulted.rdf –activate rdf**

Same situation applies when failing back to Source using –restore—may need to use server\_standby on Source DM

**# server\_standby server\_2.faulted.rdf –restore rdf**

**Note:** In general, do not run the server\_standby command without TS or Eng approval. Many things should be verified before this command is run.

**IMPORTANCE OF SERVER SETUP FILE: /nas/server/server\_setup**

The server\_setup file is crucial in defining the role of Local Data Mover standbys on a Celerra, and the Remote RDF Standby relationships that may be in place for MirrorView DR. This file is dynamically updated during –activate & -restore operations, hence is susceptible to corruption or damage if the operation does not complete successfully. Examining this file is useful in understanding the current state of the Servers.

→Example of the Server\_setup file for Active/Passive configuration

**EXAMPLE 1:** Active side with Server\_2 Primary & local Standby defined as Server\_3. Local Standby Server\_3 has RDF failover relationship on slot\_3 on the Remote Celerra & Local Primary Server\_2 has RDF Standby (failover) relationship on slot\_2 on Remote Celerra

**# nas\_server -l** (Active Source side)

```
id    type acl slot groupID state name
1     1   1000 2      0   server_2
2     4   1000 3      0   server_3
```

**# cat /nas/server/server\_setup**

**2:0:1:1:3,1000,0,: -->Server\_3: no local bkup server:1=n/a:1=manual fail:3,1000,0=RDF Stdby slot\_3, ACL 1000, State 0**

**1:2:1:3:2,1000,0,: -->Server\_2:local bkup server\_3:1=n/a:3=auto fail:2,1000,0=RDF Stdby slot\_2, ACL 1000 State 0**

**Server\_setup file Fields Defined:**

**Primary\_id: Backup\_id: Component n/a: Failover Policy: RDF Standby Slot#, ACL, State:**

**EXAMPLE 2:** Target side showing both Servers as RDF Standbys to the Source Celerra

# nas\_server -l (Passive Target side)

```
id type acl slot groupID state name
1 4 1000 2      0 server_2
2 4 1000 3      0 server_3
```

# cat server\_setup

1:2:1:3:: -->Server\_2:local backup server\_3:1=n/a:3=auto failover:no RDF relationships defined on this side

-->Server\_3 not referenced since it has no local Standby or RDF relationship defined

#### Data Mover Failover Policies in /nas/server/server\_setup file:

1=Manual failover (Default Celerra policy; all RDF setups are manual failover policy)

2=Retry (Panic will cause reboot to clear condition, if unsuccessful, failover occurs)

3=Auto (Data Mover will failover automatically after panicking)

#### IMPORTANCE OF NBS CONFIGURATION FILES:

NS systems use the Data Mover as NBS Server with backend visibility that the Control Station then uses as an NBS Client to see and write to the NAS DB. The NBS configuration files are especially important in the role of DR Failover, whether for SRDF or for MirrorView.

#### Normal Data Mover NBS configuration—Source Side Data Mover for MirrorView:

# ls -la /nas/server/slot\_2/nbs\*

```
lrwxrwxrwx 1 root root 28 Jul 7 15:36 nbs.cs -> /nas/server/slot_2/nbs.cs.ro
```

# cat /nas/server/slot\_2/nbs.cs

```
nbs add nbsid=1 vol=NBS1 rw=192.168.1.100:192.168.1.101:...2.101 exclusive raw share (NBS1 LUN 0 /dev/nda1 DOS)
```

```
nbs add nbsid=5 vol=NBS5 rw=192.168.1.100:192.168.1.101:...2.101 exclusive raw share (NBS5 LUN 4 /dev/nde1 NBSNAS)
```

```
nbs add nbsid=6 vol=NBS6 rw=192.168.1.100:192.168.1.101:...2.101 exclusive raw share (NBS6 LUN 5 /dev/ndf1 VAR)
```

```
nbs add nbsid=7 vol=RDF7 exclusive raw ro=192.168.1.100:192.168.1.101:...2.101 (NBS7 LUN 6 /dev/ndg1 Remote)
```

```
nbs add nbsid=10 vol=RDF10 exclusive raw ro=192.168.1.100:192.168.1.101:...2.101 (NBS10 LUN 9 /dev/ndj1 Remote)
```

**Note:** LUN 6 is remote equivalent to LUN 0 DOS boot, LUN 9 equivalent to LUN 4 NBSNAS, which becomes “rw” on destination side after nas\_mview –activate. During activate, build\_config is run for Data Mover and boot.cfg copied to local /nas/dos/slot\_x directory so that DM can reboot with configuration. After activate, DOS partition is unmounted from CS. LUNs 1 & 4 failover to promoted mirror LUNs 7 & 9 and are used by Destination Data Movers.

#### NBS FILES AFTER ACTIVATE:

# ls -la nbs\* /nas/rdf/500/server/slot\_2

```
lrwxrwxrwx 1 root root 30 Aug 29 12:51 nbs.cs -> /nas/server/server_1/nbs.cs.rw
```

# cat nbs.cs.rw

```
nbs add nbsid=7 vol=RDF7 exclusive raw rw=192.168.1.100:192.168.1.101:192.168.2.100:192.168.2.101 (NBS7 LUN 6 /dev/ndg1 Remote)
```

```
nbs add nbsid=10 vol=RDF10 exclusive raw rw=192.168.1.100:192.168.1.101:192.168.2.100:192.168.2.101 (NBS10 LUN 9 /dev/ndj1 Remote)
```

**Note:** Example shows where LUNs 6 & 9 on the Target Celerra become RW to the local Servers after failover

#### TARGET DEVICES AFTER FAILOVER:

[root@nyip2 mvadmin]# nas\_disk -l

| id | inuse | sizeMB | storageID           | devID | type       | name | servers        |
|----|-------|--------|---------------------|-------|------------|------|----------------|
| 1  | y     | 11263  | APM00030600872-0006 | CMSTD | root_disk  | 1,2  | (LUN 6)        |
| 2  | y     | 11263  | APM00030600872-0007 | CMSTD | root_ldisk | 1,2  | (LUN 7)        |
| 3  | y     | 2047   | APM00023700172-0002 | CLSTD | d3         | 1,2  |                |
| 4  | y     | 2047   | APM00023700172-0003 | CLSTD | d4         | 1,2  |                |
| 5  | y     | 2047   | APM00030600872-0009 | CMSTD | d5         | 1,2  | (LUN 9)        |
| 6  | y     | 2047   | APM00023700172-0005 | CLSTD | d6         | 1,2  |                |
| 7  | y     | 10239  | APM00030600872-005B | CMSTD | d7         | 1,2  | (1st Data LUN) |

**Note:** Unlike SRDF setups, the Remote Celerra will not see its Secondary Mirrored luns until they are ‘promoted’ to Primary status during successful failover—see CMSTD devices

[root@nyip2 mvadmin]# server\_devconfig server\_2 -p -s -a |grep -v no

```

### **CONSISTENCY GROUP/DEVICEGROUP CONFIGURATION FILE:**

**Note:** Each Active Celerra configuration will have a master file that essentially defines the properties of the mirrored luns found in the Consistency Group/Devicegroup. Upon successful failover, the existing Source MirrorView configuration is disassembled and the Target Celerra LUNs are promoted from Secondary Image status to Primary Images. This file is especially important during failback and is used to reconstruct and rebuild the original Mirror relationship between Source & Target sides.

#### **# cat /nas/site/.clariion\_mg\_config**

```
Lun 0 872 Primary Side ALU 29:Celerra_nyip2:APM00030600872:0029:0000:Celerra_nyip1:APM00023700172:0201:0006

```

### **DEBUGGING MIRRORVIEW ISSUES USING XML DEBUG:**

There is a method for querying XML data and using the data for debugging MirrorView failures.

1. Find the query string relevant to a recent failure in the /nas/http/logs/access\_log file
2. Search the logfile from the end to find the last occurrence of "?UseWriteIntentLog"
3. After matching up time and date with problem being debugged, locate and copy all of the information from the indicated start and finish locations, then copy the paragraph string to notepad:  
Mode=Pre&Command=nas\_storage&arg=-query:Id==1&arg=-fields:.....abridged..... :\*&arg=-  
fields:Alu,Hlu&arg=-format:%25s:%25s;
4. Run the following command and paste the above paragraph string:  
# export QUERY\_STRING=' Mode=Pre&Command..... Alu,Hlu&arg=-format:%25s:%25s;'
5. If successfully cut and pasted, the export Query will produce debug information viewable with the following:

```
6. # nas_cmd @cs_cgi  
Content-type: text/html  
<HTML>  
<HEAD><SCRIPT language='javascript1.1'>  
var command_exit_status=0;  
var command_error_code=0;  
var command_error_msg="";  
var command_message_code='0';  
</SCRIPT></HEAD>

```

**Note:** The semi-colons separate the output by operations. Look for an operation that has failed.

## **NAS 5.5 NDMP & LEGATO NETWORKER:**

- NDMP drive sharing supported only for SAN networks
- Dynamic Device Sharing allowed between Data Movers in the same TLU
- Ports 10001 – 10004 are used for 3-way NDMP (otherwise just port 10000)
- PAX is Portable Archive Interchange, a protocol designed to work with UNIX tape formats for file-level backups/restores
- TAR format in PAX that traverses file tree in depth-first order, then across
- DUMP format in PAX that traverses file tree in mixed width-first and depth-first order
- NAS 5.5 supports File Filtering, Integrated Checkpoints, Volume Backups (VBB), and DDAR for backup solutions
- Legato requires HIST & DIRECT=y for DAR backup/recoveries
- Legato cannot scan for robot with NDMP FC unless TLU is attached to Data Mover NDMP Host

## **LEGATO DATA MANAGER FOR CELERRA (aka FILE SYSTEM MANAGER FOR NAS):**

- Strictly speaking, File System Manager for NAS version 2.0 replaces DM for Celerra version 1.0 & is not directly tied to 5.5 release
- Will support Solaris 9 & 10 & Win2k/2k3, using Java & C, and iAnywhere database
- Contains better job control & monitoring, improved user interface, integration with IIM, Fulltime AutoStart, VisualSRM
- All paths for Jobs will be absolute for Unix and UNC for Windows
- Migrated files now use file versioning (i.e., every time file is recalled and re-migrated, new version created on Secondary)
- Can use either CLI or GUI for configuring
- Fulltime AutoStart will monitor the DMC and restart and stop services as appropriate

### **Migration Policies:**

Migration → Source, Dest, Mode Filemover/Symlink, Readback method, File Match criteria

Orphan Files → Delete policy, new with v2.0, File Match criteria

Source Scan

### **Future Version of FSM for NAS:**

- .Next will be released mid 2006 and will contain HTTP and BAR support
- HTTP support direct to disk or direct to Centera
- Bulk metadata retrieval for faster file scanning
- Better migration rules via Visual SRM
- Possible support for Linux Control Station as policy engine

## **FILEMOVER METADATA RETRIEVAL (replaces Bulk Attributes Retrieval):**

- Uses XML over HTTP using port 5080 on DM
- Authentication: Digest, Null authentication, IP Address
- BAR is an extension of DHSM
- Scans file system to retrieve attributes and uses basic filtering criteria, producing XML reports, based on a targeted scans using an enhanced FileMover API and scan criteria
- Can perform full or incremental metadata retrieval using FileMover API
- When retrieving files from Secondary storage, an HTTP GET will be issued using URL for OFFLINE\_PATH
- HTTP connections will be defined as ‘persistent’ and multiple requests can go over the same connection, though all requests must be returned in the order in which they were received
- FileMover will still support up to 1024 connections to the Secondary Storage system
- Max of (4) concurrent metadata retrieval jobs at one time

DHSM\_GET\_BULK\_ATTRS

DHSM\_QUERY\_BULK\_RETRIEVAL

DHSM\_ABORT\_BULK\_RETRIEVAL

→ Two requests used: DHSM\_SET\_OFFLINE\_ATTRS & DHSM\_GET\_ATTRS

**\$server\_config server\_2 -v “bar list | help | info | abort” “printstats bar” “printstats bar full”**

## **FILEMOVER HTTP SUPPORT (aka DHSM):**

- Introduces HTTPClient v1.1 support for Secondary Storage so that other products can utilize FileMover (KVS, Documentum, Opentext, IXOS, Sharepoint)

**Note:** Up to this point, secondary storage was accessed only via NFS or CIFS interface—can now access using HTTP, so applications such as KVS can access secondary storage

→ max 32 simultaneous tcp connections for FileMover to increase HTTP Read performance

**Note:** Previously, could only use single TCP connection to conduct HTTP Client reads from Secondary Storage

→Uses mtime or entity tags for validation

→Allows for 32k reads from HTTP Client for full and partial read policies, and 8k for passthrough

**Note:** Previously, only allowed 8k Reads, creating excessive overhead for HTTP Server

→Support for CGI (Common Gateway Interface) & Non-CGI HTTP connections

→Can use either basic or digest authentication challenges

#### **CREATING CGI HTTP CONNECTION:**

**\$ fs\_dhsm -connection pfs -create -type http -secondary http://apache.njqa.us.dg.com/cgi-bin/access.sh**

**Note:** Uses default port 80, hence this feature is designed for LAN secure networks

#### **CONVERTING FILES TO STUB FILES:**

**\$ set\_attributes -v 1123623275 10.5.8.224 nfs:/pfs/foo http://apache.njqa.us.dg.com/cgi-bin/access.sh/dm2/foo**

**Note:** Offline Attributes are set via API for OFFLINE\_MTIME & OFFLINE\_ETAG (latter entity tag is new attribute for http)

#### **CREATING NON-CGI HTTP CONNECTION:**

**\$ fs\_dhsm -connection pfs -create -type http -secondary http://10.5.8.74/dir1 -cgi n**

#### **CONVERTING NON-CGI FILES TO STUB FILES:**

1. Telnet to Secondary Storage to obtain entity tag from specific file

Etag: "80f7b39566cc51:d6a"

2. Set file offline by converting to Stub:

**\$ set\_attributes -e "80f7b39566cc51:d6a" 10.5.8.224 nfs:/pfs/bar http://10.5.8.74/dir1/dir2/bar**

#### **TROUBLESHOOTING:**

##### **Non-CGI Connection Failure:**

**\$ fs\_dhsm -connection svr4fs1 -create -type http -secondary http://dhsm-w2k/dir1**

Error 5005: failed to complete command

Server\_log:

2005-08-26 09:05:46: DHSM: 3: HTTP verifyServerHealthInternal(): Unexpected HTTP status 302 : 302 Found

2005-08-26 09:05:46: DHSM: 3: If a non-cgi connection is desired "-cgi n" should be used during connection creation

Solution: Use -cgi n when creating connection

##### **Web Server Down When Trying to Create Connection:**

**\$ fs\_dhsm -connection svr4fs1 -create -type http -secondary http://apache.njqa.us.dg.com/cgi-bin/access.sh**

Error 5005: failed to complete command

Server log:

2005-08-26 10:34:42: DHSM: 3: HTTP createDartHTTPConnections(): could not connect/talk to server apache.njqa.us.dg.com

Solution: Restart Web Server

##### **Missing User Credentials will cause Connection Failure:**

**\$ fs\_dhsm -connection svr4fs1 -create -type http -secondary http://dhsm-w2k/dir1 -cgi n**

Error 5005: failed to complete command

Server log:

2005-08-26 11:44:27: DHSM: 3: HTTP: Couldn't get http response - 1001 User and password required

2005-08-26 11:44:27: DHSM: 3: HTTP createDartHTTPConnections(): could not connect/talk to server dhsm-w2k

Solution: Retry using username and password

##### **Wrong CGI Format being used by Application when accessing Stub Files:**

2005-08-26 14:15:39: DHSM: 3: HTTP: Expecting a content type of "application/octet-stream"

2005-08-26 14:15:39: DHSM: 3: response had "text/html; charset=ISO-8859-1" content type

Solution: Modify CGI application has to conform

#### **NDMP DDAR 3-WAY SUPPORT:**

→Directory DAR restore of given directory and all subdirectories and files

→Two variables required for DDAR: RECURSIVE (default=yes) & DIRECT (default=no)—if both variables set to yes, DDAR will be used for directory restores

→Incremental DUMP backup of files that have changed, and directories leading to the files, vs. backing up all dirs in past

→Depth-first file tree order traversal for merging Dump & TAR formats (traverse straight down before moving across tree)

→If DAR & RECURSIVE variables are set, recoveries of all subfolders and files under a specified directory can occur

→Incremental backups will only backup directories leading to the changed files (as opposed to the current PAX DUMP format, which uses width-first file tree traversal)

→Veritas Backup Selection window SET type=dump /ddar\_fs1

→Enable DDAR for Veritas NetBackup Server:

C:\Program Files\VERITAS\NetBackup\db\config\ndmp.cfg (add NDMP\_DAR\_DIRECTORY\_ENABLED to new file)

## **NDMP FILE FILTERING FOR BACKUPS:**

- Celerra NDMP with File Filtering allows exclusion of files and/or directories when performing NDMP backups
- Implemented in the FTS (File Traversal System—submodule used by PAX) in DART, using NASS threads
- Excludes files based on prefix or suffix set on NDMP client
- Initial support for PAX filtering only, using EMC\_EDIR0[1-5 directory filters] & EMC\_EFILE0[1-5 file filters]

### **Uses two types of filters:**

EXCLUDEDIR & EXCLUDEFILE, represented as follows:

#### **EMC\_EDIR**

#### **EMC\_EFILE**

- Filters can be pattern match or wild-cards \* and ? at beginning or end for files, and only at end for directories

EMC\_EDIR01=/fs1/dir1/temp

EMC\_EFILE01=/fs1/\*.tmp

**Note:** Only (5) directory filters and (5) file filters can be specified

## **PATTERN MATCHING AND FILTER RULES:**

### **DIRECTORIES:**

- Each filter must include path “/” with mountpoint to filesystem
- Wildcards \* or ? can only be at the end of a directory filter

EMC\_EDIR01=/EMC/dir1/temp

### **FILES:**

- No fs mountpoint path required
- Wildcard ? or \* can be at beginning or end of a filename, not in the middle

EMC\_EFILE01=\*\tmp`

## **CELLERRA NDMP FILE FILTERING RESTRICTIONS:**

- Cannot be used with NDMP VBB, only regular NDMP PAX backups

## **FILE FILTERING PARAMETERS FOR PAX:**

**param PAX filter.numDirFilter** (0=disabled; 5=default; 50=max number of directory exclusion filters)

**param PAX filter.numFileFilter** (0=disabled; 5=default; 50=max number of file exclusion filters)

**param PAX filter.caseSensitive** (0=disabled; 1=default, case sensitive)

## **CREATING FILE FILTERING JOB WITH LEGATO 7.2:**

- Enter server name in Legato Server's \Window\system32\drivers\etc\hosts file
- Legato NetWorker>NetWorker Administrator>Rightclick Windows Server>Connect to This Server>Networker Groups>Manage Groups>Groups>Create>Filtering Group
- Legator NetWorker>Client Operations>Manage Clients>Create>Name: srv2 Save set: /fs1 Group: Filtering Group
- Preferences Tab: Aliases: srv2 Storage nodes: srv2 Clone storage nodes: srv2 Ndmp: Yes
- Remote Tab: Remote access: "@" Remote user: ndmp Password: \*\*\*\*\* Backup command: nsrndmp\_save -T tar Application information: DIRECT=y; EMC\_EFILE01=\*\doc; EMC\_EFILE02=\*\tmp; HIST=y; UPDATE=y
- Create c:\bootstrap folder on Legato Server
- Legato NetWorker>Media Management>Devices>rightclick c:\bootstrap>Operations>Label: Check the 'Mount after Labeling' box
- Run manual backup: NetWorker Groups>Manage Groups>rightclick Filtering Group>Start

## **TROUBLESHOOTING FILE FILTERING ISSUES:**

EDIR or EFILE messages will be logged in Server Log

## **CELLERRA NDMP – VOLUME BACKUP [aka, VBB & RESTORES(Volume Based Backup):]**

Not a PAX-type backup. Conducts backup of used blocks at volume level, if History is set, will process metadata first. Note that this feature requires that the file system be mounted RO. 3-way VBB backups not yet supported. To conduct a VBB restore to NMFS or VDM file systems:

### **EXAMPLE:**

1. Create temp file system for the restore
  2. Create VBB restore path: \$.server\_config server\_2 -v "param vbb tempDir=/ndmpfs\_1/.vbbtemp"
  3. Allows restore to NMFS file system path /ndmpnest/abc
- NDMP, VTLU, Backup with Integrated Checkpoints, all supported
  - Idea for VBB is to increase backup performance, especially for many small files
  - NDMP VBB processes metadata first, then transfers used blocks via volume level
  - VBB uses new integrated checkpoint functionality
  - VBB performs DUMP-TAR merge using 8 threads
  - Idea is to traverse file system as fast as possible to read metadata, send file history to client while writing data to tape
  - Retrieve metadata from tape, create files and write data, set file attributes
  - VBB Full Restore overwrites everything in file system with restored data (fs must be converted to rawfs for this operation)
  - Restore of files can be done if appropriate HIST=y flag set during the Backup
  - Restores can be done at file system or individual file/directory level, but are slower than regular NDMP

→VBB Backup file system must be mounted RO or using checkpoint, or Backup with Integrated Checkpoints feature

→VBB backups up entire file system, not partials

→Does not work with DDAR or File Filtering for Backups

→VBB process based on inode order to avoid fragmentation & is multi-threaded for performance

→VBB performs Full Destructive Restore (Volume level) or File level Restore (FS level)

#### **HOW VBB BACKUP WORKS:**

→File system traversed to collect metadata

→Metadata sent to NDMP client and written to tape

→File History sent to Backup Host

→File data is written to tape in block order

#### **FULL DESTRUCTIVE or FILE LEVEL RESTORES SUPPORTED:**

→If HIST=y is done for backup, then file restore can occur

→Full restores are destructive by design, and requires that the file system be of equal size or greater, and in rawfs format

**#nas\_fs -n vbb\_bak -type rawfs -c samesize=pfs1 -pool=clar\_r5\_performance -o slice=y**

#### **FULL DESTRUCTIVE RESTORE:**

1. Have rawfs file system created & mounted

2. NetWorker User>Operation>Save Set Recover>Source Client: select Data Mover

3. Highlight Save Set to recover>Recover Options>Relocate recovered data to this path: **/celerra\_vol\_45**

**Note:** Default recover syntax is /celerra\_vol\_xx with the file system Volume ID number as the last part of the string

#### **Server Log:**

Performing a full destructive restore of filesystem ...

#### **ENABLING VBB BACKUP ON NDMP HOST:**

##### **LEGATO Backup Syntax:**

**nsrndmp\_save -Type vbb**

OTHER VARIABLES: SNAPSURE=y; VBB=y; DIRECT=y; HIST=y; UPDATE=y

##### **VERITAS & OTHERS:**

**VBB=y or set type =vbb**

→Set HIST=y if file history is desired

#### **CELLERA NDMP WITH VBB LIMITATIONS/RESTRICTIONS:**

→Backups are conducted on the entire file system only, not partial

→File system must be Read-Only (Use Checkpoint or mount file system RO)

→File Filtering and DAR/DDAR restores are not supported

→3-Way restores will not be supported

#### **NDMP BACKUP WITH INTEGRATED CHECKPOINTS (SnapSure):**

With this feature set, the Backup job will automatically create a Checkpoint, conduct the backup, and then delete the Checkpoint

→Point-in-time backups of live file systems

→Celerra NDMP Backups with Integrated Checkpoints supports regular NDMP, 3-Way NDMP, & NDMP VBB, and is based on backups of SnapSure checkpoints

→Both VBB & Restартable Backups rely on Integrated Checkpoint feature

→Set variable SNAPSURE=y to allow for creation of Checkpoints (NDMP\_CREATE\_AND\_MOUNT\_CHECKPOINT\_EVT)

→Compatible with PAX & VBB backups, and NDMP Versions 2, 3, 4, File Filtering, DDAR

→Checkpoints are created before the backup job and automatically mounted under rootfs in a directory called /.automaticNDMPCKpts (or Snaps)

→Drawbacks? Older checkpoints can create a read performance hit, use no more than (4) checkpoints for pfs

→/.etc/backupSnapDB will be the database for checkpoints for NDMP

→Checkpoints will be deleted after the successful backup (DART will send

NDMP\_UNMOUNT\_AND\_DELETE\_CHECKPOINT\_EVT to CS)

→NDMP Integrated Checkpoints reside in the PFS

automaticTempNDMPCKpt6412 [example of temporary NDMP Checkpoint name]

→NAS 5.5 maintenance release introduces Snapsure environmental variable for those sites where the Backup software does not yet have a variable to set

**# server\_param server\_3 -facility NDMP -info snapsure -v**

server\_3 :

name = snapsure

facility\_name = NDMP

default\_value = 0

current\_value = 0

configured\_value =

user\_action = none

change\_effective = immediate

range = (0,1)

description = Use SnapSure file system for backup

**Note:** Set value to 1 to allow Backup software, such as TSM, to be able to conduct Integrated Backups using Checkpoints

### **NDMP RESTARTABLE BACKUP:**

→ Purpose would be to allow for a restart of a failed backup, as long as the point prior to failure is known to be good

→ Works by using a backup context based on a checkpoint of pfs prior to backup, and deletes it after completing—DMA will restart by accessing NDMP\_MOVER\_GET\_STATE values in the checkpoint, via the BRE (Backup Restart Extension) interface

### **iSCSI LUN REPLICATION:**

→ Providing for asynchronous remote point in time copies of LUNs—copies difference between two local snaps to remote Celerra

→ Snaps managed by Hosts, as hosts own iSCSI LUNs, and snap functionality exported to host via NBS protocol.

→ Host runs the CBMAPI (Celerra Block Management API) NBS client and provides API to ERM

→ Architecture requires Host and two data movers

→ ERM is user interface to manage iSCSI snaps and replication of snaps

→ CBMAPI is extension to SNAPAPI

→ Only CLI can be used for iSCSI replication in this release

## **CELERRA REPLICATOR FOR iSCSI (iSCSI-COPY with RM/SE 3.1.0.1):**

**Note:** GA NAS 5.5, Celerra Replication Manager/SE

→ Application consistent point-in-time replication of iSCSI LUNs using VSS technology

→ Replication of LUNs based on snaps (snaps are consistent point-in-time copies), asynchronous using RM/SE for Celerra

→ iSCSI Luns replicated to local, loopback, or remote Celerra in support of Disaster Recovery solution

→ Replication is asynchronous and based on iSCSI snaps managed by RM/SE for Celerra (config, jobs, policies)

→ Interface used will be the Windows RM/SE for Celerra to ensure applications such as SQL, Exchange, are consistent

→ Replicator will perform Baseline copy or Differential copy when replicating from Source to Target

→ Can replicate from single source LUN to multiple target LUNs

→ Production LUN remains available during replication copy session

→ Maximum number of concurrent sessions per DM is 128

### **APPLICATIONS SUPPORTED FOR iSCSI REPLICATION:**

Exchange 2000, 2003 via VSS, SQL Server 2000, 2005, NTFS

### **SUPPORTED PLATFORMS FOR RM/SE:**

Windows 2000 and Windows 2003

### **CELERRA REPLICATOR FOR iSCSI LIMITATIONS/RESTRICTIONS:**

→ Only Windows 2000/2003 support

→ No Celerra Manager configuration for destination LUN

→ Support for up to 128 active concurrent sessions

→ Manual failover & failback

→ Manually extend Source Lun, destination Lun extended using DP Mgr

### **KNOWN ISSUES:**

If iSCSI LUNs are being managed by RM/SE, and the system is upgraded from NAS 5.3/5.4 to 5.5, a code problem causes the iSCSI LUNs opaque file (attributes) to grow greater than 8k, resulting in loss of access during the Upgrade iSCSI conversion process on snap file systems. See emc158502 AR93043 for more details.

VCS: 3: Attribute file format error, fsid=60, path=fs60\_T4\_LUN1\_000187910099\_008D.vs

name=fs60\_T4\_LUN1\_000187910099\_008D.ckpt044.opaque offset=8196 status=OK

### **COMPONENTS THAT COMPRIZE CELERRA REPLICATOR FOR iSCSI:**

RM/SE for Celerra (ERM); CBMAPI (SNAPAPI); NBS Server; DP Manager; File Version Delta; RCP Transport; DART Interconnect (DIC); VersionSet/Version (VCS); Control Station

**CBMAPI**→Windows API that exports Celerra Block Management for Snapshot, Replication, OSL, runs as NBS Client on CS and is used by RM/SE. From CLI, SNAPTEST.exe is used to connect to API.

**NBS Server**→Enhanced to support Replication & Snapshots, processes request from CBMAPI NBS Client, and calls DP Service. Packets are in XML format with 128-byte header

**DP Manager**→DpInit—Starts DP service; DpConfig—XML encoding/decoding; DpContext—keeps track of replications;

DpService—interfaces for managing replication; DpPolicy—policy engine; DpTaskManager—handles failover and restores from remote snap; DpTunnel—tunneling service for NBS; DpCopier—sends and receives data

### **/nas/server/slot\_\*/eof**

dpinit [dpinit service is started after the httpd secmac service]. Dpinit always starts during failover operations, but if commented out in the eof file, will not start during system reboots.

**RCP**→data transport service

**DIC**→Dart Interconnect—XML over HTTP uses digest authentication

**Note:** The Dart Interconnect layer will use HTTP client and server protocols to exchange XML packets between Darts—Phase I Burgundy, Phase II Cognac, at which time DART will run an HTTP Server.

VCS→Version Control System—interface for snapshot operations, maintains on-disk and in-memory databases

### **THREE TYPES OF REPLICATION:**

Local→replication between two data movers on local Celerra system

Loopback→replication on same data mover

Remote→replication between data mover on Source CS to data mover on Target CS

### **Replication Control Management:**

RM/SE for Celerra; SnapApi; Control Station

→Used by RM/SE & Host applications to communicate with NBS Server on DART

→Windows API exports block management function for Snapshot, Replication

### **Server Components:**

NBS Server; DP Manager;FileVersion Delta; RCP Transport; DART Interconnect (DIC); VCS (Version Control System)

→NBS Server is enhanced for snapshot functionality

→Management records require upgrading, and are stored in /nasmcd/rootfs/slot\_x/.etc/nbsdb

→DP Manager is the iSCSI replication engine, runs on both Source & Target servers

→dpinit is included in boot.cfg to recover replication sessions during server reboots

→Databases reconstructed into memory after reboots using on-disk databases /nasmcd/rootfs/slot\_x/.etc/dp

→Only one snap can be running at a time, but can have 128 active sessions

→File versioning based on ufs extents (extent tables and data versions)

→RCP (Replication Control Protocol) transport used as data transfer service over TCP/IP (same service as used in fs\_copy & IP Replicator)

### **RCP Transport Parameters:**

#### **\$server\_param server\_2 -f RCP -m tcpwindow -v 1048576**

**Note:** Default tcp window size is 128kb—above example shows setting param to 1MB. Window\_Size = Round Trip Delay \* Desired Rate. This setting is the HWM value.

#### **param RCP allowipX=<ip address>**

**Note:** Use above param to set 1-8 IP addresses (X) for access control

#### **\$server\_param server\_2 -f RCP -m tcpwindowlowat -v 0 | 614400** (600kb)

**Note:** Default value 0 = 64k. Low\_Watermark = Window\_size - #Bytes ACK'd when TCP transmit stops

DIC→Dart Interconnect uses XML over HTTP for communication. Digest authentication using shared secret & MD5 hash. Nas\_cel is used to configure password/passphrase on both Source/Target

VCS→Manages snapshot operations via File Version & File Version Set objects

→File Version is abstraction for storage object file

→File Version set is a collection of objects stored in directory

Control Station→New command nas\_replicate. Other commands modified, nas\_cel and server\_iscsi

### **iSCSI COMMAND SET:**

→nas\_replicate -list | -info | -abort id=<sessid> -local | -failover id=<sessid>

→nas\_cel -name eng1 -create 192.168.2.30 -passphrase xtratree

→server\_iscsi server\_2 -lun -n 10 -create mytarget -size 100M -fs fs1 -readonly (creating RO destination LUN)

### **CONFIGURING iSCSI LUN REPLICATION:**

#### **Overview:**

Setup iSCSI source Lun

Create RO destination Lun of same size as source

Configure authentication Source & Target

Login to source target from iSCSI initiator

Create iSCSI-Copy job with destination IP address and authentication name

Create ERM schedule (RM/SE) to create local snap and mark snap for replication

#### **STEPS:**

1. Setup communication link and trust relationship between Local & Remote Control Stations:

# nas\_cel -name cs\_remote 10.241.168.52 -passphrase replication (repeat on Remote CS for cs\_local)

2. Create samesize destination iSCSI LUN for replication (Source LUN already exists):

# server\_iscsi server\_2 -lun -number 50 -create t1 -size 40G -fs remote\_fs -readonly yes

# server\_iscsi server\_2 -lun -number 50 -create t1 -size 40G -fs remote\_fs -vp yes -readonly yes [virtually provisioned fs]

3. Configure iSCSI LUN Replication Session:

From Windows host, log into Celerra iSCSI target for Source iSCSI LUN, create iSCSI Copy job using RM/SE and specify the destination Data Mover IP address. Create an RM/SE job for snapshot creation and mark snapshot for replication

### **VERIFYING REPLICATION ROLE FOR LUNS AND REPLICATION SESSIONS:**

**\$ server\_iscsi server\_2 -lun -info -all**

**\$ nas\_replicate -list**

**\$ nas\_replicate -info -all**

**SETTING RCP PORT NUMBER:**

**\$ .server\_config server\_2 -v "param RCP port=20000"**

**Note:** Default port 8888

**CHANGING TCP WINDOW SIZE:**

**\$ .server\_config server\_2 -v "param RCP tcpwindow=65536"**

**Note:** Default value 128kb

**STEPS FOR PERFORMING iSCSI SNAP REPLICATION:**

→data written to iSCSI lun

→iSCSI snap is taken from RM/SE console on Source side (S1)

→Snap is marked for replication

→Baseline copy of Source snap replicated to Target side

→Snap is made of Target side iSCSI lun (D1)

→Source & Target snaps become the ‘common’ base

→as data changes on Source, the process is repeated with creation of new Snap on source, replication to destination iSCSI Lun, new Destination Snap created, and new ‘common’ base becomes S2 and D2

**Note:** Destination lun is RO

**FAILING OVER iSCSI REPLICATION SESSION:**

→Failover initiated: **\$nas\_replicate -failover -id=<sessid>** (source becomes RO and destination RW)

**Note:** Destination iSCSI LUN takes over as PLU—initiated from remote CS only. See Using Celerra Replicator for iSCSI Tech Module--there are many steps involved in actually performing a complete failover.

**ABORTING AN iSCSI REPLICATION SESSION:**

**\$ nas\_replicate -abort id=<sessionID> | -local**

**Note:** Might need to do this when other side is unavailable or RM/SE is unavailable. This command is run on the local CS to abort either the local session only or both sides of the session.

**RESTORING FROM DESTINATION TO SOURCE WITH COMMON BASE SNAPS:**

→Differential snap taken on Destination and delta between D2 and D3 is copied back to Source, which becomes RO

**RESTORING FROM DESTINATION TO SOURCE WITHOUT COMMON BASE SNAPS:**

→Baseline copy of destination snap is copied back to Source, which is RO

**Troubleshooting:**

\$nas\_replicate -info shows configured parameters, replication states, and control/data states

Replication Log Events (V2RPL & DPSVC)—Lun full, network down, db access error, other errors

Disable replication by removing dpinit and eof from boot.cfg file

Replication database found in /etc/dp/replica, /etc/dp/policy, /etc/dp/version, /etc/dp/info, /etc/dp/taskManager

**Control Station commands to use in troubleshooting iSCSI snaps, etc.:**

**# /usr/local/bin/nbs-snap**

Usage: nbs-snap -a action [-i PluNbsId] [-n snapId] -s serverName [-v]

nbs-snap -a listPLU -s serverName

nbs-snap -a getPLUAttr -i PluNbsId -s serverName

nbs-snap -a listSnap -i PluNbsId -s serverName

nbs-snap -a create -i PluNbsId -s serverName

nbs-snap -a delete -i PluNbsId -n snapId -s serverName

nbs-snap -a getSnapAttr -i PluNbsId -n snapId -s serverName

nbs-snap -a getAppData -i PluNbsId -n snapId -s serverName

nbs-snap -a createTWS -i PluNbsId -n snapId -s serverName

nbs-snap -a deleteTWS -i PluNbsId -n snapId -s serverName

nbs-snap -a promote -i PluNbsId -n snapId -s serverName

nbs-snap -a demote -i PluNbsId -n snapId -s serverName

nbs-snap -a restore -i PluNbsId -n snapId -s serverName

nbs-snap -a commitRestore -i PluNbsId -n snapId -s serverName

nbs-snap -a undoRestore -i PluNbsId -n snapId -s serverName

nbs-snap -a refresh -i PluNbsId -n snapId -s serverName

nbs-snap -a setAppData -i PluNbsId -n snapId -s serverName -d <data>

nbs-snap -a deleteALL -i PluNbsId -s serverName

nbs-snap -a getSN -i NbsId -s serverName

nbs-snap -a getNBSIdbySN -i SN -s serverName

nbs-snap -a asyncCreate -i PluNbsId -s serverName

```
nbs-snap -a asyncQuery      -i infoId -s serverName  
nbs-snap -a deleteCookie    -i infoId -s serverName
```

# **/usr/local/bin/nbs-snap -a listPLU -s server\_2**

```
fs35_T15_LUN0_APM00042403638_0000  
fs35_T15_LUN1_APM00042403638_0000
```

**Note:** Listing Production LUNs on the Data Mover

# **/usr/local/bin/nbs-snap -a listSnap -i fs35\_T15\_LUN0\_APM00042403638\_0000 -s server\_2**

```
fs35_T15_LUN0_APM00042403638_0000.ckpt000
```

**Note:** Listing specific snap for the PLU

# **/usr/local/bin/nbs-snap -a delete -i fs35\_T15\_LUN0\_APM00042403638\_0000 -n**

```
fs35_T15_LUN0_APM00042403638_0000.ckpt000 -s server_2
```

Delete snapshot succeed.

**Note:** Deleting a snapshot for the PLU

### **MORE EXAMPLES:**

\$ **server\_iscsi server\_2 -lun -info 4**

server\_2 :

## **CELERRA iSCSI DR SOLUTION:**

→Configuring Disaster Recovery using iSCSI and Celerra Replicator

→Failing over to DR site

→Preparing Failback

→Failing back to Source site

### **Requirements:**

NAS 5.5, Windows 2000/2003 Servers running hotfixes KB891957/KB898790, 2.0 Initiators, Solutions Enabler 6.2, and Replication Manager/SE 3.1.0.2

### **CONFIGURING DR:**

#### **Setup Source & Remote Side Windows 2000 Servers:**

→Windows 2000/2003 Server with hotfixes, KB891957 & KB898790, install MS Initiator 2.0, install Solution Enabler v6.2, install Replication Manager/SE 3.1, install applicable NTFS, SQL, or Exchange application

→Setup Replication relationship & sessions between Local & Remote Celerras

### **CONDUCTING FAILOVER:**

- Failover using nas\_replicate –failover, log into destination Windows Server--mask luns for access and mounting, clearing the readonly attributes using bat file against device and drive number: #RmMountVolume.bat 2 R:
- Change RMSE database location on the remote Windows Server to point to the location of db on production system
- Update SQL or Exchange db hostname entries
- Enable DR mode on Host Windows system and restart RM/SE
- Recover replicas from RM/SE Host by selecting Restore for applications

#### **FAILING BACK:**

- Assuming true disaster, rebuild Windows 2000 Server on original Source & setup Replication sessions for applications
- Take remote Windows Server offline and prepare applications for failback
- Record current replication session information and perform failback using nas\_replicate –failover
- Make LUNs visible to original Source Server, mount volumes, clear readonly flag from device & drive letter
- Change RMSE database location to source Windows Server and update application db pointers
- Enable DR mode on Host and recover replicas, then recover applications

## **CELLERRA MANAGER ENHANCEMENTS:**

### **iSCSI WIZARD:**

iSCSI Target Wizard → Creating new iSCSI target LUN using Target name and portals

iSCSI LUN Wizard → Creating new iSCSI LUN or multiple LUNs of same size by selecting or creating target, selecting or creating file system, configuring LUN masks, and other settings if necessary

**Note:** Enable multiple access for clustered Servers during LUN Masking setup page. You might use this feature for Microsoft Cluster Services for Exchange, for example, in which each Cluster Server must share the external storage. MSCS nodes will have access to the LUN in case of failover if multiple initiators are listed here.

### **MaxRequestHoldTime:**

The default HoldTime for the MS Initiator is 60 seconds, and is defined as the time in seconds that iSCSI requests will be queued if a connection to the Target is lost, and the connection is being retried. After the Hold period expires, further requests fail with “error no device” and the disk is removed from the Windows host list. Increasing the MaxRequestHoldTime value to 600 seconds, or 10 minutes, is recommended for VMWare and Exchange/SQL iSCSI environments where requests may need more time:

**HKLM>System>CurrentControlSet>Control>Class>4D36E97B-E325-11CE-BFC1-**

**08002BE10318>0000>Parameters>MaxRequestHoldTime = 600** → Increased value from 1 to 10 minutes

### **CREATING AN iSCSI LUN:**

1. Create Target first [unique alias name & portal]
2. Select File System to hold LUN
3. Enter LUN information and configure LUN Masking (initiators added to grant access to LUNs)
4. Configure CHAP access on initiators
5. Set iSCSI/iSNS settings

### **MS iSCSI INITIATOR VERSIONS:**

Version 1.06=Build 302

Version 2.02=Build 1895

Version 2.03=Build 3099

Version 2.04=Build 3273

Version 2.05=Build 3392

Version 2.06=Build 3497

Version 2.07=Build 3640

Version 2.08=Build 3825 (latest—Vista & Windows Server 2008 comes pre-installed with the iSCSI Initiator software)

### **REPORT LUNS:**

→New SCSI-3 specification used only with Symm & Clariion arrays to speed fibre channel discovery of luns, channel failover, and channel failback

### **NAS VPL (VIRTUALLY PROVISIONED LUNS--THIN PROVISIONING):**

A marketing concept that calls for sparse luns for regular NAS file systems and iSCSI file systems—also known as thin provisioning, over-provisioning, etc., with claims of lowering TCO & yielding greater availability for applications, though the reality will most likely become a support millstone. Concept was introduced in order to compete with NetApps, though NetApps can logically shrink file systems to reclaim space, whereas EMC’s solution cannot.

→Client systems see max logical size of file system, which is not the actual size from DM perspective

→Requires that auto-extension feature be used and a Max size be specified

### **iSCSI VIRTUAL PROVISIONING LUN (aka sparse lun):**

**Note:** Purpose of VPL is to create largest LUN possible, but underlying file system can be much smaller, and extended when needed. Purpose is to not use disk space until required. Auto-fs extend fits nicely into this feature, but IS NOT a guarantee against data loss. It is very possible to fill a file system faster than the auto-extend feature can extend, since VPL does not use PBR to reserve blocks.

#### **BEST PRACTICES FOR iSCSI VPL LUNS:**

- Use auto-fs extend feature
- Monitor fs capacity and logs
- Hosts do not need to rescan storage when underlying file system is extended, no disruption to service
- Formerly called iSCSI Sparse Lun, basically means you can create a Lun >in size than the actual file system underneath
- Max size for VPL LUN is still 2TB less 1MB
- As best practice, always use auto-fs extend feature with VPL
- Do not mix DENSE and VPL luns on the same file system
- LUNs have space allocated as blocks are used, and file system blocks are allocated when a chosen HWM is reached
- Main drawback, however, is that allowing a VPL file system to fill to 100% will cause data corruption/loss (no PBR used)
- Can only create the VPL lun via CLI, but can list, delete, extend via GUI
- Can list, delete, extend VPL via Celerra Manager
- Sparse luns do not need to reserve blocks when extended

#### **CREATING iSCSI VPL FROM CLI:**

```
# server_iscsi server_2 -lun -number 0 -create target1 -size 10G -fs sparsefs1 -virtually_provisioned yes  
$server_iscsi server_2 -lun -create t1 -0 -size 1000M -fs fs_iscsi -vp yes  
$server_iscsi server_2 -lun -info 0 -target t1  
    max_extension_size=537794MB
```

→ Can create virtually provisioned temporary writable snaps (TWS) for regular Luns only (aka Dense Luns), used for Snaps

#### **Set following param:**

**param nbs sparseTWS=1**

#### **DYNAMIC iSCSI LUN EXTENSION:**

- Supports dynamic extension of regular iSCSI luns and virtually provisioned iSCSI (PLU) LUNs by increasing visible size to Hosts
- Total LUN size cannot exceed 1MB < than 2TB
- Celerra iSCSI target allows lun to be created in dense or sparse mode
- Do not use both dense & sparse LUNs in same file system
- Dense luns required block reservations when extending
- Extend using CLI or Celerra Manager
- Celerra Replicator for iSCSI LUNs will extend destination side first, then source side
- Cannot be used for extending promoted Snaps or Destination IP Replication iSCSI luns

#### **DYNAMIC iSCSI LUN EXTENSION LIMITATIONS/RESTRICTIONS:**

- All dynamic iSCSI lun extensions require specific host-side actions to actually extend the volume and file system for the Host
- Cannot increase LUN size past that which the file system can support
- Max extension size of VPL lun is max LUN Size (2 TB) less current LUN size
- Max extension size of DENSE LUN limited to free space in the file system itself

#### **Extension Rules:**

- With iSCSI replication, destination LUN will be extended after the Source when the Data Protection service detects LUN change
- Note:** Destination LUN cannot be extended from Control Station for iSCSI replication (Only the DP service)
- Can extend regular iSCSI Lun via CLI or GUI, but for active iSCSI Sessions, the actual rediscover should be done offline for both Windows and Linux
- Promoted Luns cannot be extended
- Cannot shrink Lun size once extended
- Cannot restore from old snapshots once Lun has been extended

#### **Querving iSCSI LUN to Determine Extension Size:**

```
$ server_iscsi server_2 -lun -info 0
```

Logical Unit 0 on target t1:

(Production) fsid=40 **size=1000MB** alloc=0MB dense

**max\_extension\_size=537794MB**

#### **Extending iSCSI LUN from CLI:**

```
$ server_iscsi server_2 -lun -extend 0 -target t1 -size 1000 (MB)
```

#### **EXTENDING iSCSI LUN FROM WINDOWS HOST:**

1. Extend iSCSI Lun from Control Station
2. Run rescan for extended Lun size using Disk Manager or CLI diskpart “rescan” command
3. Unmount file system on Data Mover
4. Extend volume using CLI diskpart “extend” command
5. Remount file system

### **Windows Diskpart Utility:**

- Diskpart extends partitions by restriping, without downtime
- Does not support Dynamic partitions or Extended partitions, only NTFS basic primary partitions.
- Supports Windows 2000/2003

### **USING DISKPART TO EXTEND CELERRA iSCSI LUNs:**

1. Download diskpart\_setup.exe from Microsoft and install on Windows host
2. c:\>diskpart.exe
  - DISKPART>list disk
  - DISKPART>rescan
  - DISKPART>select disk x
  - DISKPART>list partition
  - DISKPART>list disk
  - DISKPART>rescan
  - DISKPART>select partition x
  - DISKPART>extend

**Note:** iSCSI LUNs for Exchange Server databases should have an offset of 64, which equals 32KB

### **EXTENDING iSCSI LUN FROM LINUX HOST:**

1. Extend iSCSI Lun from Control Station
2. Allow Linux to discover extended Lun by restarting the iSCSI service
3. Unmount file system on Data Mover
4. Use fdisk to recreate the newly extended partition
5. Extend the file system using #resize2fs command
6. Remount file system

### **CELLERRA iSCSI OSL API SUPPORT(Open Storage Library):**

Collection of block storage API's used to manage heterogeneous storage arrays while presenting a common storage information model and programming interfaces, Open Storage APIs v 5.4. Celerra will use Celerra Block Management API (CBMAPI)

- Already supported by Clariion and Symmetrix backends
- Supports Microsoft VDS (Virtual Disk Service) v.1.1 & VSS functionality
- Storage APIs will support storage discovery, LUN provisioning, LUN masking
- Various enclosures are DAEs, SPEs, DPEs, DMEs; Klondike DPEs are SATA disk drives; Katana for FC, and Katina for 4GB FC
- Debug Log module for STORAPI is called LOG\_OSL

### **RESTRICTIONS:**

- Only supports iSCSI objects

### **SNAP MANAGEMENT FOR OSL:**

- NbsStorSnapDisk—snapshot for production Celerra iscsi drive
- NbsStorDeleteSnap—delete a snapshot
- NbsStorQuerySnaps—list of existing snapshots
- NbsStorPromoteSnap—promote a snapshot as RW and assigns a LUN
- NbsStorDemoteSnap—demotes a snapshot & unassigns the LUN
- NbsStorRestoreDisk—restore a snapshot
- NbsStorUndoRestoreDisk—undo a restoration, step 1
- NbsStorCommitRestoreDisk—undo a restoration, step 2
- NbsStorDeviceCreate—create LUN and associate with target
- NbsStorDeviceDelete—delete LUN
- NbsStorDeviceExplan—expand a LUN
- NbsStorDeviceSizeInfo—LUN inquiry

### **DYNAMIC VOLUME CREATION:**

In current implementation, CS is used to issue command to create a new volume to DART, and DART responds by creating volume with CTL. In new implementation, DART will automatically create new basic volumes when it bus scans and finds new devices on the backend. Purpose is to provide for better path failover, better handle configuration changes, and to avoid mismatches.

- CS will still be required to ‘discover’ the volume and matchup to a CTL (must know either dvolume name or CTL for CS command)

→Bus scan is done on Server reboot, link-up event, or by server\_devconfig command

### **AUTOMATIC FILE SYSTEM AUTO EXTENSION:**

- Defined by HWM from 50-99%, default HWM is 90% (nas\_fs -hwm <50-99%>)
  - Must define the max extension limit of the fs using nas\_fs -max\_size <integer>[T|G|M] (default=10GB)
- Note:** Generally, once HWM reached, fs will extend by 5% of fs size if greater than 10GB, or 10GB, whatever is larger. Extensions of 5GB will occur again if fs usage is less than 3% below HWM.
- Auto-extension is only supported for file systems created or modified using AVM (uxfs, mgfs, FileMover)

→Supports auto-extension for iSCSI fs using Virtually Provisioned LUNs, but NOT regular iSCSI LUNs

→Supports auto extension of destination, then source file system for IP Replication or FS Copy

→Supports auto extension of Timefinder PFS, then mirrored snaps

→DART will generate the event at the HWM, Control Station will catch with event handler to extend file system

→Virtual provisioning allocates storage but it is not actually used by file system until needed

**\$ nas\_fs -name auto\_noprovision\_fs1 -c size=10G pool=<pool\_type> -auto\_extend yes -hwm 90% - max\_size 2G -o slice=y**

**Note:** Creating auto extend file system without virtual provisioning and max extend size of 2GB

**\$ nas\_fs -name auto\_provision\_fs1 -c size=10G pool=<pool\_type> -auto\_extend yes -vp yes -hwm 90% - max\_size 2G -o slice=y**

**Note:** Auto extend file system with virtual provisioning set and max extend size of 2GB

**\$ nas\_fs -modify fs1 -auto\_extend yes -hwm 50%**

**\$ nas\_fs -i fs1**

auto\_ext = hwm=50%,virtual\_provision=no

**Note:** Default behavior is to not auto-extend unless “-auto\_extend yes” is specified (set by options in nas\_fs)

→Feature interoperates for replication, timefinder, filermove, snapsure, but not MirrorView, SRDF, VDM

## **AUTO FS EXTENSION RESTRICTIONS/LIMITATIONS:**

→Does NOT support auto-extension of regular dense iSCSI lun file systems

→Does NOT support auto-extension for checkpoint file systems, nmfs file systems, or raw file systems

→Does NOT support auto-extension of file systems that are used with SRDF or MirrorView

→Once allocated, unused space cannot be reclaimed

## **HTTP CLIENT FOR DART:**

→HTTP Client 1.1 is necessary to support FileMover and DART Interconnect features (Dart-to-Dart comms)

→Typical exchange is that Client opens TCP connection to Server with request; Server sends back response; connection closed

→Multiple requests can be sent for same TCP connection, Client & Server can authenticate using digest or basic authentication

→Client will not be a Web Browser (which interprets body data), but will allow for sending/receiving messages, and connection parameters

→Choices of Security: No security; Basic authentication; Digest authentication

## **NFS VERSION 4:**

See NFS Protocol section of TechGuide

## **NAS 5.5 POST GA RELEASES--NAPA:**

NAPA is used to indicate various maintenance releases for NAS 5.5 that include special features, fixes, etc.

### **NAPA 1 GA 9 June 2006 NAS 5.5.21.4:**

**NAPA 1 SUPPORTED ITEMS:** Main purpose of this release is to support the CX3 Clariion hardware/flare versions

→4Gb Fibre Channel UltraPoint (Stiletto) DAE3P 3U drive enclosures (5.25”)

→Support in Celerra Manager for new CX3 hardware components

→10Gb Ethernet & 4Gb FC support

→FLARE 22 Atlas support, needed to support new CX3 arrays, 4Gb Stiletto DAE3Ps, with NAS NaviCLI & Widesky updates

→Support for new 4Gb Stiletto DAEs, Jackhammer, Sledgehammer, & Hammerhead arrays, for CX3-20, CX3-40, & CX3-80 series

→Automatic Log & Dump Collection and Transfer tool (Introduced NAS 5.5.21.4 & 5.4.25.1)

A feature that automatically collects and gzips logs or dumpfiles to /nas/var/log or /nas/var/dump, respectively, or if configured, can transfer the dumpfile or logs directly to a specified FTP server. Only auto-collect enabled, transfer piece must be enabled separately. See emc135846.

→New UFS ACL DB Cache mechanism

**Note:** The “old” ACL cache will still be used regardless of the initialization of the “new” ACL cache. If the “new” cache is initialized, there will be two levels of ACL caches. The “old” ACL cache will always be checked first for lookups in the write path. If there is a cache miss in the “old” cache, and the new cache is initialized, then the lookup will be done with the new ACL cache.

→Default AVM stripe size changing from 8kb to 32768 for Clariion Storage Pools (clar\_r5\_performance; clar\_r5\_economy; clar\_r1)

**Note:** This means that a file system that is extended may use the 32k stripe depth if new volumes are added to the pool—according to Eng., this is not a problem

### **DAE3P Disk Enclosure:**

(15) Low profile 2/4Gbps FC Drives using new Frumon-based spinup, and (2) 4Gbps LCC Cards

**Note:** DAE3P can use either FC or SATA drives

### **Atlas 22 FLARE Support:**

New Bus architecture, Full SW replication, more reserved space on Vault drives, SP reboot and shutdown from GUI, 2Gb/4Gb speed changes, Auto Dump analysis

**NAPA 2:** NAS 5.5.22.2 GA August 11, 2006

→Hammerhead NSX Generation II hardware (H2G2) XBlade-65 Data Movers with 10GbE and 4GB FC support

→Ultrapoint Stiletto 4Gb DAE fibre channel drive support with Atlas flare support [3.22.020.5.0xx]

→NS40 introduction & support for Sledgehammer arrays

→Single port 10GbE Neterion Xframe Optical NIC I/O Module support

→4Gb Fibre Channel Support

→DUDL thread deadlock detection for NFS & CIFS

→500GB LCFC drive support introduced for Gateway models (NS500, 700, NSX, NS40, & NSX2)

**Note 1:** LCFC drives are not sold with NS20 systems, therefore are not supported on that platform

**Note 2:** Though documentation and Release Notes only talk of Clariion support, DMX-3 symmetrix also supports LCFC drives. This is seen in the following cryptic clip from eLab Navigator support matrix:

15. Symm DMX-3

\* All shipping drives are supported

#### **Symmetrix DMX-3 ...Low-Cost Fibre Channel Drives:**

Technical Note p/n 300-004-737 discusses performance characteristics related to use of 500GB LCFC drives

→LCFC drives can be used for performance-insensitive, sequential read/write (such as Backup-to-disk), or low access density applications

→LCFC should not be used as R2 or BCV in write-intensive environments, where random IO performance is important, or disk response is important, etc.

#### **NAS NS40 GATEWAY & INTEGRATED SERIES:**

→Min. NAS 5.5.22.2 code and CLARiiON CX3-40 array with Flare 22

→Gateway & Integrated models available

→Available as factory racked (factory-install, configuration wizard setup) or field mounted (fresh install)

→Does not contain UPS

→Dual 2.8GHz P4 CPUs, 4-8 GB memory, 1, 2, or 4Gb Fibre Channel speeds, (4) GigE Ethernet ports

→Single or dual-Data Mover configurations available based on XBlade technology, but only Single Control Station allowed

→Based on Sledgehammer hardware, DM blades are dual Intel 2.8Ghz Pentium IV processors with 4GB memory & 800MHz fsb

→Capacity per Blade is 16TB fibre channel drives, 32TB mix fibre channel & ATA

→SAN Gateway versions can connect to most array backends, while Integrated model connects only to Sledgehammer (CX3-40)

→Projected replacement for NS500 & NS700 models based on Clariion CX3-40 platform

**Note:** An NS40 with (2) Data Movers is considered equivalent to NS700 with (2) DMs. If an NS700 has (4) DMs and requires larger disk capacities, then the NS80 would be the replacement for that level of NS700

→1U Enclosures, 1 or 2 blades only (Data Movers), single Chivas Control Station (2GB memory), (4) Power Supplies, Internal Management Switch, (2) serial ports for DART console—COM1 & COM2, 40GB ATA drive, CD-ROM, Floppy

→Chivas Pentium IV 2.8GHz Control Station with 2GB memory; (1) 10/100/1000 GbE controller; (2) 10/00/1000 Mb/s Ethernet LAN ports; (1) 10/100 Mb/s Ethernet port; 80Gb harddrive; (2) Serial ports, one for CallHome modem and one for Laptop connection

→NS40 Blade with NAS personality will have dual 2.8GHz Nocona P4 processors, 4GB memory, (2) serial console ports on lower left side, (2) RJ45 connectors to Internal Management switch, (4) Broadcom 5704 Gigabit Ethernet Optical ports (cge0-cge3) [or (2) Copper fge ports & (2) Optical cge ports], (2) Agilent 1/2/4Gb Aux Fibre Ports, and (2) Agilent 1/2/4Gb BE Fibre Ports

→SAN blades for SP's can have either (2) or (4) Fibre ports each, while NAS blades have only (2) Fibre ports

→Internal Management switch is built into Motherboard, as opposed to NSX, where Management Switches are FRU's, with (2) RJ45 ports for access—switch monitors Fan modules, peer management switch function, Data Mover status registers, power & reset states of DMs

mgmt\_2\_3 192.168.1.50 Enclosure 0 management switch A

mgmt\_2\_3b 192.168.2.50 Enclosure 0 management switch B

spa 192.168.1.200 Integrated BE SPA on Network A Gateway 192.168.1.100 [to primary CS on primary network]

spb 192.168.2.201 Integrated BE SPB on Network B Gateway 192.168.2.100 [to primary CS on secondary network]

#### **DAE3P ENCLOSURE ADDRESSING FOR CX3-40 ARRAY:**

| Type, Loop Address | Description          | Enclosure Address (aka EA or Enclosure ID) |
|--------------------|----------------------|--------------------------------------------|
| DAE3P; 0,0         | First Encl           | 0                                          |
| DAE3P; 1,0         | 2 <sup>nd</sup> Encl | 0                                          |
| DAE3P; 0,1         | 3 <sup>rd</sup> Encl | 1                                          |
| DAE3P; 1,1         | 4 <sup>th</sup> Encl | 1                                          |
| DAE3P; 0,2         | 5 <sup>th</sup> Encl | 2                                          |
| DAE3P; 1,2         | 6 <sup>th</sup> Encl | 2                                          |
| DAE3P; 0,3         | 7 <sup>th</sup> Encl | 3                                          |
| DAE3P; 1,3         | 8 <sup>th</sup> Encl | 3                                          |

#### **Other NAPA 2 Items—5.5.22.2:**

→Six new checks added to PUHC, Error, Warning, Info

→**500GB capacity, 2GB speed, 7200RPM Low Cost (LCFC) Drives**, which will be supported with NAPA 2 5.5.22.x maintenance release, will be treated as CLATA drives by Celerra and will use the clarata\_r3 storage pool. They will use RAID3 4+1(single lun RG) and 8+1 (dual-lun RG) templates. Available only for Gateway NS500, 700, 40, NSX models at this point, but only with CX3 array hardware(?)

#### Server Thread Utility:

→Thread deadlock detection for CIFS & NFS. If one NFSD thread, or all CIFS threads are blocked for 6 minutes or more, the system will panic if the parameter has been set, since by default the system will not panic for deadlocked threads:

**# .server\_config server\_2 -v "param kernel threads.maxBlockedTime"**

kernel.threads.maxBlockedTime INT 0x014772a4 **360 360** (8,4294967295) FALSE NONE '

Time in seconds defining the global time before we consider a pool is in deadlock'

**Note:** Default deadlock detection value is 360 seconds, 6 minutes—warnings are logged in sys\_log

**# .server\_config server\_2 -v "param kernel threads.panicIfHung"**

kernel.threads.panicIfHung INT 0x014772a8 **0 0** (0,1) FALSE NONE 'Parameter to force panic if a pool is considered in deadlock'

**Note:** Default is not to panic when threads are hung

#### Server Thread Commands:

**\$ server\_thread server\_2 -report | -service | -list | -pool | -stats**

**Note:** In order to use the server\_thread command, you must either create a link to server\_mgr or use the nas\_cmd facility to directly execute the command, as follows:

**\$ /nas/bin/nas\_cmd @server\_thread server\_2 -list** [please note there is a space before the @ symbol]

server\_2 : done

**GEN 2 (H2G2) HARDWARE SUPPORT:**

→Hammerhead Gen 2 (H2G2) hardware called Hammerhead, Sledgehammer, &amp; Jackhammer, SAN-attached arrays for UltraScales family, CX3-80, CX3-40, &amp; CX3-20, respectively

2<sup>nd</sup> Generation for NSX platform, Server blades are called XB-65. 3.6GHz Irwindale Xeon processor, 4GB RAM, 64-bit capable, Wildfire motherboard, with PLX PCI-Express switch to communicate to I/O Annex via mid-plane connection. Replaces 1<sup>st</sup> Generation Tsunami (4) Port 2Gbps FC I/O Module with new Twister (4) Port 4Gbps FC I/O Module based on Agilent Tachyon chipset. New FC I/O modules will also present Blue/Green LEDs to indicate 4Gbps/1 or 2Gbps link speeds. Blizzard SFP Modules for GbE can have copper SFP (8-ports for NAS), which would be hard-coded to 4G, or optical SFP ports, which would autonegotiate 1, 2, or 4G. An optional Xtreme E 10GbE NIC will be available (fxg0). For backward compatibility, the XB-65's can be put into an existing NSX frame, provided the NAS software has been upgraded first to a version that supports the H2G2 hardware (5.5.22.2+).

→10GbE Neterion single port I/O Module

→CX3 arrays still use first 5 drives for O/S boot, system configuration, &amp; as cache vault for normal operation

→First 3 drives are used for FLARE configuration database and PSM

**Hammerhead CX3-80 (Used for NS80 [not supported until NAPA III], the replacement series for NS700):**

Dual 3.6GHz P4 Xeon processors per SP; 8GB RAM per SP for 16GB total, max. write cache size 3GB; (8)@4Gb FC SAN ports; (4)@4GB FC BE ports per SP; (8)@GbE NAS ports; LH side Management Module B for SPA &amp; RH side Management Module A for SPB; 16Gb cache; 480 drives; 213TB total; up to 2048 LUNs per system; 256 HA Hosts; 73Gb or 146Gb 15K rpm FC 4Gbps Drives; 73Gb, 146Gb, or 300Gb 10K rpm FC 2Gbps Drives; 500Gb 7200rpm 2Gbps LC-FC drives; (4) FC FE Ports per SP &amp; (4) FC BE Ports per SP

**Sledgehammer CX3-40 (Used for NS40, the replacement series for NS500):**

Dual 2.8GHz P4 Xeon processors per SP; 4GB RAM per SP for 8GB total, with max. of 2500MB write cache; (4)@4Gb FC Frontend ports; (2) or (4)@4Gb FC Backend ports per SP; 8GB cache; 240 drives; 119TB total; up to 1024 LUNs per system; 128 HA Hosts; 73Gb or 146Gb 15K rpm FC 4Gbps Drives; 73Gb, 146Gb, or 300Gb 10K rpm FC 2Gbps Drives; 500Gb 7200rpm 2Gbps LC-FC drives; (2) FC FE Ports per SP &amp; (2) FC BE Ports per SP

**Jackhammer CX3-20:**

The CX3-20 uses the same chassis as the CX3-40. Single 2.8GHz P4 Xeon CPU per SP; 2GB RAM per SP; (4)@4Gb FC FE ports; (1)@4Gb FC BE loop per SP; 4Gb system memory, max. write cache size 1053MB; 120 drives; 59TB total; 512 LUNs per system;

128 HA Hosts; 73Gb or 146Gb 15K rpm FC 4Gbps Drives; 73Gb, 146Gb, or 300Gb 10K rpm FC 2Gbps Drives; 500Gb 7200rpm 2Gbps LC-FC drives; (2) FE FC ports per SP; (1) BE FC port per SP

→Piranha-2 & Bigfoot Clariion AX arrays, NS500G/NS700G

→Stiletto UltraPoint 4GB FC Drive DAE3P Enclosure support, with either 4Gbps or 2Gbps drives using (2) 4Gbps LCCs (Link Control Cards). Drives to use Frumon vs. Address-based spinup (Can mix 2GB & 4GB drives on same array, but not recommended on the same loop, as the loop speed would downgrade to the slowest drive)

→Blinking Blue & Green LED's on SP's indicate link failure

→Northstar paddle card to plug SATA drives into Stiletto DAE, supported by Vulcan FLARE

→NS350 (can upgrade to NS500G), new Integrated-only mid-tier entry level platform to be released for NAS & iSCSI, in single or dual DM versions, as well as an Integrated NS704 model. NS350 can have 30 drives for max. storage of 6TB. Each SP will have (4) Cu Gbe Ethernet connections. New 'Ease of Use' packaging for installation.

→Minimum DM hardware 510

→Direct Upgrades from 5.2, 5.3, 5.4 (5.1 or lower must first upgrade to 5.3, then to 5.5)

→Max. mixed FC/ATA capacity 16TB across all platforms except for NS350, 10TB

→Max. FC Capacity 16TB for NSX & NS700, 6TB for NS600 & NS350, and 10TB for NS500, 4TB for 510 DM, 8TB for 514 DM

→Max number FSIDs 4096 for NSX only, 2048 for all other platforms

→Max number Replication Sessions 64 for NSX only, 32 for all other platforms

→Max Snaps per file system 96 for all platforms except 64-only for 510 DM Hardware

## **NAPA 3:**

**NAS 5.5.23.2 Oct 16, 2006**

→MirrorView release with RPQ only

→Vulcan Flare 22 support for Hammers, Bigfoot, and Northstar SATA II drives

Control Station will need new Vulcan NaviCli and Widesky support

→Northstar SATA II Drives with DAE paddle card support for UltraPoint 4GB enclosures, supported by Vulcan Flare

[3.22.020.5.5xx]

Northstar 7200RPM SATA II Drives are for use with CX3 Arrays and NS40 Celerra (SATA technology plugged into fc backplane) SATA II drives run at 3Gb link speeds but must go into 4Gb Enclosures

Celerra will see Northstar SATA II drives as ATA CLATA disk type

Drives cannot be located in 1<sup>st</sup> shelf [i.e., boot enclosure]

Flare 3.22.0x0.5.5xx Vulcan required

Cannot mix SATA II drives with Klondike ATA drives in same RG or any other drive type within same enclosure

SATA II can be used as a HotSpare for FC drives but not for Klondike drives

NS40 Integrated systems require use of setup\_clariion -init and User-defined configuration for shelves (array templates disabled)

Only RAID3 4+1 and/or 8+1 RGs allowed (CLATA or CMATA)

Northstar SATA II and LCFC drives can be mixed in the same FS or clarata\_r3 Storage pool

RAID 3 4+1 will have Single LUN per RG while RAID 3 8+1 will have 2 LUNs per RG

New Shelf Template used: HS=Slot0, then RAID3 4+1 and/or 8+1 for up to 15 drives per shelf

→Support for NS80G Gateway Celerra for Hammerhead

Touted as the replacement platform for Gateway NS704G's—no support yet for Integrated models

No UPS offered; 2-4 Data Movers; Single CS but 2<sup>nd</sup> could be added; Capacity increases to 20TB/blade with fibre channel drive

→LCFC Blizzard Drives for NS40 Celerra & CX3 arrays (Sledgehammer)

500Gb drives at 2Gb bus speed running 7200RPM

Supports only RAID3 4+1 and/or 8+1 RGs (CLATA or CMATA)

Also used on Symmetrix platforms

Introduces support for Integrated Celerras, cannot mix LCFC and FC drives within same Enclosure (Gateway support in NAPA II)

But can mix LCFC, SATA II, or ATA drives in the same file system since all are recognized as clarata\_r3 Storage Pool types

Integrated systems require use of setup\_clariion -init and User-defined configuration for shelves (array templates disabled)

New Shelf Template used: HS=Slot0, then RAID3 4+1 and/or 8+1 for up to 15 drives per shelf

Celerra treats LCFC drives as ATA CLATA disk type. See AR87112 for issue with setup\_clariion script and disk.pm script that looks for specific TLA number, and if it doesn't find 005048596, assumes the drives are to be setup for Raid 5.

→Multi-level NFS Export capability

DART will have the ability to NFS export multiple directories within a single file system

For both NFSv2 & v3, if toplevel fs is exported RO, and nested exports RW, then the effective access for all clients will be RO

Conversely, if nested exports are given RW access, then the parent and other directories exported RO, effective access for all clients will be RW across all directories.

For NFSv4 clients, access permissions are calculated every time a client crosses a directory, therefore, RW and RO access will be enforced.

NMFS is not compatible with this feature

Nested NFS Exports will be enabled by default—to disable, enter param and reboot

## **param nfs multiLevelExports=0**

A known issue is that Clients could possibly have two different versions of a file cached if using multiple exports

### **→PUHC [Pre Upgrade HealthCheck] Checks Added for Upgrades (8 Errors and 1 warning)**

Upgrade will fail if Autoassign or Autotrespass are not properly set; Read Cache on SPs must be enabled; Backend connectivity to SPs checked; /etc/nas\_device.map checked for correct root partition OS1DSK for CS; Unique IDs checked in /nas/server/slot\_x/start file; Control Reserve LUNs validated; /etc/resolv.conf checked for valid DNS names

### **→Clariion Sector Error handling Phase I**

DUDL fix to reduce downtime of file systems. Uncorrectables issue on CLARiiON will still trigger panic, but Data Mover will reboot and come up with all other file systems mounted and will have pfs, checkpoint, replication file systems unmounted until fixed by revector and fsck process.

DART-only fix for Phase I, meaning that potentially, you could drop a patch on the Data Mover to perform the Revector repair File System corruption and recovery applies only to user data and not metadata sectors

Scenarios could involve Production File Systems (Server panic & reboot with affected fs <unmounted>), Checkpoints (Inactive), Replication Sessions (Inactive), or FS Copy operations (Aborted)

Requires use of new sense codes from Flare 16 & 19 for 0311 media errors

Revector tool works better than previous method since only the affected sector is checked and repaired vs. whole lun

### **PFS RECOVERY: →Data Mover Panicks with bad Clariion sector**

#### **Server\_log:**

2006-07-24 09:40:55: CAM:3: I/O Error: c96t117 Irp Oxbb711104 CamStatus Ox84 SesiStatus 0x02 Sense **0x3/0x11/0x00**

#### **Dump Header:**

PANIC in file ..BVolumeIrp.cxxx at line: 323: IO failure on Vol: 271, blkNo:36048, SKey: 0x311

271 is volume number; 36048 is physical sector triggering anic, and 0x311 is the Clariion Sense Error

#### **Sys\_log:**

UFS: 3:7:Slot\_2 Mount failed, Please start Revectoring using “revector start vol=449”

**Note:** Approximately 4 minutes total for the timeouts to trigger Data Mover panic

Step 1. Must run the Revector Utility against the affected volume referenced in the sys\_log—remaps bad sectors & 0’s out

### **\$ .server\_config server\_2 “revector start vol=xxx”**

**Note:** Tool also creates a textfile report placed in rootfs, later used by MapBlock utility. Revector command should work, but affected volume must be available to Data Mover. If command fails, use \$ server\_mount server\_x -v to establish db link to fs for DM Step 2. Monitor Revector work until completed:

### **\$ .server\_config server\_2 “revector display vol=xxx”**

**Note:** Output will display progress and then “No Revectoring session found...” when process completes

Step 3. Remount file system on Server to initiate FSCK & MapBlock Report

\$ server\_mount server\_2 fs1 /fs1

**Note:** Remounting the file system will kick off an auto-fsck and the MapBlock utility using information found from revector report to complete work and output list of files affected

### **CHECKPOINT, REPLICATION, FS COPY RECOVERY:**

Replication & Checkpoints will become Inactive on affected production file systems, and FS\_Copy will abort

1. Use revector tool against pfs & recover file system
2. Create new pfs checkpoint and then refresh any others (fs\_ckpt fs1 –list should show checkpoints going from INACTIVE to %)
3. Abort and then restart fs\_copy
4. Abort Replication and Playback services (Source/Target sides) and restart replication

→Printstats command for sysstat data—(19) Data Mover statistics can be collected via snapshots—not a public tool

### **NAPA 4:**

NAS 5.5.24.2, November 2006

→NS & NSX support for CX3-20c & CX3-40c CLARiiON iSCSI platforms with 4-Front-End IO ports (Flare 22 with special SW Enabler)

→CIFS Troubleshooting tool: server\_cifssupport

→Large Major & Minor Device numbers (32-bit up to 4G values)

→NS80 Celerra Hammerhead Integrated Platform using direct optical fibre connections to CX3-80 array (Blades & SP’s have built-in SFP connectors), replacement for NS702/704; 2-4 DM’s or 1-2 CS’s; Chivas CS (same as NSX); either XB-60 or XB-65 Data Mover blades; SP’s will use a Nor’easter Management Module with each SP on a separate network and vlan (192.168.1.200/192.168.2.201), and two Ethernet ports per module, one for Service and one for Customer LAN; the NAS Management Modules are built into the Typhoon board

**Note:** The SP Resume PROM personality should be set to “SAN”. This is referred to as an Integrated Celerra that runs in SAN mode vs. AUX, mainly due to the use of LC-to-LC fibre optic cables between DM & SPs.

### **SERVER CIFSSUPPORT TOOL:**

The server\_cifssupport tool was developed as a troubleshooting aid for EMC Support and its Customers. Its primary focus with the 5.5.24.2 release is to assist in troubleshooting various CIFS issues. The tool is comprised of several different segments, and depending on the nature of the issue being investigated, different switches and associated options may be selected. The four major sections are -pingdc, -accessright, -cred, and -secmap. When the command is run, certain output goes to screen and to the Server Log using the CIFSSUPPORT topic & other appropriate headers, such as SMB.

Specifically, the server\_cifssupport is a multi-purpose tool that can validate connectivity between CIFS Server & Domain Controllers, manage & verify access rights for Users, produce User credentials & validate mappings to Celerra, and manage Secure Mapping cache (SecMap)

#### Documentation:

Server\_cifssupport not documented in Release Notes, Doc CD, or Man Pages

“Using the Celerra server\_cifssupport Command Rev A01” (Powerlink Customer Service document)

Tool not published for customers, but there is no reason that customers cannot be made aware of this tool for their own troubleshooting, etc.

#### Example Server Log Heading:

2006-10-25 09:36:38: CIFSSUPPORT: 4: pingDC compname=sector DC=GEORGE Step='Lookup trusted domains' OK

#### I. \$ server\_cifssupport -pingdc -compname or -netbios -dc -verbose

The -pingdc switch is used to validate the current status of the CIFS server in the declared Windows Domain, and processes a series of checks each time the command is run. Warnings and Errors are outputted to screen for the appropriate check when an Error or Warning condition occurs. When using the -verbose switch, output of the tests, are logged to the Server Log under the CIFSSUPPORT heading. Pingdc verifies CIFS and DC connectivity. The following actions are tested whenever the pingdc command is run, for either the compname or netbios name indicated, and to the specific DC if stipulated, with additional information written to the Server Log if the -verbose switch is used:

#### Actions Taken by Command—from TTT Documentation:

- DC availability from WINS or DNS
- DC connectivity via CIFS ports and ICMP ping
- Compname Join status with the domain
- Server authentication with a DC
- Access to the IPC\$ share
- Access to NETLOGON pipe for NTLM authentication
- Access to LSA pipe for mapping SIDs to Users and Groups
- Access to SAMR pipe for merging UNIX & Windows groups when using NTCredential option
- Status of trusted domain queries
- Status of privilege name queries such as those used with I18N in Usrmgr

**Note:** The test will stop upon the first Error, but will continue if only Warnings are received

#### Actions Taken as Shown by Server Log:

2006-10-25 09:43:32: CIFSSUPPORT: 4: Starting test Pre-conditions  
2006-10-25 09:43:32: CIFSSUPPORT: 4: Starting test Test-setup

2006-10-25 09:43:32: CIFSSUPPORT: 4: pingDC compname=sector DC=GEORGE Step='Lookup trusted domains' OK

2006-10-25 09:43:32: CIFSSUPPORT: 4: End of test Lookup trusted domains

**Example of Error seen when Administrator cannot be Mapped:**

# server\_cifssupport server\_2 -pingdc -compname sector -verbose

server\_2 : done

Error 13160939577: server\_2 : pingdc failed due to NT error INVALID\_ID\_AUTHORITY at step LSA lookup mappings

**Note:** Would mean that there is a mapping issue. To recreate the problem, stopped the Usermapper service and removed the SecMap cache entry for Administrator, as this is the default account that is used by pingdc for the LSA Lookup test.

**Example of Error seen when Compname has not been Joined:**

# server\_cifssupport server\_2 -pingdc -compname nobody -verbose

Error 13160939589: server\_2 : The server has not been joined to domain Active Directory.

**II & III. \$ server\_cifssupport -cred -name -domain -sid -uname -uid -build [-admin] -netbios -compname -standalone & -accessright**

The -cred switch allows the Administrator or troubleshooter to build a Windows or Unix credential for a particular User, useful for determining how the Celerra has resolved the User's Security Access Token, Group Memberships, Unix permissions, and GPO privileges, into a mapping of credential information. This tool also uses the -build option to create a credential when the User is not physically connected to the Celerra.

**The following actions are tested when using the -cred switch:**

**\$ server\_cifssupport -cred -name mcdougal -domain 2k3 -build -admin administrator**

→Build either a Windows or UNIX User credential to see if cred build & resolution are correct (No requirement for User or Client logon). Use the -admin switch with the -build option, if you know an Administrative User account—this will allow ability to obtain output even if the Compname is invalid. Credential is printed for review. -ldap switch used to resolve any Universal Groups found.

**Note:** It should be noted that the -build will force a mapping if a mapping does not already exist, and that if using local passwd/group files or NIS for the source of mappings, the CIFS Resolver param should be set to 1 to ensure that both “user & “user.domain” are

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
queried—if not used, it would be possible that the desired account would not be queried by name and if Usermapper were running, would result in an unintended mapping. For example, NIS has user defined as “user” but with CIFS resolver set to default 0, DART will only look for “user.domain”, NIS mapping would fail, and Usermapper would create a new mapping for “user.domain”.

**Example of Windows User:**

**# server\_cifssupport server\_2 -cred -name backup -domain 2k3 -build**

server\_2 : done

**# server\_cifssupport server\_2 -cred -uname tom -build**

server\_2 :

Error 5005: server\_2 : The user tom doesn't exist.

**Note:** Example of error that would be seen when the User cannot be found in NIS or local passwd file

**# server\_cifssupport server\_2 -cred -uname tom**

server\_2 :

Error 5005: server\_2 : The UNIX user tom has no credential in the cache

**Note:** User is found but is not connected/or does not have an NTCredential in the cache

**# server\_cifssupport server\_2 -cred -uname tom -build**

server\_2 : done

**Note:** User is found and a UNIX Credential is created for the UNIX user using the –build option. Keep in mind that eventhough the User was found in the local passwd file and a credential was created, the user is not added to Secmap cache as a result of this mapping.

**User access to files or shares are tested using the –accessright switch. Accessrights can be checked against all the various file system accesspolicies:**

**\$ server\_cifssupport -accessright**

The –accessright switch can be used to verify the effective access rights for Users to specific Shares, or specific Directories and Files, both from a Windows and Unix context. When using the -build option, this tool can evaluate access rights even when the User is not connected to the Celerra. When using the -policy option, this tool allows Administrators to evaluate the effects on access rights that may vary depending on the Celerra AccessPolicy in effect on the file system [e.g., NT, UNIX, SECURE, NATIVE, MIXED, MIXED\_COMPAT].

**ACCESS MASK VALUES:**

Whenever the –accessright command is run for Windows Users, an Allowed Mask is generated that essentially summarizes what DART will provide as the effective accessright to the Share or Files provided in the –path statement. DART compares the access mask to the masks contained in the ACE entries, looking for bits that match, when granting or restricting access:

**How do we translate the mask into accessrights?**

- 1.) From visual inspection of Windows permissions via Explorer interface
- 2.) Each value is outputted by the command in human readable form too—see example below
- 3.) Can also translate Mask into Windows permissions (if you know how)

**MASK EXAMPLE:**

**# server\_cifssupport server\_2 -accessright -name thomas –domain 2k3 -path /sector/thomas -build**

Path : /sector/thomas

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!

Allowed mask : **0x301ff** →32-bit binary access mask value in hex, which translates to 11000000011111111 binary

Action : List Folder / Read data  
 Action : Create Files / Write data  
 Action : Create Folders / Append Data  
 Action : Read Extended Attributes  
 Action : Write Extended Attributes----output abridged-----

### **BITS 0-31 DEFINED:**

Bits 0-15 are considered low-order bits used for object specific access rights

Bits 16-22 are the bits used to define Standard Access Rights

DELETE is used to delete an object

READ\_CONTROL is the right to read an object's SD information

SYNCHRONIZE allows the object to use synchronization and allows threads to wait for the correct state

WRITE\_DAC is the right to modify DACL in the SD of the object

WRITE\_OWNER is the right to change the owner in the SD of the object

Bit 23 →Identifies the object's SACL, or System Access Control List, used for auditing purposes only—sets or gets SACL

Bits 24-27 are reserved & not used

Bits 28-31 →Used to define Generic Access Rights & are considered the high-order bits in the access mask

GENERIC\_ALL is used to indicate Read, Write, & Execute access

GENERIC\_EXECUTE is used to indicate Execute access

GENERIC\_READ indicates read access

GENERIC\_WRITE indicates Write Access

```
$ server_cifssupport -accessright -name -domain -sid -uname [uid] -path [-share] -policy [mixed, native, secure, nt, unix] -build [-admin] -compname -standalone
$ server_cifssupport -accessright -name jamoke -domain 2k3 -share public -build
$ server_cifssupport -accessright -sid S-1-5-15-597e341a-ce8e74d1-46b -path /fs1/homedirs/joe -build
$ server_cifssupport -accessright -name harry -domain 2k3 -path /fs1/homedirs/harry -build -policy unix
# server_cifssupport server_2 -accessright -name james -domain 2k3 -path /sector/tmatta -build
```

 Action : Delete Subfolders and Files  
 Action : Read Attributes  
 Action : Write Attributes

Action : Delete

Action : Read Permissions

→Accessrights to files, directories, & shares using Windows mask

#### **IV. \$ server\_cifssupport -secmap -report -list [-name -domain -sid -uid -gid] -create [-name -domain -sid] -verify [-name -domain -sid] -update [-name -domain -sid] -delete [-name -domain -sid] -export [-file <filename>] -import**

The -secmap switch allows Administrators to verify and export the contents of the SecMap cache database, useful when trying to resolve UID/GID mapping or permissions issues. The tool also allows the ability to delete database entries, modify entries, add entries, etc. Please keep in mind that the SecMap cache is a persistent repository of the first time that a SID-to-UID/GID mapping occurred on the Data Mover or VDM Server, and records where the mapping entry originated from [e.g., NIS lookup, Usermapper lookup, etc Passwd file lookup, etc]

##### **EXAMPLE OUTPUT:**

**# server\_cifssupport server\_2 -secmap -list**

server\_2 : done

SECMAP USER MAPPING TABLE

| GID | : | 32768 |
|-----|---|-------|

**# server\_cifssupport server\_2 -secmap -create -name percy -domain 2k3**

server\_2 : done

#### SECMAP USER MAPPING TABLE

| UID                                     | Origin     | Date                     | Name      |
|-----------------------------------------|------------|--------------------------|-----------|
| SID                                     |            |                          |           |
| 32771                                   | usermapper | Fri Oct 20 17:54:58 2006 | 2K3\percy |
| S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4c5 |            |                          |           |

**# server\_cifssupport server\_2 -secmap -verify -name thomas -domain 2k3.pvt.dns**

server\_2 : done

**Note:** Apparently, all the verify command does is tell you whether the name or sid is in the database, but doesn't give you any details.

**# server\_cifssupport server\_2 -secmap -update -name percy -domain 2k3**

server\_2 : done

**Note:** Update command can be used to update entries in secmap with values stored in the mapping source, then performs ACL update on file systems(?). Also used to update records with specified domain and SID entries.

**# server\_cifssupport server\_2 -secmap -delete -name percy -domain 2k3**

server\_2 : done

**# server\_cifssupport server\_2 -secmap -delete -name "Domain Controllers" -domain 2k3**

server\_2 : done

**Note:** To delete names that have spaces, use quotations

**# server\_cifssupport server\_2 -secmap -export -file sec\_dmp**

server\_2 : done

**# cat sec\_dmp**

S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-200:2:96:8002:8002:2K3\Domain Admins

S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-4da:1:96:8001:8000:2K3\backup

**Note:** Unfortunately, the dump does not separate into Users and Groups like the list function does.

**# server\_cifssupport server\_2 -secmap -import -file sec\_dmp**

server\_2 :

Error 5005: server\_2 : Unexpected MAPPING\_RECORD element in Import request

**Note:** Could not get the import function to work at all—this is a known bug

#### REMOVING ENTIRE SECMAP CACHE WITHOUT STOPPING CIFS:

```
$ server_cifssupport server_x -secmap -list |grep "S-1" | sed 's/S-1@/ /' | awk -F '@'{printf "S-1%s\n", $2}' |xargs -i  
$ server_cifssupport server_x -secmap -delete -sid {}
```

#### USING SERVER PARAM AND DISABLING SECMAP CACHE:

**# server\_param server\_2 -facility cifs -info secmap.enable**

server\_2 :

|                  |                                           |
|------------------|-------------------------------------------|
| name             | = secmap.enable                           |
| facility_name    | = cifs                                    |
| default_value    | = 1                                       |
| current_value    | = 1                                       |
| configured_value | =                                         |
| user_action      | = restart Service                         |
| change_effective | = restart Service                         |
| range            | = (0,1)                                   |
| description      | = Control CIFS Secure Mapping cache state |

**# server\_param server\_2 -facility cifs -modify secmap.enable -value 0**

server\_2 : done

Warning 17716815753: server\_2 : You must stop and start cifs for secmap.enable changes to take effect

#### NAPA 5:

NAS 5.5.26.4 ETR Jan 25, 2007

→ RAID5 4+1 & 6+1 Support for LCFC & SATA II drives, but only for CX3 arrays

→ Support for new Dewars Control Station (Possibly released with GNapa instead, hard to determine exactly)

→ Flare 24 Mars support, and support for CX3-20F/CX3-40F arrays in Gateway configurations

→ Support added for new Headhunter IO module on backend arrays CX3-20F & CX3-40F for Gateway systems--adds (4) FC front-end ports on Jackhammer CX3-20F arrays [total of (12) front-end fibre ports and (6) backend fibre ports], and Sledgehammer CX3-

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
40F arrays [total of (4) front-end fibre and (4) backend fibre ports]. Headhunter is a Quad 4Gb controller using PCI express bus and FPGA for Diplexing.

**Note:** With this NAS release, CX Fish arrays are only supported for Flare 19 and higher, while CX3 Hammer arrays are only supported for Flare 22 and higher.

## **GRANDNAPA:**

A special TLC release (NAS 5.5.27.5) to port serviceability items into the product, GA 14 March 2007

### **CONTROL STATION SESSION TIMEOUT GNAPA:**

→Applies to CLI shell sessions only, with csh & tcsh governed by variable called “autologout” in minutes and bash/ksh governed by variable called “TMOUT in seconds

**EXAMPLE:** /etc/profile

```
TMOUT=3600
```

```
export TMOUT
```

→Default value will be 60 minutes and is enabled by default

#### **# /nas/sbin/nas\_config -sessiontimeout**

Session timeout value is 60 minutes

```
done
```

→Celerra Manager is not setup with a session timeout by default (480 minutes)

→Values are set in /etc/profile & /etc/csh.cshrc

**# nas\_config -sessiontimeout <minutes>** | 0 or off disables timeout

**Note:** Timeout values will be between 5-240 minutes--translated into seconds for /etc/profile & in minutes for /etc/csh.cshrc and updates appropriate config files—log off and back on for the values to go into effect

### **CONFIGURABLE LOGIN BANNER GNAPA:**

→Both login banner and MOTD (Message of the Day) will be displayed on Console, SSH, or Celerra Mgr login  
/etc/issue & /etc/motd, respectively

→NAS Upgrades will not overwrite or replace these files

→Banner is not enabled by default for SSH, nor does Celerra Mgr support any kind of Login Banner or MOTD

### **FIREWALL FRIENDLINESS GNAPA:**

Network Service management added to Celerra Manager based on services outlined in white paper, “The Celerra Network Server on the Enterprise Network”

Feature allows an Admin to Enable/Disable ‘non-essential’ services on Data Movers & Control Stations [DM will indicate reboot needed for certain services]

Changes will be logged in /nas/log/sys\_log, facility is ADMIN

### **AUTOMATIC LOG COLLECTION & TRANSFER PHASE II GNAPA:**

Adds GUI functionality for Enabling/Disabling transfer feature, not the collection portion of the feature

Adds GUI capability to collect logs, but does NOT collect dumps [GrandNapa /nas/var/log, but puts materials in /nas/var/emcsupport in Cognac NAS 5.6]

Events & Alerts posted for the LogCollect facility [nas\_event -l -f LogCollect]

### **MPFSi ENHANCEMENTS GNAPA:**

#### **Large File fix:**

→Reduces metadata logging required when writing many blocks at once, translating to less CPU overhead and less ufslog contention, as well as improved scalability

#### **Hierachical Volume Management:**

→Improves Client caching and offloads more volume tree traversals to the Client, reducing Server processing required & RPC overhead

→Enhances FMP protocol—Clients request space allocation and Server used to provide multiple extents across LUNs—improvement will be to provide only a single extent back to the Client, and the Client will determine which LUN to write to

→This enhancement requires updated Client software—LinRoad 5.0, Windows will be post-5.0

#### **CIFS Fixes:**

→More detailed info returned to FMP Client

→FMP client will use multiple interfaces for CIFS, FMP, iSCSI whereas previous behavior was to use single interface for all protocols

→Multiple CIFS hosts can be defined

### **MPFSi LINUX CLIENT CHANGES GNAPA:**

→install-mpfs script for the 4.3 Client, which will support RHEL 3 & 4, SuSE, et.al.

→New mpfsinfo validates accessibility of each file system, lists LUNs

→mpfsinq modified to show more CLARiiON information, such as active & passive paths to LUNs

/proc/mpfs/devices (devices seen by kernel)

/proc/mpfs/params (mpfs parameter values)

/proc/hrdp (HighRoad protection status)

→Persistent parameters /etc/mpfs.conf

globPrefetchSize default 128, but can increase to 2048—this determines how many blocks are returned by Server to Client allocation requests. Values changed in mpfs.conf file become persistent during reboots; use mpfscctl to update kernel memory until next reboot.

→mpfsdiscover daemon uses /etc/sysconfig/EMCmpfs file for parameters & is used to detect new devices and trespassed LUNs (every 15 minutes)

→mpfsi enhanced to be as robust as NFS and can now replay uncommitted writes after system crash—dirty pages are maintained until committed via FMP flush; replay does AllocSpace reissue, rewrites data, then does FMP flush

## **CELLERRA iSCSI SNAP/REPLICATION ON LINUX GNAPA:**

→PLU is a version file with blocks allocated on-demand

→Snaps are point-in-time version files that do not change, unless they are a TWS (one Temporary Writeable Snap), which can be modified

→Snaps are created instantaneously. New writes to PLU are written to new location. Snaps can only be promoted once, becomes RW. Newer snaps are deleted as part of the restore procedure. Snaps can be deleted in any order except for promoted & restore.

→iSCSI Replication is LUN-based vs. File System-based, with Source & Destination pair, and allows one-to-many sessions

→iSCSI Replication uses baseline copy to create common base, then incremental transfers

→iSCSI destination snaps can be promoted for Replication sessions

### **I. iSCSI SNAP CREATION & DATA OPERATION:**

→PLU LUN with data blocks B1, B2, etc

→Snap S1 created, assumes ownership of data blocks, though PLU still points to original data blocks

→New data written to PLU Lun block B1

→Modified block B1' is created and owned by PLU

### **II. iSCSI SNAP PROMOTION:**

→PLU LUN has several Snaps, of which one will be promoted

→Writeable snap for S2 created, called S2'

→S2' is given a LUN identity and promoted

### **III. iSCSI SNAP RESTORE:**

→Writeable snap for S2 created, called S2'

→S2' becomes new PLU & newer snaps are deleted

### **iSCSI REPLICATION:**

→Create Snap

→Mark Snap for replication

→Perform baseline copy of Snap to Destination LUN

→D1 snap created on destination & becomes commonbase with S1 source snap

### **Linux Platform:**

→iSCSI devices presented as regular SCSI devices on Linux, supporting RHEL 3 U5, RHEL 4 U2, SuSE SLES 9 Sp2

→iSCSI initiators 3.6.x for Linux 2.4.x & 4.0.x for Linux 2.6.x

→Install using rpm –Uvh iscsi-initiator-utils-x.x.x.rpm

→Configure initiator name /etc/initiator.name, target info /etc/iscsi.conf, service info /etc/init.d/iscsi start, setup the auto-start on boot service using chkconfig –a iscsi, session & connection status using iscsi-ls command, mount devices during boot using /etc/fstab.iscsi

### **Host Utilities (CBM=Celerra Block Management):**

# cbm\_security –c cbmadmin\* –s secret →used to configured authorized user credential

# cbm\_iscsi →List LUNs on host, detailed info, perform snapshot operations

# cbm\_replicate used for replication operations

# lun\_discover used for dynamic LUN discovery

→Configuration file /etc/cbm/cbm.conf

### **Celerra Commands:**

# server\_security server\_x –a –p chap –n cbmadmin –s secret

#server\_iscsi server\_x –lun –n 10 –create mytarget –size 100M –fs fs1 –readonly yes

# nas\_replicate

# nas\_cel –name eng001 –create 10.241.168.23 –passphrase cbmcmbcm (Dart Interconnect Authentication for Remote Replication)

**Note:** DIC password entries in DM passwd file are used only for Local or Loopback Replication authentication

### **Troubleshooting:**

/nas/var/messages

# iscsi-ls; /proc/partitions; /proc/scsi/scsi

Log Facility /etc/cbm/cbm.conf with different levels

Use server\_iscsi on CS for service, configuration, and mask information

Use nas\_replicate to verify Replication sessions

Check Server Log, looking for NBS, ISCSI, DP, VCS facilities

## **XLT CORRUPTION DETECTION & RECOVERY GNAPA:**

- CIFS issues can occur affecting Data Mover Joins, case sensitivity to Shares and pathnames, etc.
- Feature will detect XLT corruption on-disk, not DART in-memory corruption, and take automatic recovery steps
- (3) types of XLT files that DART is concerned with: Stored in rootfs etc\_common on DART & /nas/site/locale on CS  
  unidata.txt>contains upper & lowercase mappings in UTF-16 format  
  xlt.cfg>contains applicable translation information for Host/Network encodings  
  specific code pages have mappings between client locale and UTF-16
- Mechanism will be that any time that XLT files are updated (such as uc\_config –update), the files will be verified against CRC32 Checksums and stored in xlt.crc
- When corruption is detected, CS will log an event, CallHome, and copy source files from /nas/site/locale to Data Mover
- If etc\_common requires fsck, there is no easy method except to take all DMs offline

## **CLI CHECKPOINT SCHEDULING GNAPA:**

- Similar functionality as in Celerra Manager using the # nas\_ckpt\_schedule command, using 24-hour clock times
- # **nas\_ckpt\_schedule –list** [outputs all Checkpoint schedules] | **-info id=x** [outputs Checkpoint schedule for PFS] **-modify**
- Note:** -create used to create single use or recurrent checkpoints; -modify used to change active & pending schedules

### **Creating Schedule:**

# **nas\_ckpt\_schedule –create ckpt\_sched –filesystem id=x –description “my new schedule” –recurrence once –ckpt\_name <ckpt\_name> -start\_on 2007-3-17 –runtime 13:15**

**Note:** Schedules can also be created for daily, weekly, or monthly periodicity

Daily Schedule:

# **nas\_ckpt\_schedule –create –recurrence daily –end\_on 2007-12-31 –runtimes 08:00,15:00,23:00 –keep 21**

Weekly Schedule:

# **nas\_ckpt\_schedule –create –recurrence weekly –days\_of\_week Fri,Thu,Wed,Tues,Mon –runtimes 17:30 –keep 20**

Monthly Schedule:

# **nas\_ckpt\_schedule –create –recurrence monthly –days\_of\_month 1,15 –runtimes 3:30 –keep 6**

Other Options:

-delete to remove a schedule

-pause will skip the next scheduled checkpoint -resume will restart the schedule

## **CELERRA PAHC--PROACTIVE HEALTH CHECK NAS 5.5.27.5:**

**Note:** Pre & Up = PUHC; Pro = PAHC

**PAHC AUTO-CHECKUP runs every two weeks!**

### **PAHC CRON JOB:**

# **cat /nas/site/cron.d/nas\_sys|grep auto**

31 3 \* \* 7 root /nas/tools/up > /dev/null 2>&1

→In the above example, the PAHC cron fires at 3:31 a.m. every Sunday, but, the auto\_checkup script checks to see when the script last ran, and will not run unless it's been two weeks. So, it really runs the PAHC checks every two weeks, not every week as the CRON job suggests

### **/nas/tools/auto\_checkup**

```
touch /nas/site/.checkup.autorun
      /nas/bin/nas_checkup -auto > /dev/null 2>&1
    fi
    # if it is > 2 wks old, touch it and run pahc
    # otherwise do nothing
```

### **SCRIPT USED TO RUN PAHC:**

### **/nas/bin/nas\_checkup**

#### **REVIEWING CURRENT PAHC CHECK ERROR NUMBERS & MESSAGES:**

### **/nas/tools/upgrade\_check\_tools/messages.txt**

**Note:** Review the messages.txt file for verbose output of PAHC checks and messages

### **Example:**

```
~dm::check_for_excessive_memory_utilization~
--abridged----
```

3 | external | Cannot determine the memory usage status. | Run "%s" manually to investigate further. The output from the above command should be in the following format: \* "type,slot,histogram"

"cached,2,0:0:0:1629:0:0:0:0:0:0:0:0:0:0:0:2:3:4"

### **/nas/tools/upgrade\_check\_tools/checks.txt**

**Note:** Review this file to when, what NAS version, and on what platforms a check is run on

**Example:**

[\*\*/nas/tools/upgrade\\_check\\_tools/checks.txt file\*\*](#)

```
#check           | modes | start | remove | nbsacc | prim | sec | platform ~
dm::check_for_excessive_memory_utilization | pre+pro | 5.6 | | yes | no | ns+ns40+nsx+cfs ~
```

**LOGS CREATED WHEN PAHC RUNS:**

```
-rw-rw-r-- 1 nasadmin nasadmin 8803 Feb 22 03:32 checkup.090222-033102.log -->PAHC scheduled checkup
-rw-rw-r-- 1 nasadmin nasadmin 8803 Mar 8 03:32 checkup.090308-033101.log -->PAHC scheduled checkup
-rw-rw-r-- 1 nasadmin nasadmin 27403 Feb 22 03:32 .checkup_support.090222-033102.log -->PAHC scheduled checkup
-rw-rw-r-- 1 nasadmin nasadmin 27403 Mar 8 03:32 .checkup_support.090308-033101.log -->PAHC scheduled checkup
Note: When nas_checkup is run manually or as a result of a NAS Install, the word "run" is included in the filename
-rw-rw-r-- 1 nasadmin nasadmin 8803 Mar 13 16:29 checkup-run.090313-162800.log -->Manual /nas/bin/nas_checkup
-rw-rw-r-- 1 nasadmin nasadmin 27403 Mar 13 16:29 .checkup_support-run.090313-162800.log -->manual /nas/bin/nas_checkup
```

→CLI version of PAHC tool runs On-demand or at end of NAS Install from /nas/bin/

→Runs as a Cron job or from CLI on-demand [CRON=auto\_checkup; On-demand=nas\_checkup, but really calls /nas/tools/check\_nas\_upgrade using "pro" switch]

→Reports are collected by SYR

→The scheduled Cron is called the "auto\_checkup", alerts will be seen in Celerra Manager, nas\_checkup will create two logs each time it is run (one log in normal line output & one log in XML output for CallHome--system will CallHome when appropriate event)

**PAHC LOGGING:**

[\*\*# nas\\_logviewer -t /nas/log/sys\\_log |grep Scheduled\*\*](#)

Mar 8 03:32:57 2009:87519264880::Scheduled nas\_checkup has posted a warning. See /nas/log/checkup.090308-033101.log for more details.

[\*\*# strings /nas/log/webui/alert\\_log|grep checkup\*\*](#)

```
/nas/log/checkup.090208-033102.log
/nas/log/checkup.090222-033102.log
/nas/log/checkup.090308-033101.log
```

**Celerra Manager:**

Scheduled nas\_checkup posted a warning. EMC Customer Service will contact you. Please see /nas/log/checkup.Mar-11-3:34:02.log.

**Manual On-Demand Run of Nas Checkup & Logs generated (or by NAS Install script at end of a new installation):**

```
-rw-rw-r-- 1 nasadmin nasadmin 3408 Mar 22 22:38 checkup-run.Mar-22-22:36:16.log →Results of each of the 41+ checks
-rw-rw-r-- 1 nasadmin nasadmin 13808 Mar 22 22:38 .checkup_support-run.Mar-22-22:36:16.log →XML CallHome format
```

-----Warnings-----

Storage System: Check if FLARE is supported

Symptom: Backend Storage Requirements Check Failed:

REQUIREMENT: CX600\_Software >= 2.19 AND CX600\_Software < 2.25

ID: APM00030600863 FOUND: 02.16.600.5.024 INSTRUCTIONS: Upgrade Flare.

\*Action : If you are setup for Call-Home: Your EMC Service Provider will be in contact with you in order to resolve this issue. If you are not setup for Call-Home: Contact EMC Customer Service and refer to EMC Knowledgebase emc146016. Include this log with your support request.

-rw-rw-r-- 1 nasadmin nasadmin 3408 Mar 23 16:51 checkup.Mar-23-16:50:01.log  
-rw-rw-r-- 1 nasadmin nasadmin 13808 Mar 23 16:51 .checkup\_support.Mar-23-16:50:01.log

### **MANUALLY RUNNING PAHC HEALTHCHECK:**

# **/nas/bin/nas\_checkup | -drinkmoreovaltine | -debug | -auto** (don't use this from CLI) | **-help | -version**

**Note:** Run –drinkmoreovaltine switch when troubleshooting output issues, will provide suggested fixes

# **/nas/bin/nas\_checkup** [Performs checks on CS, DM, and Storage system]

#### **Control Station Checks:**

- Check if minimum free space exists
- Check if minimum free space exists ns
- Check if enough free space exists
- Check if enough free space exists ns
- Check if NAS Storage API is installed correctly
- Check if NAS Storage APIs match
- Check if NBS clients are started
- Check if NBS configuration exists
- Check if NBS devices are accessible
- Check if NBS service is started
- Check if standby is up
- Check if Symapi data is present
- Check if Symapi is synced with Storage System
- Check integrity of NASDB
- Check if primary is active
- Check all callhome files delivered
- Check if NAS partitions are mounted

#### **Data Mover Checks:**

- Check boot files
- Check if hardware is supported
- Check if primary is active
- Check if root filesystem has enough free space
- Check if using standard DART image
- Check MAC address
- Check network connectivity
- Check status

#### **Storage System Checks:**

- Check disk emulation type
- Check disk high availability access
- Check disks read cache enabled
- Check disks and storage processors write cache enabled
- Check if access logix is enabled
- Check if FLARE is committed
- Check if FLARE is supported
- Check if microcode is supported
- Check no disks or storage processors are failed over
- Check that no disks or storage processors are faulted
- Check that no hot spares are in use
- Check that no hot spares are rebuilding
- Check control lun size
- Check if storage processors are read cache enabled

→Default schedule every other Sunday at 3:30-4:00 a.m. /nas/site/cron.d/nas\_sys

**Note:** The actual trigger time in minutes is randomly assigned at install time between 3:30-4:00 a.m., so each system will have slightly different times

# cat /nas/site/cron.d/nas\_sys

**33 3 \* \* 7 root /nas/tools/auto\_checkup > /dev/null 2>&1**

### **CHANGING THE PRESET PAHC CRON SCHEDULE:**

1. vi edit the entry in /nas/site/cron.d/nas\_sys to the desired time & day
2. Remove following file:  
# rm -f /nas/site/.checkup.autorun →File exists only if scheduled job has run at least once
3. Restart cron daemon:  
#/sbin/service crond restart or # touch /etc/crontab

4. Confirm change: /nas/log/sys\_log or /nas/log/nas\_checkup.log

### **NAS EVENTS FOR NAS CHECKUP:**

#### **# nas\_event -l -a callhome |grep Checkup**

```
Checkup    221 Scheduled nas_checkup posted information. EMC Customer Service has been contacted. See nas_checkup log.
Checkup    222 Scheduled nas_checkup posted a warning. EMC Customer Service has been contacted. See nas_checkup log.
Checkup    223 Scheduled nas_checkup discovered an error. EMC CustomerService has been contacted. See nas_checkup log.
```

#### **# nas\_event -list -a callhome |grep -i checkup**

```
|-> Checkup(142)
223     ERROR(3)     Scheduled nas_checkup has discovered an error. The file ${src_file_path},8,%s} with the extension
${dest_extension},8,%s} is attached.
```

#### **\$ nas\_event -list -f Checkup (NAS 5.5)**

#### **# nas\_event -list -c CS\_PLATFORM -f Checkup (NAS 5.6 syntax)**

```
id      description
10     nas_checkup found no problems.
11     nas_checkup posted information. See /nas/log/nas_checkup-run.*.log.
12     nas_checkup posted a warning. See /nas/log/nas_checkup-run.*.log.
13     nas_checkup discovered an error. See /nas/log/nas_checkup-run.*.log.
19     nas_checkup had to exit before performing any checks.
21     nas_checkup posted information. Contact EMC Customer Service and refer to EMC Knowledgebase emc146016.
22     nas_checkup posted a warning. Contact EMC Customer Service and refer to EMC Knowledgebase emc146016.
23     nas_checkup discovered an error. Contact EMC Customer Service and refer to EMC Knowledgebase emc146016.
110    Scheduled nas_checkup found no problems.
111    Scheduled nas_checkup posted information. See /nas/log/nas_checkup.*.log.
112    Scheduled nas_checkup posted a warning. See /nas/log/nas_checkup.*.log.
113    Scheduled nas_checkup discovered an error. See /nas/log/nas_checkup.*.log.
119    nas_checkup had to exit before performing any checks.
121    Scheduled nas_checkup posted information. EMC Customer Service will contact you. See nas_checkup log.
122    Scheduled nas_checkup posted a warning. EMC Customer Service will contact you. See nas_checkup log.
123    Scheduled nas_checkup discovered an error. EMC Customer Service will contact you. See nas_checkup log.
221    Scheduled nas_checkup posted information. EMC Customer Service has been contacted. See nas_checkup log.
222    Scheduled nas_checkup posted a warning. EMC Customer Service has been contacted. See nas_checkup log.
223    Scheduled nas_checkup discovered an error. EMC Customer Service has been contacted. See nas_checkup log.
```

#### **# cat /nas/sys/nas\_eventlog.cfg**

```
# CS_PLATFORM:Checkup
#
facilitypolicy 6:142, 7
    disposition range=1-199, logfile "/nas/log/sys_log"
    disposition range=112-113, mail user
    disposition range=122-123, mail user
    disposition range=200-300 severity=3-3, callhome binary
    disposition range=301-301 severity=6-6, callhome immediate
## need to check later
```

### **Adding email notification for PAHC for Customers:**

- Add email notifications via Celerra Manager from new facility called ‘Checkup’, specify severity and mail action

- Using CLI

- check to see if checkup\_eventlog.cfg file is loaded (# nas\_event -L -i)
- If loaded, unload the checkup\_eventlog.cfg file before editing (# /nas/bin/nas\_event -Unload /nas/site/checkup\_eventlog.cfg)
- vi edit the /nas/site/checkup\_eventlog.cfg file and add email addresses [format?]
- Reload the /nas/site/checkup\_eventlog.cfg file (#/nas/bin/nas\_event -Load /nas/site/checkup\_eventlog.cfg)
- Verify that file loaded using # nas\_event -L -i
- Confirm change by posting an event for 112 or 113 (# /nas/sbin/postevent -f 142 -i 112 -s 4)

### **SAMPLE CHECKUP\_EVENTLOG.CFG FILE AFTER NAS UPGRADE:**

#### **# cat /nas/site/checkup\_eventlog.cfg**

```
# Checkup
# This file provides you an example of how to receive email notification for aut
omatic nas_checkup
# You can change the email address 'root@localhost' to your desired address
# To activate this feature, you need to run the following command
# /nas/bin/nas_event -L /nas/site/checkup_eventlog.cfg
```

```
# To disable it, you need to run the following command  
# /nas/bin/nas_event -U /nas/site/checkup_eventlog.cfg  
facilitypolicy 142,6  
    disposition range=112-113 severity=3-4, mail "root@localhost"  
    disposition range=122-123 severity=3-4, mail "root@localhost"
```

### **SYR REPORTING:**

→For NAS 5.6, search in SYR for “CS\_PLATFORM\_CHECKUP:223”

### **CELERRA SETUP WIZARD IMPROVEMENTS GNAPA:**

→Mainly just minor usability improvements, and CIFS service will start automatically after successful Join

### **XML API v2 SERVER GNAPA:**

→Ongoing effort to join the XHMP JServer interface with the APL schema, compatible with active & passive management of Celerra

→XML API v2 will be built on top of APL Middleware and JServer, used specifically for monitoring & managing Celerra

→Introduced for 3<sup>rd</sup> Party API integrations, may later replace JServer XML API V1 (aka XHMP)

→HTTP(S) will be transport between XML client and Celerra

→XML API Server talks to both APL & XHMP (JServer), all of which are run on the Control Station

→XML API will receive indications from APL objects and JServer

→XML API talks to APL for config info and for active management of Celerra components

→XML queries will be synchronous, but XML operations will be asynchronous—XML API Client will submit operation request and internal task is created on Celerra. Completed tasks will have task indication returned to XML client as an indication

→Multiple requests can be put into XML API packets:

Query—query for instances of Celerra objects

QueryStats—query for history of statistics

Task—management action requested, such as creating new file system

ScheduleTasks—scheduling of tasks

Subscribe—subscribe for indications, which will be for Stats and Tasks for Burgundy release, Clients will register and receive updates

Unsubscribe—Unsubscribe for indications

→Burgundy release of XML API will be limited and cannot do Replication, iSCSI, VTLU, Licensing, Usermapper, CAVA, HighRoad, FileMover, or CDMS APIs

→Provides for configuration info, statistics, management, and indications of changes for Celerra

→GrandNapa improvements are in iSCSI Management, support for File System auto-extension, Symmetrix queries, Clariion queries, and additional statistics

→New public API interface on Control Station using XML data carried over HTTPS & Interfaces defined using XML schema

→Protocol between Client and XML API in two parts: Request/Reply (HTTP POST) & Indications (HTTP GET)

**Note:** Currently, the XML API v2 interface is not enabled on the Celerra—will be enabled in GrandNapa

### **XML API SERVLET:**

→CelerraManagementServices servlet runs on Control Station and will listen for https requests from clients, forward to API Server, and then return results from API Server to clients

### **STARTING XML API V2 SERVER:**

**# /nas/sbin/start\_xml\_api\_server**

**# cat /nas/sys/nas\_mcd.cfg**

```
daemon "XML API Server"  
executable  "/nas/sbin/start_xml_api_server"  
optional    yes  
canexit     yes  
autorestart yes  
ioaccess    no
```

### **STOPPING XML API V2 SERVER:**

**Note:** Comment out the nas\_mcd.cfg entries and use following command to stop

**# /nas/sbin/hup\_api** [Also use to restart the server without commenting out entries]

### **XML API V2 CONFIGURATION FILE:**

#### **CONFIG FILE:**

**# cat /nas/sys/xml\_api.conf**

```
jsserver.req.server.port = 8020  
xml.api.req.server.port = 8050  
xml.api.ind.server.port = 8051  
xml.api.server.log = log/cel_api.log  
xml.api.server.log.generations = 5  
xml.api.servlet.log = log/webui/cel_api.log
```

```
xml.api.servlet.elog = log/webui/cel_api_error.log
xml.api.servlet.logmask = 0
apl.ind.server.port = 8886
xml.api.user.debug.flag = false
xml.api.user.request.validation.flag = true
xml.api.trace.apl.calls = true
xml.api.enable.indications.ext = true
xml.api.trace.apl.indications = true
xml.api.trace.user.requests = true
xml.api.quota.poll.offset = 150
```

### **/nas/sys/xml\_api.conf**

→Config file contains information on Ports used by various applications (JServer & XML API Server) & configuration params  
→Any changes to the config would require restart of the XML API v2 Server  
→Port 8020 is JServer port used by Celerra Monitor, Celerra Manager Tomcat servlet, and XML API Server  
→Port 8050 is XML Server port used in socket creation for sending Tomcat servlet requests, & Indications from JServer, to XML Server  
→Port 8051 is XML Server port used in socket creation for receiving Tomcat servlet indications from XML API Server

### **# cat /nas/sys/xml\_api.conf**

```
# This file defines properties that are used by Tomcat servlet component,
jsrver.req.server.port = 8020
xml.api.req.server.port = 8050
xml.api.ind.server.port = 8051
xml.api.server.log = log/cel_api.log
xml.api.server.log.generations = 5
xml.api.servlet.log = log/webui/cel_api.log
xml.api.servlet.elog = log/webui/cel_api_error.log
xml.api.servlet.logmask = 0
apl.req.server.port = 9824
apl.ind.server.port = 8886
xml.api.user.debug.flag = false
xml.api.user.request.validation.flag = true
xml.api.trace.apl.calls = true
xml.api.enable.indications.ext = true
xml.api.trace.user.requests = true
xml.api.quota.poll.offset = 150
```

### **XML API V2 Log Files:**

/nas/log/webui/cel\_api.log (Servlet log file)  
/nbsnas/log/webui/cel\_api\_error.log (Servlet log file)  
/nas/log/cel\_api.log (Server log file, logs requests from XML users, requests & replies to APL, & APL indications received)

### **XML API V2 JAR FILE:**

### **/nas/api**

```
# ls -la
-rw-rw-r-- 1 root    sys      308232 Dec 19 21:37 api_server.jar
-rw-r--r-- 1 root    root        0 Jan 14 02:21 jvm.err
-rw-r--r-- 1 root    root        0 Jan 14 02:21 jvm.out
```

**Note:** If XML API V2 Server fails to restart after 3 tries, an “api\_retry” file is created in /nas/api—retries every 20 minutes

### **XML API V2 Server Processes:**

### **# ps fax|grep api**

```
2220 ? S 0:00 \_ /bin/sh /nas/sbin/start_xml_api_server
```

### **# ps fax |grep java |grep -i xmx180**

```
2240 ? S 0:07 \_ /usr/java/bin/java -server -Xmx180m -Xss10485
2337 ? S 0:00 \_ /usr/java/bin/java -server -Xmx180m -Xss1
2339 ? S 37:10 \_ /usr/java/bin/java -server -Xmx180m -
2342 ? S 0:00 \_ /usr/java/bin/java -server -Xmx180m - [many more processes running]
```

### **Special Debug Flags for xml\_api.conf that are not enabled by default:**

xml.api.user.debug.flag →Java stack traces  
xml.api.trace.apl.calls →logs requests & responses to APL  
xml.api.trace.apl.indications →logs indications from APL  
xml.api.trace.user.requests →logs XML API user requests

## **CLARIION SECTOR ERROR PHASE I PRIME GNAPA:**

- Flare 19 Patch 030 minimum
- Data Mover will panic for 03/11 error but not failover, and will reboot and recover—only affected fs will be <unmounted>
- Key point is that the list of BadBlocks is obtained directly from CLARiiON, and the cse\_recover uses CLARiiON to repair
- Repair using “cse\_recover server\_x bvid=x phyblkno=yyy” derived from panic string, sys\_log, or “mepanic dump” output
- Note:** cse\_recover will require Username & Password to activate if Clariion security is set
- Run fsck (includes MapBlock—maps logical blocks to actual objects in file system)
- Remount file system
- Create new Checkpoint and then refresh others (if Checkpoints are involved)
- Abort replication session on each side, then restart from scratch
- Provide Report.txt to customer

### **# /nas/sbin/cse\_recover**

```
*****/nas/sbin/cse_recover version 2.0 *****  
* Usage: /nas/sbin/cse_recover  
    <movername>  
    bvid=<Basic_LUN_number>  
    phyblkno=<Bad_block_number>  
*****
```

## **CELERRA SUPPORT FOR SECURE CLI:**

- 5.5.27.5 supports navisecli on Gateway Celerras (when used by the Clariion environment)
- 5.5.30.4 supports navisecli on Integrated Celerras (sets up Array security domain on new installs)
- Beginning with 5.5.30, /nas/sbin/navicli has become a link which calls /nas/sbin/nas\_navi. The nas\_navi executable checks for local security files on the Control Station (/nas/site/.clar\_security or /etc/.clar\_security), and if finding the username and password entries, will pass the appropriate credentials to the array via /nas/opt/Navisphere/bin/navisecli. If the local CS security cache files are not present, the nas\_navi command will route the command to /nas/sbin/classic\_navicli.

### **Debugging Issues:**

```
# export SYMAPI_DEBUG=-1  
# export SYMAPI_DEBUG_FILENAME=/tmp/symapi_debug.log  
# /nas/symcli/bin/symcli
```

Symmetrix Command Line Interface (SYMCLI) Version V6.4.2.17 (Edit Level: 845)  
built with SYMAPI Version V6.4.2.17 (Edit Level: 845)

```
# /nas/sbin/navicli -help |head -3
```

@(#)Navisphere CLI Revision 6.26.0.5.1 for Linux on 8/20/2007 8:12:01

Copyright (c) 2007 EMC Corporation. All Rights Reserved

Release (output) level: 26 (17):

## **SECURE NAVICLI SUPPORT GNAPA:**

- GNapa 5.5.27 Gateway systems support Secure CLI, Secure Navi, navisecli, etc.—Integrateds will support with Napa 8 release (5.5.30)

**Note:** /nas/sbin/navicli is replaced after GNapa upgrade with nas\_navi executable. nas\_navi will be used to check for cached credentials on the Celerra, read the username & password, fill in the credentials, then send Secure CLI commands to array (/nas/sbin/navisecli)

```
-rwxr-xr-x 1 root root 1691996 Jan 16 10:20 nas_navi
```

```
lrwxrwxrwx 1 root root 8 Feb 2 15:14 navicli -> nas_navi
```

- Flare 19 introduced the Secure Navi (navisecli) commandset based on the Navisphere 6.x security model (role-based management; auditing; SSL protection; centralized account management)—provides for connection security to arrays using navisecli

→Replacement for the less secure Classic NaviCLI

→Celerra will cache the Global username and password on the Control Station during install using encryption

→Use # nas\_storage –modify –security to setup or change authentication to Clariion backends

→Integrated System would not normally require the use of CLARiiON username and password—will use the Classic NaviCLI

→Navisecli is only used or required if the Backend has security initialized

→Navisecli will be located in following directories: /nas/opt/Navisphere/bin/navisecli; /nas/sin/navisecli; /nasmcd/sbin/navisecli

→For installs, only the boot CLARiiON will require security—additional backends will have security setup afterwards

### **Using /nas/sbin/navisecli (Host-based) Commands:**

Storage systems will not allow the use of Host-based Secure CLI (navisecli) commands unless a security file is created on the array with either a Global or Local context (0, 1 respectively). For Global security, the username, password, & scope must match that of the Domain security account. Use the -AddUserSecurity to create the security file for the user account on the Host running the SecureCLI

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
commands. When running naviseccli commands from the Celerra Control Station, with or without an array security model in place, the user would have to add the CS Host to the array security file using –AddUserSecurity.

## **FLARE 28 BEHAVIOR:**

There are situations where the security information on the array has been damaged or otherwise removed, that may subsequently cause navicli commands to output the following Error, particularly if changing the IP Addresses on the SPs, or using the nas\_raid –s script to perform a backend cleanup:

**# ./navicli -h 128.221.252.200 networkadmin -get**

Error 12031: CLARiiON 128.221.252.200 running FLARE R28 requires security for "navicli" commands.

See emc211557 and AR141973. The solution should be to run nas\_storage –modify id=x –security to recreate and synchronize the array security information in the Celerra security cache files (.clar\_security) and update the storageAPI password in /nas/symapi/config/emcpwddb.dat file. Alternatively, running **/tftpboot/bin/setup\_clariion\_security <spa\_ip> <spb\_ip> nasadmin nasadmin -initialize** should also work.

## **REINITIALIZING ARRAY SECURITY DOMAIN:**

**Note:** In some cases the security domain may need to be destroyed on the array, then re-created, before the Celerra can authenticate with the Array

1. Open a web browser and go to the setup page for SP A:  
[http://<Current\\_IP\\_Address\\_of\\_SP\\_A>/setup](http://<Current_IP_Address_of_SP_A>/setup)
2. Scroll to the bottom of the screen and click Destroy Security and Domain Information.
3. A warning screen will appear. Select Yes and click Submit to reset the security and domain information for SP A.
4. Wait for the management server to stop and then restart.
5. Go back to the setup page for SP A:  
[http://<Current\\_IP\\_Address\\_of\\_SP\\_A>/setup](http://<Current_IP_Address_of_SP_A>/setup)
6. Scroll down and click Restart Management Server.
7. A warning screen will appear. Select Yes and click Submit to restart the management server.
8. Repeat the previous step to reset the security and domain information for SP B.
9. After the management server has been restarted on SP B, the array's security and domain information will be in an un-initialized state, similar to the way it is shipped from the factory.
10. Change IPs on the SPs (if required)
11. Use Navisphere Manager to connect to SP A and re-create the Domain Security domain
  - a. The “Confirm: Navisphere Security” dialog box opens, indicating that global security is not initialized. Select Yes to reinitialize the array's security settings.
  - b. Enter the global user name and password that was originally in use on the array.
  - c. Log in to the array with the user name and password you just entered.
  - d. From the Navisphere Manager main menu, select File > Set Up Domain > Select Master. The Select Master dialog box appears.
  - e. Highlight the IP address of SP A and click OK.

## **IMPLEMENTING THE CLARiiON DOMAIN SECURITY MODEL ON CELERRA**

### **INTEGRATEDS & GATEWAY SYSTEMS:**

Beginning with NAS 5.5.30, all NS20, NS40, NS350, NS80 integrateds will install and setup the Clariion Domain Security model, using a default username “nasadmin” and password “nasadmin”. Additionally, the Clariion User account and Password information is cached on the Celerra Control Station in the form of a /has/site/.clar\_security file, which is then used internally by the Control Station to authenticate to the array in support of the Secure NaviCLI model.

**# /tftpboot/bin/setup\_clariion\_security <spa\_ip> <spb\_ip> nasadmin (user) nasadmin (password) –initialize**

**Note:** -initialize found with 5.5.32, and 5.6.36 and above

**# nas\_storage –modify <array\_ID> –security –username nasadmin –password nasadmin**

In addition, any password changes to the backend that may be made as a result of the CSA configuration process, are synchronized on the Celerra Control Station using nas\_storage –modify –security. An unresolved issue is that the Clariion security model has not been implemented on any Integrated system installed prior to 5.5.30, unless someone has consciously setup Clariion Domain security after the initial installation.

**Typical Symptoms when Array security has not been established on an Integrated System:**

**nas\_diskmark, server\_devconfig, or Celerra Manager "Rescan" disk discovery operations fail:**

**ERROR: 3501: Storage API Code=3593: sysmapi\_C\_clariion\_load\_error**

\$ nas\_storage -c -a

Discovering storage (may take several minutes)

**Error 3501: Storage API code=3593: SYMAPI\_C\_CLARIION\_LOAD\_ERROR**

An error occurred while data was being loaded from a Clarion

**# /nas/sbin/navicli -h 192.168.1.200 getcrus**

SPE3 Invalid Enclosure

```
Invalid SP State: Present
Invalid SP State: Present
Invalid Power State: Present
Invalid Power State: Present
Invalid Power State: Present
Invalid Power State: Present
Invalid SPS State: Present
Invalid SPS State: Present
Invalid SPS Cabling State: Valid
Invalid SPS Cabling State: Valid
```

**Note:** Please see emc193775 (AR122612) for guidance on permanently implementing Array security after upgrading to NAS 5.5.32.4 or higher. See emc194888 for an interim procedure for setting up Navisecccli security for use with the SYMAPI on systems prior to 5.5.32. See emc203143 if implementing CLARiiON security for the first time on Celerra Integrateds running NAS 5.5.37+ or 5.6.40+ (AR122612).

**UPDATING/CHANGING/SYNCHRONIZING INTEGRATED ARRAY SECURITY INFORMATION:**

The preferred method to use for changing the array security account password on the Integrated platform is to use the following syntax, since this will automatically change the password on the array while simultaneously updating the Control Station security cache files (.clar\_security) and symapi database password (emcpwddb.dat):

**# nas\_storage -modify id=1 -security -username nasadmin -password nasadmin -newpassword <passwd>**

If you simply want to synchronize the Celerra security cache and symapi db with the password on the array, without changing the array password, use the following command:

**# nas\_storage -modify id=1 -security** (enter username and password at the prompt)

If the User wants to use Navisecccli commands directly via Control Station CLI, you must either specify the array security account name and password as part of the command syntax, or perform a one-time add of the local host information to the array security file, using the following commands, respectively:

**# /nas/sbin/navisecccli -h 10.241.168.183 -user nasadmin -password nasadmin -scope 0 <command>**

**# /nas/sbin/navisecccli -h 10.241.168.179 -AddUserSecurity -scope 0 -user nasadmin**

**I. IMPLEMENTING THE CLARiiON DOMAIN SECURITY MODEL ON PRE-5.5.32.4****INTEGRATEDS (emc194888):**

1. Enable CLARiiON Navisecccli authentication for the SYMAPI using the user nasadmin with password nasadmin:

```
# /usr/symcli/bin/symcfg authorization add -hostname 192.168.1.200 -username nasadmin -password nasadmin
# /usr/symcli/bin/symcfg authorization add -hostname 192.168.2.201 -username nasadmin -password nasadmin
```

2. Set correct permissions and ownership on the SYMAPI password file:

```
# chmod 664 /nas/symapi/config/emcpwddb.dat
# chown nasadmin:nasadmin /nas/symapi/config/emcpwddb.dat
```

```
# ls -la emc*
```

```
-rw-rw-r-- 1 nasadmin nasadmin 230 Aug 12 12:35 emcpwddb.dat
```

3. Confirm the effectiveness of the workaround:

**# nas\_storage -check -all**

Discovering storage (may take several minutes)

done

4. Verify the SYMAPI security credentials:

**# /usr/symcli/bin/symcfg authentication list**

| Hostname      | Username | Namespace | Port |
|---------------|----------|-----------|------|
| 192.168.1.200 | nasadmin |           |      |
| 192.168.2.201 | nasadmin |           |      |

5. At the customer's convenience, schedule a NAS upgrade to 5.5.32 or later, then implement the fix to permanently setup the Array Domain Security Model using emc193775 (applies to NAS 5.5.32-5.5.36 or 5.6.36-5.6.39) or emc203143 (applies to NAS 5.5.37+ or 5.6.40+).

**Note:** One of the byproducts of this issue is that the getcrus command may still show “Invalid” states for components. If this is seen, enable IP Forwarding:

```
# /nas/sbin/navicli -h 192.168.1.200 getcrus
SPE3 Invalid Enclosure
Invalid SP State: Present
# echo 1 > /proc/sys/net/ipv4/ip_forward
# cat /proc/sys/net/ipv4/ip_forward
1
```

## **II. IMPLEMENTING THE CLARiiON DOMAIN SECURITY MODEL ON 5.5.32-5.5.36, or-5.6.36-**

### **5.6.39 INTEGRATEDS (emc193775):**

1. Login to the Control Station as nasadmin, then su to Root.
2. Check for the existence of the /tftpboot directory on the Control Station:

```
# cd /
# ls -->look for the tftpboot directory in the ls output
tftpboot
```

3. If the tftpboot directory is not present, create the directory by using the following utility (otherwise continue to Step 4):

```
# /nasmcd/sbin/t2pxe -tftp start
```

```
=====
EMC NAS PXE-BOOT Setup
=====
```

Starting TFTP Service...

Done.

4. Enable CLARiiON security using the following example (SP IP Addresses may be different--verify IP addresses in the /etc/hosts file):

```
# /tftpboot/bin/setup_clarion_security 192.168.1.200 192.168.2.201 nasadmin nasadmin -initialize
```

**Note:** No output returned by command. The -initialize option is new with 5.5.32, and sets up the Array account, then creates the .clar\_security cache files on the Control Station. It does not, however, update the emcpwddb.dat cache, which is the reason why nas\_storage -m -s needs to be run in Step 5. Beginning with NAS 5.6.40, the nas\_storage -m -s command will be able to create an Array account for Integrated and FC-Enabled models, and also update the .clar\_security and /nas/sympapi/config/emcpwddb.dat files

5. Synchronize the CLARiiON Security credentials with the Celerra Control Station cache files:

```
# nas_storage -modify <array_id or name> -security -username nasadmin -password nasadmin
```

Setting security information for SL7E1080700121

done

**Note:** Use nas\_storage -l to identify Array ID or Name

6. If t2pxe was used to create the tftpboot directory, stop PXE services now:

```
# /nasmcd/sbin/t2pxe -tftp stop
```

```
=====
EMC NAS PXE-BOOT Setup
=====
```

Stopping TFTP Service...

Done.

7. Verify that the array security credentials have been properly established and run nas\_storage -check -all:

```
# /nas/sbin/navicli -h 192.1.4.231 security -list
```

Username: nasadmin

Role: administrator

Scope: global

```
# nas_storage -info id=1 |grep -C1 username
```

authenticated = True

username = nasadmin

```
# nas_storage -check -all
```

Discovering storage (may take several minutes)

Done

## **III. IMPLEMENTING THE CLARiiON DOMAIN SECURITY MODEL ON NAS 5.6.40+ or 5.5.37+**

### **INTEGRATEDS (emc203143, AR122612):**

1. Setup the array security model on the Integrated Celerra

```
# nas_storage -modify id=x -security -username nasadmin -password nasadmin
```

**Note:** Beginning with NAS 5.6.40.0 and 5.5.37.0, the nas\_storage -m -s command will create the Array account (if it doesn't exist) for Integrated and FC-Enabled models, and also updates the appropriate Celerra cache files--clar\_security and /nas/sympapi/config/emcpwddb.dat

## 2. Verify

```
# /nas/sbin/navicli -h 192.1.4.231 security -list
```

Username: nasadmin

Role: administrator

Scope: global

## **IV. IMPLEMENTING THE CLARiiON DOMAIN SECURITY MODEL ON GATEWAY CELERRAS (emc195868):**

### **Option 1:**

With NAS 5.5.27.5 and later, Celerra Gateways support the CLARiiON security model. Use the following procedures to establish security between the Celerra and the array if not already setup.

- Verify that Global Array security has already been setup on the array(s) using Navisphere or CLI (or setup now)
- Use the following command to update or create the security cache files used by Celerra to authenticate internally with the array:

```
# nas_storage -modify <storage_id> -security -username <array_admin_account_name> -password <array_admin_account_password>
```

### **Example when entering incorrect array password:**

```
# nas_storage -modify id=1 -security -username nasadmin -password nasadmin
```

Setting security information for APM00083201184

Error 3502: APM00083201184: Storage API code=4651: SYMAPI\_C\_CLAR\_NOT\_PRIVILEGED

Operation denied by Clariion array - you are not privileged to perform the requested operation

### **Example when using correct array password:**

```
# nas_storage -modify id=1 -security -username nasadmin -password nasadmin1
```

Setting security information for APM00083201184

done

### **Security and Password files updated on Celerra:**

```
# ls -la /nas/site/.clar*          -rw-rw-r-- 1 nasadmin nasadmin 276 Dec  5 12:48 /nas/site/.clar_security
# ls -la /nas/symapi/config/emcpwd* -rw-rw-r-- 1 nasadmin nasadmin 237 Dec  5 12:48 /nas/symapi/config/emcpwddb.dat
```

### **Option 2:**

For NAS 5.5.26.x or earlier, the steps to establish authentication between the Celerra and the array are different and are considered an interim fix only:

### **Interim Fix:**

- Enable CLARiiON authentication for the SYMAPI on the Celerra using the user nasadmin with password nasadmin:

```
# /usr/symcli/bin/symcfg authorization add -hostname 192.168.1.200 -username nasadmin -password nasadmin
```

```
# /usr/symcli/bin/symcfg authorization add -hostname 192.168.2.201 -username nasadmin -password nasadmin
```

- Set correct permissions and ownership on the SYMAPI password file:

```
# chmod 664 /nas/symapi/config/emcpwddb.dat
```

```
# chown nasadmin:nasadmin /nas/symapi/config/emcpwddb.dat
```

```
# ls -la emc*
```

-rw-rw-r-- 1 nasadmin nasadmin 230 Aug 12 12:35 emcpwddb.dat

- Verify communications with the Array from Celerra:

```
# nas_storage -check -all
```

Discovering storage (may take several minutes)

done

- Verify the SYMAPI security credentials:

```
# /usr/symcli/bin/symcfg authentication list
```

| Hostname     | Username | Namespace | Port |
|--------------|----------|-----------|------|
| 10.150.90.10 | nasadmin |           |      |
| 10.150.90.11 | nasadmin |           |      |

- As a permanent fix, once the system has been upgraded to 5.5.27 or later, apply the nas\_storage command to update the Celerra Security cache files. Repeat the command whenever User or Password changes are made to the array's Global Administrator account:

```
# nas_storage -modify <storage_id> -security -username <array_admin_account_name> -password <array_admin_password>
```

## **ENABLING/DISABLING CLASSIC CLI WITH FLARE 26 (emc173093):**

### **Disable ClassicCLI from Navisphere or from Naviseccli command:**

- Navisphere>arrayname>rightclick and select “Enable/Disable Classic CLI” on the fly

- From CLI:

```
# /nas/sbin/naviseccli -h 192.1.4.214 classiccli -disable
```

Do you really want to disable Classic cli(y/n) y

ClassicCLI: Disabled Succesfully

# /nas/sbin/navisecli -h 192.1.4.214 classiccli -status

ClassicCLI ENABLED: No

# /nas/sbin/navisecli -h 192.1.4.214 classiccli -enable

Do you really want to enable Classic cli?(y/n) y

ClassicCLI: Enabled Succesfully

# /nas/sbin/navisecli -h 192.1.4.214 classiccli -disable -o [Use to bypass prompt]

ClassicCLI: Disabled Succesfully

## **SYMPTOM SEEN IF CLASSIC CLI DISABLED OR IF CLARIION SECURITY CACHE FILES**

### **MISSING ON CELERRA:**

# /nas/sbin/classic\_navicli -h 192.1.4.214 getagent

Error returned from Agent

Agent denied request -- Caller not privileged.

# /nas/sbin/navicli -h 192.1.4.214 getagent

Error returned from Agent

Agent denied request -- Caller not privileged.

### **SECURITY CACHE FILES MISSING ON CELERRA CONTROL STATION:**

# nas\_storage -modify <array\_ID> -security -username <array\_admin\_name> -password <array\_password>

Setting security information for SL7E1080700121

done

**Note:** Above command recreates the /nas/site and /etc/.clar\_security files with the proper Username and Passwords for use by the Celerra when authenticating to the Backend. See emc173093 for more information.

### **NAVISECCLI EXAMPLE:**

# /nas/sbin/navisecli -h 192.168.1.200 getagent

Security file does not exist. Use navisecli -AddUserSecurity to create a security file. You must also have a valid user account on the storage system to issue this command. If you do not have a user account, use navisecli -address <IPAddress | NetworkName> security -adduser to add a user account.

**Note:** The above output means that array security is set on the backend and that the navisecli files on the array have not been updated to allow the Secure CLI to run from the Control Station. Use the following command to add the correct password to the navisecli file on the array for the Celerra, specifying the Scope, Username, and Password.

# /nas/sbin/navisecli -h 192.168.1.200 -AddUserSecurity -Scope 0 –user nasadmin

Enter password:

# /nas/sbin/navisecli -h 192.168.1.200 getagent (navisecli now succeeds)

Agent Rev: 6.22.21 (4.0)

Name: K10

Desc:

Node: A-APM00063303725

-----output abridged-----

# /nas/sbin/navisecli -h 192.168.1.200 -user emc -password emc -scope 0 getlog -h -10

**Note:** Scope 0 indicates Global security, while Scope 1 indicates Local array security—running the command for both Scopes is o.k. if unsure.

### **Dummy Celerra Issue:**

# /nas/sbin/navisecli -h 172.24.159.122 -user emc -password emc -scope 0 getlog -h -10

Date Time CRU EvtCd Event Message SnsKey XCd1 XCd2 Source

02/27/2007 18:36:46 (4640)Access is denied to Navisphere CLI called by 'dummy\_celerra' from '172.24.164.13'.

**Note:** If the Celerra needs to authenticate with the array, and a valid user and password are not cached on the CS (.clar\_security files), then the communicate will fail and result in the “dummy\_celerra” message in the SP logs. AR91272 and 5.5.28.0 addresses an issue seen with log flooding of dummy\_celerra messages.

### **Celerra Security Files for Clariion:**

→Kept in two locations: /nas/site/.clar\_security (primary source) & /etc/.clar\_security (used when /nas is unavailable)

-rw-rw-r-- 1 nasadmin nasadmin 552 Feb 2 15:33 .clar\_security

-rw-rw-r-- 1 nasadmin nasadmin 0 Feb 2 15:33 .clar\_security.lck

→The security files are synchronized at Install time, CS failover/failback, and when using nas\_storage –modify –security command

→If security files become corrupted, remove .clar\_security from both locations and run nas\_storage –modify to add back

**Note:** Celerra Manager uses the cached security credentials to log into the Storage systems that are displayed—would see “Unauthenticated” icon if security was set on Clariion but not yet updated on Celerra: Celerras>Storage>Systems><array>

## **BEHAVIOR WHEN USING AN INVALID ARRAY USER ACCOUNT FROM CELERRA:**

### **# nas\_storage -modify id=1 -security**

Enter the Global CLARiiON account information

Username: mark

Password: \*\*\*\*\* Retype your response to validate

Password: \*\*\*\*\*

Setting security information for APM00063303725

Error 3502: APM00063303725: Storage API code=4651: SYMAPI\_C\_CLAR\_NOT\_PRIVILEGED

Operation denied by Clariion array - you are not privileged to perform the requested operation

**Note:** The above error is generated when trying to modify security cache files on the Celerra when the actual user account "admin" does not exist on the array. Corrective action would be to re-issue the command using a valid array account & password, which would then update the /etc.clar\_security files on the Celerra.

### **Log Errors:**

#### **# /nas/sbin/naviseccli -h 192.168.1.200 -user nasadmin -password nasadmin -scope 0 getlog -h -5**

08/23/2007 08:34:50 (4640)Access is denied to Navisphere CLI called by 'dummy\_celerra' from '192.168.1.100'.

#### **cmd\_log**

2007-08-23 11:38:14.193 db:0:2881:S: nas\_storage -modify id=1 –security →Command starts, but never completes

#### **sympapi\_log**

2007-08-23 11:44:18.789 6694 1026 EMC:Celerra CS User Generated

Error returned from the Management Server on 192.168.1.200

Authentication failed. Possible reasons for failure are invalid security file, invalid username, password and/or scope.

2007-08-23 11:44:18.850 6694 1026 EMC:Celerra CS User Generated

/nasmcd/sbin/naviseccli -User 'mark' -Password -Scope 0 -Address 192.168.1.200 -Timeout 30 security -list -user 'mark' 2>&1

## **.clar\_security File Observations:**

### **# /nas/sbin/navicli -h 192.168.1.200 security -list**

/nas/sbin/classic\_navicli [-p] [-vlq] [-m] [-np] [-t timeout] [-h hostname] [-d device] [-help] [-f filename] CMD <optional-args>

**Note:** Above output abridged. The navicli security -list command will only work if there are properly updated local .clar\_security cache files on the Control Station, since this command requires the CS to use naviseccli in the background. Removing both sets of .clar\_security files from /etc and /nas/site directories will reproduce the above output.

### **# /nas/sbin/navicli -h 192.168.1.200 security -list**

Username: nasadmin

Role: administrator

Scope: global

### **Missing .clar\_security files will not affect the ability to run the following commands:**

#### **# nas\_storage -check -all**

Discovering storage (may take several minutes)

done

#### **# nas\_storage -sync -all**

done

## **Three Methods for changing Global Array Security Password/Role:**

1. Navisphere>Tools>Security>Change Password

### **# /nas/sbin/naviseccli -h 10.241.168.179 -user nasadmin -password Engpasswd2 -scope 0 security -changeuserinfo -user nasadmin -scope 0 -newpassword nasadmin**

WARNING: You are about to change user: nasadmin (global)

Proceed?(y/n) y

#### **Alternate Syntax:**

##### **a) # /nas/sbin/naviseccli -h 10.241.168.179 -AddUserSecurity -scope 0 -user nasadmin**

Enter password: <nasadmin>

##### **b) # /nas/sbin/naviseccli -h 10.241.168.179 security -changeuserinfo -user nasadmin -scope 0 -newpassword nasadmin1**

WARNING: You are about to change user: nasadmin (global)

Proceed?(y/n) y

### **3. # nas\_storage -modify id=1 -security -username nasadmin -password nasadmin -newpassword <passwd>**

Changing password on APM00071600514

done

**Note:** Of the (3) methods mentioned above, only the nas\_storage –modify command is recommended since it updates the password on the array, and the local /etc/.clar\_security cache files, whereas the other two methods only change the password on the array itself. The ability to change array security passwords using nas\_storage is limited to the new NS20/20FC/40/40FC models, but an NS80I can have Array security in place and use the nas\_storage –m –security to update the .clar\_security cache files.

## **ADDING OR REMOVING SECURITY INFORMATION FOR NAVISECCLI ON THE ARRAY:**

**# /nas/sbin/navisecccli -h 192.168.1.200 security -list**

Security file not found. Already removed or check -secfilepath option.

**Note:** Above message indicates that the navisecccli security is not set for the Celerra Control Station

**Resolution:**

**Adding User account(s) on the array for the Celerra CS, using Scope & Password Options:**

**# /nas/sbin/navisecccli -h 192.168.1.200 –AddUserSecurity -scope 0 -user nasadmin**

Enter password:

**# /nas/sbin/navisecccli -h 192.168.1.200 security -list**

Username: nasadmin

Role: administrator

Scope: global

**Removing User accounts from Navisecccli files on the array for Celerra:**

**# /nas/sbin/navisecccli -h 192.168.1.200 -removeusersecurity -scope 0**

**Note:** Above command will remove all Global account information from the Navisecccli security files stored on the array

**# /nas/sbin/navisecccli -h 192.1.4.214 security -list**

Security file not found. Already removed or check -secfilepath option.

## **CREATING GLOBAL ARRAY SECURITY ACCOUNT IF NONE EXISTS ON ARRAY:**

**CLI:**

**1. Create User & Initialize security using NAVISECCLI:**

**# /nas/sbin/navisecccli -h 10.241.168.179 security -adduser -user nasadmin -password nasadmin -scope global -role administrator**

WARNING: You are about to add user: nasadmin

Proceed?(y/n) y

**# /nas/sbin/navisecccli -h 10.241.168.179 domain -list**

Node: APM00083201184

IP Address: 10.241.168.179 (Master)

Name: SPA

Port: 80

Secure Port: 443

IP Address: 10.241.168.180

Name: SPB

Port: 80

Secure Port: 443

**Note:** With Flare 28, the –adduser command adds the admin user, initializes Domain security, & sets SPA as the Master

**2. Create User and Initialize security using GUI:**

Navisphere Manager>File>Initialize Security

**3. Create User and Initialize security using Celerra CLI nas\_storage command:**

**CREATE SECURITY DOMAIN, MASTER, & CELERRA CACHE FILES NAS 5.5.37+ or NAS 5.6.40+**

**# nas\_storage -modify id=1 -security -username nasadmin -password nasadmin**

Setting security information for APM00083201184

done

Info 26306750341: Security has been initialized on CLARiiON backend APM00083201184.

**Note:** Command initializes the security domain with SPA as the domain master, creates the array Global Administrator nasadmin, and updates the symapi password and security cache files on the Celerra

# ls -la /nas/site/.clar\*

-rw-rw-r-- 1 nasadmin nasadmin 276 Dec 5 13:24 /nas/site/.clar\_security

-rw-rw-r-- 1 nasadmin nasadmin 0 Dec 5 13:24 /nas/site/.clar\_security.lck

# ls -la /nas/symapi/config/emcpwd\*

-rw-rw-r-- 1 nasadmin nasadmin 234 Dec 5 13:24 /nas/symapi/config/emcpwddb.dat

## SETTING THE DOMAIN MASTER:

```
# /nas/sbin/navisecli -h 192.168.1.200 domain –setmaster 192.168.1.200
```

## ADDING AN SP TO DOMAIN SECURITY:

```
# /nas/sbin/navisecli -h 192.168.1.200 domain –add 192.168.1.200
```

## ADDING ANOTHER GLOBAL USER SECURITY ACCOUNT TO THE ARRAY:

```
# /nas/sbin/navisecli -h 192.168.1.200 –user nasadmin –password nasadmin –scope 0 security -adduser -user second_admin -password second_admin -scope global -role administrator
```

## LISTING DOMAINS:

```
# /nas/sbin/navisecli -h 192.168.1.200 domain -list
```

## DESTROYING DOMAIN SECURITY:

**Note:** Flare 28 doesn't let you remove the only Administrator account on the array, so use the following to destroy domain security & its associated Users:

### EXAMPLE:

```
# /tftpboot/bin/navisecli -h 128.221.252.200 security -messner -rmuser -user nasadmin -scope 0
```

WARNING: You are about to remove user: nasadmin (global)

Proceed?(y/n) y

Delete user operation failed. The selected user is the only global administrator.

## USE TO REMOVE DOMAIN & ALL SECURITY ACCOUNTS:

```
# /nas/sbin/navisecli -h 10.241.168.179 domain -remove 10.241.168.179
```

WARNING: You are about to remove the master node or its peer node. THIS WILL DESTROY THE DOMAIN. Proceed? (y/n) y

**Note:** Using either SP address destroys the global security domain

### Verify:

```
# /nas/sbin/navisecli -h 10.241.168.179 domain -list
```

Domain operation failed. User does not exist.

```
# /nas/sbin/navisecli -h 10.241.168.180 domain -list
```

Domain operation failed. User does not exist.

### GUI:

Optionally can destroy domain security using Navisphere's /setup program>Destroy Security and Domain Information

## ACCESSING SETUP PROGRAM FROM CELERRA CS USING LYNX:

→Use the lynx http client to connect directly to the SP's /setup program over the internal or external network

**Note:** From minimal testing, best results came from using an SSH session to the Control Station using Putty, as it tends to set the right environmental screen variables to handle the following program [i.e., sets TERM=xterm, sets LS\_COLORS=xxxxxxxx, etc.]

```
# lynx http://128.221.252.200/setup
```

→Using the interface is tricky. To log into a system with security initialized, use the down arrow key to get to the user line and enter "nasadmin", then arrow down to password and enter the password, then arrow down to "submit" line, press enter. Arrow down to Host and IP address lines and edit if needed. Arrow down to "Restart Management Server" or "Destroy Security and Domain Information" if you need to destroy the Global security setup on the array, etc.

## REMOVING USER ACCOUNTS FROM THE DOMAIN:

```
# /nas/sbin/navisecli -h 192.168.1.200 security –rmuser –user nasadmin –scope global
```

**Note:** Works only if there are other Domain Administrative accounts available

## UPDATING or RECREATING THE CLARiiON SECURITY CACHE FILES ON CELERRA:

```
# nas_storage -modify APM00030600872 -security
```

Enter the Global CLARiiON account information

Username: nasadmin

Password: \*\*\*\*\* Retype your response to validate

Password: \*\*\*\*\*

Setting security information for APM00030600872

done

```
# ls -la /etc.clar*
```

```
-rw-rw-r-- 1 nasadmin nasadmin 276 Aug 23 08:34 .clar_security  
-rw-rw-r-- 1 nasadmin nasadmin 0 Aug 23 08:34 .clar_security.lck
```

```
# ls -la /nas/site.clar*
```

```
-rw-rw-r-- 1 nasadmin nasadmin 276 Aug 23 08:34 /nas/site.clar_security  
-rw-rw-r-- 1 nasadmin nasadmin 0 Aug 23 08:34 /nas/site.clar_security.lck
```

```
/nas/symapi/config
```

```
-rw-rw-r-- 1 nasadmin nasadmin 216 Aug 23 08:34 emcpwddb.dat
```

## **CHANGING ARRAY SECURITY ACCOUNT PASSWORD:**

**# nas\_storage -modify id=1 -security -username nasadmin -password nasadmin -newpassword nasadmin**

Changing password on APM00063303725

done

**Note:** Above syntax is available in later NAS 5.5 code & updates array password for account named, and updates the local .clar\_security cache files on the Celerra

## **VIEWING CLARIION SECURITY ACCOUNT INFO ON BACKEND:**

**# nas\_storage -info id=1 |grep -C1 username**

authenticated = True

username = nasadmin

**# /nas/sbin/nas\_navi -h 10.241.168.52 remoteconfig -getconfig -users**

Users: nasadmin@10.241.168.63

**Note:** This command reads the list of Privileged Users, as seen in Navisphere>SPA>Properties>Agent tab, which is located locally on the Clariion SP in the c:>Emc\Navisphere\common\agent.config file. Privileged Users are used for Host authentication, such as to support Unix systems.

**\$ /nas/sbin/navisecli -h 10.241.168.52 security -list**

Username: nasadmin

Role: administrator

Scope: global

**# /nas/sbin/navicli -h 192.168.1.200 security -list**

/nas/sbin/classic\_navicli [-p] [-vlq] [-m] [-np] [-t timeout] [-h hostname] [-d device] [-help] [-f filename] CMD <optional-args>

**Note:** Above output abridged. The navicli security -list command will only work if there are properly updated local .clar\_security cache files on the Control Station, since this command requires the CS to use navisecli in the background. Removing both sets of .clar\_security files from /etc and /nas/site directories will reproduce the above output.

**# /nas/sbin/navicli -h 192.168.1.200 security -list**

Username: nasadmin

Role: administrator

Scope: global

**# /usr/symcli/bin/symcfg authentication list**

| Hostname      | Username | Namespace | Port |
|---------------|----------|-----------|------|
| 10.241.168.55 | nasadmin |           |      |
| 10.241.168.56 | nasadmin |           |      |

## **EXAMPLES OF CLARiiON SECURITY PREVENTING NAS COMMANDS FROM WORKING:**

**# nas\_diskmark -m -a**

Discovering storage (may take several minutes)

Error 5008: root\_disk root\_ldisk root\_ldisk root\_ldisk : volume is unreachable by server\_2

**# server\_devconfig server\_3 -c -s -a**

Discovering storage (may take several minutes)

server\_3 :

Error 5008: server\_3 : root\_disk root\_ldisk d10 d9 root\_ldisk root\_ldisk : volume is unreachable by server\_3

**# /nas/sbin/setup\_slot -i 3**

Initializing server in slot 3 as server\_3

Error 5008: server\_3 : root\_disk root\_ldisk d10 d9 root\_ldisk root\_ldisk : volume is unreachable by server\_3

or

Error 5002: server\_2: APM00055003968

    SMAPI\_C\_CLAR\_NOT\_PRIVILEGED

Operation denied by Clariion array – you are not privileged to perform the requested operation

**Note:** Operations such as setup\_slot, devconfig -create, or nas\_diskmark will fail if CLARiiON security is set and the Celerra does not have a correctly populated /etc/.clar\_security file in order to authenticate to the backend.

## **MUST CORRECT ARRAY USER WHEN TRYING TO MODIFY CELERRA CACHE:**

**# nas\_storage -modify APM00030600872 -security -username root -password nasadmin**

Setting security information for APM00030600872

Error 3502: APM00030600872: Storage API code=4651: SYMAPIC\_C\_CLAR\_NOT\_PRIVILEGED

Operation denied by Clariion array - you are not privileged to perform the requested operation

**Note:** You would use the above command syntax to add the Clariion Global Security account username & password to the local Celerra cache for all Clariion backends that are attached and using Global security

**Conditions where Secure CLI may apply:**

1. For new NAS Gateway installations, where CLARiiON security has been set on the Celerra's boot array, the User will be prompted to enter the CLARiiON username and password in order to authenticate to the CLARiiON backend. Beginning with NAS 5.5.27.5 and higher, if the array(s) has been configured with global domain security, use the # nas\_storage -modify <array\_name> -security command against each array listed in the nas\_storage -l output, then follow the prompts to enter the correct username and password for the Clariion security account. This will then produce an /etc/.clar\_security cache on the local Celerra system, which will then allow the Celerra, or Users on the Celerra, to use navisecccli commands without username & password prompting, and will allow devconfig, setup\_slot, and other commands that need to reconfigure the backend, to run.

**Note:** Anytime that the Clariion security account is changed, or password is changed, the corresponding nas\_storage -modify -security should also be run on the Celerra to update the .clar\_security cache file.

2. If a CLARiiON system is using Classic CLI prior to a NAS Upgrade, the upgrade will proceed using Classic Navi commands. Just be aware that if CLARiiON security is subsequently set on the array, the nas\_storage -modify command will need to be run in order to build the authentication cache on the Celerra Control Station [/nas/site/.clar\_security file]

3. If a CLARiiON system is using Secure CLI, and then a NAS Upgrade is performed, the User will be prompted to enter the CLARiiON security account and password, or the Upgrade will fail with a PUHC [Pre Upgrade Health Check] error.

4. If a new array is added, and CLARiiON security is set, then the User will need to enter the CLARiiON Username and password when prompted prior to complete discovery of the new CLARiiON.

5. For Integrated Celerra arrays prior to NAS 5.5.30.x [Integrated systems do not normally have any Clariion security attributes], use of the navisecccli command set can be accomplished by adding a password to the Clariion cache for the Control Station Host:

**# /nas/sbin/navisecccli -h 192.168.1.200 -AddUserSecurity -Scope 0**

Enter password:

**Note:** Run the nas\_storage -modify <array\_name> -security if CLARiiON security is set and the setup\_slot, devconfig -create, nas\_diskmark, or other backend configuration commands are failing, and security credentials are required on the local Celerra Control Station. Celerra Users will also have the ability to create or update the .clar\_security credential cache via the Celerra Manager interface: Celerras>Storage>Systems:<array>

6. Beginning with NAS 5.5.30.x, Integrated NAS system installs will automatically create a Global Scope 0 security account on the array, with SPA as the Domain Master, using nasadmin as the user account and “nasadmin” as the password, until otherwise reconfigured. Please note that any changes to the Clariion security account on the backend array must then be updated in the .clar\_security cache file on the Celerra Control Station using the nas\_storage -modify -security command.

**Two Steps Required on NAS Integrated Systems when adding or changing Clariion security account or password:**

**/nas/sbin/navisecccli -h 192.168.1.200 -AddUserSecurity -Scope 0** (Scope 0 is Global, Scope 1 is local to array)

**/nas\_storage -modify APM00071600514 -security**

**Locations of Celerra Credential Cache for CLARiiON Security:**

**/nas/site**

|             |   |          |          |                  |                |                                                                                           |
|-------------|---|----------|----------|------------------|----------------|-------------------------------------------------------------------------------------------|
| -rw-rw-r--  | 1 | nasadmin | nasadmin | 552 Feb 2 15:33  | .clar_security | (Primary copy used to authenticate Celerra to CLARiiON)                                   |
| <b>/etc</b> |   |          |          |                  |                |                                                                                           |
| -rw-rw-r--  | 1 | nasadmin | nasadmin | 552 Feb 19 10:22 | .clar_security | (Backup copy, used when /nas partitions are not available, or if manual restore required) |

**Example Showing that Clariion security set, account name known, and Celerra has been authenticated:**

**# nas\_storage -info id=1 |grep -C1 username**

authenticated = True

username = nasadmin

**Note:** True indicates that the Celerra has authenticated to the backend, and username shows a valid user account was found in the .clar\_security file on the Control Station. False and/or blank username field would indicate that nas\_storage -modify would need to be run in order to populate the local Celerra /etc/.clar\_security cache file if CLARiiON security is set.

**Example of CLARiiON user account not found in Celerra .clar\_security cache:**

**# nas\_storage -info id=1 |grep -C1 username**

authenticated = True

username = →Missing username and/or security cache files--run nas\_storage -modify <array> -security to update or create security cache files

**Note:** Security cache files exist with 5.5.27 Gateways and 5.5.30 Integrateds, and later

**NS40/NS40 NEBS (Network Equipment Building Systems) GNAPA:**

→Special platform to conform to NEBS standards. Blades increase to 2U in height with DC Power supplies; CS remains 1U in size

→Supported arrays: CX700, CX3-20, CX3-40, CX3-80

→NS40 has dual 2.8GHz processors, 4GB memory, 16TB capacity (1-16 DAE's of 15 drives each, 6-240 disks total)

→Lightning Surge Protector—Firefly—for Ethernet ports

→Product being shipped only with single Data Mover (Standby to be available later)

## **DATA LUN MIGRATION (RG0) & CONTROL LUN EXTENSION (5.5.32.x min.):**

Purpose is to ensure that LUN0 (root\_disk) and LUN 1 (root\_ldisk) are 11GB in size prior to upgrading to Cognac and allows for migration of User LUNs from RAID Group 0, if required, and extension of LUNs 0 & 1 (root\_disk & root\_ldisk, respectively) to 11GB using /nasmcd/sbin/nas\_extlun –check l -init. All systems must be at 11GB for LUN 0 & 1 prior to upgrading to NAS 5.6. One of the technical challenges addressed by the script is to preserve and move the diskmark information on the 128<sup>th</sup> sector from the end of the LUN, as well as the first 8kb information for each volume. Though the script guides the User through some checking and prompts, the actual LUN extension is a manual task, and varies depending on Symmetrix (metavolume aggregation) or CLARiiON.

## **LUN 0/1 EXTENSION/MIGRATION REQUIREMENTS:**

- Gateway or Integrated NAS systems, Clarion or Symmetrix backends
- Minimum NAS 5.5.32.x before LUN extension process can be run.
- Offline procedure [Data Movers are halted by –init script & rebooted]
- LUN 0/1 can only be migrated to same RG Type, Protection, FC Drive types [Raid 5 4+1], same RG as other Control LUNs, and same block count in target LUN
- Flare 19 minimum on Clariion array
- Must have diskspace on the backend to migrate User luns if not enough space in Control LUN Raid Group to expand LUNs 0/1

### **Clarion Behavior:**

- Uses Clariion LUN migration tool to migrate smaller size lun to 11GB size. Migrates from original LUN name to target LUN and then renames target to original name
- Use nas\_extlun tool on MirrorView Source side only
- Clariion uses block counts for volume size info
- nas\_extlun –check checks for MB & Block counts for disk space requirements
- Clariion platforms will have Backout Procedure based on Clones

### **Symmetrix Behavior:**

- Smaller lun is appended with new metavolume
- Use nas\_extlun on RDF Source side only
- Symmetrix uses cylinder sizes for volume size info
- nas\_extlun –check checks for MB & cylinders for disk space requirements
- Special consideration required for SRDF environments

## **SYSTEMS INELIGIBLE FOR COGNAC UPGRADE:**

1. Any system that cannot perform the LUN extension to 11GB for Luns 0 & 1
2. NS600 arrays
3. CNS or CFS if they have any 507 or 510 Data Movers [Only 514 DMs acceptable]
4. Data Mover rootfs extended using root\_disk\_reserve region of LUN 0 & starting offset for partial dump 0 matches up

**Synopsis of LUN Extension script:** Version 1.2 with NAS 5.5.32.x

Run nas\_extlun –check first to verify whether extension is necessary. The -init checks Backend & Data Mover state, builds minimum boot.cfg, reboots all Data Movers, Stops NAS Services, Prompts User to extend LUNs, DART moves diskmark & first 8kb info (used by MPFSi Solaris clients), NAS starts, Diskmarks updated, new boot.cfgs created and all Servers rebooted.

### **# /nasmcd/sbin/nas\_extlun -check**

NAS Control LUN Extension Utility - Version 1.1

Fri Apr 20 09:54:10 2007

Enter Service Password [or type "ABORT" to exit]:

Validating Primary Control Station ... OK

Mounting system mountpoints ... OK

Fri Apr 20 09:58:33 2007

Verifying Platform type ... OK

Verifying NAS version ... OK

Selecting an active slot ... OK (Slot\_2)

Collect NAS system Information:

Reading NAS system Database info ... OK

Reading storage system info ... OK

Verifying no MirrorView setup on this system ... OK

\*\*\*\*\* Summary of Control LUN info \*\*\*\*\*

Storage System: Clariion 600

Storage ID: APM00023801040

root\_disk: ALU 0, Current size = 4096 MB (8388608 blocks);

Proposed New size = 11264 MB (23068672 blocks).

root\_ldisk: ALU 1, Current size = 4096 MB (8388608 blocks);

Proposed New size = 11264 MB (23068672 blocks).

\*\*\*\*\*

<<DIRECTION>>

Must run "nas\_extlun -init" to initiate the above LUN extension operation.

Unmounting system mountpoints ... OK

Operation Succeeded.

### **CCA POLICY FOR CONTROL LUN EXTENSION:**

→See NAS CCA Guide for requirements

→Upon CCA approval for CLARiiON LUN Extension, a link to the procedure is provided

→A link to the procedure is provided with the RPQ approval for the Symmetrix LUN Extension

### **SYMMETRIX BOOT ARRAY CONTROL LUN EXTENSION (Non-RDF):**

→Overall, procedure is similar to CLARiiON LUN Extension and uses nas\_extlun script

→Requires NAS 5.5.32 or higher

→Supports SYMM-5, DMX, DMX-2, DMX-3, DMX-4

→LUN Extension requires Server downtime

→Uses Symmetrix MetaVolume method for extension

→Cylinder count differs depending on SYMM model

DMX-3 or newer systems would use 12394 cylinders to achieve 11619 MB LUN size

DMX-2 or older systems would use 12788 cylinders to achieve 11619 MB LUN size

1. Run LUN Extension HealthCheck:

**# /nasmcd/sbin/nas\_extlun -check**

2. Run extension script:

**# nas\_extlun -init**

→prompts for password, does healthcheck, stops IO to Data Movers, stops NAS services, reboots Data Movers to minimum boot.cfg mode, waits for User to extend LUNs by appending previously created meta volumes

→When nas\_ext script detects that LUNs are now correct size, will move diskmarks on LUNs 0 & 1, relocates first 8k block for LUN1 & create root\_ldisk\_reserve\_2\_slice (used to extend Data Mover rootfs when upgrading to NAS 5.6), updates database, restores boot.cfg files, and restart Data Movers, then NAS services

→Extension progress recorded in /var/log/nas\_extlun.log

### **CLARiiON CONTROL LUN EXTENSION/MIGRATION (and Data LUN Migration):**

1. Determine whether an extension is required:

```
# nas_disk -l
id inuse sizeMB storageID-devID type name servers
1 y 4095 APM00023801040-0000 CLSTD root_disk 1,2
2 y 4095 APM00023801040-0001 CLSTD root_ldisk 1,2
```

2. Run LUN Extension HealthCheck:

The nas\_extlun -check script should be run to provide the proposed new LUN size & block count for LUN 0 & 1.

**# /nasmcd/sbin/nas\_extlun -check**

NAS Control LUN Extension Utility - Version 1.1

-----abridged-----

\*\*\*\*\* Summary of Control LUN info \*\*\*\*\*

```
Storage System: Clariion 600
Storage ID: APM00023801040
root_disk: ALU 0, Current size = 4096 MB (8388608 blocks);
           Proposed New size = 11264 MB (23068672 blocks).
root_ldisk: ALU 1, Current size = 4096 MB (8388608 blocks);
           Proposed New size = 11264 MB (23068672 blocks).
```

3. Determine size/block count of LUNs requiring migration and availability of R5 (4+1) storage:

In order to migrate User LUNs from RaidGroup 0, available storage will be required, most likely requiring R5 (4+1) raid groups. If storage cannot be found or added to the system, this procedure cannot go forward.

**# /nas/sbin/navicli -h 192.168.1.200 getrg 0 -lunlist**

RaidGroup ID: 0

List of luns: 0 1 2 3 4 5 16 17

**# /nas/sbin/navicli -h 192.168.1.200 getlun 16 -capacity**

LUN Capacity(Megabytes): 115491

LUN Capacity(Blocks): 236527008

# /nas/sbin/navicli -h 192.168.1.200 getlun 17 -capacity

LUN Capacity(Megabytes): 115491

LUN Capacity(Blocks): 236527008

4. Determine target LUNs & make sure Raid Types and Storage Pool disktypes are identical:

# nas\_disk -i

9 n 272815 APM00023801040-0012 CLSTD d9 1,2 -->LUN 18

19 n 272815 APM00023801040-0013 CLSTD d19 1,2 -->LUN 19

# nas\_disk -info d9

id = 9

name = d9

acl = 0

in\_use = True

size (MB) = 272815

type = CLSTD

protection= RAID5(4+1)

5. Delete d9 and d19 from Celerra database, unbind from CLARiiON backend, then rebind luns as the same size as each of the Data LUNs that are being migrated:

# nas\_disk -d d19

id = 19

name = d19

acl = 0

in\_use = False

size (MB) = 272815

type = CLSTD

protection= RAID5(4+1)

# /nas/sbin/navicli -h 192.168.1.200 unbind 18

Unbinding a LUN will cause all data stored on that LUN to be lost.

Unbind LUN 18 (y/n)? y

# /nas/sbin/navicli -h 192.168.1.200 unbind 19

Unbinding a LUN will cause all data stored on that LUN to be lost.

Unbind LUN 19 (y/n)? y

#### Removing RG if desired:

# /nas/sbin/navicli -h 192.168.1.200 removerg 8

# /nas/sbin/navicli -h 192.168.1.200 bind r5 18 -rg 12 -sq bc -cap

236527008

# /nas/sbin/navicli -h 192.168.1.200 bind r5 19 -rg 12 -sq bc -cap

236527008

# /nas/sbin/navicli -h 192.168.1.200 getlun 18 -state -bind

State: Binding

Prct Bound: 22

# /nas/sbin/navicli -h 192.168.1.200 getlun 18 -capacity

LUN Capacity(Megabytes): 115491

LUN Capacity(Blocks): 236527008

6. Perform Data LUN Migration:

# /nas/sbin/naviseccli -AddUserSecurity -scope 1

Enter password:

# /nas/sbin/naviseccli -h 192.168.1.200 migrate -start -source 16 -dest 18 -rate asap

# /nas/sbin/naviseccli -h 192.168.1.200 migrate -start -source 17 -dest 19 -rate asap

# /nas/sbin/naviseccli -h 192.168.1.200 migrate -list

Source LU Name: LUN 17

Source LU ID: 17

Dest LU Name: LUN 19

Dest LU ID: 19

Migration Rate: ASAP

Current State: MIGRATING

Percent Complete: 3

Time Remaining: 49 minute(s)

**Note:** Please note that the original LUN numbers 16 & 17 in the above example, which were located in RG0, are migrated to LUNs 18 & 19 in RG12. The target LUNs, however, are replaced by the original LUN numbers 16 & 17, and original Clariion device numbers, and therefore retain their original d volume number.

7. Update Diskmarks on Celerra volumes:

# **nas\_diskmark -m -a**

8. Create new 11GB LUNs in RG0 for Control LUN 0 & 1 expansion:

# **/nas/sbin/navisecccli -h 192.168.1.200 bind r5 50 -rg 0 -sqbc -cap 23068672**

# **/nas/sbin/navisecccli -h 192.168.1.200 bind r5 51 -rg 0 -sqbc -cap 23068672**

9. Run the nas\_extlun –init script to perform the LUN migration/extension:

# **/nasmcd/sbin/nas\_extlun –init**

**Note:** Script will require a password to continue with the –init migration process. Also, the script will notify the user when an SSH session to the CS is required in order to manually extend LUNs 0 & 1

“Waiting for user to finish the backend LUN extension tasks on the above LUN(s)...

10. Connect to CS using SSH, mount /nas, and run migration on LUN0/1 to LUN 50/51:

# **mount /nas**

# **/nas/sbin/navisecccli -h 192.168.1.200 migrate -start -source 1 -dest 51 -rate asap**

WARNING: The destination LUN is larger than the source. Performing this operation will increase the size of your LUN. Please verify that any hosts attached to this volume can handle dynamic changes to volume size.

Do you really want to perform the action (y/n)? y

**Note:** A LUN migration from smaller to larger LUN is also an automatic LUN Extension. At the end of the migration, the nas\_extlun script will resume and complete the process, and restart NAS Services.

“Fri Apr 27 11:39:33 2007

Initiating NAS service start ... OK

Waiting for NAS service to start ..... OK

Operation Succeeded.”

## **TROUBLESHOOTING:**

**/var/log/nas\_extlun.log**

### **SERVER CHECKUP TOOL GNAPA:**

**Purpose:** This is a new troubleshooting tool that has the ability to check a single Component (CIFS) and (26) CIFS dependencies, and outputs CCMD Warnings or Errors if a potential problem is discovered. See –info –all output below for listing of all dependencies. This tool is meant to check configuration, status of resources, verify some best practice configurations, report anomalies, and provide recommended actions to resolve detected issues. In future releases, this tool may be tied into the Celerra PAHC tool.

→The only ‘Component’ being checked with this release is CIFS—others to be added later are, NFS, HTTPS, DHSM, REPLICATION, iSCSI, etc.

→Tool is not designed to automatically fix any issues found

→Check man page for further syntax information

**\$ server\_checkup server\_2 -list | -info <component> -all | -test <component> -subtest <dependency> -quiet [run checks & output status only] -full [runs more extensive tests]**

**# server\_checkup server\_3 -list**

server\_3 :

CIFS →CIFS is the only ‘component’ currently incorporated into this utility

**# server\_checkup server\_3 -quiet |grep “\*”**

#### **Run Full Test if any Asterisks are seen in the Output:**

ACL : Checking the number of ACL per file system.....\*Pass

DC : Checking the connectivity and configuration of the DCs.....\*Fail

SmbList : Checking the range availability of SMB ID.....\*Pass

UM\_Server : Checking the consistency of usermapper server database.....\*Pass

NB: a result with a '\*' means that some tests were not executed. use -full to run them

#### **Testing Specific Dependencies:**

**# server\_checkup server\_3 -test CIFS -subtest dns**

#### **Example of Domain Guests Group Anomaly:**

**# server\_checkup server\_3 -test CIFS -subtest localgrp**

-----Checks-----

Component CIFS :

LocalGrp : Checking the local groups database configuration..... Fail

-----CIFS : LocalGrp Warnings-----

Warning 17451974726: server\_3 : The local group 'Guests' of server 'MVVIEW\_DM3' contains an unmapped member: S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-202. The access to some network resources may be refused (access right checking in Secure or Unix

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
mode). --> According the configured resolver of your system (NIS, etc config files, usermapper, LDAP...),add the missing members. Refer to the commands reference manual for more details.

**Note:** The above anomaly is actually normal in W2k/W2k3 domains. The domain “guest” account is disabled by default, meaning that the default Domain Guest group (RID 202) and its members are not mapped by Celerra since the account is disabled and not normally used. If lsarpc were run against the default user and domain group account, a mapping would be generated, the Celerra LocalGroups file would map the “Domain Guests” group and this warning would go away.

# .server\_config server\_3 -v "lsarpc if=s2 user='domain guests'"

# .server\_config server\_3 -v "lg list" |grep guests

1172156923: LGDB: 4: group 2K3\domain guests 8005 S-1-5-15-bfc56af5-d6cf8701-5f67b1a3-202 \*

**Running Checks in Quiet Mode:**

# server\_checkup server\_3 -quiet -full

-----Checks-----

Component CIFS :

ACL : Checking the number of ACL per file system..... Pass  
Connection: Checking the load of TCP connections of CIFS..... Pass  
Credential: Checking the validity of credentials..... Pass  
DC : Checking the connectivity and configuration of the DCs..... Fail  
DFS : Checking the DFS configuration files and DFS registry..... Pass  
DNS : Checking the DNS configuration and connectivity to DNS servers. Fail  
EventLog : Checking the configuration of Windows Event Logs..... Pass  
FS\_Type : Checking if all file systems are all DIR3 format..... Pass  
GPO : Checking the GPO configuration..... Pass  
HomeDir : Checking the configuration of home directory share..... Pass  
I18N : Checking the I18N mode and the Unicode=UTF8 translation tables. Pass  
Kerberos : Checking machine password update for Kerberos..... Pass  
LocalGrp : Checking the local groups database configuration..... Pass  
NIS : Checking the connectivity to the NIS servers, if defined..... Pass  
NTP : Checking the connectivity to the NTP servers, if defined..... Pass  
Security : Checking the CIFS security settings..... Pass  
Server : Checking the CIFS files servers configuration..... Pass  
Share : Checking the network shares database..... Pass  
SmbList : Checking the range availability of SMB ID..... Pass  
Threads : Checking for CIFS blocked threads..... Pass  
UM\_Client : Checking for the connectivity to usermapper servers, if any.... Pass  
UM\_Server : Checking the consistency of usermapper server database..... Pass  
UnsupOS : Checking for unsupported client network OS..... Pass  
UnsupProto: Checking for unsupported client network protocols..... Pass  
VC : Checking the configuration to Virus Checker servers..... Pass  
WINS : Checking for the connectivity to WINS servers, if defined..... Pass

# server\_checkup server\_3 -info -all

**DEPENDENCY : ACL**

DESCRIPTION : Number of ACL per file system.

TESTS :

In full mode, check if the number of ACL per file system doesn't exceed 90% of the maximum limit.

**DEPENDENCY : Connection**

DESCRIPTION : TCP connection number

TESTS :

Check if the number of CIFS TCP connections doesn't exceed 80% of the maximum number.

**DEPENDENCY : Credential**

DESCRIPTION : Users and groups not mapped

TESTS :

Check if all credentials in memory are mapped to a valid SID.

**DEPENDENCY : DC**

DESCRIPTION : Connectivity to the domain controllers

TESTS :

Check the connectivity to the favorite DC (DCPing), In full mode, check the connectivity to all DC of the domain, Check if DNS site information are defined for each computer name, Check if the site of each computer name has an available DC, Check if trusted domain of each computer name can be reached, Check the ds.useDCLdapPing parameter is enabled, Check the ds.useADSite parameter is enabled.

**DEPENDENCY : DFS**

DESCRIPTION : DFS service configuration on computer names

TESTS :

Check the DFS service is enabled in registry if DFS metadata exists, Check the DFS metadata of each share with DFS flag are correct, Check if share names in DFS metadata are valid and have the DFS flag, Check if each DFS link is valid and loaded, Check in the registry if the WideLink key is enabled and corresponds to a valid share name.

**DEPENDENCY : DNS**

DESCRIPTION : DNS domain configuration

TESTS :

Check if each DNS domain has at least 2 defined servers,

Check the connectivity to each DNS server of each DNS domain, Check if each DNS server of each DNS domain supports really the DNS service, Check the ds.useDSFile parameter (automatic discovery of DC), Check the ds.useDSFile parameter is enabled if the directoryservice file exists.

**DEPENDENCY : EventLog**

DESCRIPTION : Event Logs parameters on servers

TESTS :

Check if the pathnames of each event logs files are valid (application, system and security), Check if the maximum file size of each event logs file doesn't exceed 1GB, Check if the retention time of each event logs file doesn't exceed 1 month.

**DEPENDENCY : FS\_Type**

DESCRIPTION : DIR3 format of filesystems

TESTS :

Check if each file system is configured in the DIR3 format

**DEPENDENCY : GPO**

DESCRIPTION : GPO configuration on Win2K servers

TESTS :

Check if the size of the GPO cache file doesn't exceed 10% of the total size of the root file system, Check the last modification date of the GPO cache file is up-to-date, Check the cifs.gpo and cifs.gpoCache parameters have not been changed,

**DEPENDENCY : HomeDir**

DESCRIPTION : Home directory shares configuration

TESTS :

Check if the home directory shares configuration file exists, the feature is enabled, Check if the home directory shares configuration file is optimized(40 lines maximum), Check the syntax of the home directory shares configuration file.

**DEPENDENCY : I18N**

DESCRIPTION : Internationalization and translation tables

TESTS :

Check if computer name exists, the I18N mode is enabled, Check the .etc\_common file system is correctly mounted, Check the syntax of the definition file of the Unicode characters, Check the uppercase/lowercase conversion table of Unicode character is valid.

**DEPENDENCY : Kerberos**

DESCRIPTION : Kerberos configuration

TESTS :

Check the machine password update is enabled and up-to-date.

**DEPENDENCY : LocalGrp**

DESCRIPTION : Local groups and local users

TESTS :

Check the local group database doesn't contain more than 80% of the maximum number of servers, Check if the servers in the local group database are all valid servers, Check the state of the local group database (initialized and writable), Check if the members of built-in local groups are all resolved in the domain, Check the number of built-in local groups and built-in local users, Check if the number of defined local users doesn't exceed 90% of the maximum number.

**DEPENDENCY : NIS**

DESCRIPTION : Network Information System (NIS) configuration

TESTS :

If NIS is configured, check at least 2 NIS servers are defined (redundancy check), Check if each NIS server can be contacted on the network, Check if each NIS server really supports the NIS service.

**DEPENDENCY : NTP**

DESCRIPTION : Network Time Protocol (NTP) configuration

TESTS :

If NTP is configured, check at least 2 NTP servers are defined (redundancy check), Check if each NTP server can be contacted on the network, If computer names exist, check if NTP is configured and is running.

**DEPENDENCY : Security**

DESCRIPTION : Security settings

TESTS :

If the I18N mode is enabled, check the share/unix security setting is not in use, Discourage to use the share/unix security setting, Check the cifs.checkAcl parameter is enabled if the security setting is set to NT.

**DEPENDENCY : Server**

DESCRIPTION : Files servers

TESTS :

Check if each CIFS server is configured with a valid IP interface, Check if each computer name has joined its domain, Check if each computer name is correctly registered in their DNS servers, Check if the DNS servers have the valid IP addresses of each computer name, Check if a DNS domain exists if at least one computer name exists,

**DEPENDENCY : Share**

DESCRIPTION : Network shares

TESTS :

Check the available size and i-nodes on the root file system are at least 10% of the total size, Check the size of the share database doesn't exceed 30% of the total size of the root file system, Check if the pathname of each share is valid and is available, Check if each server in the share database really exists, Check if the I18N mode is enabled, all the share names are UTF-8 compatible, Check the list of ACL of each share contains some ACE, Check the length of each share name doesn't exceed 80 Unicode characters.

**DEPENDENCY : SmbList**

DESCRIPTION : 64k UID, TID and FID limits

TESTS :

In full mode, check the 3 SMB ID lists (UID, FID and TID) don't exceed 90% of the maximum ID number.

**DEPENDENCY : Threads**

DESCRIPTION : Blocked threads and overload

TESTS :

Check CIFS threads blocked more than 5 and 30 seconds, Check the maximum number of CIFS threads in use in the later 5 minutes doesn't exceed 90% of the total number, Check the number of threads reserved for Virus Checker doesn't exceed 20% of the total number of CIFS threads.

**DEPENDENCY : UM\_Client**

DESCRIPTION : Connectivity to the usermapper server

TESTS :

If usermapper servers are defined, check each server can be contacted, Check if usermapper servers are defined, NIS is not simultaneously activated.

**DEPENDENCY : UM\_Server**

DESCRIPTION : Usermapper server

TESTS :

If a usermapper database is defined locally, check its size doesn't exceed 30% of the total size, Check if configuration file is in use, the filling rate of the ranges doesn't exceed 90%, Check if configuration file is in use, 2 ranges do not overlap, Check if secmap is enabled, In full mode, check the SID/UID and SID/GID mappings and reverses are correct and coherent.

**DEPENDENCY : UnsupOS**

DESCRIPTION : Client OS not supported

TESTS :

Check for unsupported client network OS.

**DEPENDENCY : UnsupProto**

DESCRIPTION : Unsupported protocol commands detected

TESTS :

Check for unsupported client network protocol commands.

**DEPENDENCY : VC**

DESCRIPTION : Virus checker configuration

TESTS :

If VC is enabled, check the syntax of the VC configuration file, Check if the VC 'enable' file and the VC configuration are compatible, Check the number of VC servers. Make sure at least 2 servers are defined, for redundancy, Check if there are offline VC servers, Check if the VC high watermark has not been reached, Check the connection of VC servers to the Data Mover.

**DEPENDENCY : WINS**

DESCRIPTION : WINS servers.

TESTS :

If NetBIOS names are defined, check if at least one WINS server is defined, Check the number of WINS servers. check if two servers are defined for redundancy, Check if each WINS server can be contacted on the network, Check these servers are really WINS servers, Check if the NetBIOS are correctly registered on the servers.

**INFORMATION WRITTEN TO SERVER LOG:**

2007-02-23 11:27:23: ACLUPD: 4:11: check acl on 14 ended successfully

2007-02-23 11:27:23: SMB: 4: >tmpDC=GEORGE(192.1.4.217) R=6 T=1000 ms S=0,1/-1

2007-02-23 11:27:23: CIFSSUPPORT: 4: compname mview\_dm3 DC=GEORGE Trusted domain='NTDOMAIN' status='There are currently no logon servers available to service the logon request'  
2007-02-23 11:27:23: LIB: 3: 1: DNS: unable to connect to name server 10.241.168.113: I/O error  
2007-02-23 11:27:27: LIB: 3: 1: DNS: unable to connect to name server 10.241.168.113: Connection timed out  
2007-02-23 11:27:27: SMB: 4: Unknown OS logons: 0 Policy=GrantAll  
**Note:** Looks as if server\_checkup also calls the server\_cifssupport tool for certain functions

## **DUMP COMPRESSION & ENHANCEMENTS ON BACKEND GNAPA:**

Dumps will be automatically compressed when written to the backend slots—more useful information is also supposed to be provided. Following example is a dumpfile automatically extracted and zipped by the automatic collect utility—if automatic collect is not configured or running, the dumpfile remains on LUN0 on the backend, which can be checked using the dump\_slot command:

1. Checking for dumpfile and compression on Backend dumpslot:

**# /nas/sbin/dump\_slot -v -F**

Checking LBA 0xf3800 for Full Dump...

Dump info FOUND:

Dart Slot 2

Full Dump incomplete!

Do you wish to save this dump anyway? [y or n] y

COMPRESSED = YES

2. Checking dumpfile if already extracted by automatic collection script, which gzips the dump—unzip file:

**# gzip -d dump\_ML2803000397.070123\_0723.dump.gz**

3. Verifying whether new compression technique has been applied to the dumpfile:

**# /nas/sbin/nas\_crash /nas/var/dump/dump\_ML2803000397.070123\_0723.dump**

DART time of dump: Tue Jan 23 07:39:40 2007 UTC

Product: EMC Celerra File Server

Uptime: 006 days, 18:33:55

Version: T5.5.80.0

IP Address: 192.168.1.2

Host Name: server\_2

COMPRESSED = YES

4. Use the dump\_slot utility to uncompress the dump

**# /nas/sbin/dump\_slot -i dump\_ML2803000397.070123\_0723.dump -o**

**<provide\_name\_for\_uncompressed\_dump>**

Dump size is 704203264 bytes (671 MB) . A dump file of this size will be created.

Done

5. Verifying:

**# /nas/sbin/nas\_crash /nas/var/dump/dump\_ML2803000397.070123\_0723.uncompressed**

COMPRESSED = NO

6. Help usage for dump\_slot command:

**# /nas/sbin/dump\_slot -h**

usage: dump\_slot [-f device\_name] [-d dump\_output\_file ] [-Dump\_number n]

[-x sysinfo only] [-w upload one dump only] [-verbose] [-help]

<[-Fulldump] | slot\_id>

| -i compressed\_dump\_file -o uncompressed\_dump\_file\_to\_create

## **OTHER GNAPA ENHANCEMENTS:**

→Upgrades will produce a nas\_prestage.tar.gz tarball in /var/tmp, which will reduce time by not requiring multiple extraction calls during the upgrade and allows for quicker restarts after failures

→Mars Flare support, Dewars CS support for NS40/NS80, iSCSI Snaps and replication for Linux, MPFSi Phase 4, limited support for CLARiiON AX150 arrays, Celerra Manager support for IE 7.0, 750GB SATA drives on CLARiiON

→NFSv4 statistics and other calls are now supported on the Data Mover

→Support for CLARiiON Gateway AX150 arrays, using ax1mpfs license key

## **NAPA 6:**

NAS 5.5.28.x ETR April 2007

→Gateway NAS support for new CX3-10C Tackhammer arrays [Arrays could have either all FC drives, all ATA drives including vault, or a combination of FC (vault) with ATA drives, min. Flare 24 Patch 008]

**Note:** The iSCSI combo cards will be used to support Hosts other than the Celerra in this configuration. All ATA configuration would mean use of ATA drives for both Clariion Vault drives and NAS Control Luns

→Some iSCSI Replication performance enhancements

→Support for Vista O/S clients and Celerra, but in W2k or W2k3 domains only (Not Longhorn)

→Firefox 1.5 Browser support

→Psuedo IP Interface support for Morgan Stanley only

## **NAPA 7:**

NAS 5.5.29.x ETR June 2007

→Introduces support for Enginuity microcode 5772 on Symmetrix for RAID 6 configurations (Raid 6 6+2).

**Note:** Symmetrix supports Control Luns only on Mirrored devices, not RAID of any kind, nor is Celerra AVM able to use RAID with Symmetrix devices.

## **NAPA 8:**

NAS 5.5.30.x ETR Aug 2007

→Tiered Services Model for Customers on NS20 platform initially (Enhanced, & Premium Support)

→NS20 & NS40 Factory or Field install models will ship with pre-installed NAS & FLARE software within a Celerra StorageGroup and Access Logix enabled, & pre-configured LUNs that marry the Backend to the Celerra

→An NS20 could be configured with all ATA drives (meaning vault drives & Control LUNs)

→Second SPS on array is optional

→Customer-Installable NS20/20FC WagonWheel install approach, Peel-off CS info label, Read Me First, Placemat, Powerlink Landing Page, CSA tool with Registration capability

→Landing Page for specific platform troubleshooting, CRU/FRU procedures (Pwr Supplies, SFPs, Disks, etc), support information

→CSA Celerra Startup Assistant for cable check and basic system configuration (replaces InitWizard, but uses iwd process)

→New NS20 Integrated & NS20FC-Enabled models (latter model is not called a Gateway) using CX3-10 & CX3-10F, respectively

→New NS40 Integrated & NS40FC-Enabled models (the FC is not a Gateway, but a variant of the Integrated), using CX3-40F for both models

→CSA Celerra Startup Assistant, RegWiz, & NAT-enabled NST utilities to be provided on Apps & Tools CD

→NS20 & NS40 Integrated (no more old style Integrateds) SPs will operate in SAN mode, with direct fibre optic connections between DM blades and SPs, use of Storagegroups & AccessLogix for Integrated & FC Enabled models

→“All-in-One” NS20F & NS40F Fibre Channel Enabled Models (additional Hosts can connect to array directly or via switch)

→Network access to SPs using Flare 26 version of NST tool (20/20FC/40/40FC) for standard troubleshooting & CRU wizards

→Network access to SPs using Flare 24 version of Navisphere OffArray Mgr tool (20FC/40FC only) for storage management of arrays

→CX3-10, CX3-10F, CX3-40F Arrays, Flare 24 running CelerraService pkg on backend to identify Celerra-owned arrays

→Celerra NAT Service (IPTables), Internal Network changes, & Public IP address for SPA & SPB built on CS aliases to allow network connection from NST & Navisphere

→Dewars Control Station for NS20 & NS40 models

→CAVA version 3.5.8 to be introduced, which supports Automatic Pattern Update with Trend Micro ServerProtect 5.5.8 Build 1176+

**Note:** ServerProtect will be able to tell CAVA when a new pattern update is available, and CAVA will inform DART through the use of the heartbeat mechanism—this will essentially invalidate the “scan on first read” cache to that files will be rescanned when accessed.

→Introduces ability to create a RW iSCSI LUN clone from an iSCSI Snap using server\_iscsi –modify option

### **CREATING iSCSI LUN CLONE:**

**Note:** Essentially, would need to use either Linux or Windows RM or RM/SE application (cmd\_cli) to do the following:

a) Create iSCSI copy job Source to Destination LUN using RM or RM/SE

b) Expire the last replica/snap to destroy iSCSI replication sessions

c) Use # server\_iscsi –modify to change iSCSI replication destination LUN from RO to R/W

**Note:** LUN attribute cannot be changed if LUN replication in use, LUN being accessed by Host, LUN has been promoted

d) Create LUN mask of clone to Windows Host and login via iSCSI

e) Remove VSS R/O and hidden bits on the clone LUN using diskpart utility, or RmMountVolume.bat utility with RM or RM/SE

f) Resulting clone can be Snapped, Replicated, or Extended

→New installs will enforce use of Secure Navi [Naviseccli], while upgrades to 5.5.30.x will support Naviseccli, but not require it

**Note:** New installs will apply default User “nasadmin” and Password “nasadmin” to setup security with SPA as the Domain Master

→Celerra will support Enginuity 5772 and Symmetrix RAID 6

## **NS20/40 INTEGRATED, NS20FC/40FC ENABLED CELERRA:**

GA August 2007 NAS 5.5.30.x

**What's different about the new SAN Mode on the SPs vs. the typical Integrated SAN AUX Mode:**

- CSA utility replaces InitWizard for initial system setup (Windows utility, Apps CD or Powerlink—csa\_install.exe)
- Celerra implements the IPTables Service, the Linux version of NAT (Network Address Translation), to translate public SP IP's to internal SP IP's (actually, CS acts as a Router and rewrites source/destination addresses in IP packets to allow SP hosts access)
- Control Station is configured with (2) aliases on eth3 for Public IP addresses to SPs, and (2) internal network aliases (used for internal SP-to-SP communication when dual CS platforms are involved), & IP Forwarding set to 1 by default
- DMs connect to upper LAN Mgmt port on SPs for the internal Celerra network, as opposed to the lower LAN Service port

**Note:** Original NS40 connected to Service Ethernet ports on SPs and SPs ran in SAN-AUX mode

→No more SAN AUX mode or copper cables between SPs and DMs

→DMs connect to SPs using Fibre Optic LC-to-LC cables (SFP connectors) instead of copper HSSDC2 cables

→DMs will connect to Ports 2 & 3 fibre for CX3-20F & CX3-40F arrays (NS20FC, NS40, NS40FC), & Ports 0 & 1 Fibre for NS20

→SPs run in SAN mode, similar to what NS80 Integrated already does, not SAN-AUX, & means that the two LAN ports on the SP are now separated by VLAN security

**Note:** VLAN security means that Service & Mgmt ports are separated. Can no longer access Internal Celerra network from Service port, but could use the Service port to connect to the SPs default CLARiiON IP network (128.221.1.250/251). With the original NS40 Integrated model running in SAN AUX mode, you could connect to the Internal Celerra network over either the Service or Mgmt LAN port since there was no VLAN security

→Both models support the Celerra Integrated NST utility, but the NS20FC will also support the Navi OffArray Manager

**Note:** “CelerraService” pkg is installed only on dedicated backends (NS20, NS20FC), and is used as a CelerraIdentifier for the NST, via a cimom API call to the SPs after a User first logs in via the NAT Service on the Control Station.

→NS20 (aka Sledgetack) Integrated is the replacement for NS350, in either an EMC rack or customer-provided racks, no Gateway model to be offered

→NS20 introduces first Tiered Service Support for Celerra—Enhanced & Premium Support with 5x9 or 7x24 onsite support, and 4-hour vs. 2-hour remote Support Center support, respectively

→NAS software upgrades are not gratuitous and should be covered under a separate SW maintenance contract

→Upgrades of DAEs & Disks via Clariion tools, Upgrades from Single to Dual Blades (EMC), Upgrades from NS2-AUX to NS2-AUXF supported

→SRDF & MPFS will not be supported on the NS20

#### **FRONTEND FIBRE CHANNEL PORTS ON NS20/NS20FC/NS40/NS40FC SPs:**

→CX3-10F configurations (NS20FC) will have a total of (6) frontend fibre channel ports per SP, (2) for Celerra connectivity, and (4) for other Hosts to connect via FC optic cable directly or via Switched Fabric

→CX3-10 configurations (NS20) will have a total of (2) frontend fibre channel ports per SP, both for Celerra connectivity to backend

→CX3-40F configurations (NS40 & NS40FC) will have a total of (4) frontend fibre channels per SP--(2) ports are unused for NS40, while (2) ports are used for Celerra connectivity for NS40; (2) ports are available for Windows Hosts for the NS40FC shared array model

→CX3-40 configurations (original NS40 Integrated) have only (2) frontend fibre channel ports per SP, both for Celerra connectivity

#### **CELLERRA TIERED SERVICES:**

##### **I. Enhanced Support (CallHome)**

5x9 Next Business Day Onsite support, 7x24 Call Center support with 4-hour response times, 3-year HW warranty

Customer to replace CRUs (fans, pwr supplies, SFPs, drives via DRU tool)

Onsite support for FRUs failures

CallHome to Celerra Support and/or Partners

NAS & Flare Upgrades

System installation included by default but can be deselected on Sales Order for customer installation

Software updates require separate maintenance contract

##### **II. Premium Support (CallHome)**

7x24 Onsite Support with 4-hour response & 7x24 CallCenter Support with 2-hour response, 3-year HW warranty

CRUs & FRUs replaced by EMC, but customers can replace some parts

CallHomes to Celerra Support and/or Partners

Software updates require separate maintenance contract

#### **NS20/20FC, NS40/40FC INSTALLATIONS:**

→Preloaded NAS/Flare & Control Luns on all Integrated & FC Enabled systems

→All models will run AccessLogix and have a Celerra Storage Group for both Integrated & FC Enabled models

**Note:** NAS Upgrades (old NS40 Integrated) will not implement Storage Group or use Access Logix

→New installs implement Navisecccli using SPA as Domain Master with Global security enabled (Scope 0), default user “nasadmin” and password “nasadmin”, while upgrades to Napa 8 will keep existing security (Classic or Secure CLI)

→Control Station will be pre-configured with two new internal Gateway IP address aliases (eth0:1, eth2:1—strictly speaking only used for SP-to-SP communications for dual CS environments), as well as POSTROUTING entries in /etc/sysconfig/iptables for the Internal IP addresses of SPA & SPB—the CS acts as a router and rewrites Host and Destination IP addresses in IP packets

→Physical installation of system guided by WagonWheel Steps and Placemat document, along with Read Me First summary of the installation process

→Control Station will have a peel-off label documenting TLA serial #, Model #, NAS & Flare versions, Unit Tested date, Pre-Configured (yes), MAC address of CS, SP gateway addresses

→System cabling to be color-coded for ease of hookup

→On system powerup, Users will use CSA wizard to configure the system and Register the Celerra, along with Powerlink Landing Page for Information, Troubleshooting, Documentation, Procedures, etc.

→After CSA configuration, the Control Station will have a new Public IP address for both SPA & SPB, respectively (aliases eth3:1, eth3:2), along with IPTables entries for NAT translation services that perform a passthrough service between Public and Private addresses on the SPs--all designed to allow connectivity from the public network using either the NAT-enabled NST or Navi OffArray Mgr tools

→Intent is that “reinstalls” & “fresh installs” will not be required

→/etc/rc3.d/S95cable\_check script prevents casual “reinstall” over factory system; Runs on factory system prior to S95nas startup script; Starts up the IWD nas\_ipinit daemon on CS so that CSA can be used to configure the system; Removes itself as a startup script after successful CSA configuration; Starts NAS, Web, & Tomcat services after successful application of Pre-Configuration

→Use the CSA to configure Control Station IP, new Public IPs for SPA/SPB, perform Cablecheck, and complete customer-configurable setup and testing for NFS or CIFS or iSCSI using single Export/Share/File System, as well as to Register system with EMC/CSI database for Callhome/Service Support

→Clariion SPs will reboot after configuration of the new alias IP's for SP-to-SP communications [192.168.1.104 & 2.104], but this is part of the factory install and should not normally be required unless doing a complete reinstall

#### **Example Command to Change SP Gateway IPs:**

# /nas/sbin/navicli -h 192.168.1.200 networkadmin -set -gateway 192.168.1.104

# /nas/sbin/navicli -h 192.168.2.201 networkadmin -set -gateway 192.168.2.104

→AccessLogix will be enabled & Storage Group for Celerra created [info stored in /etc/be\_sg\_info & be\_rg\_info]

#### **Example of NAS Upgrade on ‘old’ NS40 Integrated (to NAS 5.5.30+)**

→Upgrade on old NS40 Integrated systems does not enable AccessLogix [Data Access control: DISABLED], though AccessLogix service on array is “Active”

→Upgrade does not configure Secure CLI if using Classic CLI

→Upgrade checks for and then installs the CelerraService pkg on the array

→Upgrade does not change the existing Gateway addresses on SPs, but recommends changing at the earliest convenience, though neglects to mention that this change requires SP reboot:

#### **Upgrade Log:**

SPA's gateway is not 192.168.1.104. Please change it at the earliest convenience

SPB's gateway is not 192.168.2.104. Please change it at the earliest convenience

→Upgrade creates the alias files on the Control Station to support internal network SP-to-SP communications

# cat ifcfg-eth0:1

DEVICE=eth0:1

IPADDR=192.168.1.104

# cat ifcfg-eth2:1

DEVICE=eth2:1

IPADDR=192.168.2.104

→Aliases did not appear in CS memory until after running following:

# /sbin/ifconfig (no entries for eth0:1 or eth2:1)

# /nasmcd/sbin/cs\_dhcpd\_monitor (run this command or reboot CS to bring eth0:1 & eth2:1 UP)

# /sbin/ifconfig

eth0:1 Link encap:Ethernet HWaddr 00:00:F0:9F:B3:74

inet addr:192.168.1.104 Bcast:192.168.1.255 Mask:255.255.255.0

UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1

eth2:1 Link encap:Ethernet HWaddr 00:00:F0:9F:53:07

inet addr:192.168.2.104 Bcast:192.168.2.255 Mask:255.255.255.0

UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1

Base address:0xd880 Memory:fbea0000-fbec0000

→Upgrade starts the IPTables service, flushes IPTables, and creates new entries to support internal network SP-to-SP communications

→Upgrade permanently enables IP Forwarding

# cat /proc/sys/net/ipv4/ip\_forward

1

## **STORAGE MANAGEMENT OF ARRAY:**

→NS20 & NS40 Integrated models will require use of Celerra Manager to configure backend storage

→NS20FC/40FC will require use of Navisphere OffArray Manager to configure backend storage

**Note:** Celerra Manager & CLI are disabled. Setup\_clariion script recognizes the FC Enabled system and will display message: “Additional configuration of this shared storage array may be required by the SAN administrator.”

## **Control & Data LUNs on NS20 FC or NS40 FC Enabled Systems**

- All storage to be managed by Navisphere OffArray Manager
- Celerra Manager>Tools>Navisphere is greyed out and Storage>Systems>array\_ID>Configure button is not displayed
- Note:** If trying to use /nas/sbin/setup\_clariion to configure storage, script will provide message: “Additional configuration of this shared storage may be required by the SAN administrator.”
- Single Data LUN is created with Install image, at 25% of the available storage space left in RG0 (allows other Hosts to use the remaining 75% from RG0)

# nas\_disk -l

```
id inuse sizeMB storageID-devID type name servers
1 y 11263 APM00071600514-0000 CLSTD root_disk 1,2
2 y 11263 APM00071600514-0001 CLSTD root_ldisk 1,2

```

## **CONFIGURING STORAGE USING CELERRA MANAGER:**

Celerra Mgr>Storage>Systems>array\_ID>Configure, brings up (3) options

- o CX\_All\_4Plus1\_Raid\_5 (default selection)
- o CX\_Standard\_Raid\_5
- o User Defined (this option does not work in Celerra Manager—must use CLI setup\_clariion)

## **CONFIGURING STORAGE USING SETUP CLARIION CLI SCRIPT:**

# /nas/setup/setup\_clariion

Clariion Array: APM00071600514 Model: CX3-40f Memory: 4096

The following 4 template(s) available:

1. CX\_All\_4Plus1\_Raid\_5
2. CX\_Standard\_Raid\_5
3. User Defined → Selected the User Defined template
4. None

Configuration for APM00071600514

1. FC\_RAID5\_4+1\_HS\_4+1\_HS\_HS\_HS\_HS
2. FC\_RAID5\_4+1\_HS\_R1\_R1\_R1\_R1\_HS → Selected this template to complete shelf configuration
3. FC\_RAID5\_4+1\_HS\_8+1
4. FC\_RAID5\_4+1\_HS\_R1\_R1\_4+1
5. None

Do you want to continue and configure as shown [yes or no]?: yes

Enclosure 0\_0.

Created disk group 8, luns 18,19

Created disk group 9, luns 20,21

Created disk group 10, luns 22,23

Created disk group 11, luns 24,25

Created spare 201

Binding complete.

All luns are created successfully!

Enclosure info:

---

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14

---

0\_0: 300 300 300 300 300 300 300 300 300 300 300 300 300 300 300

FC 0 0 0 0 HS 8 8 9 9 10 10 11 11 HS MIX

---

Configuration completed!

Setup of CLARiiON APM00071600514 storage device complete.

Discovering storage (may take several minutes)

### **RECONFIGURING STORAGE ON CELERRA INTEGRATED ARRAYS:**

#### **/nas/site/ APM00071600514.cfg**

If you had a system where you were rearranging LUNs on the backend, you would need to rename the above file in order to be able to run the setup\_clariion script successfully, as the saved configuration file does not allow the Celerra to reconfigure storage. Rename the file and then proceed with /nas/sbin/setup\_clariion –init to reconfigure storage.

### **ARRAY EVENT MANAGEMENT/CALLHOME:**

NS20, NS40, NS20FC, NS40FC models all use the Celerra as the Event Monitoring and Reporting system for the Array (there is no separate CLARAlert agent running on a Windows system since the Celerra “owns” the array)

#### **NAS EVENT MONITORING FOR CLARIION ARRAY**

/nas/sys/nas\_mcd.cfg →Basic configuration file  
daemon “Navi Event Monitor” →Basic monitoring process on Celerra  
/nas/sbin/navilog\_mon →Serves as event collector for backend from Navi Agent and uses postevent to log Information, Warning, Error, & Critical events to the Celerra Eventlog  
/nas/log/agent.log [Navisphere agent log]  
/nas/log/navimon.log [Navisphere monitor log]

#### **Control Station Processes:**

```
# ps -eafl |grep navi
000 S root 5816 2941 0 69 0 - 816 pipe_w Aug14 ? 00:00:00 /usr/bin/perl /nas/sbin/navilog_mon
100 S root 5819 2941 0 69 0 - 3729 do_sel Aug14 ? 00:00:02 /nas/opt/Navisphere/bin/naviagent -d -f
/nas/etc/Navisphere/agent.config -r /nas
```

#### **# nas\_event -list -a callhome |grep Navi**

```
NaviEventMonitor 4 Navi Event with severity CRITICAL was received
NaviEventMonitor 100 A control lun has been cache compromised
```

#### **# nas\_event -l -f NaviEventMonitor**

|     |                                                    |
|-----|----------------------------------------------------|
| id  | description                                        |
| 1   | Navi Event with severity INFORMATION was received  |
| 2   | Navi Event with severity WARNING was received      |
| 3   | Navi Event with severity ERROR was received        |
| 4   | Navi Event with severity CRITICAL was received     |
| 5   | Unknown Navi Event was received                    |
| 10  | Navi Event Monitor has terminated                  |
| 100 | A control lun has been cache compromised           |
| 101 | A control lun has been trespassed                  |
| 200 | Device group has changed status                    |
| 201 | A SFP on the CLARiiON is reporting an error status |

### **EXAMPLE SYS LOG EVENT ERROR & EVENT ID:**

Aug 27 11:42:51 2007 NaviEventMonitor:3:3 Backend Event Number 0x904 Host →Navi Severity 3=ERROR, Event ID 3

Aug 27 12:09:54 2007 NaviEventMonitor:4:2 Backend Event Number 0x850 Host →Navi Severity 4=CRITICAL, Event ID 2

### **Required O/S Versions & packages for Napa 8 Platforms**

→Celerra O/S NAS 5.5.30.x (Napa 8)  
→Clariion O/S Flare Version 24  
→Clariion Array AccessLogix package  
→Clariion Array CelerraService package

### **Necessary Celerra Utilities & Versions for Napa 8 Platforms**

→NST (Navisphere Service Taskbar)

**Note:** NST\_setup\_6.26.50.1.14.exe (47MB), Flare 26 version required, Apps & Tools CD, or Clariion sw site

Windows application allowing Customers to access the Array on Integrated & FC-Enabled platforms for limited hardware troubleshooting, healthchecks, and hardware maintenance functions

→Navisphere Manager (OffarrayUI)

**Note:** Windows\_UIs\_6.24.2.5.0.exe (25MB), Flare 24 version required, download from CLARiiON SW site & being shipped with all NS20FC & NS40FC models or available from <http://www.cs.isus.emc.com/csweb2/dgweb/>

Windows application required for managing all Array Storage on the FC-Enabled platforms for Celerra and/or other Hosts—not for use with pure NS20 or NS40 Integrateds

→CSA (Celerra Startup Assistant)

**Note:** csa\_install.exe (38MB), Apps & Tools CD or Powerlink>Celerra Tools site

Windows application required for initializing and minimally configuring new Celerra installations, with built-in Registration wizard

→Stand-alone Registration Wizard (RegWiz)

**Note:** regwiz\_install.exe (34MB), Apps & Tools CD or Powerlink>Celerra Tools site

Windows application allowing for stand-alone Registration of the Celerra system after CSA configuration, required in order to obtain proper EMC Support

→Celerra Manager

**Note:** Built into NAS code, requires compatible Client Web Browser & min. JRE version (no downloads, etc.)

NAS application used for configuring, monitoring, and managing the Celerra; Required for the management of all Array Storage for NS20/NS40 Integrated Celerras

## **NS20 INTEGRATED:**

Uses NS40 blades connecting to CX3-10 array (called the NS2-AUX)

**Note:** CX3-10 is stripped down version of CX3-20—no Combo card, SP's have only 1GB memory, default configuration is for single SPS

(2) Front-end FC Ports BE0 & BE1 for Celerra backend connectivity, to SP ports 0 & 1 Fibre (No Headhunter IO card)

(1) Front-end FC Port for Tape connectivity on DM Blade

## **NS20FC ENABLED (“All-in-One”):**

Uses NS40 blades connecting to CX3-10F array (called the NS2-AUXF)

Ships with Headhunter FC IO Module to add (4) FC Ports on each SP, Blades connecting to Ports 2 & 3 Fibre

(2) Front-end FC Ports for Celerra backend connectivity to SPs, ports 2 & 3 Fibre

(1) Front-end FC Port for Tape connectivity on DM Blade

(4) Front-end FC ports on SPs for other Hosts direct or FC Switch-attached [Ports 0, 1, 4, & 5 Fibre; Mirrorview Port 1]

## **ARRAY MODELS—minimum Flare 24:**

NS2-AUX (CX3-10) & NS2-AUXF (CX3-10F) Models—Integrated Model only, no Gateway systems

**Note:** The CX3-10 & CX3-10F are Celerra array-variants only and not offered elsewhere. The name “SledgeTack” is based on the fact that the DM hardware is an NS40 (CX3-40 array is called Sledgehammer) & the Backend array is Tackhammer (CX3-10 variants)

## **DETERMINING NS20/20FC BACKEND ARRAY TYPE:**

**/nas/sbin/navicli -h 192.168.1.200 getagent**

Model: CX3-10 or CX3-10f

→Output will show whether system is CX3-10 or CX3-10F, the latter which would mean that FC is Enabled for other Hosts

**/nas/sbin/navicli -h 192.168.1.200 storagegroup -list**

**Note:** Both models will use a Celerra Storage Group

50:06:01:60:C1:E0:24:00:50:06:01:69:41:E0:24:00 SP B 3 →Ports 3 & 2 are used for NS20FC or NS40FC

50:06:01:60:C1:E0:24:00:50:06:01:68:41:E0:24:00 SP A 3 →Ports 0 & 1 are used for NS20

**# /nas/sbin/model**

NS20 or NS20FC

**Note:** Command calls /nas/bin/nas\_xml –info and obtains model name from the 2<sup>nd</sup> entry in the PRODUCT\_NAME field. However, the model command also needs to run server\_sysconfig to determine blade motherboard type and CPU information in order to determine model type. If the model command cannot run server\_sysconfig for some reason, the blade model will return as “UnknownFC”, “UnknownG”, etc.

**# nas\_xml -info head**

```
<CELERRA SRC='controlstation'>
<CELERRA_CABINET NAME='APM000738018380000' TYPE='Celerra SledgeHammer'
PRODUCT_NAME='Celerra NS20FC' SERIAL_NO='APM00073701085'
```

**Celerra Manager>Celerra Home>System Info screen will show model number**

## **BASIC SPECS FOR NS20 MODELS:**

→1-2 Data Mover 1U blades, Dual Intel 2.8GHz processors, (4) GB Memory, 800MHz FSB speeds, (4) 10/100/1000 GbE ports, (2) FC ports to the array, & (1) FC port for tape backups—FC port speeds support 2-4Gbps, 16TB capacity per blade FC

**Note:** Data Movers will connect to the SPs on the Internal network to the upper Management port on the SPs vs. the lower Service port used on the NS40—this is because the NS20 will run in SAN mode. NS20 will use NS40 frontend blades, and either CX3-10 (2 FE FC ports) or CX3-10F (6 FE FC ports) backends.

→Single Dewars 1U Control Station with 2GB memory & 2.4GHz CPU, 1 serial RS-232 port for modem, 1 serial RS-232 port on the front of the CS for serial access, 1 External 10/100 Ethernet port for customer's network [eth3—upper left LAN port], & (2) 10/100/1000 Ethernet ports for Internal Network [eth2 is labeled #2, located upper right LAN port; eth0 is labeled 10/100, located lower right LAN port]. Control Station will be labeled with Flare & NAS versions, date, & CS MAC address

→SPE enclosure contains (2) SPs, (1) Standby Power Supply (SPS), (1) or (2) NS20 Blades, and (1) Control Station

→DAE Enclosures have 3U footprint, max. of 60 FC and/or ATA drives allowed in same cabinet, but not same DAE3

## **DEWARS CS ETHERNET PORTS & LABELS:**

eth3 eth2 [labeled #2, connects to lower lan port on DM3]

eth1 eth0 [labeled 10/100, connects to lower lan port on DM2]

### **Raid Configurations:**

1+1 R1, 4+1 R5, 8+1 R5 for Fibre Channel drives

4+1 R5, 6+1R5, 4+1R3, 8+1R3 for SATA drives

**Drives Supported:** Max capacity 35TB

FC 73, 146GB, & 300GB 15K rpm drives

FC 146 & 300GB 10K rpm drives

SATA II Northstar 500 & 750GB 7200rpm drives

FC & SATA II drives can share same array but not same DAE

Minimum configuration of (6) SATA II or FC drives in 6+1 R5

**Note:** FC & SATA II drives can share the same array, but not the same shelf—system drives still require Fibre Channel Drives could be all SATA II, all FC, or mix of FC/ATA on the array, with max of (15) drives per DAE

## **IMPORTANT CHANGES WITH NS20/NS20FC/NS40/NS40FC MODELS:**

**Tiered Service Support model (NS20/20FC only), Enhanced Installability (preloaded code, Placemat, Landing Page, CSA), All-in-One FC Enabled model, new Integrated model, Clariion Mgmt access to Integrated backend SPs (Via new Control Station NAT Service, Clariion NST & OffArrayMgr tools)**

→SPs run in SAN Mode, DMs connect to SPs using Fibre Optic LC-to-LC cables, DMs connect to upper LAN Mgmt port on SP for internal network, Access Logix & Storage Groups used for all models, NST tool connects to new public IPs on the CS, in order to access private IP addresses for SPs on backend (via NAT service)

→NS20FC model adds additional FC ports FE ports for customer SAN Hosts, and BE ports 2/3 for additional DAE buses

→Mirrorview setups will now use Port 1 vs. the highest array Port number, meaning that new installs of NS20FC/NS40FC will have the DMs cabled to SP ports 2 & 3 Fibre vs. ports 0 & 1 Fibre

→All models should be shipped with pre-installed software and will use a colored Placemat contained in the Open Me First package, a Landing Page website for product information and support, and Celerra Startup Assistant (CSA) to configure the box on initial startup

→Based on CX3-10 or CX3-10F array (Celerra variants only), which are really stripped down CX3-20 arrays, less memory, use of all ATA drives is allowed, etc.

**Note:** Only CLARiiON-sold version is the CX3-10C combo

## **CHANGES ON NS80 INTEGRATED FOR NAPA 8:**

--NS80 already uses fibre optic DM-to-SP cabling & topology, as well as SPs that use the “SAN” RESUME personality

--NS80 will be factory-installed with AccessLogix & Celerra Storage Group on the Backend [same as what is being done with NS20]

--Storage & RAID Group info resides in /etc/be\_sg\_info, /etc/be\_rg\_info, resp.

--NS80 will incorporate SPA—SPB communication gateway aliases on CS, meaning that IPTables and NAT Service will be used for SP-to-SP communication when dual Control Stations are configured

--IP Forwarding will be set to 1 with upgrade or from new installs: /proc/sys/net/ipv4/ip\_forward

--The array will have security setup as a Global Domain with user “nasadmin” and default password “nasadmin” assigned, and the Celerra will have array security credentials cached in /nas/site/.clar\_security, for new installs of NS80I

--NS80 will not be configured to support the NST or OffArray Navi Mgr

**Note:** When adding blades to an existing NS80I configuration running NAS 5.5.30 or higher, use the following syntax in order to add the Blade FC ports to the default Storage group, which is a change from the traditional syntax for Integrateds

**# /nas/sbin/setup\_slot -i -g 4** [i.e., -gateway\_auto\_config]

### **Workaround:**

1.) Add Data Mover HBA WWNs manually to both SPs using navicli:

**# /nas/sbin/navicli -h <sp> storagegroup -setpath -o -gname Celerra\_emcnas\_i0 -hbauid <hbauid> -spa | -spb -spport 0 | -spport 1**

2.) Then use setup\_slot -i 4 to complete setup

## **CELERRA DHCP:**

**Two processes are running on the Control Station:**

# ps -eafl |grep dhcp

```
4 S root    3165  1 0 76 0- 779 wait 14:42 ? 00:00:02 /bin/sh /nasmcd/sbin/cs_dhcpd_monitor
1 S root    4473  1 0 75 0- 1015 - 14:43 ? 00:00:00 /usr/sbin/dhcpd -cf /etc/encl_dhcpd.conf eth0 eth2
```

/etc/encl\_dhcpd.conf

--dhcp is used to manage and enforce rules for IP address allocation for Primary (128.221.252.0) & Secondary (128.221.253.0) internal networks

--dhcp is used to assign an IP address to Data Movers when PXE booting for recovery purposes

--dhcp is used to assign APC\_UPS ranges when applicable [via static entries]

--dhcp is used to assign Primary & Secondary mgmt switch IP addresses on mgmt\_2\_3 & mgmt\_2\_3b (internal switches)

--dhcp is used for Enclosure Management for Blades when blades are set to NAS Resume Prom personality

/nas/sbin/cs\_dhcpd\_monitor

--CS monitors dhcp process (/var/run/dhcpd.pid) & automatically restarts if the daemon is stopped for some reason

--dhcp daemon only runs on the Control Station which is running as the Primary

--dhcp monitor service is used to bring up the alias interfaces eth0:1 & eth2:1 that are used for gateway IP addresses for SPA & SPB communications

--dhcp monitor service is used to monitor NAT/Proxy ARP service and restart if required using clarion\_mgmt –start\_service (checks that Proxy RP service is up every 30 secs)

--dhcp monitor feature is only used with IPDART systems (Hammer, Sledgehammer)

--dhcp monitor service ensures ip\_forwarding is always set to 1

--mounts /ftpboot directory

/etc/rc.d/init.d/dhcpd

--startup script which starts the dhcpcd daemon during Control Station reboots

/nas/site/encl\_dhcpd

--starts up dhcpcd dameon using /nas/sbin/setup\_enclosure –dhcpcd start &> /dev/null, and is used to restart daemon when necessary by **DOES CS ETH3 RUN DHCP Client?**

No, not normally. However, a person could run /usr/sbin/netconfig and select [ ] Use dynamic IP configuration (BOOTP/DHCP), and change the eth3 interface to run using DHCP. This would not be a supported function for Celerra.

**CELLERRA NAT (Linux IPTables, aka NAT Network Address Translation):**

**Purpose:**

→Beginning with new installations for Napa 8 (NAS 5.5.30.x), NS systems will implement NAT translation using the IPTables service on the CS.

→NAS Upgrades to Napa 8 also implement NAT & will recommend that the new gateway IPs be configured separately on the SPs

→Main purpose of NAT is to support the Clariion CRU & Storage Management tools [NST & Navisphere OffArray Manager]

→From a Linux perspective, IPTables are used in setting up IP forwarding, packet filtering rules, and Routing rules in tables, with the Linux system acting as a Gateway between Public and Private networks, usually in conjunction with NAT (Network Address Translation) or masquerading. Each table can consist of built-in chains and user-defined chains. Some default tables are “filter”, “nat”, “mangle”, etc., and have built-in chains, such as INPUT, FORWARD, OUTPUT, PREROUTING, POSTROUTING, etc.

**Important IPTables Commands/Files, etc.**

/sbin/service iptables start | stop | restart | status

/sbin/chkconfig iptables –list | -on

# /sbin/chkconfig --list iptables

```
iptables      0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

# rpm -q iptables

iptables-1.2.5-3

/etc/sysconfig/iptables

/sbin/iptables-save >/home/nasadmin/ibak.doc (command will save the /etc/sysconfig/iptables)

/etc/init.d/iptables →initial install script to setup iptables

/nasmcd/sbin/cs\_dhcpd\_monitor →Used to bring up CS aliases if down

Monitors for DHCP daemon and starts; checks that CS aliases for gateway IPs to array are up; checks NAT/Proxy service is started

# /nasmcd/sbin/clarion\_mgmt –info | -stop | -start (Use to verify or recreate public SP IP addresses, NAT entries, and Aliases on Control Station)

**CONFIGURING NAT ON NAS 5.6.37:**

# /nasmcd/sbin/clarion\_mgmt -start -spa\_ip 192.1.4.220 -spb\_ip 192.1.4.221 -use\_nat

Checking if running as root...yes

Checking if model is supported...yes

Checking for integrated system...yes  
Checking if interface eth3 is configured...yes

**# /sbin/iptables -t nat -L POSTROUTING**

### **Removing CS aliases for gateway IPs, NAT entries for SPs, & gateway IPs on SPs (if required):**

1. Remove existing gateway aliases for eth0:1 & eth2:1

```
# /sbin/ifdown eth0:1
# /sbin/ifdown eth2:1
# rm -f /etc/sysconfig/network-scripts/ifcfg-eth0:1
# rm -f /etc/sysconfig/network-scripts/ifcfg-eth2:1
```

2. Remove POSTROUTING entries in /etc/sysconfig/iptables related to SPA-to-SPB

```
/sbin/iptables -t nat -D POSTROUTING -p tcp -s 192.168.1.200 -d 192.168.2.201 -j SNAT --to-source 192.168.1.200
/sbin/iptables -t nat -D POSTROUTING -p tcp -s 192.168.2.201 -d 192.168.1.200 -j SNAT --to-source 192.168.2.201
/sbin/iptables -t nat -D POSTROUTING -p udp -s 192.168.1.200 -d 192.168.2.201 -j SNAT --to-source 192.168.1.200
/sbin/iptables -t nat -D POSTROUTING -p udp -s 192.168.2.201 -d 192.168.1.200 -j SNAT --to-source 192.168.2.201
```

3. If necessary, delete gateway addresses on SPs (requires SP reboot)

```
# /nas/sbin/navicli -h 192.168.1.200 networkadmin -set -gateway 0.0.0.0
# /nas/sbin/navicli -h 192.168.1.200 networkadmin -get
```

Storage Processor: SP A

Storage Processor Network Name: SPA

Storage Processor IP Address: 192.168.1.200

Storage Processor Subnet Mask: 255.255.255.0

Storage Processor Gateway Address: 192.168.1.104

**Note:** NAS 5.6.45 introduces the /nas/sbin/spa\_spb\_comm script, which maintains rules for SP-to-Control Station communications.

Among the rules are checks to ensure that the original default internal IP address entries are maintained in the iptables file, that the alias interface files are maintained with a default gateway for SPA of 128.221.252.104, and SPB 128.221.253.104, even though Proxy ARP may be configured.

### **Rebuilding Gateway addresses & NAT entries for SPA/SPB on CS & SPs:**

1. Recreate CS aliases, IPTTables entries, and Gateway addresses on SPs:

- a. Vi edit to create alias files /etc/sysconfig/network-scripts/ifcfg-eth0:1, ifcfg-eth2:1
 

```
# vi ifcfg-eth0:1
DEVICE=eth0:1
IPADDR=192.168.1.104
# vi ifcfg-eth2:1
DEVICE=eth2:1
IPADDR=192.168.2.104
```
- b. Bring alias interfaces up:

```
/nasmcd/sbin/cs_dhcpd_monitor
c. Rebuild the proper gateway SP-to-SP routing rules using /sbin/iptables:
/sbin/iptables -t nat -A POSTROUTING -p tcp -s 192.168.1.200 -d 192.168.2.201 -j SNAT --to-source 192.168.1.200
/sbin/iptables -t nat -A POSTROUTING -p tcp -s 192.168.2.201 -d 192.168.1.200 -j SNAT --to-source 192.168.2.201
/sbin/iptables -t nat -A POSTROUTING -p udp -s 192.168.1.200 -d 192.168.2.201 -j SNAT --to-source 192.168.1.200
/sbin/iptables -t nat -A POSTROUTING -p udp -s 192.168.2.201 -d 192.168.1.200 -j SNAT --to-source 192.168.2.201
# /sbin/iptables-save >/etc/sysconfig/iptables →This takes the new entries from memory and writes to the iptables file
d. Rebuild SP gateway addresses (only if required, since SPs will need reboot)
# /nas/sbin/navicli -h 192.168.1.200 networkadmin -set -gateway 192.168.1.104
# /nas/sbin/navicli -h 192.168.2.201 networkadmin -set -gateway 192.168.2.104
```

## **CONTROL STATION AND SP COMMUNICATIONS:**

Beginning with NAS 5.6.43, a new script /nas/sbin/spa\_spb\_comm was created to enforce certain rules for the maintenance of a framework for communication between the Control Station and SPs. The rules themselves are checked whenever the PUHC or PAHC scripts are run, or when spa\_spb\_comm –status or –setup is run. The main rules check to ensure that the interface aliases for eth0:1 and eth2:1 exist with the correct gateway entry for the respective SP, that the /etc/hosts have entries for each SP, and that the internal IP address routes for the SPs exist in the /etc/sysconfig/iptables file.

### **Examples:**

#### **/nas/bin/nas\_checkup**

Storage System : Checking SPA SPB communication..... Fail  
-----Errors-----

Storage System: Check SPA SPB communication

Symptom: At least one iptables rule is missing.

Action : Run "spa\_spb\_comm -setup" to fix the problem.

### **Fix:**

#### **# /nas/sbin/spa\_spb\_comm -setup**

Setting up SPA-SPB communication

Flushing firewall rules: [ OK ]  
Setting chains to policy ACCEPT: nat filter [ OK ]  
Unloading iptables modules: [ OK ]  
Applying iptables firewall rules: [ OK ]

Setup completed OK

### **Status Examples:**

#### **# /nas/sbin/spa\_spb\_comm -status**

Checking Gateway of SPA

Gateway for SPB not found

**# /nas/sbin/spa\_spb\_comm -status** -->Example of normal output with no problems detected

Checking Gateway of SPA

Checking Gateway of SPB

### **Example interface alias file is created if missing:**

#### **# /nas/sbin/spa\_spb\_comm -setup**

Setting up SPA-SPB communication

Flushing firewall rules: [ OK ]  
Setting chains to policy ACCEPT: filter nat [ OK ]  
Unloading iptables modules: [ OK ]  
Applying iptables firewall rules: [ OK ]

Checking Gateway of SPA

SPA gateway is already set to 128.221.252.104

SPB's gateway is not 128.221.253.104. Please change it at the earliest convenience.

**Note:** Though the message says to change SPB's gateway at the earliest convenience, the interface alias file is in fact created if it is missing, though it may not be loaded into Control Station memory. Run /sbin/ifup <alias\_name> followed by /sbin/ifconfig to verify whether the alias is up. The User should verify that the SP in question is setup with the correct Network and Gateway IP addresses, and change accordingly using Navisphere or Navicli.

#### **/nas/sbin/spa\_spb\_comm -setup force**

**Note:** This syntax will apply the default internal IP address gateway address to the SP's, and will reboot the SPs. The “force” switch also recreates the gateway alias eth0:1 or eth2:1 files if none exists, or creates a new alias file if the existing one has something other than the default .104 gateway. Additionally, the “force” switch will load the newly created alias file into Control Station memory. See emc210468 for additional information.

#### **# /nas/sbin/spa\_spb\_comm -setup force**

Setting up SPA-SPB communication

Flushing firewall rules: [ OK ]  
Setting chains to policy ACCEPT: filter nat [ OK ]  
Unloading iptables modules: [ OK ]  
Applying iptables firewall rules: [ OK ]

Checking Gateway of SPA

SPA gateway is already set to 128.221.252.104

Changing the gateway of SPB → In this example, had 128.221.253.10 as gw—force changes back to 128.221.253.104

## **GLOBAL ARRAY SECURITY FOR NEW PLATFORMS, & NAVISECCLI:**

- A factory-installed Celerra system will setup Global Domain Security on SPA using a default User “nasadmin” with Password “nasadmin”, with Global Scope 0 and Role of “administrator”
- Existing system upgrades will not modify Global Array Security settings or add Global Security settings—it will allow continued use of Classic Navi
- Array security & local Celerra /etc/.clar\_security cache files are in sync at install to support Classic Navicli commands

## **CREATING ARRAY SECURITY FILE FOR USING NAVISECCLI COMMANDS:**

- Navisecccli security files are stored separately on the Clariion from the Global Array security files, though the username and password are the same
  - In order to use Navisecccli commands, an additional step needs to be taken to create the Navisecccli security file, using the same Username and password as that created by the install for Clariion Global security
- a.) # /nas/sbin/navisecccli -h 192.168.1.200 getagent** [no security file for Secure CLI]  
Security file does not exist. Use navisecccli -AddUserSecurity to create a security file. You must also have a valid user account on the storage system to issue this command. If you do not have a user account, use navisecccli -address <IPAddress | NetworkName> security -adduser to add a user account.

## **b.) # /nas/sbin/navisecccli -h 192.168.1.200 –AddUserSecurity –Scope 0 –user nasadmin**

- Enter password: [enter same password as used for Global Array security acnt]  
→ Storage systems do not allow the use of Secure CLI (navisecccli) commands until the User accountname, password, and scope are defined on the array

## **Viewing Global Array Security from GUI or CLI:**

### **Navisphere>Tools>Security>User Management**

- shows Username ‘nasadmin’ with Administrator Role and Global scope

### **# /nas/sbin/navisecccli -h 192.168.1.200 security -list**

Username: nasadmin  
Role: administrator  
Scope: global

### **# nas\_storage -info id=1 |grep -C1 username**

authenticated = True  
username = nasadmin

## **Three Methods for changing Global Array Security Password/Role:**

1. Navisphere>Tools>Security>Change Password
2. # /nas/sbin/navisecccli -h 192.168.1.200 security -changeuserinfo -user nasadmin -scope global -newpassword nasadmin  
WARNING: You are about to change user: nasadmin (global)  
Proceed?(y/n) y
3. # nas\_storage -modify id=1 -security -username nasadmin -password nasadmin -newpassword ns20isforme  
Changing password on APM00071600514  
done

**Note:** Of the above methods, only nas\_storage -modify command is recommended since it updates the password on the array & the local /etc/.clar\_security cache file on the Celerra—if the other two methods were used, would need to run nas\_storage -modify –security to update .clar\_cache files.

## **USING NAVISECCLI COMMANDS FROM CELERRA:**

**Note:** We still require the following step in order to update the security file for Navisecccli in order to use navisecccli commands

### **# /nas/sbin/navisecccli -h 192.168.1.200 –AddUserSecurity –scope 0 –user nasadmin**

Enter password:

## **CREATING A GLOBAL ARRAY SECURITY ACCOUNT IF NONE EXISTS ON ARRAY:**

### **# /nas/sbin/navisecccli -h 192.168.1.200 security -adduser -user nasadmin -password nasadmin -scope global -role administrator**

WARNING: You are about to add user: nasadmin

Proceed?(y/n) y

This storage system is not in a domain. It is highly recommended you create a domain.

**Note:** If this is a Celerra-owned array (e.g.,NS20/20FC), log into the array using Navisphere and then set the Domain Master to SPA

### **ADDING ANOTHER GLOBAL USER SECURITY ACCOUNT TO THE ARRAY:**

# /nas/sbin/navisecli -h 192.168.1.200 –user nasadmin –password nasadmin –scope 0 security -adduser -user second\_admin -password second\_admin -scope global -role administrator

## **NS20 FIBRE CHANNEL & NETWORK CABLING:**

### **DM-to-SP Connectivity:**

DM Blades connect to (2) FE FC ports on the SPs (Fibre Optic cables & SFP connectors)

Total of (2) FE Fibre Channel ports on the array

--DM2 Blade BE0 connected to SPA port 0 Fibre

--DM2 Blade BE1 connected to SPB port 0 Fibre

--DM3 Blade BE0 connected to SPA port 1 Fibre

--DM3 Blade BE1 connected to SPB port 1 Fibre

### **DM, CS, & SP LAN Connectivity:**

--DM2 blade lower LAN port to CS 10/100 port

--DM2 blade upper LAN port to SPA upper Management LAN port

--DM3 blade lower LAN port to CS #2 Port

--DM3 blade upper LAN port to SPB upper Management LAN port

### **SP-to-DAE Connectivity:**

--SPA FC Port BE0 to LCCA PRI port on DAE3P

--SPB FC Port BE0 to LCCB PRI port on DAE3P

## **NS20FC ENABLED FIBRE CHANNEL & NETWORK CABLING:**

### **DM-to-SP Connectivity:**

DM Blades connect to (2) FE FC ports on the SPs (Fibre Optic cables & SFP connectors)

Additionally, SPs have (4) extra FE FC optical ports for direct-connect or Switched Fabric Host connections

Total of (6) FE Fibre Channel ports on the array

--DM2 Blade BE0 connected to SPA port 2 Fibre

--DM2 Blade BE1 connected to SPB port 2 Fibre

--DM3 Blade BE0 connected to SPA port 3 Fibre

--DM3 Blade BE1 connected to SPB port 3 Fibre

**Note:** SP FC ports 0, 1, 4, 5 available for other Hosts, with Port 1 recommended for Mirrorview

### **DM, CS, & SP LAN Connectivity:**

--DM2 blade lower LAN port to CS 10/100 port

--DM2 blade upper LAN port to SPA upper Management LAN port

--DM3 blade lower LAN port to CS #2 Port

--DM3 blade upper LAN port to SPB upper Management LAN port

### **SP-to-DAE Connectivity:**

--SPA FC Port BE0 to LCCA PRI port on DAE3P

--SPB FC Port BE0 to LCCB PRI port on DAE3P

## **USING NAT-ENABLED TOOLS TO ACCESS CLARIION BACKENDS:**

→NST can be used on NS20/40 & NS20FC/40FC models, selecting NAT option on connection screen

→Navisphere OffArray Manager can only be used on NS20FC/40FC models, selecting NAT option

**Note:** OffArray restriction has been lifted with the advent of the Proxy ARP solution, which became the standard CSA configuration with 5.5.31

## **NAVISPHERE SERVICE TASKBAR (NST):**

→NST Version 6.26.50.1.14 or higher is required to support the Celerra Integrated functionality that the NST tool provides

→JRE 1.5.0\_06

**Note:** When properly connected to both SP's on an Integrated Celerra using the NAT option with the NST logon screen, certain functionality is restricted and a popup will be displayed when a User clicks on one of the following items:

Download and Install Hot Fix

Prepare for Installation

Register Storage

Software Assistant>Install Software

Software Assistant>Help menu

**“This feature is not supported on your Celerra integrated system.”**

→For the new NS20/20FC and the new NS40/40FC Celerras, the Navisphere Service Taskbar will be available to Customers for performing limited troubleshooting tasks and hardware maintenance, and is considered an off-array tool.

→The NST & OffArray Navisphere will be allowed for the NS20FC/NS40FC models (Navisphere Web Manager is not NAT aware and will not work).

→NST will be capable of auto-updates, a new feature in Flare 26

**Note:** Since the SPs are not normally accessible via the public network for Integrated units, a new strategy has been devised to allow for two new public IP addresses on the Control Station, and a “Celerra Identifier” flag will be set by the “Celerra Service Enabler” API in Flare that will allow the NST to access either SPA or SPB from a Windows host by using NAT translation to pass requests from the Windows Host to the SPs via the Control Station.

**# /nas/opt/Navisphere/bin/navicli -h 192.168.1.200 ndu -list**

Name of the software package: -CelerraService

Revision of the software package: -

Commit Required: NO

Revert Possible: NO

Active State: YES

Is installation completed: YES

Is this System Software: NO

## **HOW NST WORKS**

→User must select Options from NST screen and enter the public IPs for both SPA & SPB in the NAT connection dialogue box in order to connect to the internal IP addresses on the SPs

→User then logs into Clariion with username and password

→After logon, a CIMOM API call is made to the SP in order to retrieve the CelerraIdentifier flag (if the flag exists with the CelerraService pkg running on the backend, that indicates an array dedicated to Celerra)

→Once CelerraIdentifier is found, the JnfxRunEnvironment sets the bCelerraEnabled flag to true, at which point certain NST functions will become “disabled” and made known to the User via the use of system PopUps

## **NST/NAT COMPONENTS:**

→CelerraService pkg running on Array

→NST API to check CelerraIdentifier flag on backend

→NAT (Network Address Translation) service running on Control Station, performs pass-through routing to SPs from the NST using Linux IPTables that will be created initially from the CSA interface, or manually by using clarion\_mgmt, and creates the NAT Service and IPTables, Control Station aliases eth3:1 & eth3:2 will be configured for the two new IP addresses (SPA, SPB) that will allow the Public-to-Private NAT pass-through service from the NST and/or OffArrayMgr utility, and Control Station aliases eth0:1 & eth2:1 will be created to provide for the SP-to-SP communications that are needed in order to route packets between the 192.168.1 and 192.168.2 networks (192.168.1.104 SPA 192.168.2.104 SPB), with the CS acting as the Router between the SPs.

→The Windows host would open the NST application, select the “Network Address Translation (NAT) Connection” option, then enter the public IP addresses (Hosted on Control Station) for both SPA & SPB. Once the connection is made, the User logs in using the username and password configured on the Clariion backend for global security. An API in the NST tool contacts the SPs and checks for the existence of the CelerraService. If found, the system is considered a Celerra backend configuration and certain tasks will be disabled by the NST tool.

## **Functions that are disabled on the NST utility for Celerra Integrateds:**

NST>Tools>Software Maintenance Status →Unsupported Feature popup

Hardware Registration>Register Storage System →Unsupported Feature popup

Software Assistant: →All wizards disabled, Unsupported Feature popup

Download and Install Hot Fix

Prepare for Installation (Step-1)

Install Software (Step-2)

## **Functions that are Enabled for the NST Wizard:**

Hardware Installation> Install Disk Array Enclosure & Install Disk

Hardware Maintenance

Verify Storage System →Array Healthcheck tool that does System check, captures config data, and reports on issues found. XML & .zip captures are written to c:\EMC\repository\APM00071600514\HCK directory

Replace Disk →This is commonly known as the “DRU Tool”, copies of analysis summary kept in c:\EMC\repository\APM00071600514\DRU directory

Capture SPCollect →Gathers SPCollects and writes to c:\EMC\repository\APM00071600514\HCK directory, though offers ability to Browse to document Repository or use the “Save as” to save to new location

Engineering> Upgrade Disk Firmware (for disks, accessed in Eng Mode only)

Engineering Mode Offers one additional wizard

Ctrl + shift + f12 Password: SIR

Engineering>Upgrade Disk Firmware

## **Testing “Replace Disk” DRU Tool using Navicli:**

1. Pick drive to disable (must be part of a RAID Group—will not show up otherwise in getcrus list)
2. Disable drive using navicli and verify:

```
# /nas/sbin/navicli -h 192.168.1.200 cru_on_off -messner 0_0_12 0 (this places disk 12 in Bus 0 Enclosure 0 down)
# /nas/sbin/navicli -h 192.168.1.200 getcrus
```

DAE3P Bus 0 Enclosure 0 \*FAULT\*

(Bus 0 Enclosure 0 : Faulted; Bus 0 Enclosure 0 Disk 12 : Removed)

3. Perform Replace Disk procedure using NST Hardware Maintenance>Replace Disk Wizard

4. At last screen after replacing disk, you will need to issue following command to let the tool find the drive and complete task (since we manually disabled, need to manually re-enable)

```
# /nas/sbin/navicli -h 192.168.1.200 cru_on_off -messner 0_0_12 1 [places drive back up]
```

**Note:** If there are two faulted drives in the same Raid Group, the “Disk Analysis Summary” says that the “Storage system is not a candidate for customer disk replacement” and the Details button shows the “Override Issues” option as greyed out, meaning that the issue needs to be escalated to EMC support.

## **How NST connects to backend SPs over public network:**

→Start NST from Windows, click radial button for “Network Address Translation” (NAT), select “both” SPA & SPB’s public IP address, enter username & password, and connection is established if the CelerraEnabler was discovered via the Clariion Identifier API, and IP requests are forwarded to the SP via the NAT Service & IPTables

## **CONTROL STATION, SPA & SPB, COMMUNICATION PATHS:**

### **Public Passthrough eth3:1 or eth3:2:**

→NST User connects to public IP for SPA, which resides on CS alias eth3:1, and passes traffic to Internal CS eth0 via NAT, to SPA  
→NST User connects to public IP for SPB, which resides on CS alias eth3:2, and passes traffic to Internal CS eth2 via NAT, to SPB

**Note:** The SP’s public IP addresses & aliases, and IPTables NAT entries are configured on the Control Station, either during CSA setup or separately by the clarion\_mgmt CLI tool

### **SP-to-SP Communications over Internal Network eth0:1 & eth2:1:**

→Communications between SPA & SPB are routed by CS between Internal gateway aliases eth0:1 192.168.1.104 (SPA) and eth2:1 192.168.2.104 (SPB) in situations where Dual Control Stations are setup (e.g., NS80 platform)

**Note:** Secondary CS is setup with the same ‘Floating IP’ configuration & is not enabled until failover—the CS running NAS Services also runs the Floating IP scheme.

→SP-to-SP communication paths are setup during system factory install, as are the requisite NAT rules

## **CELLERRA CONFIGURATION CHANGES FOR NST SUPPORT:**

→During initial setup using the CSA (Celerra Startup Assistant), two public IP Addresses will be configured as aliases eth3:1 & eth3:2 for SPA & SPB on the Control Station

→A new NAT translation service on the Control Station will serve as a passthrough service for the NST & OffArray Utilities (NS20FC/NS40FC only)

→The NST or OffArray Navi Manager runs on a Windows system on the customer’s public network

→The OffArray Navi Manager software & FC Enablement license will not be licensed for non-FC models

→For the Internal Celerra network, the Control Station will host two new aliases, eth0:1 & eth2:1, that will use the 192.168.1.104 (SPA) & 192.168.2.104 (SPB) IPs as gateways for SP-to-SP access

→CSA calls the following script to configure the NST interfaces, or could be used manually:

```
/nasmed/sbin/clarion_mgmt -stop | -start -spa_ip xxx.xxx.xxx -spb_ip xxx.xxx.xxx
```

→LUNs 16 & 17 will be created on the exclusive Celerra RAIDGroup 0 for Integrateds, and for the All-in-One if more than 6 disk drives are detected—otherwise will reserve some LUN 0 space

### **Maintenance Scenarios:**

Disk to be replaced by EMC using DRU (Clariion Disk Replacement Utility—part of the NST)

Pwr Supplies, Fans, SPS to be replaced by EMC using Landing Page link

SFP/Cabling, Blade, SP, LCC, CS, & Enclosure/Midplane will be replaced by EMC using Landing Page

## **NAVISPHERE OFFARRAY MANAGER:**

→Storage management application to be used with NS20FC & NS40FC systems for configuring additional storage for Celerra and for other Hosts on the array

→Flare 24 version of the application is used with the new Celerra FC platforms [version 6.24.2.5.0] and is NAT capable  
Download from CLARIION Software site: <http://www.cs.isus.emc.com/csweb2/dgweb/software/index.asp#CX3%20-%20ARRAY%20BASED%20SOFTWARE>

Navisphere OffArray UI’s (Windows) 6.24.2.5.0

Install the “Windows\_UIs\_6.24.2.5.0.exe” on the Windows system

Installation places a “Navisphere Manager” shortcut on the Desktop

- a.) Launching “Navisphere Manager” brings up a Web Browser using the following URL, which is just the path to, C:\Program Files\EMC\ManagementUI\6.24.2.5.0\WebContent\start.html, followed by a Navisphere Connection screen
- b.) Select Options>Network Address Translation (NAT) Connection & enter the public IP addresses of SPA and SPB
- c.) Once connected, use the righthand pane to conduct traditional storage-management activities, such as configuring new Raid Groups, Binding Luns, adding Luns to Storage Groups, assigning proper HLU assignments when Celerra Luns are involved, etc.
- d.) Use the lefthand pane to access various Wizards for “Storage Management”, “Monitoring”, “Replication”, “Reporting”, & “Service”

**Note 1:** When managing/adding storage for Celerra NS20FC/NS40FC systems, the wizards are not particularly useful. The “Storage Management” wizard can Allocate storage by creating new RGs, new LUNs, and assigning to Servers, but since Celerra doesn’t run an agent, it cannot make use of this feature. Luns could be created for Celerra using the “Create LUN without Host assignment” option in the wizard, but the Assign wizard could not be used to assign to the Celerra Storagegroup for the reason already mentioned—logged as a bug and fixed with 5.6.39.x release.

**Note 2:** Beginning with Napa 9 and the Proxy ARP implementation, either Navisphere Offarray or Onarray Manager utilities are acceptable. Onarray Navisphere runs on the SPs and is more easily accessed since there is no separate application that needs to run on the client PC.

### **Using the Storage Management>Allocate wizard & Navisphere GUI to add Storage on the Celerra:**

- a.) Create new RAID Group (or use existing RG) using Allocate wizard
- b.) Select newly created RG and bind desired number of LUNs (since Celerra is not seen on the assignment list, select “Create LUN without Host assignment”)
- c.) In the Navisphere pane (righthand side) of GUI, highlight Celerra\_emcnas\_i0 Storage Group>Select LUNs
  - Available LUNs
    - Expand list on each SP and click the checkbox for the desired LUNs
  - Selected LUNs
    - Locate LUNs that are being added and assign a valid HLU number (>than 16) in the far right of the screen
- d.) Add the new LUNs to the Celerra database using either the GUI Rescan function or the CLI nas\_diskmark option  
Celerra Manager>Celerras>Storage>Systems>Rescan

# nas\_diskmark -m -a

### **Using the Navisphere GUI to add Storage on the Celerra:**

- a.) Create new RAID Group by rightclicking RAID Groups>Create RAID Group (select number of disks, RAID protection, etc.)
- b.) Rightclick new RAID Group>Bind LUN (create desired luns, SPs to use (auto), size of LUNs, ALU number, etc.)
- c.) Rightclick Storage Groups>Celerra\_emcnas\_i0>Select LUNs
  - Available LUNs
    - Expand list on each SP and click the checkbox for the desired LUNs
  - Selected LUNs
    - Locate LUNs that are being added and assign a valid HLU number (>than 16) in the far right of the screen
- d.) Add the new LUNs to the Celerra database using either the GUI Rescan function or the CLI nas\_diskmark option  
Celerra Manager>Celerras>Storage>Systems>Rescan

# nas\_diskmark -m -a

### **UPGRADING FLARE USING NAVISPHERE OFFARRAY MANAGER:**

- When in Non-Engineering mode and using Software Operations, a popup says that NST is the tool to use for SW updates
- In Engineering mode>Array>Software Operations>Software Installation Wizard>it is possible to perform NDU

### **SOFTWARE UPGRADES TO NS20/40 INTEGRATED SYSTEMS (NAS/FLARE):**

- Software upgrades to Napa 8 are allowed for Celerra—use CD-ROM setup script
  - Only thing to know is that it will change the configuration on certain models (NS40I, NS80I)
    - Adds CelerraService pkg to backend array
    - Permanently enables IP Forwarding
    - Starts IPTables NAT Service and adds aliases eth0:1 & eth2:1 to support new backend gateway SP-to-SP communication scheme (though doesn’t actually change the SP gateway IP on its own—advises User to do this when the SPs can be rebooted)
  - Flare upgrades are also allowed, but not via NST or Navisphere tools
  - Though not yet revised, the Flare NDU procedure from NAS ProcGen is adequate to perform the NDU using CLI from the Celerra
- Note:** Officially, you are not allowed to use the Navisphere GUI for NDU, but this does work if using Engineering Mode and the SIW
1. Open Navisphere, select Options>NAT and enter IP’s for both SP’s
  2. Log into array using security account and password
  3. Do ctrl + shift + F12 and password to enter Engineering Mode
  4. Perform NDU: **Navisphere Manager>Array>Properties>Software Operations>Software Installation Wizard**
- Note:** Either GUI or CLI methods requires that Statistics Logging be disabled on both SPs for the NDU process
5. CLI commandline example:  
**#/nas/sbin/navicli -h 192.168.1.200 ndu -install /home/nasadmin/flare/CX3-40-Bundle-03.24.040.5.014.pbu -delay 360**

## **CELERRA AND PROXY ARP IMPLEMENTATION**

→Beginning with Napa 9 release, Proxy ARP will automatically be setup during the CSA Pre-Configuration “Apply” screen phase for all NS20 & NS40 models—we will no longer be using the NAT implementation that shipped with Napa 8.

→SPs will be assigned a public IP address and will reboot during the CSA setup phase

→A status bar on the righthand side of the CSA screen will inform user of the progress made for the (12) steps that are part of the Proxy\_ARP upgrade process

### **CSA Example:**

“Setting up backend IP…

Backend IP Setup | Step 11/12: Waiting for CLARiiON software to start on SPB.”

### **Troubleshooting:**

**/sbin/arp -n -i eth3**

**/nasmed/sbin/clariion\_mgmt -start\_service -v** [Fixes ARP entries, adds Host routes, enables Proxy ARP on interfaces]

**Note:** This option is no longer functional in NAS 5.6

**/sbin/sysctl net.ipv4.conf.eth0.proxy\_arp net.ipv4.conf.eth2.proxy\_arp net.ipv4.conf.eth3.proxy\_arp** [Enables Proxy ARP svc]

## **MANUALLY SETTING PROXY ARP TO 1:**

```
# echo 1 >/proc/sys/net/ipv4/conf/eth0/proxy_arp  
# echo 1 >/proc/sys/net/ipv4/conf/eth2/proxy_arp  
# echo 1 >/proc/sys/net/ipv4/conf/eth3/proxy_arp
```

## **PROXY ARP CONFIGURATION ON 5.5.31.6—Dual Blade NS40FC:**

**# /nasmed/sbin/clariion\_mgmt -info**

Public IP address for SPA: 192.1.4.220

Public IP address for SPB: 192.1.4.221

Start on boot : yes

Current implementation : Proxy-ARP

Status : Started

done

**# cat /etc/sysconfig/static-routes** →These routes are created during Proxy ARP setup during CSA configuration

eth0 host 192.1.4.220 dev

eth2 host 192.1.4.221 dev

**Note:** The static-routes file is used for single blade systems to define a path between the CS, using eth2, and SPB, using an internal IP address of 128.221.253.102, but after Proxy ARP is setup, the public IP addresses are used as the routes to SPA & SPB.

**# cat static-routes**

eth2 host 128.221.253.201 dev

eth0 host 192.1.4.220 dev

eth2 host 192.1.4.221 dev

**# cat /etc/sysconfig/network-scripts/ifcfg-eth3** →Normal external interface configuration file after Proxy ARP setup

DEVICE=eth3

IPADDR=192.1.4.218

NETMASK=255.255.255.0

NETWORK=192.1.4.0

BROADCAST=192.1.4.255

## **ADDING A WINDOWS HOST TO FC ENABLED ARRAY & IMPLEMENTING PROXY ARP:**

Powerlink>Celerra Tools>NS20 Integrated>under the Install section Step 5 provides link to procedure to add a Direct-connect or Fabric Switch-connected Windows Host to the FC-Enabled array

### **Host Requirements:**

Windows 2000/2003 with QLogic or Emulex Fibre Channel HBA (check eLab)

Navisphere\_Server\_Utility\_6.24.1.4.0.exe installed on Windows client, which uses a Registration Service Feature to register Host HBA's with the array

Install PowerPath on the Windows Server

### **Configuring Host:**

Connect to Ports 0, 1, 4, or 5 fibre on NS20FC array [Ports 0 & 1 Fibre NS40FC]

Create zone entries on Fabric Switch

Register the Windows Host with the array

Upgrade Celerra NAT to Proxy ARP

Connect to SPs using either Navisphere Manager or NST

Allocate Storage & create LUNs for the new Host

Verify PowerPath sees all paths & write disk signature to LUNs

### **What is Proxy ARP?**

→Proxy ARP is a Linux feature that bridges broadcast traffic using host routing for defined interfaces

→Celerra Control Station becomes a Layer 2 Bridge, and SPs are converted to Public IP Addresses, yet still connect to private network

→SNAT (Static Network Address Translation) works by using a one-to-one mapping of a public IP address to a masqueraded private IP address (on the Server), whereas Proxy ARP allows the public IP address to be routed to the protected side of the Router (i.e., Control Station)

→In practice, this means that the SPs will be configured with public IP address & Gateway addresses and the private IP addressing scheme is dropped

→Please note that the Proxy ARP conversion requires that SPs be rebooted!

→Proxy ARP is the default implementation model for all Celerra Integrated installs of NS20/20FC, NS40/40FC, NX4/NX4FC

→Proxy ARP is needed because of Clariion issues related to multiple Domain management and Layered applications, in which NAT for the NST & Navisphere Mgr tools may not otherwise always work correctly—Proxy ARP solves this

### **Clariion mgmt Script NAS Version Rules:**

#### **Rule 1:**

For NAS 5.5.30.5 systems, the clariion\_mgmt.zip download is no longer available from Powerlink—if running 5.5.30 with NAT and needing to convert to Proxy ARP, the recommendation would be to upgrade to the latest NAS code, then convert using clariion\_mgmt

#### **Rule 2:**

For NAS 5.5.31.6 systems, or higher, use the clariion\_mgmt script that is resident on the system with the respective NAS version

**Note 1:** Last-minute changes were made to the original clariion\_mgmt script in order to convert a Celerra from NAT to ProxyARP, and is available on Powerlink. Download & unzip the following file, place the file onto portable media, mount the media to the CS, and copy the clariion\_mgmt.exe script to /nasmcd/sbin and /nas/sbin, overwriting the existing clariion\_mgmt script.

[http://powerlink.emc.com/km/live1/en\\_US/Offering\\_Technical\\_Documentation/clariion\\_mgmt.zip](http://powerlink.emc.com/km/live1/en_US/Offering_Technical_Documentation/clariion_mgmt.zip)

**Note 2:** The above instruction only applies when upgrading to Proxy ARP for NAS 5.5.30 systems! Beginning with Napa 9, all new NS20 or NS40 installs will implement Proxy ARP during CSA configuration.

### **Basic implementation of Proxy ARP on Celerra involves the following:**

- I. Enabling proxy arp in the kernel for eth0, eth2, eth3: proxy\_arp=1
- II. Adding Routes on CS to SPs using static-routes file
- III. Changing IP & gateway addresses on SPs to public
- IV. Updating /etc/hosts with new SP addresses
- V. Upgrading CS NAT to Proxy ARP implementation [clariion\_mgmt.cfg]
- VI. Updating Clariion Domain Security cache files on Celerra
- VII. Automatically fails Celerra luns back after SPs have rebooted

### **Things to know before running clariion mgmt script:**

- Do not upgrade from NAT to Proxy ARP if running 5.5.30 (Upgrade latest 5.5 first, then convert to Proxy ARP)
- Be aware that script will require that both SPs be rebooted in order to change the network & gateway IP addresses
- Be aware that the script reapplies the Clarion array security settings on the Celerra, so the User must know the username & password [a default FC Enabled Celerra will have username of “nasadmin” and password “nasadmin”, though customer may have changed the password—the username remains the same]
- Be aware that there are hidden options in clariion\_mgmt to assist in upgrading in the face of problems, as well as to revert to the original NAT configuration
- If a problem cannot be surmounted during the conversion to Proxy ARP, open a case with EMC Support

### **Upgrading from NAT to Proxy ARP with NAS 5.5.30\*:**

\*The following procedure is no longer recommended since the clariion\_mgmt.zip file is no longer maintained on Powerlink. The recommendation would be to upgrade to latest 5.5 code, then convert to Proxy ARP by first doing clariion\_mgmt –stop to cleanup NAT, then clariion\_mgmt –start –use\_proxy\_arp to convert.

1. Verify current NAT configuration:

```
# /nasmcd/sbin/clariion_mgmt -info
Public IP address for SPA: 10.241.168.151
Public IP address for SPB: 10.241.168.152
Start on boot      : yes
Current implementation : NAT
Status           : Started
```

2. Download latest clariion\_mgmt script from Powerlink, unzip, and copy to the following locations on the Control Station:

[http://powerlink.emc.com/km/live1/en\\_US/Offering\\_Technical/Technical\\_Documentation/clariion\\_mgmt.zip](http://powerlink.emc.com/km/live1/en_US/Offering_Technical/Technical_Documentation/clariion_mgmt.zip)

```
# cp clariion_mgmt /nasmcd/sbin
# cp clariion_mgmt /nas/sbin
```

**Note:** If the system is running NAT and has been upgraded to 5.5.31 or higher, you should not use the Powerlink “clariion\_mgmt.zip” file—the correct clariion\_mgmt script is already in /nasmcd/sbin.

3. Execute the Proxy Upgrade:

```
# /nasmcd/sbin/clariion_mgmt -upgrade_to_proxy_arp
```

4. Verify connectivity with SPs after upgrade completes:

```
# /nas/sbin/navicli -h 10.241.168.151 getagent [repeat for SPB]
```

5. Verify results of Proxy ARP Upgrade:

```
# /sbin/sysctl net.ipv4.conf.eth0.proxy_arp
```

net.ipv4.conf.eth0.proxy\_arp = 1

```
# /sbin/sysctl net.ipv4.conf.eth2.proxy_arp
```

net.ipv4.conf.eth2.proxy\_arp = 1

```
# /sbin/sysctl net.ipv4.conf.eth3.proxy_arp
```

net.ipv4.conf.eth3.proxy\_arp = 1

```
# /nasmcd/sbin/clariion_mgmt -info
```

Public IP address for SPA: 10.241.168.151

Public IP address for SPB: 10.241.168.152

Start on boot : yes

Current implementation : Proxy-ARP

Status : Started

```
# cat static-routes
```

eth0 host 10.241.168.151 dev

eth2 host 10.241.168.152 dev

```
/etc/sysconfig/network-scripts
```

```
# cat route-eth0
```

scope host 10.241.168.151 dev eth0

```
# cat route-eth2

### Abridged output from /nasmcd/sbin/clariion\_mgmt -upgrade to proxy arp:

Removing network alias eth3:1...done

Removing network alias eth3:2...done

Adding rules to allow outbound traffic from SPA

Changing SPA IP from 192.168.1.200 to 10.241.168.151 (subnetmask 255.255.255.0, gateway 10.241.168.128)

Waiting for SPA to go down...done

Waiting for SPA to come back up.....done

Adding host specific route for SPB

Adding rules to allow outbound traffic from SPB

Adding ARP entry for SPB

Updating /etc/hosts entry for SPB

Changing SPB IP from 192.168.2.201 to 10.241.168.152 (subnetmask 255.255.255.0, gateway 10.241.168.128)

Waiting for SPB to go down...done

Waiting for SPB to come back up.....done

Updating NAS database with new CLARiiON IP addresses

Updating NAS cache of CLARiiON password

Enter the Global CLARiiON account information

Username: nasadmin

Password: \*\*\*\*\*

Retype your response to validate

Password: \*\*\*\*\*

Setting security information for APM00071600514

Done

### UPGRADING TO PROXY ARP WITH NAS 5.5.31:

**Note:** Original documentation says that to convert from NAT to Proxy ARP only required the –upgrade\_to\_proxy\_arp switch for clariion\_mgmt. This method does not work and must be modified. See emc175337.

#### Workaround:

##### 1. Breakdown NAT configuration:

```
# /nasmcd/sbin/clariion_mgmt -stop (removes eth3:1 & eth3:2 aliases and IPTables entries)
```

Checking if running as root...yes  
Checking if model is supported...yes  
Checking for integrated system...yes  
Checking if interface eth3 is configured...yes  
Checking if interface eth3:1 is configured...yes  
Checking if interface eth3:2 is configured...yes  
Checking if SP (128.221.110.200) is up...yes  
Checking if SP (128.221.111.201) is up...yes  
Removing network alias eth3:1...done  
Removing network alias eth3:2...done  
done

**# /nasmcd/sbin/clariion\_mgmt -info**

Error 12: Not configured

**2. Convert directly to Proxy ARP from an Unconfigured state:**

**# /nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.220 -spb\_ip 192.1.4.221 -use\_proxy\_arp**

Checking if running as root...yes  
Checking if model is supported...yes  
Checking for integrated system...yes  
Checking if interface eth3 is configured...yes  
Checking if interface eth3:1 is configured...no  
Checking if interface eth3:2 is configured...no  
Checking if SP (128.221.110.200) is up...yes  
Checking if SP (128.221.111.201) is up...yes  
Checking if a gateway is setup for eth3...yes

Step 1/12: Setting up Proxy ARP for SPA on Control Station

Adding host specific route for SPA  
Adding rules to allow outbound traffic from SPA

Adding ARP entry for SPA

Updating /etc/hosts entry for SPA

Step 2/12: Changing SPA IP address.

Changing SPA IP from 128.221.110.200 to 192.1.4.220 (subnetmask 255.255.255.0, gateway 192.1.4.254)

Step 3/12: Waiting for SPA to reboot.

Waiting for SPA to go down...done

Step 4/12: Waiting for SPA to boot up.

Waiting for SPA to come back up...done

Step 5/12: Waiting for CLARiiON software to start on SPA.

Waiting for CLARiiON software to start on SPA.....done

Step 6/12: Updating NAS database with SPA IP address

Updating SYMAPI database with new CLARiiON IP addresses...done

Step 7/12: Setting up Proxy ARP for SPB on Control Station

Adding host specific route for SPB

Adding rules to allow outbound traffic from SPB

Adding ARP entry for SPB

Updating /etc/hosts entry for SPB

Step 8/12: Changing SPB IP address.

Changing SPB IP from 128.221.111.201 to 192.1.4.221 (subnetmask 255.255.255.0, gateway 192.1.4.254)

Step 9/12: Waiting for SPB to reboot.

Waiting for SPB to go down.....done

Step 10/12: Waiting for SPB to boot up.

Waiting for SPB to come back up...done

Step 11/12: Waiting for CLARiiON software to start on SPB.

Waiting for CLARiiON software to start on SPB.....done

**MANUALLY RECOVERING OR SETTING UP PROXY ARP WITH NAS 5.6:**

**Note:** Both SP's could either be on the Celerra internal network (128.221.252.200/128.221.253.201), or on a Public IP address, but the following example is shown with both SPs beginning on the Celerra internal networks. The following example presumes that the Control Station Hostname and external IP address are already configured.

**2) Edit the /etc/hosts and /nas/site/sp\_info files so that both SPA & SPB reflect their public IP addresses:**

**# vi /etc/hosts # vi /nas/site/sp\_info**

**3) Enable Proxy ARP on the eth0, eth2, and eth3 Control Station interfaces:**

```
# /sbin/sysctl net.ipv4.conf.eth0.proxy_arp
```

net.ipv4.conf.eth0.proxy\_arp = 0 → 0 indicates that Proxy ARP is disabled

```
# /sbin/sysctl net.ipv4.conf.eth0.proxy_arp=1
```

```
# /sbin/sysctl net.ipv4.conf.eth2.proxy_arp=1
```

```
# /sbin/sysctl net.ipv4.conf.eth3.proxy_arp=1
```

**4) Build the IP Tables entries for the SP Public IP addresses for TCP, UDP, & ICMP:**

```
# /sbin/iptables -t nat -A POSTROUTING -p tcp -s 10.241.168.179 -d 0.0.0.0 -j SNAT --to-source 10.241.168.179
# /sbin/iptables -t nat -A POSTROUTING -p udp -s 10.241.168.179 -d 0.0.0.0 -j SNAT --to-source 10.241.168.179
# /sbin/iptables -t nat -A POSTROUTING -p icmp -s 10.241.168.179 -d 0.0.0.0 -j SNAT --to-source 10.241.168.179
# /sbin/iptables -t nat -A POSTROUTING -p tcp -s 10.241.168.180 -d 0.0.0.0 -j SNAT --to-source 10.241.168.180
# /sbin/iptables -t nat -A POSTROUTING -p udp -s 10.241.168.180 -d 0.0.0.0 -j SNAT --to-source 10.241.168.180
# /sbin/iptables -t nat -A POSTROUTING -p icmp -s 10.241.168.180 -d 0.0.0.0 -j SNAT --to-source 10.241.168.180
```

**5) Save the IP Tables entries from memory to the IP Tables file:**

```
# /sbin/iptables-save >/etc/sysconfig/iptables
```

**6) Verify IP Tables entries:**

```
# cat /etc/sysconfig/iptables
```

-----abridged-----

```
:POSTROUTING ACCEPT [2984081:210282993]
:OUTPUT ACCEPT [0:0]
-A POSTROUTING -s 128.221.252.200 -d 128.221.253.201 -p tcp -j SNAT --to-source 128.221.252.200
-A POSTROUTING -s 128.221.253.201 -d 128.221.252.200 -p tcp -j SNAT --to-source 128.221.253.201
-A POSTROUTING -s 128.221.252.200 -d 128.221.253.201 -p udp -j SNAT --to-source 128.221.252.200
-A POSTROUTING -s 128.221.253.201 -d 128.221.252.200 -p udp -j SNAT --to-source 128.221.253.201
-A POSTROUTING -s 10.241.168.179 -d 0.0.0.0 -p tcp -j SNAT --to-source 10.241.168.179
-A POSTROUTING -s 10.241.168.179 -d 0.0.0.0 -p udp -j SNAT --to-source 10.241.168.179
-A POSTROUTING -s 10.241.168.179 -d 0.0.0.0 -p icmp -j SNAT --to-source 10.241.168.179
-A POSTROUTING -s 10.241.168.180 -d 0.0.0.0 -p tcp -j SNAT --to-source 10.241.168.180
-A POSTROUTING -s 10.241.168.180 -d 0.0.0.0 -p udp -j SNAT --to-source 10.241.168.180
-A POSTROUTING -s 10.241.168.180 -d 0.0.0.0 -p icmp -j SNAT --to-source 10.241.168.180
```

**7) Change the IP addresses on the SPs using Secure Navicli:**

```
# /nas/sbin/navisecli -h 128.221.252.200 -user nasadmin -password nasadmin -scope 0 networkadmin -set
-address 10.241.168.179 -subnetmask 255.255.255.0 -gateway 10.241.168.128
```

**Note:** Wait approximately 5 minutes to ensure that SP has completely rebooted. You may need to use ctrl + c to return to the command prompt after issuing the IP address change command.

```
# /nas/sbin/navisecli -h 128.221.253.201 -user nasadmin -password nasadmin -scope 0 networkadmin -set
-address 10.241.168.180 -subnetmask 255.255.255.0 -gateway 10.241.168.128
```

**Note:** SPs will need to reboot prior to Flare 29. Check and restore luns after both SPs have been rebooted.

**8) Add the route entries for SPA and SPB to the Control Station:**

```
# /sbin/route add 10.241.168.179 eth0 -->For SPA
```

```
# /sbin/route add 10.241.168.180 eth2 -->For SPB
```

**Note:** After the routes have been added, you should be able to ping the SPs by IP address or name. If you cannot, verify the route entries exist for eth0 and eth2 for the SPs. Verify that Arp Table entries also exist. Re-add the routes if necessary, and stop and restart the interface aliases if required to refresh the arp entries.

```
# /sbin/route -n |egrep "eth0|eth2"
```

```
10.241.168.179 0.0.0.0      255.255.255.255 UH  0    0      0 eth2
```

```
10.241.168.180 0.0.0.0      255.255.255.255 UH  0    0      0 eth0
```

```
# /sbin/arp -n
```

```
# /sbin/ifdown eth0:1
```

```
# /sbin/ifup eth0:1
```

```
# /sbin/ifdown eth2:1
```

```
# /sbin/ifup eth2:1
```

**9) Verify that you can ping the SPs by IP address and issue navicli commands:**

```
# ping spa
```

```
# ping spb
```

```
# /nas/sbin/navisecli -h 10.241.168.179 -user nasadmin -password nasadmin -scope 0 getagent
```

# /nas/sbin/naviseclli -h 10.241.168.180 -user nasadmin -password nasadmin -scope 0 getagent

Note: Check for trespassed luns using getlun -trespass, and trespass respective luns back to their owner SPs

**10) At this point, the security credentials and symapi database needs to be updated with the new SP IP addresses:**

# /tftpboot/bin/setup\_clariion\_security 10.241.168.179 10.241.168.180 nasadmin nasadmin –initialize

Note: Syntax calls for SPA IP, then SPB, followed by <admin\_account> and <admin\_password>. There is no output returned after issuing this command

**11) Perform a storage health check:**

# nas\_storage -c -a

Discovering storage (may take several minutes)

done

**12) Use clariion\_mgmt to start the Proxy ARP service:**

# /nasmcd/sbin/clariion\_mgmt –start –spa\_ip 10.241.168.179 –spb\_ip 10.241.168.180 –skip\_rules

**13) Verify the Proxy Arp service:**

# /nasmcd/sbin/clariion\_mgmt –info

Public IP address for SPA: 10.241.168.179

Public IP address for SPB: 10.241.168.180

Start on boot : yes

Current implementation : Proxy-ARP

Status : Started

## **TROUBLESHOOTING PROXY ARP SETUP/CONVERSIONS:**

**I. Proxy ARP will not upgrade if NAT is not completely setup, or if NAT is corrupt**

Use following to upgrade directly to Proxy ARP without a prior NAT config:

# /nasmcd/sbin/clariion\_mgmt –info

Error 12: Not configured

# /nasmcd/sbin/clariion\_mgmt –start –spa\_ip 10.241.168.151 –spb\_ip 10.241.168.152 –use\_proxy\_arp

Use following to fix NAT, then rerun –upgrade\_to\_proxy\_arp command:

# /nasmcd/sbin/clariion\_mgmt –start\_service

# /nasmcd/sbin/clariion\_mgmt –info →Output from 5.5.30 for NAT configuration

Public alias IP address for SPA: 192.1.4.214

Public alias IP address for SPB: 192.1.4.215

Start on boot : yes

Status : Started

Done

# /nasmcd/sbin/clariion\_mgmt –info →5.5.31 adds “Current implementation” field to output

Public IP address for SPA: 10.241.168.151

Public IP address for SPB: 10.241.168.152

Start on boot : yes

Current implementation : NAT

Status : Started

done

# /nasmcd/sbin/clariion\_mgmt –upgrade\_to\_proxy\_arp

**II. Proxy ARP Upgrades has one SP on public but other on private network**

Stop NAT and then run conversion to Proxy ARP:

# /nasmcd/sbin/clariion\_mgmt –stop –skip\_rules

# /nasmcd/sbin/clariion\_mgmt –info

Error 12: Not configured

# /nasmcd/sbin/clariion\_mgmt –start –spa\_ip 10.241.168.151 –spb\_ip 10.241.168.152 –use\_proxy\_arp

Or, try reverting back to NAT and starting again:

# /nasmcd/sbin/clariion\_mgmt –revert\_to\_nat

# /nasmcd/sbin/clariion\_mgmt –upgrade\_to\_proxy\_arp

**III. Run following if arp or route entries are not seen for eth0, eth2, and eth3, or if Proxy ARP is not enabled on the interfaces**

# /nasmcd/sbin/clariion\_mgmt –start\_service | -v

Note: The above option is no longer valid with NAS 5.6.

**III. Inspect the clariion\_mgmt Log to determine issue when failures occur:**

# ls -la /var/log/clariion\_mgmt.log

-rw-r--r-- 1 root root 246144 Mar 16 21:06 /var/log/clariion\_mgmt.log

→All clariion\_mgmt actions are recorded in this log

## **SUPPORT GUIDANCE—5.5.30 & 5.5.31:**

### **PUTTING SYSTEM BACK TO UNCONFIGURED STATE (i.e., no NAT or Proxy-ARP configuration)**

**Note:** When a system is in a misconfigured state, the recommended action is to revert back to a completely unconfigured state, as shown below, and then perform the Proxy ARP setup using one of the applicable scenarios outlined in Step 9.

**Step 1. Verify whether System is reporting a NAT, Proxy ARP, Error: Not configured state, or some other condition:**

**# /nasmcd/sbin/clariion\_mgmt -info**

Error 12: Not configured -->This output shows neither NAT or Proxy\_ARP configured and represents the correct state for an "unconfigured" system

#### **Recommended Actions:**

a.) If any output other than "Error 12: Not configured" is displayed, return the system to an unconfigured state as outlined in the following steps.

**Step 2. Verify the following files and edit if required:**

**/etc/hosts /nas/site/sp\_info /etc/sysconfig/iptables** (iptables used only with NAT--editing not required)

**Note:** SPs should have internal IP addresses for an unconfigured or NAT state

SPA: 192.168.1.200 or 128.221.252.200

SPB: 192.168.2.201 or 128.221.253.201

#### **Recommended Actions:**

a.) Edit the /etc/host and /nas/site/sp\_info files to the default internal IP addresses for both SPs.

**Step 3. Verify actual IP addresses on SPs using ping or navicli networkadmin -get, etc.**

#### **Recommended Actions:**

a.) Use "navicli networkadmin -get" to verify SP IP addresses, or use "ping spa" or "ping spb" from the Control Station  
b.) If required, restore SPs to the default internal IP & gateway address scheme using navicli -h <spa or spb> networkadmin -set -address 192.168.x.x -gateway 192.168.x.x. If the SPs cannot be reached via navicli from the Control Station, connect directly to the SP's bottom LAN port (service port), configure a 128.221.1.254 IP address on the Client PC, open a browser and enter either 128.221.1.251/setup if connected to SPA's LAN port, or 128.221.1.250/setup if connected to SPB's LAN port. Use the /setup program to enter the internal IP address and Gateway on each SP.

b.) Wait until the SP reboots and is completely up before repeating step b. to set the internal IP & gateway address on the peer SP.

c.) Use "navicli getlun -trespass" to check for trespassed luns and use "trespass lun x" to restore the lun to the proper SP Owner

**Step 4. Check for the existence of /nas/site/clariion\_mgmt.cfg & /etc/clariion\_mgmt.cfg files**

#### **Recommended Actions:**

a.) Delete the clariion\_mgmt.cfg files if they exist

**Note:** The clariiom\_mgmt.cfg file should exist only when NAT or Proxy-ARP are configured on the Celerra. The SP IP addresses in this file always represent the Public IP addresses set when using the CSA wizard to configure the system (true for either the 5.5.30 NAT implementation or 5.5.31 Proxy-ARP implementation).

**Step 5. Check for existence of interface alias files on the Control Station /etc/sysconfig/network-scripts/ifcfg-eth3:1 & eth3:2**

#### **Recommended Actions:**

a.) Delete the alias files eth3:1 and eth3:2 if they exist

b.) Reboot the Control Station to clear any memory remnants that may confuse the state of the Celerra

**Note:** The eth3:1 & eth3:2 alias files should only exist for a NAT configuration. These files are deleted when the system is converted to Proxy-ARP and do not exist at all in an Unconfigured state. NAT is only configured by default with NAS 5.5.30 installs.

Beginning with NAS 5.5.31, the CSA wizard configures the system for Proxy-ARP and does not use NAT.

**Step 6. Verify state of system after Control Station Reboot:**

#### **Recommended Actions:**

a.) Verify SP addresses in /etc/hosts & /nas/site/sp\_info are now reflecting the default internal IP addresses

b.) Verify that eth3:1 & eth3:2 aliases are gone and not in memory (/sbin/ifconfig)

c.) Verify that clariion\_mgmt.cfg files are NOT present

d.) Verify that system is in an unconfigured state:

**# /nasmcd/sbin/clariion\_mgmt -info**

Error 12: Not configured

**Note:** If system was properly torn down to an unconfigured state, command should show the above output

**Step 7. Verify SYMAPI db Integrity:**

#### **Recommended Actions:**

a.) Run **# nas\_storage -check -all**

**Note:** Should return without any errors

b.) If errors are seen, use nas\_storage -modify id=x -security to renew local security cache files on Celerra, or use nas\_storage -modify id=x -network -spa xxx -spb xxx to update the SYMAPI database with the correct IP address for the SPs if required, or an error is returned from nas\_storage -check -all that seems to indicate an SP IP address discrepancy in the database.

**Step 8. Verify Clariion Security Cache on Celerra:**

**Recommended Actions:**

a.) Use the following to check for the integrity of the Clariion security cache files, and then update the local cache files if required:

**/nas/sbin/navicli -h 192.168.1.200 security -list**

Username: nasadmin

Role: administrator

Scope: global

**Note:** If the command does not return the above output, the security cache files are corrupt and need to be refreshed

b.) Refresh Celerra's Clariion security cache files (/nas/site/.clar\_security) by entering the proper Clariion Username & Password at the appropriate prompts:

**# nas\_storage -modify id=x -security**

**Step 9. Proceed with NAT or Proxy-ARP reconfiguration by selecting one of the following scenarios:**

**Setting up NAT from unconfigured state (NAS 5.5.30 only):**

**/nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.214 -spb\_ip 192.1.4.215**

**Setting up Proxy\_ARP from unconfigured state (NAS 5.5.31 only):**

**/nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.214 -spb\_ip 192.1.4.215 -use\_proxy\_arp**

**Converting from NAT to Proxy-ARP (NAS 5.5.30 only):**

Download the clariion\_mgmt.zip script from Powerlink, unzip, and upload the new clariion\_mgmt script to the Control Station, and overwrite the existing clariion\_mgmt script in /nasmcd/sbin and /nas/sbin with the uploaded version.

[http://powerlink.emc.com/km/live1/en\\_US/Offering\\_Technical/Technical\\_Documentation/clariion\\_mgmt.zip](http://powerlink.emc.com/km/live1/en_US/Offering_Technical/Technical_Documentation/clariion_mgmt.zip)

**/nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.214 -spb\_ip 192.1.4.215 -upgrade\_to\_proxy\_arp**

**Converting from NAT to Proxy-ARP (NAS 5.5.31 only):**

**/nasmcd/sbin/clariion\_mgmt -stop** [Removes existing NAT or Proxy ARP configuration]

**/nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.214 -spb\_ip 192.1.4.215 -use\_proxy\_arp**

**Converting directly to Proxy-ARP (NAS 5.5.31 only):**

**/nasmcd/sbin/clariion\_mgmt -start -spa\_ip 192.1.4.251 -spb\_ip 192.1.4.252 -use\_proxy\_arp**

**Differences between NAT vs. Proxy-ARP implementations on the Celerra and array:**

1. For NAS 5.5.30 installations, NAT is setup by default on all NS20/20FC/NS40/40FC systems during CSA configuration
2. For NAS 5.5.30 systems, NAT to Proxy-ARP conversions are allowed only on the NS20FC & NS40FC platforms
3. For NAS 5.5.31 and higher, all NS20 & NS40 systems can be converted to Proxy-ARP implementations, which is the new standard configuration
4. For NAS 5.5.31 and higher installations, Proxy-ARP is setup by default on all NS20/20FC/NS40/40FC systems during CSA configuration
5. During NAS 5.5.30 CSA configuration, NAT creates two aliases on the Control Station, which are used as Routing Table entries by the Control Station that represent the Publicly assigned IP addresses for SPA (eth3:1) and SPB (eth3:2)
6. During NAS 5.5.30 CSA configuration, NAT creates the proper entries in /etc/sysconfig/iptables that allow for the communication by external Hosts from the Public network, to the backend SPs on the private internal network (with NAT, SPs retain their default internal IP addresses), with the Control Station acting as a Router
7. For Proxy-ARP implementations, eth3 aliases and NAT are not used, though NAT entries are purposely retained in the /etc/sysconfig/iptables file if the system was converted from NAT
8. For NAT implementations, the /etc/hosts & /nas/site/sp\_info files should contain Internal IP addresses for both SPs
9. For Proxy-ARP implementations, the /etc/hosts & /nas/site/sp\_info files should contain the actual Public IP addresses of the SPs
10. For NAT implementations, the SPs use the default Celerra Internal addresses [192.168.1.200/192.168.2.201 or 128.221.252.200/128.221.253.201]
11. For Proxy-ARP implementations, the SPs are assigned a true public IP address & gateway (SPs no longer using internal IP addresses or gateways)
12. For either NAT or Proxy-ARP implementations, the /nas/site/clariion\_mgmt.cfg file will exist, and the IP addresses in this file always represent the Publicly assigned IP addresses for the SPs (whether NAT alias IPs or true Public IPs for Proxy ARP), and is created during the CSA configuration process
13. For Proxy-ARP implementations, the Control Station serves as a bridge between the Public network and the private Celerra network, eventhough the SPs themselves have true Public IP address assignments (network packets bound for SPA or SPB must still pass through the Control Station whenever Users connect to the SPs using NST or Navisphere)
14. For NAT implementations, external Clients must use the Offarray Navisphere or NST with the NAT option in order to properly communicate to the backends.
15. For Proxy ARP implementations, external Clients can use the Onarray or Offarray Navisphere and NST without specifying the NAT option during the connection process.

## Unsuccessful Proxy ARP conversion on NAS 5.5.31:

### Summary of System State:

--No navicli communication with SPA  
--SPB still on internal IP address and can be communicated with  
--The eth3:1 & eth3:2 aliases were never deleted, and all other files reflect a Proxy-ARP implementation

### 1. Attempted to convert a 5.5.31 system from NAT to Proxy ARP using an Engineering workaround:

#### **# /nasmd/sbin/clariion\_mgmt -upgrade\_to\_proxy\_arp -skip\_rules**

**Note:** This left the system in a NAT state according to clariion\_mgmt -info, but updated most files for Proxy ARP, left SPA configured with the external IP address, and left SPB on the default internal IP address

### 2. The recovery steps involved examining the following files and taking appropriate actions:

#### **# /nasmd/sbin/clariion\_mgmt -info** -->Output should show "Proxy-ARP" and not "NAT"

Public IP address for SPA: 192.1.4.251

Public IP address for SPB: 192.1.4.252

Start on boot : yes

Current implementation : NAT

Status : Started

Done

#### **# cat /nas/site/sp\_info** -->File was updated for Proxy-ARP with public IP addresses for SPs

192.1.4.251 A\_APM00073801838 SPA # CLARiiON SP

192.1.4.252 B\_APM00073801838 SPB # CLARiiON SP

#### # tail /etc/hosts -->File was updated for Proxy-ARP with public IP addresses for SPs

192.1.4.251 A\_APM00073801838 SPA # CLARiiON SP

192.1.4.252 B\_APM00073801838 SPB # CLARiiON SP

/etc/sysconfig/network-scripts/ifcfg-eth3:1 & eth3:2 files were present and in Control Station memory (used only for NAT)

#### **/sbin/ifconfig** -->eth3:1 & eth3:2 aliases still exist and should have been removed during the Proxy-ARP conversion

eth3:1 Link encap:Ethernet HWaddr 00:1B:21:05:C6:68

inet addr:192.1.4.251 Bcast:192.1.4.255 Mask:255.255.255.0

eth3:2 Link encap:Ethernet HWaddr 00:1B:21:05:C6:68

inet addr:192.1.4.252 Bcast:192.1.4.255 Mask:255.255.255.0

#### **# cat /nas/site/clariion\_mgmt.cfg**

SPA\_PUBLIC\_IP=192.1.4.251

SPB\_PUBLIC\_IP=192.1.4.252

ONBOOT=yes

**Note:** File should show the Public IP addresses assigned to the SPs after CSA configuration for either NAT or Proxy-ARP. This file should not exist when the system is in an unconfigured state.

### 3. Overview of Recovery steps:

I. a.) Used clariion\_mgmt -stop -skip\_rules, which managed to restore communications with SPA [still on external IP though] and removed eth3:1/eth3:2 aliases

b.) Used navicli -h 192.1.4.251 networkadmin -set -address 192.168.1.200 -gateway 192.168.1.104 to change SPA back to an Internal IP address configuration

c.) Edited /etc/hosts & /nas/site/sp\_info files to restore default internal IP addresses for both SPs

d.) Rebooted Control Station

e.) Verified that files remained unchanged

f.) Verified communication with both SPs on internal IP address via Navicli

g.) Failed back trespassed luns

h.) Used nas\_storage -check -all successfully

i.) Fixed broken Clariion security cache files on Celerra by using nas\_storage -modify id=x -security to update cache files

### 4. Results should show unconfigured state

#### **# /nasmd/sbin/clariion\_mgmt -info**

Error 12: Not configured

**Note:** System unconfigured and ready to be converted directly to Proxy-ARP using clariion\_mgmt -start -spa\_ip xxx -spb\_ip xxx -use\_proxy\_arp

## CELLERRA STARTUP ASSISTANT (CSA):

→The CSA is a stand-alone GUI-based wizard with NS20 & NS40's that replaces the NS350 InitWizard (but uses same iwd process and InitWizard function on Control Station side) and assists in pre-configuring Celerra installations

**Note:** CSA is currently available on all shipping Integrated systems

→All NS20 & NS40 factory & field-install models are expected to have NAS, Flare, & Control LUNs ready for system configuration on power-up, complete with physical label on CS indicating a Factory install, plus an “electronic seal” that will warn a User that the system has been pre-installed if a boot floppy & CD-ROM are used to boot the system (on such a bootup, the system will check for the

CableCheck script and if found, will consider it a factory install and notify the User). In order to perform a true fresh install, the system would require that the Backend be cleaned of Celerra LUNs and RGs before proceeding.

→S95cable\_check script first checks to see if eth3 files exist on CS in /etc/nas\_device.map (fails if IP already created), runs a /nas/tools/.factory\_check script, starts the iwd daemon using /sbin/service nas\_ipinit, mounts /nas, verifies the NAS Model, untars /nas/tools/tftpboot.tar.gz to /tftpboot, creates /tmp/.factory\_check\_successful file, runs .factory\_check again, waits for User to run CSA

→Beginning with Napa 9 release, Proxy ARP will automatically be setup during CSA Pre-Configuration “Apply” screen phase for all NS20 & 40 integrated installations in a series of (12) steps that will be seen on the progress bar, and involves rebooting the SPs for the change from Internal to External IP addressing

→CSA support has been extended to NX4, NS-120, NS-480, & NS-960 platforms

## **CSA VERSIONS & NAS SUPPORT (CSA Compatibility Guide—emc186947):**

### **NAS 5.5:**

CSA 5.5.30 supports NAS 5.5.30 only, and sets up NAT by default during the configuration process

CSA 5.5.31 supports NAS 5.5.31 only, and sets up Proxy ARP by default during the configuration process

CSA 5.5.32 supports NAS 5.5.32 and 5.5.31, setting up Proxy ARP by default

CSA 5.5.33 supports NAS 5.5.33, 5.5.32, and 5.5.31, failing with version not compatible message on NAS versions > than 5.5.33

**Note:** There is no CSA version for NAS versions 5.5.34, 5.5.35, or 5.5.36

CSA 5.5.37 supports NAS 5.5.37, 5.5.36, 5.5.35, and 5.5.34

### **NAS 5.6:**

CSA 5.6.36 supports NAS 5.6.36 only

CSA 5.6.37 supports both NAS 5.6.36 and 5.6.37 (Due to issues, use only 5.6.38 CSA with NAS 5.6.37 installs)

CSA 5.6.38 supports NAS 5.6.36, 5.6.37, and 5.6.38 (But use only the 5.6.38 CSA posted on Powerlink, not the Apps & Tools CD)

CSA 5.6.39 supports NAS 5.6.39 only (introduces ConnectHome and Email Notification changes within CSA)

CSA 5.6.40 is compatible with NAS versions 5.6.40 and 5.6.39 (CSA is backwards compatible with 5.6.39 NAS version)

CSA 5.6.41 is compatible with NAS versions 5.6.41, 5.6.40, and 5.6.39 (CSA is backwards compatible with 5.6.40 & 5.6.39 NAS versions)

CSA 5.6.42 is compatible with NAS versions 5.6.42, 5.6.41, 5.6.40, and 5.6.39 (CSA is backwards compatible with 5.6.41, 5.6.40, & 5.6.39 NAS versions)

CSA 5.6.43 is compatible with NAS versions 5.6.40, 5.6.41, 5.6.42, and 5.6.43, but NOT with NAS 5.6.39 systems

CSA 5.6.43.84 is compatible with NAS versions 5.6.39, 5.6.40, 5.6.41, 5.6.42, & 5.6.43 Installs. This version also introduces the new Celerra Provisioning Wizard functionality, presented as the ‘Configure’ option when first opening the CSA application. This version of the CSA supports provisioning on NX4, NS20, NX40, NS-120, & NS-480 systems, with NAS versions 5.6.40, 5.6.41, 5.6.42, or 5.6.43. This version is also only available for EMC employees and Partners for the initial release, and is downloadable from Powerlink.

**Note:** With NAS 5.6, the CSA version is displayed on the righthand side in the Welcome screen. Additionally, the complete NAS version can be seen on the last line of the c:\Program Files\EMC\CSA\startup\config\startup.ini file.

### **Example:**

CSA\_Version = 5.6.44.4

## **HOW THE WINDOWS CSA & CONTROL STATION IWD DISCOVERY PROCESS WORKS:**

→At initial bootup, the Control Station console should display the following: “Waiting for Celerra Startup Assistant (CSA), to continue...”

→At this point, the “iwd” process should be running on the Control Station and listening on Port 60260 for UDP broadcast traffic

→CSA application is started on the Windows client and on “Welcome” screen, selecting ‘Next’ begins a UDP broadcast from the CSA client to 255.255.255.255 to Port 60260

→The iwd process on the Control Station receives the broadcast packet and replies with a UDP packet containing the MAC address and NAS version to the CSA client

→CSA client then displays the MAC address in the ‘Select a MAC address’ dropdown bar & pre-populates various network & dns parameters in the CSA screen by parsing the Client’s ipconfig/all output

→User enters Control Station IP, Hostname, Gateway, and other information on the CSA “Initialization” screen, and a UDP packet is sent to the MAC address

→The iwd process parses the UDP packet, compares that Client & CS IP Address are on same subnet, and sets the CS IP address, netmask, Hostname, and Gateway

→CSA presents logon screen (with option to change default passwords), and then logs into Control Station using IP (all further communications between CSA and CS are via IP)

## **PREREQUISITES FOR USING CSA:**

→Windows Host with csa\_install.exe application installed (Apps & Tools CD or powerlink)

→Windows host using CSA must be on same physical subnet as Control Station in order to receive the UDP MAC address broadcasts from Control Station

→Control Station must not have any eth3 IP entries. If the CS has an external IP address already configured, the CSA will error out on the Initialization screen past the Welcome screen:

**ERROR: Celerra not found**

→Control Station must have S95cable\_check script running in order to start the IWD daemon, which then listens for udp broadcasts on Port 60260 and responds to CSA broadcasts to physical network 255.255.255.255

→Remove /tmp/.factory\_check\_successful file if CSA is not discovering the Control Station [presence of this file may not prevent CSA from discovering the Celerra, but will prevent the console ‘Waiting for Celerra Startup Assistant’ message from being displayed, which is one of the key indicators that the CSA is ready for discovering the Control Station]

→If the Client Windows system has already been used to configure other NS20/20FC/40/40FC systems, the user will need to remove the previous XML configuration file in order to run the CSA wizard:

Program Files>EMC>CSA>startup>test>CSA\_APM000e0ccfc72a.xml

**Note:** This issue was resolved with AR100493 NAS 5.5.32, which will now allow the User to select a “New Configuration” or existing MAC address from a Dropdown menu [Welcome page > Select configuration profile]

**JAVA VERSION OF CLIENT:**

C:>java -version

java version "1.5.0\_05"

**CONTROL STATION JAVA VERSION 5.6.43:**

# cd /nbsnas/http/webui

# java -version

java version "1.5.0\_11"

Java(TM) 2 Runtime Environment, Standard Edition (build 1.5.0\_11-b03)

Java HotSpot(TM) Client VM (build 1.5.0\_11-b03, mixed mode, sharing)

**JAVA VERSION OF CSA:**

CSA comes bundled with its own jre version, such as 1.5.0\_09, so it does not matter what version is on the client

**STANDARD WORKAROUND FOR "Celerra not found" CSA DISCOVERY ISSUES:**

**Note:** When there is any doubt as to whether the Windows Client is on the same physical network as the Celerra Control Station, use the following workaround procedure to directly connect a straight-through (or crossover) Ethernet cable between the Windows Client and the Control Station:

1. Configure the Windows Client with a static IP address on the same logical network being used by the Control Station, using a netmask of 255.255.255.0, and no default gateway address.
  2. Use a straight-through Ethernet cable to connect the CSA client directly to the external port on the Control Station (labeled as “eth3”).
  3. Reboot the Control Station and wait for the reboot to complete.
  4. Verify that the CSA Client does not have a pre-existing CSA configuration XML file (check Program Files>EMC>CSA>startup>test>CSA\_000e0ccfc72a.xml), and remove the file if present.
5. Restart the CSA wizard and click Next at the Welcome screen to initiate the broadcast and discovery process, then continue with the CSA configuration.

**REASONS AND RESOLUTIONS FOR THE "Celerra not found" ERROR REPORTED BY CSA**

**WIZARD DURING CONTROL STATION DISCOVERY/INITIALIZATION PROCESS:**

**Note:** Please refer to emc173495 for additional information

**1. The Control Station external interface (eth3) is already configured.**

**Explanation:**

Once the external interface has been configured, NAS Services are started and the IWD daemon, which is the Linux process that provides the interface MAC address and NAS version to the CSA, is no longer needed and is shutdown.

**Resolution:**

The existence of a configured interface would mean that the Celerra was previously configured, perhaps because of earlier customer or installer testing. Whatever the reason, if the desire is to completely “reconfigure” the Celerra system, refer to solution emc166265 to restore the Celerra to a pre-CSA configuration state. In other situations it may be best to conduct a complete Backend Cleanup and fresh NAS factory installation in order to return a Celerra system to a state where it is ready for CSA configuration - see emc171121 for the link to an internal EMC procedure to cleanup and reinstall an Integrated Celerra system.

**2. The IWD Daemon is not running.**

**Explanation:**

Missing /etc/rc3.d/S95cable\_check script or the iwd process was killed.

**Resolution:**

Reboot the Control Station and log into the system as root user from the serial console. Check to see whether the IWD process is running. If the process has not started, try to manually start it by running /sbin/service nas\_ipinit start. Check the /var/log/messages for additional information on the “InitWizard” to determine why the iwd process may not have started:

```
# ps -eafl |grep -i iwd  
/nasmcd/sbin/iwd 040 R root 3429 3428 0 76 0 - 348 - 11:59 pts/0 00:00:00
```

**Note:** For further troubleshooting, refer to solution emc166265 for advice on how to restore the system to a state where the CSA configuration can begin.

### **3. The Windows client is not on the same physical network (or does not have an IP on the same logical network) as the Control Station.**

The Windows client running the CSA application must be on the same physical broadcast network as the Control Station in order for the MAC address CSA discovery feature to find the unconfigured Control Station. It must also be using an IP address from the same subnet that is applied to the Control Station

#### **Explanation:**

By definition, the CSA client and the Control Station must be co-located on the same physical broadcast domain, and likewise be configured to use the same logical network in order for the CSA "discovery" process to find the unconfigured Control Station.

#### **Resolution:**

When there is any doubt as to whether the Windows client is on the same physical network as the Celerra Control Station, use the "Standard Workaround for 'Celerra not found' CSA discovery issues" above.

### **4. The Celerra Control Station may not be properly powered up.**

#### **Explanation:**

The Control Station may not have been properly powered on or has hung during bootup.

#### **Resolution:**

- a. Manually reboot the Control Station and verify that the system powers up.
- b. For additional troubleshooting, follow the steps in "Accessing the Linux Serial Console Directly to log into the Celerra" above.
- c. The Windows client running the CSA may be running any combination of VMWare, using multiple physical NICs, firewall software, or VPN software.

#### **Explanation:**

VMWare and multi-homed Windows clients running the CSA can negatively affect the Control Station MAC address discovery process. Additionally, a Windows client running the CSA with firewall and VPN applications can also impact Control Station discovery and initialization using the CSA Wizard.

#### **Resolution:**

Manually disable all firewall and VPN applications on the Windows client. Manually disable all virtual or physical NICs on the Windows client, with the exception of the LAN port. See solution emc171539 for more information on the effects of VMWare and multi-homed hosts on the CSA configuration process.

### **6. The Cisco Security Agent (also known as CSA, CSAgent, etc.) security application blocks JRE requests to discover the Celerra Control Station on clients running the Celerra CSA Wizard.**

#### **Explanation:**

The Cisco Security Agent blocks the Celerra CSA JRE application when it attempts to send UDP packets to port 60260, which is used to discover the Celerra MAC address. The Event Viewer>Application Log clearly shows the Cisco Security Agent (CSA) preventing the Celerra CSA process from succeeding, with "The process 'C:\Program Files\EMC\CSA\jre1.5.0\_09\bin\javaw.exe'...attempted to accept a connection as a server on UDP port 60260...The operation was denied."

#### **Resolution:**

The permanent resolution is for the Cisco Security Agent to allow the Celerra CSA Wizard to use UDP port 60260 so that the Control Station 'discover' process can occur. The current status of this issue is that the problem is resolved. Any EMC user that experiences this problem should make sure that they first log into the Corporate network to update their logon profiles, which will then allow the Celerra CSA wizard to function as designed. For troubleshooting purposes, review the Event Viewer>Application log for more information on what applications are and are not affected by the Cisco Security Agent/Firewall.

### **CONTROL STATION CONSOLE DISPLAY ON INITIAL POWERUP OF FACTORY SYSTEM:**

"Starting cable\_check: This is an NS40FC system waiting to be configured by Celerra Startup Assistant (CSA). Use CSA to verify that the system has been cabled properly. Once the check is complete, CSA will instruct the Cable Check Utility to continue and NAS services will be started and a login prompt provided.

If you want to break out from this and login to the Control Station (you must really know what you are doing) press "L".

Waiting for Celerra Startup Assistant (CSA), to continue....."

→NAS Services & Box Monitor are not running at this stage (S95cable\_check script is set to run prior to S95nas)

→/etc/rc3.d/S95cable\_check script runs, does cable check, starts up iwd daemon

→You can get to login prompt by pressing shift + L"

### **CSA BYPASS PROCEDURE emc166266 NS20/NS40:**

**Warning:** You should not normally need to bypass the CSA process, but, in the event the CSA has encountered a bug or some other undetermined reason for not being able to complete a factory configuration, then it might be possible to skip the CSA altogether and use the following steps to setup the system—please consider this a last-resort measure as the CSA is not intended to be circumvented.

1. Press shift + L keys and log into the Control Station over the serial connection as root user
2. Rename the /etc/rc3.d/S95cable\_check file (to prevent it from running on reboot)
3. Rename the /etc/rc3.d/ccS95nas link to S95nas (link to NAS startup script /etc/rc.d/init.d/nas)

**Note:** The S95cable\_check script renames S95nas to ccS95nas when it starts up to prevent NAS from starting, then renames the file back at a certain point in the CSA process, which allows NAS services to start.

4. Set Hyperterm session emulation to VT100

5. Edit the following files using the vi editor:

a.) Add line to /etc/hosts for Control Station IP & Name

10.241.168.150 sludge4 #Control Station

b.) Edit hostname & add Default Route in /etc/sysconfig/network

Hostname=sludge4

Gateway=10.241.168.128

c.) Edit /etc/sysconfig/network-scripts/ifcfg-eth3 file to configure public IP address

DEVICE=eth3

IPADDR=10.241.168.150

NETMASK=255.255.255.0

NETWORK=10.241.168.0

BROADCAST=10.241.168.255

ONBOOT=yes

BOOTPROTO=none

d.) Ensure all ifcfg\* files have root ownership and proper permissions

# chmod 755 /etc/sysconfig/network-scripts/ifcfg\*

6. Reboot Control Station and wait for NAS Services to fully start

7. Verify that eth3 and Hostname of CS are correct

8. Run clarion\_mgmt script to build NAT [builds alias & IPTables entries] or Proxy ARP configurations:

a. First verify that neither NAT or Proxy ARP are configured:

# /nasmcd/sbin/clarion\_mgmt –info

Error 12: Not configured

b. Rebuild NAT or Proxy ARP configuration:

→NAS 5.5.30.5 only, for NAT: # /nasmcd/sbin/clarion\_mgmt –start –spa\_ip 10.241.168.251 –spb\_ip 10.241.168.252

→NAS 5.5.31.6+ only, for Proxy ARP: # /nasmcd/sbin/clarion\_mgmt –start –spa\_ip 10.241.168.251 –spb\_ip 10.241.168.252

#### **use\_proxy\_arp**

**Note:** To rebuild NAT on 5.5.30 only, must use 5.5.30 version of clarion\_mgmt script, using –start syntax. If the same command were issued using NAS 5.5.31.6 or higher, the default would be to setup Proxy ARP, not NAT.

9. Use Celerra Manager to configure Celerra

### **FACTORY INSTALL PROTECTION MECHANISM AGAINST ACCIDENTAL REINSTALL:**

If a system has been factory-installed, the /etc/rc3.d/S95cable\_check script will provide the following console warning if a User attempts to perform a fresh install by using a boot floppy, cd-rom, and uses serialinstall method:

“EMC Celerra Control Station Linux

```
+-----+ Installation Exists +-----+
| This system has been pre-installed in the factory. It is ready to be configured using |
| Celerra Startup Assistant. |
| See solutions emc159893, emc163261 and emc163262 for more details.|
| Press OK to reboot the Control Station. |
| Press <Alt-F2> to enter a command shell. |
| |
| +---+ |
| | OK | |
| | “ |
```

**Note:** The purpose of this mechanism is to prevent casual reinstallation of the entire system when minimal configuration is required to get the system up and running using the CSA utility

At this point, reboot CS without install media, and once logged in, remove the /etc/rc3.d/S95cable\_check script, then determine whether Backend Cleanup procedure is needed before attempting NAS reinstallation

### **CSA BYPASS PROCEDURE FOR NS-120/NS-480 SYSTEMS:**

1. Connect a null modem serial cable between a service laptop and the Serial Console port on the back of the Control Station.

**Note:** Serial Console port is located on the right-hand side of Control Station when viewed from the back of the system, indicated by a "wrench" symbol.

2. Open a HyperTerminal session on the Client Workstation using the following settings:

19200 bits per second, 8 data bits, parity None, 1 stop bit, flow control None, and terminal emulation Auto Detect/ANSI.

3. Click the phone icon to establish the serial output in HyperTerminal

4. Press the shift + L keys and log into the Control Station over the serial connection as nasadmin, then su to root. Or, if the login screen is already displayed, login as nasadmin, then su to root.

5. Rename the /etc/rc3.d/S95cable\_check file to prevent it from running on reboot.

# mv S95cable\_check s95cable\_check ori

6. Verify that /etc/rc3.d/S95nas shows up as a link to /etc/rc.d/init.d/nas:

```
# ls -la /etc/rc3.d/S95nas
```

```
lrwxrwxrwx 1 root root 20 Apr 29 11:00 /etc/rc3.d/S95nas -> /etc/rc.d/init.d/nas
```

**Note:** Create the link if it does not already exist

```
# ln -s /etc/rc.d/init.d/nas /etc/rc3.d/S95nas
```

7. Verify that the /etc/sysconfig/network-scripts/ifcfg-eth3 file exists with the following entries. Vi edit to create the file if necessary:

```
# cat ifcfg-eth3
```

```
DEVICE=eth3
```

```
USERCTL=no
```

```
ONBOOT=no
```

```
BOOTPROTO=none
```

8. Use the following steps to temporarily assign an IP and Gateway Address to the Control Station:

```
# /sbin/ifconfig eth3 10.241.168.150 netmask 255.255.255.0 broadcast 10.241.168.255
```

```
# /sbin/route add default gw 10.241.168.254
```

**Note:** The address and gateway are not yet written to the Control Station configuration files

9. Use the assigned CS IP address to open and log into Celerra Manager, which will be used to assign the permanent Hostname, IP Address, Gateway Address, and other network information:

- Log into Celerra Manager as Root

- Go to Celerra Home>Control Station Properties

- Set Hostname, IP Address, Netmask, Gateway, and any other relevant network information, then "Apply", then "o.k."

10. Reboot the Control Station, login as nasadmin, then su to root, and wait for the NAS partitions to mount (wait 5-10 minutes):

```
# df -h
```

|                                         |      |      |      |     |             |
|-----------------------------------------|------|------|------|-----|-------------|
| /dev/nude1                              | 1.7G | 752M | 861M | 47% | /nbsnas     |
| /dev/hda5                               | 2.0G | 589M | 1.3G | 31% | /nas        |
| /dev/ndal1                              | 134M | 54M  | 80M  | 41% | /nbsnas/dos |
| /dev/mapper/emc_vg_lun_5-emc_lv_nas_var | 97M  | 5.6M | 87M  | 7%  | /nbsnas/var |

11. Verify Control Station Hostname & External IP information:

```
# hostname
```

```
sleet-120
```

```
# /sbin/ifconfig eth3
```

|                                                     |                                              |
|-----------------------------------------------------|----------------------------------------------|
| eth3                                                | Link encap:Ethernet HWaddr 00:15:17:67:32:F4 |
| inet addr:10.241.168.178                            | Bcast:10.241.168.255 Mask:255.255.255.0      |
| inet6 addr: 3ffe:80c0:22c:139:215:17ff:fe67:32f4/64 | Scope:Global                                 |
| inet6 addr: fe80::215:17ff:fe67:32f4/64             | Scope:Link                                   |
| UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1    |                                              |

12. Run the following healthcheck:

```
# nas_storage -check -all
```

Discovering storage (may take several minutes)

done

13. Use the clariion\_mgmt script to setup the Proxy ARP configuration:

- Verify the state of the current configuration (should be in a 'Not configured' state):

```
# /nasmcd/sbin/clariion_mgmt -info
```

Error 12: Not configured

- Setup Proxy ARP (SPs must reboot during this process):

```
# /nasmcd/sbin/clariion_mgmt -start -spa_ip 10.241.168.251 -spb_ip 10.241.168.252 -use_proxy_arp
```

Checking if running as root...yes

Checking if model is supported...yes

Checking for integrated system...yes

Checking if interface eth3 is configured...yes

Checking if interface eth3:1 is configured...no

Checking if interface eth3:2 is configured...no

Checking if IP (10.241.168.179) is available...yes

Checking if IP (10.241.168.180) is available...yes

Checking if SP (128.221.252.200) is up...yes

Checking if SP (128.221.253.201) is up...yes

Checking if a gateway is setup for eth3...yes

Step 1/12: Setting up Proxy ARP for SPA on Control Station

Adding host specific route for SPA

Adding rules to allow outbound traffic from SPA

Adding ARP entry for SPA

Updating /etc/hosts entry for SPA

Step 2/12: Changing SPA IP address.

Changing SPA IP from 128.221.252.200 to 10.241.168.179 (subnetmask 255.255.255.0, gateway 10.241.168.128)

Step 3/12: Waiting for SPA to reboot.

Waiting for SPA to go down.....done (93 secs)

Step 4/12: Waiting for SPA to boot up.

Waiting for SPA to come back up.....done (167 secs)

Step 5/12: Waiting for CLARiiON software to start on SPA.

Waiting for CLARiiON software to start on SPA....done (88 secs)

Step 6/12: Updating NAS database with SPA IP address.

Updating SYMAPI database with new CLARiiON IP addresses...Ignoring signal in critical section

.Ignoring signal in critical section

.done (107 secs)

Step 7/12: Setting up Proxy ARP for SPB on Control Station

Adding host specific route for SPB

Adding rules to allow outbound traffic from SPB

Adding ARP entry for SPB

Updating /etc/hosts entry for SPB

Step 8/12: Changing SPB IP address.

Changing SPB IP from 128.221.253.201 to 10.241.168.180 (subnetmask 255.255.255.0, gateway 10.241.168.128)

Step 9/12: Waiting for SPB to reboot.

Waiting for SPB to go down.....done (77 secs)

Step 10/12: Waiting for SPB to boot up.

Waiting for SPB to come back up.....done (162 secs)

Step 11/12: Waiting for CLARiiON software to start on SPB.

Waiting for CLARiiON software to start on SPB....done (93 secs)

Step 12/12: Updating NAS database with SPB IP address.

Updating SYMAPI database with new CLARiiON IP addresses...done (81 secs)

FINISH: Operation took a total time of 15 minutes 12 seconds to complete.

14. Verify the Proxy ARP configuration and healthcheck the backend and Celerra systems:

**# nas\_storage -c -a**

Discovering storage (may take several minutes)

done

**# /nas/bin/nas\_checkup**

**# /nasmcd/sbin/clarion\_mgmt -info**

Public IP address for SPA: 10.241.168.179

Public IP address for SPB: 10.241.168.180

Start on boot : yes

Current implementation : Proxy-ARP

Status : Started

15. Verify access to the SPs using ping and log into the array using the NST tool, etc.

**# ping <sp\_ip>**

16. Configure ConnectHome and Email User Notification features:

a) Open Celerra Manager>Support>ConnectHome and EmailUser

17. Run the Registration Wizard and submit the registration file to EMC

## **BACKEND CLEANUP PROCEDURE & FACTORY REINSTALL:**

**Note:** Occasionally, a system will require a complete “factory” reinstallation of NAS, especially for systems that require the use of an Internal Celerra IP address scheme that is different than the 192.168.x defaults. NS systems cannot be reinstalled, however, until the backend Luns, Raid Groups, & Storage Groups are removed. The following procedure can be used on NS20, NS40, & NS80 Integrated systems. Also important to note is that the SPs need to be on the same Internal networks as the Primary & Secondary internals on the Celerra for the install to complete.

**Warning:** The nas\_raid -s cleanup command will remove the default Celerra\_emcnas\_i0 Storage group and all associated Raid Groups and LUNs, including the Hot Spares, and destroys array security and disables AccessLogix. If there are other Storage Groups on the backend, then the nas\_raid cleanup command assumes that the array is shared and will not remove any other Storage Groups and associated RGs & LUNs, nor will it remove Hot Spares, leaves Domain security enabled, and keeps AccessLogix Enabled.

1. Perform the following steps to cleanup a system in preparation of a “factory reinstallation” of NAS on an Integrated platform:

**Note:** If the system is already a factory shipped installation, and a fresh installation is required, you may need to remove any floppy or CD-ROM media, reboot the Control Station, login at the prompt as root, then rename the /etc/rc3.d/S95cable\_check file before

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
proceeding. If the system hangs and does not come up with a login prompt, reboot the system again, and press “Shift + I” keys during bootup when the screen suggests Interactive Startup mode—then, start all services except for the “cable\_check” & “nas\_ipinit” services to complete bootup to the command prompt, then rename the S95cable\_check file.

a.) Login and rename the /etc/rc3.d/S95cable\_check file

# mv /etc/rc3.d/S95cable\_check /etc/rc3.d/cable\_check.ori

b.) Disable NAT or Proxy ARP array management (may or may not be applicable):

# /nasmed/sbin/clariion\_mgmt -stop

**Note:** If the above fails, run again and add the –skip\_rules switch

c.) If the /tftpboot directory does not exist, extract from /nas/tools

# cd /nas/tools

# gzip -d tftpboot.tar.gz

# cd /

# tar -xvf /nas/tools/tftpboot.tar

d.) Unset NAS\_DB, stop NAS Services, and run nas\_raid cleanup script from /tftpboot/setup\_backend, then verify

# unset NAS\_DB

# /sbin/service nas stop

# cd /tftpboot/setup\_backend

# ./nas\_raid -n ./bin/navicli -a 192.168.1.200 -b 192.168.2.201 -s cleanup

Log will be created in the current directory →/tftpboot/setup\_backend/nas\_raid.log

Do you want to clean up the system [yes or no]?: yes

Cleaning Storage Group "Celerra\_emcnas\_i0"

Removing LUN .....

Removing diskgroup ..

Removing initiators ...

Removing storage group "Celerra\_emcnas\_i0"

Removing spares

Cleanup (200) ..

Access Logix disabled

Security domain removed

Done

# navicli -h 192.168.1.200 getrg -lunlist

# navicli -h 192.168.1.200 storagegroup -list | -status

**Note:** Script removes Celerra Storage Group, LUNs, and RAID Groups, Host initiator records from Storage Group, Deletes Storage Group, Deletes Hot Spare & RAID Group 200, Disables Access Logix, and removes Domain Security. However, if this is a ‘Shared’ backend with other SG’s created, then Access Logix, other SG’s & luns, and Hot Spares are not touched. Also, ThinPools and ThinLuns are not deleted.

e.) If additional cleanup is desired to achieve a complete factory “reinstall” of the backend components, use Navisphere to connect to SPA and perform the following steps:

1.) Navisphere>Engineering Mode [ctrl + shift + F12]>Array>Properties>Software>CelerraService>uninstall>yes

2.) After CelerraService package is removed, log into each SPs /setup program and reset SP IP & Gateway addresses to the old defaults: 192.168.1.200/2.201 & 192.168.1.100/2.100

**Note:** Will need to use 128.221.1.250/setup & 128.221.1.251/setup & wait as SP reboots before updating the other SP. You would connect Ethernet cable from Client to SPB’s Service LAN port to connect to SPA, and vice versa.

3.) Optionally, deconfigure Write & Read cache on the array from the GUI.

Array>Properties>Cache: uncheck Write and SPA/SPB Read Cache boxes

Array>Properties>Memory: toggle write and read cache values to 0

f.) Perform ‘fresh’ install using floppy boot & CD, specify “serialinstall”, follow prompts, & DO NOT setup external LAN on Control Station

**Note:** Fresh install creates Backend gateway addresses, reboots SPs, sets up Domain Security on array, installs the CelerraService pkg on backend, provides option to configure system as “Fibre Channel Enabled” or “Integrated” [On NS40 systems only, since both models ship with Headhunter IO card on SPs]

g.) Use CSA wizard after factory reinstall to complete the Customer setup/Registration, followed by further configuration of Backend on Integrateds using Celerra Mgr/CLI, or Navi OffArray Mgr for further Backend configuration on FC models.

### **What to do if nas raid -s cleanup cannot be run?**

→Use straight ethernet cable & connect directly to SPB’s service LAN port (btm), configure workstation with IP address on 128.221.1 network, open web browser, enter default CLARiiON IP address for SPA for Navisphere: 128.221.1.250

(1) Rightclick Celerra Storage Group>Connect Hosts>Select Hosts and remove

(2) Rightclick Celerra Storage Group>Destroy

- (3) Navisphere>Expand SPA and highlight LUNs 0-5>Unbind
- (4) Navisphere>Unowned LUNS>LUN 200>Unbind
- (5) Highlight RAID Group 0>Destroy
- (6) Highlight RAID Group 200>Destroy
- (7) Destroy ThinLuns and ThinPools, if required
- (8) ctrl + shift + f12 messner for Engineering Mode:  
Rightclick Array>Select Engineering Mode>Disable Access Logix
- (9) Navisphere (Engineering Mode)>Array>Properties>Software>select CelerraService>Uninstall
- (10) Enter Clariion Setup Program (128.221.1.250/setup), change Gateway IP if necessary, on SPA, which requires reboot (then connect to SPA's service port to access SPB and change Gateway IP address)
- (11) Reconnect to SPA /setup program, choose the option “Reset all domain information and restart the Management Server” to “Destroy Security and Domain Information” on array, if required—no reboot necessary

### **CLEANING UP BACKEND VIA CLI:**

- a) Remove all HS luns & delete RGs 200-204
- b) Remove SG MPFS\_Client\_0
- c) Remove initiator records (check for HBA records using navicli -h <sp\_ip> port -list)

# **/tftpboot/bin/navicli -h 128.221.252.200 unbind 200**

Unbinding a LUN will cause all data stored on that LUN to be lost.

# **/tftpboot/bin/navicli -h 128.221.252.200 removevg 200**

# **/tftpboot/bin/navicli -h 128.221.252.200 storagegroup -destroy -gname MPFS\_Client\_0**

Destroy Storage Group MPFS\_Client\_0 (y/n)? y

# ./navicli -h 128.221.252.200 port -list -hba |grep Logged

Logged In: YES

Logged In: YES

# /nasmcd/sbin/t2reset reboot -s 2

# **/tftpboot/bin/navicli -h 128.221.252.200 port -removehba -all | -host <host\_name>**

Remove the following initiator records for all attached hosts:

Only logged out but registered initiator records will be removed. Do you want to continue (y/n)? y

**Note:** There have been reports of Initiator Records that have not been removed by the Backend Cleanup script. If the navicli port –removehba –all command fails because the Host Initiator is logged in, reboot the blades or unseat them from the midplane, then run the removehba –all command.

# **/tftpboot/bin/navicli -h 128.221.252.200 thinlun -destroy -l <lun\_number>**

# **/tftpboot/bin/navicli -h 128.221.252.200 storagepool -type <pool\_type> -destroy -id <poolID> -name <pool\_name>**

### **FC ENABLED SYSTEMS MAY NOT BE TOTALLY CLEANED UP USING NAS RAID:**

If other Hosts are sharing the array, their Raid Groups & LUNs will most likely be configured under different Storage Groups than the default Celerra SG. Please be aware that the nas\_raid cleanup script will only destroy RGs & LUNs that are grouped under the Celerra\_emcnas\_i01” Storage Group. If other Storage Groups exist, their respective luns & RGs will remain intact. Additionally, Array Security is left intact and Access Logic is not disabled. The default Hot Spare 200 and RG 200 are also left alone and not deleted. Use Navisphere to remove luns from all Storagegroups, unbind all luns, then destroy all remaining Raid Groups and Storage Groups, then run the /setup program to destroy domain security on the array.

### **FACTORY REINSTALL ON OLD NS40 INTEGRATED USING NAS 5.5.31.x CODE:**

**Note:** NAS 5.5.30.x and above will install without issue on the ‘first generation’ NS40 Integrateds, and you could choose not to setup the external CS LAN IP address during the install, and you could use the CSA to assign the Hostname & external IP Address, but the CSA will thereafter fail with a NAS Model error, meaning that there is nothing more than can be configured from that point. So, the more logical approach would be to just reinstall old systems that are not qualified to use the CSA with the external LAN IP address and CS hostname during the NAS install and not use the CSA at all.

### **WHAT NAS 5.5.30.x & HIGHER CONFIGURES ON OLD NS40 HARDWARE DURING INSTALL:**

- AccessLogix is enabled
- LUNs are added to a storage group that is created during the installation, and is based on the Control Station’s assigned hostname Example: Celerra\_sludge3
- /nas/sbin/model reports NS40 (no change)
- (2) Data LUNs are created that consume all available space in RG0
- CelerraService package is installed on the array (at least if already run Flare 24 on the backend)
- eth0:1 & eth2:1 aliases are created on the Control Station for the gateway IPs on the SPs [192.168.1.104 & 192.168.2.104]
- IPTables service is started and NAT entries are created for SPs
- A POSTROUTING -s 192.168.1.200 -d 192.168.2.201 -p tcp -j SNAT --to-source 192.168.1.200
- A POSTROUTING -s 192.168.2.201 -d 192.168.1.200 -p tcp -j SNAT --to-source 192.168.2.201

-A POSTROUTING -s 192.168.1.200 -d 192.168.2.201 -p udp -j SNAT --to-source 192.168.1.200

-A POSTROUTING -s 192.168.2.201 -d 192.168.1.200 -p udp -j SNAT --to-source 192.168.2.201

→Sets up IP Forwarding with a value of 1 [/proc/sys/net/ipv4/ip\_forward]

→Sets up Domain array security using the NAS installation default account name of ‘nasadmin’ with password ‘nasadmin’

→Deletes the /etc/rc3.d/S95cable\_check script after the first reboot of the CS

## **VARIOUS PHASES DURING CSA CONFIGURATION:**

### **Welcome screen & Initialization Phase**

→After Welcome screen, enter Username and Password

→Select the Control Station that was discovered during the MAC broadcast in the dropdown menu; plugin the CS Hostname and IP information, then Next

→Setting up blade page, enter DNS, NTP Server, and Gateway information, and Public IP Addresses for SPA and SPB (calls clarion\_mgmt script to configure CS aliases and NAT entries to support the public SP addresses)

→Collecting license and site information page, add Site ID and Modem information, apply licenses that apply, select “Call EMC” or “Email Home” option (calls nas\_support script to configure NAS Events, Sendmail, and other files)

→During initialization, the CSA application runs on a Windows Host over the same physical network as that of the external network interface of the Control Station. The application locates the CS via MAC address broadcasts, and checks that the Electronic Seal for the system is intact [i.e., checks to see if an IP address has been already configured for the external CS interface], at which point the configuration wizard would start. If the CS was previously configured with an external IP address, the MAC address broadcast mechanism will not work and the CSA installer will fail to find a configurable Celerra. The functional spec advises that a fresh install of the system is required at this point, though there may be workarounds. For example, if a network connection was terminated in the middle of initial preconfiguration, the CSA should be able to continue from where it left off

### **Health Check Wizard Phase**

→After Initialization is completed, a system CableCheck is conducted (using a modified setup\_enclosure script) and the state of the software is checked

### **Pre-Configuration Phase**

→After the Healthcheck phase, all configuration changes are presented for review. After applying changes, the configuration is saved to the local Windows Host in XML format, making the CSA wizard restartable from last point of exit, and NAS Services, Web, Apache, & Tomcat services are started

→Click ‘Next’, then ‘Finish’ to move to the Wizards page, where CIFS Shares, NFS Exports, iSCSI LUNs, and Reg. can be done

### **Configuration Wizards**

→Various servlets that are derived from Celerra Manager code, are called to assist in setting up a file system, Share, Export, iSCSI LUNs, & CIFS Server

→NFS, iSCSI, and CIFS icons are presented

### **Registration Phase**

As a final step, the Celerra can be registered with EMC using the Celerra Platform Registration Wizard

→Enter IP address (or Hostname) and User and Password for Control Station, select Installer identity, then enter Customer Information and Address

→Wizard then runs /nas/sbin/log\_config script on CS to gather up necessary data, then gives options on how to transmit the information to EMC (Automatic, Manual, Email)

### **Finish Phase**

The Finish page gives User the option of connecting to the product “Landing Page” (on Powerlink) or starting a Celerra Manager session.

## **SCRIPTS USED BY CSA DURING CONFIGURATION:**

1. Initial bootup starts /etc/rc3.d/S95cable\_check before S95nas

2. Initial bootup also calls /nas/sbin/nas\_ipinit to startup the IWD daemon in order to broadcast MAC address of CS

3. Upon CSA Initialization screen, a **/nas/sbin/setup\_enclosure –factoryCableCheck** script is run to validate system cabling and integrity of the communication network—broadcast determines if all Mgmt Switches are present, in their correct slots, and that enclosures are ordered correctly

**Note:** CableCheck will compare MAC addresses found against what is stored in /etc/nas\_enclosure.map, checks that all mgmt switches are present and in their correct slot, and verify that enclosure order is correct

### **CABLE CHECK CODES & ACTIONS:**

| CODE       | DESCRIPTION                       | ACTION Required                                             |
|------------|-----------------------------------|-------------------------------------------------------------|
| 1001000000 | CableCheck successful, no errors  |                                                             |
| 1001010200 | Mgmt switch for Slot_2 missing    | Check that lower mgmt port on DM2 is cabled to CS port eth0 |
| 1001010300 | Mgmt switch for Slot_3 missing    | Check that lower mgmt port on DM3 is cabled to CS port eth2 |
| 1001030200 | Mgmt switch for Slot_2 not cabled | Check that lower mgmt port on DM2 is cabled to CS port eth0 |
| 1001030300 | Mgmt switch for Slot 3 not cabled | Check that lower mgmt port on DM3 is cabled to CS port eth2 |
| 1001999999 | Unrecoverable error               | Contact EMC Support                                         |

4. CSA calls clariion\_mgmt to configure public IP Address aliases to support NST/Navisphere access to SPs from a Windows Host, and configures NAT IPTable entries

#### **# /nasmcd/sbin/clariion\_mgmt -start -spa\_ip 10.241.168.250 -spb\_ip 10.241.168.251**

```

Checking if running as root...yes
Checking if model is supported...yes
Checking for integrated system...yes
Checking network interface eth3...configured
Checking network interface eth3:1...no configuration file
Checking network interface eth3:2...no configuration file
Checking if IP forwarding is enabled...yes
Removing network alias :1...done
Removing network alias :2...done
Creating network alias eth3:1...RTNETLINK answers: File exists
done
Creating network alias eth3:2...RTNETLINK answers: File exists

```

5. Beginning with Napa 9 release, the Proxy ARP script is executed during the Pre-Configuration phase of the CSA to setup Proxy ARP on all NS20 & NS40 integrated models during configuration/installation.

#### **# cat /etc/sysconfig/iptables**

```

-A PREROUTING -d 10.241.168.250 -p tcp -j DNAT --to-destination 192.168.1.200
-A PREROUTING -d 10.241.168.250 -p udp -j DNAT --to-destination 192.168.1.200
-A PREROUTING -d 10.241.168.250 -p icmp -j DNAT --to-destination 192.168.1.200
-A PREROUTING -d 10.241.168.251 -p tcp -j DNAT --to-destination 192.168.2.201
-A PREROUTING -d 10.241.168.251 -p udp -j DNAT --to-destination 192.168.2.201
-A PREROUTING -d 10.241.168.251 -p icmp -j DNAT --to-destination 192.168.2.201

```

**/nas/site/clariion\_mgmt.cfg** (Configuration stored here)

**/etc/clariion\_mgmt.cfg** (Copy of configuration stored here)

#### **# cat /nas/site/clariion\_mgmt**

SPA\_PUBLIC\_IP=10.6.4.158

SPB\_PUBLIC\_IP=10.6.4.187

ONBOOT=yes

### **RECONFIGURING USING CLARIION MGMT:**

The /nasmcd/sbin/clariion\_mgmt script is invoked by CSA during system initialization, but can also be run manually to reconfigure the public IP addresses and aliases that are used on the Control Station for NST & Navi OffArray Mgr connectivity—there are no reboots required when using this tool if running a NAT configuration. For Proxy\_ARP, the SP's will need to reboot if their IP Addresses change.

#### **# /nasmcd/sbin/clariion\_mgmt -info**

```

Public alias IP address for SPA: 10.241.168.250
Public alias IP address for SPB: 10.241.168.251
Start on boot      : yes
Status           : Started
done

```

#### **# /sbin/ifconfig**

```

eth3:1  Link encap:Ethernet HWaddr 00:0E:0C:CF:C7:2A
        inet addr:10.241.168.250 Bcast:10.241.168.255 Mask:255.255.255.0
eth3:2  Link encap:Ethernet HWaddr 00:0E:0C:CF:C7:2A
        inet addr:10.241.168.251 Bcast:10.241.168.255 Mask:255.255.255.0

```

**Note:** Above entries represent public IP's and aliases for SPA, SPB, resp.

#### **# /nasmcd/sbin/clariion\_mgmt -stop**

```

Checking if running as root...yes
Checking if model is supported...yes
Checking for integrated system...yes
Checking network interface eth3...configured
Checking network interface eth3:1...configured
Checking network interface eth3:2...configured
Checking if IP forwarding is enabled...yes
Removing network alias eth3:1...done
Removing network alias eth3:2...done

```

Done

### What does running clariion\_mgmt -stop do?

- Removes Public SP IP's from Control Station aliases on eth3
  - Removes PREROUTING entries in /etc/sysconfig/iptables for translation of public IP's to internal IP addresses for SPA/SPB
  - Verifies that IP\_Forwarding is set on the Control station
- Note:** Beginning with Napa 9, the clariion\_mgmt -stop removes the Proxy ARP configuration, and resets the public IP addresses on the SPs to the default 192.168.x.x addresses, which requires SP reboots. Please note that this command does NOT prompt the User for confirmation before rebooting SPs.

# cat /proc/sys/net/ipv4/ip\_forward

1

## TROUBLESHOOTING CSA CABLE CHECK FAILURES:

- CableCheck failure messages must be resolved before the CSA setup process can continue. It's important to know that the serial Console to the Control Station is disabled until the CableCheck can be successfully run
- Serial console will be disabled, and NAS Services will not start until a successful CableCheck is run
- Users can connect to the serial console via Hyperterm or SSH for further troubleshooting, but may need to use Shift + L in order to get to a login prompt [new console locking feature]
- Use the downloaded documentation or link to Powerlink to debug CableCheck and other CSA error popups

## TROUBLESHOOTING CSA ISSUES:

- CSA Popups will display information on what to troubleshoot, but may not always be accurate
  - Powerlink access to troubleshooting information via Landing Page
- Note:** There is a downloadable 3MB NS20/40 Cable Check Troubleshooting Bundle called “InstallationTroubleshooting.zip”, available from Powerlink>Celerra Tools>NS20 Integrated>Celerra Troubleshooting>Installation Troubleshooting. Unzip the bundle in the Program Files>EMC>CSA folder on the system from which the CSA will be run & overwrite any existing files with the newer files. This will provide the proper Cable Check troubleshooting popups when running the Cable Check portion of the CSA wizard during system configuration.
- Windows workstation logs some CSA information in a startup\_wiz.log file Program Files>EMC>CSA>Startup>startup\_wiz.log
  - No CSA logs are created on the Control Station
- Note:** Beginning with NAS 5.6.39.5, the clariion\_mgmt script creates a logfile whenever run. For CSA configurations, the log is created after the Cable Check when the backend IPs are being configured.

### /var/log/clariion\_mgmt.log

- CSA Application resides in Program Files>EMC>CSA directory
- Keep in mind that once the CS IP Address & Hostname info is entered into the CSA, a “CSA...xml” file is created if the application exits prior to completion, the purpose of which is to allow restart from point of last operation:  
Program Files>EMC>CSA>startup>test>CSA\_000e0ccfc72a.xml
- Key troubleshooting tip: If stuck, exit CSA application, then reopen CSA, logon with Username & Password, and see if you get beyond last problem
- Search for Primus solutions for CSA

## RUNNING CSA CABLE CHECK SCRIPT MANUALLY:

# /nbsnas/tools/.factory\_check verify\_cable -list →This produces component list (NX4 NAS 5.6.39)

- 1,Control Station 0 MGMT A,CS Network
- 2,Control Station 0 MGMT B,CS Network
- 3,MGMT Switch,MGMT Switch
- 4,SPA,SP
- 5,SPB,SP
- 6,Blade 2,Reason Code
- 7,Blade 2 Primary Network,DM Network
- 8,Blade 2 Secondary Network,DM Network
- 9,Blade 2 BE 0,DM Fiber
- 10,Blade 2 BE 1,DM Fiber
- 11,Blade 3,Reason Code
- 12,Blade 3 Primary Network,DM Network
- 13,Blade 3 Secondary Network,DM Network
- 14,Blade 3 BE 0,DM Fiber
- 15,Blade 3 BE 1,DM Fiber
- 16,SPS A,SPS
- 17,SPS B,SPS

# /nbsnas/tools/.factory\_check verify\_cable -comp 16

1006019999

**Note:** Normal exit code for a component would be 0. The 1006019999 output reflects a cable check error, which can be found on the CSA client by looking for the matching error code html file in Program Files>EMC>CSA>help>NS20FC>cabling>1006019999.html.

# ls -la /tmp

-rw-r--r-- 1 root root 293 Aug 13 10:06 component\_list.csv →File created when script list is run

## **RETURNING TO PRE-CSA CONFIGURATION STATE:**

- a.) Run # /nasmcd/sbin/clariion\_mgmt –stop to remove Public IP aliases for the SPs from the Control Station & associated Network Address Translation (NAT) entries from IPTables
- b.) Copy the cable\_check script to /etc/rc3.d/S95cable\_check [the challenge here will be that a completed CSA configuration deletes this file—if a copy has been saved ahead of time, restore to /etc/rc3.d—if a copy cannot be found, contact EMC Support and reference the NAS version involved]
- c.) Remove /tmp/.factory\_check\_successful file if it exists
- d.) Rename the /etc/sysconfig/network-scripts/ifcfg-eth3 file to remove the Control Station's external interface configuration file
- e.) Remove any extra/unwanted entries for the Control Station Hostname and IP address from the /etc/hosts using the vi editor, etc.
- f.) Connect to the serial port on the front of the Control Station, use HyperTerminal and configure as follows:  
Connect using: COM1 or COM2; Bits per second: 19200 Data bits: 8 Parity: None Stop bits: 1 Flow Control: None (verify that Autodetect & ANSI are selected for terminal emulation)
- g.) Reboot the Control Station and wait for the following console screen message before continuing with the next step

### **Original CSA prompt screen and message after entering shift + L:**

*Starting cable\_check: This is an NS40FC system waiting to be configured by Celerra Startup Assistant (CSA). Use CSA to verify that the system has been cabled properly. Once the check is complete, CSA will instruct the Cable Check Utility to continue and NAS services will be started and a login prompt provided. If you want to break out from this and login to the Control Station (you must really know what you are doing) press "L".*

*Waiting for Celerra Startup Assistant (CSA), to continue.....*

*Terminating...*

*Renaming /etc/rc3.d/S95nas to /etc/rc3.d/ccS95nas*

*Remember to rename it back so NAS services can start when CS reboots.*

### **New CSA prompt screen and message after entering shift + L NAS 5.6.39:**

*Starting cable\_check: This is an NX4FC system waiting to be configured by Celerra Startup Assistant (CSA). Use CSA to verify that the system has been cabled properly. Once the check is complete, CSA will instruct the Cable Check Utility to continue and NAS services will be started and a login prompt provided.*

*If you want to break out from this and login to the Control Station (you must really know what you are doing) press "L".*

*Waiting for Celerra Startup Assistant (CSA), to continue.....L*

*Terminating...*

*NAS services are skipped since CSA health check is not completed yet. But if you are fully aware and would like to start the NAS services, type "service nas start" on the command line after logging in as root onto the control station.*

h.) On the Windows Client running the CSA wizard, remove the existing CSA...xml file from the following location:

Program Files>EMC>CSA>startup>test>CSA\_000e0ccfc72a.xml (example of filename)

i.) Startup the CSA wizard from the Windows Client: Welcome page>Next, should then be able to pickup the MAC address broadcast and continue with remaining configuration steps using CSA

## **STANDALONE REGISTRATION WIZARD [RegWiz]:**

→Though Registration is possible through the use of the CSA, there is also a Standalone application that can be used to perform the Registration after the system has been configured

→Download from “Celerra Tools” on Powerlink, or from Apps & Tools CD

Celerra Registration Wizard – v1.0

Windows application called “regwiz\_install.exe”

Installation creates a desktop shortcut called “Launch Regwiz”

Program Files>EMC>RegWiz

→Preference is to conduct Registration over live Internet connection, but when selecting Manual upload method, payload file can be saved locally and transferred to EMC Website later without requiring direct Internet connection

### **Temp Files Produced by Registration Wizard:**

Documents and Settings\Administrator\Local Settings\Temp\temp.xml & Celerra\_Registration.xml (Files are deleted after a successful upload)

### **Actual payload file when manually saving to Workstation:**

Celerra\_Registration\_APM00071601776.config

## **RegWiz Registration Options**

- o I want to register this product using Automatic Registration
- o I want to manually upload this information to the EMC Registration Web Site
- o I want to attach this information to an email and transmit it to EMC

**Note:** If selecting the Email method, there are two options:

1. Save to local drive and send .config payload file to email address referenced
2. Connect to email client, enter SMTP address for mail server, and send directly from internet-connected client

**Production Website for Automatic or Manual upload of the payload.config file:**

<http://iio.emc.com/colu/aru/>

**Email Registration Address:**

[b2b\\_product\\_registrations@emc.com](mailto:b2b_product_registrations@emc.com)

**What happens to the Registration payload once it is uploaded?**

1. Payload submitted automatically from application and HTTP, or via email attachment, or saved locally and sent via email
2. Encrypted payload goes to [B2BRegistrations@emc.com](mailto:B2BRegistrations@emc.com)
3. Files go to ProcessReg Queue & get pushed out to SYR DB
4. Files parsed & stored in SYR DB
5. SYR generates xml file format, opens SR and assigns to IBG, where IBG reviews and updates SR. Email sent to sender after getting payload and then after processing payload for registration

**NS40 INTEGRATED, NS40FC ENABLED (All-in-One) CELERRAs**

→ Enhanced Installability (preloaded code, Placemat (Setting up the EMC Celerra...document in Shipping envelope), Landing Page(Powerlink Celerra Tools page), CSA, All-in-One FC Enabled model, new Integrated model, Clariion Mgmt access to Integrated backend SPs (Via Control Station NAT Service, using Clariion NST & OffArrayMgr tools)

→ NS40 Integrated (CX3-40) and NS40FC (FC Enabled) All-in-One (CX3-40F)

→ Physically, the HeadHunter (4) Port FC IO card will be shipped with NS40 Integrateds beginning in August, but the additional Front-end FC Ports on the SPs themselves will be “disabled” and not available for use by other Hosts

→ Original NS40 Integrated to be replaced by the “new” NS40 Integrated

→ Both models will support the Celerra Integrated NST utility, and the NS40FC will also support the Navi OffArray Manager

→ Single or dual Blades, single Chivas or Dewars Control Station

**Note:** DC NS40F will use only the Chivas CS

→ SPs run in SAN mode, using AccessLogix & Storagegroups (vs. SAN AUX mode), meaning that network cables will be connected to upper LAN management ports on the SPs, not Service ports (original NS40 connected to Service port on SPs and SPs ran in SAN-AUX mode)

→ DMs connect to SPs using Fibre Optic LC-to-LC cables

→ DMs connect to upper LAN Mgmt port on SP for internal network

→ NST or OffArray Navi will connect to SPs via new NAT Service on Control Station (IPTables, new aliases on CS)

→ Models will ship with pre-installed software for Factory or Field-Installed cabinets, and will use a Placemat, Landing Page website, and Celerra Startup Assistant (CSA) to configure the box on initial startup

**Note:** During install, if FC option is selected, the management of the array will be done via OffArray Navisphere

→ Celerra will handle Back-End errors and CallHomes for array issues

→ Mirrorview uses Port 1 vs. the highest array Port number, and DMs will be cabled to SP Front-end FC ports 2 & 3 Fibre

→ Non-disruptive upgrades from NS41F to NS42F, and upgrades from integrated to gateway available

**NS40 INTEGRATED:**

→ Integrated Model

→ CX3-40F Array running in SAN mode, AccessLogix/Storagegroups

→ NS40 blades will use (2) FC Ports to SPs and (1) FC Port for tape device via optical fibre

→ Blade ports BE0 & BE1 will connect to SP Ports 2 & 3 Fibre [4-port FC IO Headhunter card shipped but not enabled]

**NS40F FC ENABLED (“All-in-One”):**

→ Fibre Channel Enabled Model (Not a Gateway, allows other Hosts to connect to array)

→ CX3-40F Array running in SAN mode, AccessLogix/Storagegroups

→ NS40 blades will use (2) FC fibre optic ports with SFP modules to connect to SPs and (1) FC Port for tape device via optical fibre

→ NS40FC Blades will use either (4) Copper 10/100/1000 Ethernet ports or (2) copper 10/100/1000 & (2) GbE optical ports

→ CX3-40F array adds (2) additional FC FE ports 2/3 for customer SAN Hosts, and (2) BE Ports 2/3 for additional DAE buses, for total of (4) BE DAE ports and (4) FE Host ports [Other Hosts to use Ports 0, & 1; Mirrorview to use Port 1]

**Note:** Quad IO card called HeadHunter

→ Blades will connect to SP Ports 2 & 3 Fibre [4-port FC IO Headhunter card shipped with this model & all ports FC enabled]

**DETERMINING NS40 MODELS & BACKEND ARRAY TYPE:**

[Celerra Manager>Celerra Home>System Info screen will show model number](#)

**New NS40 Integrated:**

\$ /nas/sbin/model

NS40

\$ /nas/sbin/navicli -h 192.168.1.200 storagegroup -status

Data Access control: ENABLED

\$ nas\_storage -i APM00071600514

model\_num = CX3-40f

\$ **/nas/sbin/navicli -h 192.168.1.200 getagent**

Model: CX3-40f

# **/nas/sbin/setup\_backend/get\_array\_version**

APM00071600514 CX3-40f 03.24.040.5.006 1 1

#### **New NS40FC:**

\$ **/nas/sbin/model**

NS40FC

**Note:** Both models use the same CX3-40f backend

→Examine the /etc/be\_sg\_info file and see if FC\_ENABLED=YES is set, which is for new NS40FC system, otherwise, if AccessLogix installed by FC\_ENABLED=NO, then the model would be the new NS40 Integrated

\$ **cat /etc/be\_sg\_info**

SHARED\_BE\_SYS\_RAID\_GROUP\_ID=0

STORAGE\_GROUP\_NAME=Celerra\_emcnas\_i0

STORAGE\_GROUP\_INIT\_REC=50:06:01:60:c1:e0:53:35:50:06:01:60:41:e0:53:35:emcnas\_i0\_dm2\_p0

STORAGE\_GROUP\_INIT\_REC=50:06:01:60:c1:e0:53:35:50:06:01:61:41:e0:53:35:emcnas\_i0\_dm2\_p1

STORAGE\_GROUP\_INIT\_REC=50:06:01:60:c1:e0:53:35:50:06:01:68:41:e0:53:35:emcnas\_i0\_dm3\_p0

STORAGE\_GROUP\_INIT\_REC=50:06:01:60:c1:e0:53:35:50:06:01:69:41:e0:53:35:emcnas\_i0\_dm3\_p1

STORAGE\_GROUP\_ALUS=0 1 2 3 4 5

FC\_ENABLED=YES

#### **Old NS40 Integrated:**

\$ **/nas/sbin/model**

NS40

\$ **/nas/sbin/navicli -h 192.168.1.200 storagegroup -status**

Data Access control: DISABLED [i.e., Access Logix]

\$ **nas\_storage -i APM00071600514 [Uses CX3-40 array]**

model\_num = CX3-40

#### **NS40 Integrated for MPFSi:**

\$ **/nas/sbin/model**

NS40

\$ **/nas/sbin/navicli -h 192.168.1.200 storagegroup -status**

Data Access control: DISABLED [i.e., Access Logix]

\$ **nas\_storage -i APM00071600514 [Uses CX3-40C array]**

model\_num = CX3-40C

**Note:** Supposed to use copper cables between DM & SPs; SPs run in SAN-AUX mode; Internal IP cabling plugs into SPs bottom service port, not mgmt port

#### **NS40FC Blade Front-End Connectivity:**

(2) FC optical fibre ports connecting DMs to SPs

(1) FC optical port for tape drive connectivity

Either (4) copper 10/100/1000 Ethernet ports per Blade or (2) copper 10/100/1000 & (2) GbE optical ports per Blade

#### **CLARiiON SPs and Back-End Connectivity:**

Total of (8) FC ports

(2) FE FC optical Ports for NS40F Blades-to-SP connectivity using Fibre Optic cables and SAN personality for SPs

(2) FE FC optical Ports for other Hosts direct-connected or FC Switch-attached

(4) BE FC arbitrated loop copper Ports to connect SPs to DAEs

#### **BASIC SPECS FOR NS40/NS40FC:**

→Basic hardware specs of new NS40s are similar to the original NS40 model

→1-2 Data Mover 1U blades, Dual Intel 2.8GHz processors, (4) GB Memory, 800MHz FSB speeds, (4) 10/100/1000 GbE ports,

(2) FC ports to the array, & (1) FC port for tape backups—FC port speeds support 2-4Gbps

→16TB per blade for FC drives, 32TB capacity per blade for mixed FC/ATA drives

→Allows for mixed FC, LCFC, and SATA drives in a shelf (like disks will be bound by RaidGroups)

→Recommended Hot Spares: 1/30 fibre channel drives; 1/15 ATA drives

#### **NS40FC RESTRICTIONS:**

**Note:** Not considered a Gateway, eventhough FC option is enabled for additional Hosts

→No Fabric connectivity between Blades and SPs (just direct-connect FC)

→Cannot have multiple Backends

→Can only have the CX3-40F backend

#### **NS40-to-NS40C HARDWARE UPGRADE PROCEDURE—Napa 9+:**

**Note:** The new NS40 Integrateds [with CX3-40F backend and new private network & fibre channel cabling scheme] can be upgraded after install by running the upgrade procedure

→Upgrade changes /nas/sbin/model output from NS40 to NS40FC

→Should see following line added to /etc/be\_sg\_info file

FC\_ENABLED=YES

1. Run Hardware Upgrade Script:

**# /nas/sbin/nas\_hw\_upgrade -fc\_option -enable**

2. Verify:

# /nas/sbin/model

NS40FC

# /nas/bin/nas\_checkup

**Note:** Above option does not work for 5.5.31 or 32 code—see ARs105630/117708. Must use the following workaround:

**# echo FC\_ENABLED=YES >>/etc/be\_sg\_info**

**# /nas/sbin/model -c**

NS40FC

## **NAPA 9:**

NAS 5.5.31.6 Oct 15, 2007

→Flare 26 Leo support--introduces Clariion support for RAID 6 with 4+2, 6+2, & 12+2 configurations (Can withstand loss of two drives in same RAID group without data loss)

→SCSI Asymmetrical Logical Unit Access (ALUA—multipath access to LUNs), Proactive Sparing with Hard Media errors, Vault drive load enhancements, WIL Cache improvements. Flare 26 only supported on CX3 arrays and CX300, 500, 700.

→Introduction of /nas/tools/nas\_summary and /nas/tools/sccslist utilities

**# /nas/tools/nas\_summary**

nas\_summary v0.1

Rep: False SRDF: False DHSM: False

#####

DBCHK State: No errors found

## **Symm DMX-4 support:**

Includes support for SATA 4Gb speed ATA drives on the Symm. This will require new Storage API Solutions Enabler v6.4.2; (6) new disk types for Symm: ATA, R1ATA, R2ATA, BCVA, R1BCA, R2BCA; (6) new system-defined storage pools: symm\_ata, symm\_ata\_bcv, symm\_ata\_rdf\_src, symm\_ata\_rdf\_tgt, symm\_ata\_bcv\_src, symm\_ata\_bcv\_tgt; (6) new volume profiles. Customer could use STD disks on PFS and ATA BCVs on the destination system when using Timefinder/FS and RDF. Control Volumes will not be allowed on Symm ATA drives.

## **PROXY ARP & CSA CHANGES:**

Beginning with the Napa 9 release, Proxy ARP will automatically be setup during the CSA Pre-Configuration “Apply” screen phase for all NS20 integrated, NS20FC, NS40 integrated, & NS40FC installations—the ‘Backend IP setup’ status field will inform users of the progress as different tasks are being completed during the Proxy ARP setup. Napa 8 systems that have the original NAT implementation will not be automatically upgraded to Proxy ARP. There is a hidden switch with /nasmcd/sbin/clariion\_mgmt –upgrade\_to\_proxy\_arp that can be used if the customer or support person wants a system to run with Proxy ARP after upgrading to Napa 9+.

## **FIXING ARP ENTRIES FOR CS INTERFACES, RECREATING HOST ROUTES FOR SP's, ENABLING PROXY ARP SERVICE:**

# /nasmcd/sbin/clariion\_mgmt –start\_service -v

## **SETTING UP, MODIFYING, or REMOVING PROXY ARP:**

**clariion\_mgmt –start** → to setup Proxy ARP for public access to SPs [requires SP reboots]

**clariion\_mgmt –modify –spa\_ip xxx.xxx.xxx –spb\_ip xxx.xxx.xxx** → change IP addresses for SPs on CS and SPs [requires SP reboots]

**clariion\_mgmt –stop –skip\_rules** → removes Proxy ARP setup [requires SP reboots]

**Note:** With Proxy ARP implementation in Napa 9 (NAS 5.5.31) during CSA configuration, it is more difficult to breakdown a system to a pre-CSA configuration state. May need to manually vi edit /etc/hosts, /nas/site/sp\_info, /nas/site/clariion\_mgmt.cfg files to give correct IP addresses to SPs. Additionally, may need to manually update the SP IP addresses via navicli.

### **How does Proxy ARP work?**

--Client wants to communicate with the SPA and does an ARP broadcast to locate SPs at Ethernet layer

--Control Station receives broadcast, has ARP entries for both SPs, and does ARP broadcast in reply

--Client sends TCP/IP packets to CS

--CS forwards packets to both SP's, and SPB drops packet while SPA processes

## **RAID 6 CLARIION-Flare 26:**

→uses 128 block element size, with (2) disks worth of parity per RAID 6 group spread across all spindles

→not supported for vault disks

→uses naviseccli only, no ClassicCLI commands—must configure system to use Secure CLI

→Clariion supports only even number of spindles: 2+2, 4+2, 6+2, 8+2, 10+2, 12+2, 14+2

→Supported configurations are 4+2, 6+2, & 12+2 for all disk types in clar\_r6, clarata\_r6, cm\_r6, & cmata\_r6 system pools

→Use setup\_clariion for shelf-by-shelf setup of FC , LCFC, or ATA drives

→Binds (2) luns per RG for FC drives using 4+2 or 6+2 Raid6

→Binds (4) luns per RG for FC drives using 12+2 configuration

→Binds (1) lun per RG for ATA drives using 4+2 or 6+2

→Binds (2) luns per RG for ATA drives using 12+2

## **CELLERA CONNECTHOME FEATURE (Napa 9):**

→ConnectEMC Linux 2.0 support, replaces Celerra CallHome process with Celerra ConnectHome

**Note:** ConnectEMC 2.0.27-b118 is the Linux version on the Control Station

→Supports EmailHome to EMC or to the ESRS Gateway, FTPCallHome to ESRS Gateway only, or CallHome via modem to EMC.

**Note:** Multiple callhome transports can be configured for Primary, Secondary, and Tertiary priority.

→ConnectHome maintains Modem support, and adds Email & FTP as new transport methods

→Each transport mechanism (Modem, Email, FTP) supports a Primary and optional Secondary failover destination—with multiple destinations, the connectemc daemon stops after the first successful transfer

→ConnectEMC is part of the EMA (Event Messaging Architecture) developed by the RAPiD software group for Windows & Linux

→Site ID is not required to process ConnectHomes in SYR or CSI

→System Serial Number, and one that is properly recorded in the Install Base Group database in CSI, is required for a ‘known’ callhome. Systems without serial number or unknown serial numbers would become unknown callhomes, unknown SR queue, etc.

## **PURPOSE OF CONNECTHOME:**

1. Primary purpose is to provide a method for transporting event files via email, ftp, or modem (outbound service)

2. Secondary functions include ability to set or modify the dial-in number, the System Serial number, Site ID number, and whether to Enable or Disable dial-in capability (inbound service)

## **FRESH INSTALLATIONS & CONNECTHOME:**

→Installs do not automatically configure the transport portion of ConnectHome (the default is not to configure anything)

→Installs of 5.5.31.6 and later implements the Celerra ConnectHome feature

→To make ConnectHome operational, must configure with either a selected Primary, and/or Secondary, and/or Tertiary transport mechanism, using either email (or email to ESRS gateway), FTP using ESRS gateway, Modem, or a combination of the three

→A valid Celerra Serial Number must also exist to ensure proper delivery & handling by EMC

→Configure ConnectHome using the Celerra Manager>Celerras>Support>ConnectHome tab, CLI using /nas/sbin/nas\_connecthome, or with NAS 6.0, Unisphere > System > Service Tasks: Manage Connect Home

→/nas/sys/connecthome.config replaces /nas/sys/callhome.config

→The Callhome Email message body is not human friendly. It's BASE64 encoded, irrespective of the encryption setting.

**Note:** If “Enable Encryption” is turned off for ConnectHome, the resulting CallHome payload can be decoded with a simple Base64 decoding tool, or via CLI on the Control Station:

# perl -MMIME::Base64 -ne 'print decode\_base64(\$\_)' <base\_64encoded\_file\_name>

## **BASE64 ENCODED CALLHOME TEST EVENT:**

**SETTING COUNTRY CODE ON MULTITECH MT5634ZBA MODEMS:**

**Note:** If the system ships with an MT5634ZBA modem, it may require the use of a utility or CLI procedure to correct country/regional code settings. This information is taken from the NS Setup Guides.

**Windows ZBAWizard.exe Utility:**

1. Download utility to laptop
2. Connect serial cable between modem and laptop
3. Execute ZBAWizard.exe & enter decryption password “EMC”
4. GlobalWz application queries for modem
5. Select appropriate country/region settings and click finish

**Manually Updating Country/Region settings:**

1. Connect serial cable between modem and laptop
2. Open HyperTerminal session and configure 19200 bits per second, 8 data bits, set parity to None, 1 for stop bit, flow control None, terminal emulation ANSI
3. Verify current country/region setting:  
ATI9 (returns country value in decimal)
4. Set desired country code & verify to make sure the setting was updated:  
AT%T19,0,10 (last digit is modem value in hex, which in decimal is 16 for Japan)  
ATI9

**Note:** Find the applicable country/region code from the appropriate Celerra Setup Guide for MT5634ZMA

**NEW EMC MODEM:**

Multitech MT9234ZBA, 100-602-107 →Replaces the MT5634ZBA 100-602-106

ECO 69503

**TROUBLESHOOTING MODEM ERRORS:**

**NO DIALTONE**

--telephone line might not be connected or phone line cable is bad

--modem might not recognize dial tone if PBX system (can change modem to ignore dial tones)

**BUSY**

--number being dialed is busy, or missing the 9 prefix to access an outside line when dialing

**NO ANSWER**

--answering system will not go “off-hook” (i.e., does not answer), or the number dialed is wrong

**NO CARRIER**

--system answered but did not establish a connection (wrong number, voice number vs. modem, or computer or software was off or faulty, or poor line conditions are causing connection issues)

**General Modem Issues:**

--lack of line connection or bad cable/connector

--wrong dial tone

--busy signal

--wrong number or no modem at the other end

--faulty computer, modem, or software at the other end

--modem incompatibility

--poor line conditions

**CHANGING MODEM RINGCOUNT ANSWERING:**

→Default is to have the modem answer immediately without ringing. To change the default, vi edit the /nasmed/sbin/ch\_mgetty\_monitor script and change following line:

**/sbin/mgetty -n 4 -x 0 \$(basename \$serialdev) > /dev/null 2>&1**

**DISABLING CONNECTHOME FOR NAS UPGRADES, MAINTENANCE, etc:**

**# /nas/sbin/nas\_connecthome -service stop**

Delivery of pending events has been paused.

**# /nas/sbin/nas\_connecthome -service start**

No pending events have been cleared and delivery has been resumed.

**# /nas/sbin/nas\_connecthome -service start -clear**

Any pending events have been cleared and delivery has been resumed.

**Note:** The ability to stop, restart, or clear ConnectHome events is currently undocumented: Not in Release Notes, Cmd Ref Manual, Platform Setup Guides, or Man Pages. AR112733 is getting this documented, and emc173789 shows the recommended way to stop and restart the ConnectHome service. There is also no way to tell if the delivery service has been paused or not—see AR115618. See AR115610 to add capability to pause and restart delivery service in Celerra Manager.

**NAS UPGRADES AND CONNECTHOME:**

→NAS Upgrades will convert whatever is in use to the new ConnectHome format—any errors will be noted in the NAS Upgrade log, verify using /nas/sbin/nas\_connecthome –info; Modem numbers are carried over; Email SMTP server is carried over if set in /etc/sendmail.cf; ESRS Gateway (FTP) IP Address, Username, and Password are carried over—rsc5\*\_nas\_event.cfg file is unloaded and FTP transport enabled

**Note:** NAS Upgrades should be from any prior version to any version above 5.5.31.6, which does not properly preserve custom modem settings, such as the ignore-dialtone, pulse, or tone settings--these must be reset after an upgrade.

→If /nas/sbin/ch\_dd was used to setup pre-5.5.31 systems, the dial-out prefix, and primary/backup phone numbers, will be preserved

→CNS, CFS, & older NS models will need to have Serial Number manually updated after Upgrading to ConnectHome feature

→NAS Upgrades from 5.5.30.x or earlier, to 5.5.31.6 will convert existing CallHome configurations to the new ConnectHome feature. In general, all existing callhome configuration values are preserved if upgrading to 5.5.32 or higher. This is especially significant for those sites outside of the U.S. where default EMC modem settings are usually not applicable. For example, pulse, tone, and ignore-dialtone detection settings are not preserved and will require resetting in the /nas/opt/connectemc/login.cmds file (5.5.31.6 only) and the /nas/opt/connectemc/modem.cfg file (5.5.32.x and later will use this file if there are specific non-default modem settings). Additionally, other modem-specific settings may be impacted. It is generally recommended that the callhome process be tested after a NAS upgrade to ensure the viability of the transport mechanism in use. Please use the platform-specific Celerra Network Server Setup Guide (on Powerlink) as your primary reference for resetting modem settings. Configuration information is also contained in the Setup Guides and Celerra Command Reference Manual. Please note that the Man Pages for nas\_connecthome are missing for 5.5.31.6 and will be present with the 5.5.32.x release

→NAS Upgrades from 5.5.30.x or earlier, to 5.5.31.6, will preserve only the ignore-dialtone detection setting. All other custom modem settings will need to be redefined

→NAS Upgrades from 5.5.31.6 or earlier, to 5.5.32.4, or later, will permanently preserve any custom modem settings in the /nas/opt/connectemc/modem.cfg file, instead of the /nas/opt/connectemc/login.cmds file

→Original files should be preserved in /var/sadm/pkg/emcnas/save directory after the Upgrade

**CONNECTHOME REFERENCES:**

**man pages** →Beginning with NAS 5.5.32 and higher

**Platform-specific Celerra Network Server Setup Guide** →Powerlink & Doc CD

**Celerra Network Server Systems Operations Technical Module** →Powerlink & Doc CD

**TYPICAL LOGIN.CMDS FILE AS SEEN WITH VI EDITOR:**

```
44    set dial method auto  
45    set dial timeout 300  
46    set speed 9600
```

1. Edit the line 44 in the file /nas/opt/connectemc/login.cmds & add the ignore-dialtone line if required:

set dial method auto →change word "auto" to "tone" or "pulse" to modify [ATDT=Tone; ATDP=Pulse]

set dial timeout 300

set dial ignore-dialtone on [ATX1DT—add this line to the file]

**Resetting ignore-dialtone, Pulse, or Tone dialing for 5.5.32.x:**

1. Modify or create the file /nas/opt/connectemc/modem.cfg:

set dial ignore-dialtone on (add this line if the system does not use a dial-tone)

set dial method tone - or - set dial method pulse (add one of these lines if the modem uses a tone or pulse dial-tone)

**Note:** The login.cmds file is the default file in /nas/opt/connectemc. If custom modem settings existed in prior NAS versions, the modem.cfg file would get created during the upgrade to preserve the special settings. If custom modem settings need to be created for 5.5.32 or higher, the modem.cfg file should be edited to add the appropriate custom settings

**set dial method tone | pulse**

**set dial timeout 300**

**set dial ignore-dialtone on**

**LOCATION OF ORIGINAL MODEM FILE AFTER UPGRADE:**

**/var/sadm/pkg/emcnas/save**

**MODEM SETTINGS FILE:**

**/nas/sys/callhome.modem** (original Celerra CallHome modem settings file)

**/nas/opt/connectemc/login.cmds** (Beginning with NAS 5.5.31.6, this file handles the the modem connection options and provides vax username & password automatically when calling into the EMC vax system.)

**/nas/opt/connectemc/modem.cfg** (Custom modem settings file for NAS 5.5.32.x and above; file is created during upgrades from earlier NAS versions if there was a callhome.modem file, but has to be manually created for new installations if custom settings are required)

**CONFIGURING CELERRA CONNECTHOME (root user only):**

1. CLI interface

2. Celerra Manager>Celerras>Support>Connect Home>select primary delivery mechanism--Email; FTP; or Modem: Set Secondary or Tertiary delivery methods if desired. Can modify and test using Celerra Mgr, as well as disable or enable the Transport mechanism, but cannot clear, stop, or start the service from GUI—must use CLI for this.

**Note:** Must login as Root user to edit the "Connect Home" page

**CONNECTHOME CONFIGURATION FILE:**

→Whenever ConnectHome is changed or configured, either by the GUI or by the nas\_connecthome –modify command, the changes are written to /nbsnas/sys/connecthome.config, then synchronized via cron job to the local IDE drive on the Control Station, which runs every 5 minutes, to /nasmcd/CHomeFiles/connecthome.config

→Since ConnectHome actually uses the local IDE version of the connecthome.config file, there is a potential gap between the time someone changes the config file until the change is actually seen in the ConnectHome

→This issue will be resolved with CMR10, so that both files are updated simultaneously whenever –modify is run

**EXAMPLE:**

**# /nas/sbin/nas\_connecthome -modify -service\_info -email\_to emailalert@emc.com -email\_from**

**default@emc.com**

**# ls -la /nbsnas/sys/connecth\***

**-rw-r--r-- 1 root root 686 Jul 28 15:14 /nbsnas/sys/connecthome.config**

**# ls -la /nasmcd/CHomeFiles/connecth\***

**-rw-r--r-- 1 root root 696 Jul 28 15:09 /nasmcd/CHomeFiles/connecthome.config**

→Running pstree against NAS MCD process shows hierarchy of processes. "Dirsync" is a process designed to sync any file changes on the local /nas partition with the backend /nbsnas partition, every 3 minutes. It also syncs any changes from /nbsnas/sys to the local /nasmcd/CHomeFiles directory, every 5 minutes.

**# pstree -pau 25137 | grep dirsync**

dirsync,30078 /nas/sbin/dirsync /nas /nbsnas 180

dirsync,30118 /nas/sbin/dirsync -c /nas/sys /nasmcd/CHomeFiles 300

## **SOME CONNECTHOME CONFIGURATION RULES:**

- Can have all transport mechanisms enabled at the same time, or none
- To enable or disable transport mechanisms, we are actually assigning a priority using “-modify email\_priority 1, 2, or 3”, or removing the priority setting altogether using the “-modify email\_priority Disabled” syntax
- Only root user can make transport mechanism modifications (CLI, Celerra Mgr, Unisphere)
- Cannot Enable or change a transport method [priority] without first having a valid email address, FTP IP address, or Modem number, and at least one of the mechanisms set to a priority of 1 for the Primary entry

## **NEED PRIMARY EMAIL, IPADDRESS, or MODEM NUMBER SET FIRST BEFORE TRANSPORT CAN BE ENABLED:**

### **1. Modem Number Not Set (Example):**

```
# /nas/sbin/nas_connecthome -modify -modem_priority 2
```

Error 14504231241: The Modem transport cannot be enabled because the Primary Modem Number is not configured.

```
# /nas/sbin/nas_connecthome -infotail
```

Modem :

Priority = Disabled

Primary :

Phone Number =

### **2. Setting Modem Number:**

```
# /nas/sbin/nas_connecthome -modify -modem_number 918005270941
```

### **3. Setting Modem Priority & Verifying:**

```
# /nas/sbin/nas_connecthome -modify -modem_priority 2
```

Ok

```
# /nas/sbin/nas_connecthome -infotail
```

Modem :

Priority = 2

## **DISABLING TRANSPORT MECHANISMS:**

```
# /nas/sbin/nas_connecthome -modify -modem_priority Disabled -ftp_priority Disabled -email_priority Disabled
```

Ok

## **PRIMARY CONNECTHOME APPLICATIONS & FILES:**

→ Main ConnectHome application is /nas/sbin/connectemc, which monitors the /nas/log/ConnectHome directory, delivering all files via the selected Transport mechanism whenever an RSC...xml file is detected

→ General configuration file for ConnectHome is /nas/opt/connectemc/ConnectEMC.ini

→ Transport configuration file is /nas/opt/connectemc/ConnectEMC\_config.xml

## **CONNECTHOME CLI:**

```
# /nas/sbin/nas_connecthome
```

**Note:** ConnectHome consolidates legacy CallHome scripts into one—ch\_dd, ch\_cfg, ch\_dialin\_enable, ch\_dialin\_disable, ch\_test] -info

```
| -test { -email_1 | -email_2 | -ftp_1 | -ftp_2 | -modem_1 | -modem_2 }
```

```
| -modify [ -modem_priority {Disabled | 1 | 2 | 3} ]
```

|                                              |                                                |
|----------------------------------------------|------------------------------------------------|
| [ -modem_number <phone_number> ]             | [ -modem_bt_tymnet { yes   no } ]              |
| [ -modem_number_2 <phone_number> ]           | [ -modem_bt_tymnet_2 { yes   no } ]            |
| [ -ftp_priority {Disabled   1   2   3} ]     | [ -ftp_ipport <ip_addr>[:<port>] ]             |
| [ -ftp_user <username> ]                     | [ -ftp_passwd [passwd] ]                       |
| [ -ftp_folder <path> ]                       | [ -ftp_mode {active   passive} ]               |
| [ -ftp_ipport_2 <ip_addr>[:<port>] ]         | [ -ftp_user_2 <username> ]                     |
| [ -ftp_passwd_2 [passwd] ]                   | [ -ftp_folder_2 <path> ]                       |
| [ -ftp_mode_2 {active   passive} ]           | [ -email_priority {Disabled   1   2   3} ]     |
| [ -email_to {<email_addr> ,<email_addr>} ]   | [ -email_subject <email_subject> ]             |
| [ -email_server { <hostname>   <ip_addr> } ] | [ -email_server_2 { <hostname>   <ip_addr> } ] |
| [ -dial_in_number <phone_number> ]           | [ -serial_number <serial_number> ]             |
| [ -site_id <site_id> ]                       | [ -encryption_enabled { yes   no } ]           |
| [ -dial_in_enabled { yes   no } ]            | [ -help ]                                      |

```
# /nas/sbin/nas_connecthome -service → Switches are currently undocumented and do not display with -help, etc.
```

usage: nas\_connecthome

```
-service { start [-clear] | stop | clear }
```

```
# /nas/sbin/nas_connecthome -info
```

ConnectHome Configuration:

## **CALLHOME DIRECTORY REPOSITORY:**

### **/nas/log/ConnectHome**

RSC\_APM00064001123\_102107\_034449696.xml

**Note:** Up to 100 files can be pending in the event directory, processed single-threaded FIFO manner

### **DOES CS KEEP LOCAL COPY OF SUCCESSFUL & FAILED CALLHOME XML FILES?**

#### **ANSWER: YES**

The Control Station keeps a copy of both Successful and Failed CallHome XML files.

### **Location for Successful CallHome Files:**

#### **/nas/opt/connectemc/logs**

**ConnectEMC\_email.log** → Provides timestamp and xml filename of Callhomes delivered (via email)

**ConnectEMC** → Provides timestamp when CallHome was transferred and file appended to

#### **/nas/opt/connectemc/logs/archive**

**ConnectEMC.archive** → Keeps actual copy of successful XML Callhome files

**Note:** Open the file and scroll down to the end to see the latest XML callhome content. View the numbered.archive files to find older Callhome output.

### **Location for Failed CallHomes:**

#### **/nas/opt/connectemc/logs/failed** → Individual XML callhome files that fail are stored in this directory

#### **Connect Home Log File:**

# nas\_logviewer /nas/log/connecthome\_log |tail

Feb 8 11:40:03 2010:CS\_PLATFORM:ConnectHome:INFO:25:::1265647203:ConnectHome event file(s) successfully transferred

**Note:** Useful file as quick reference to see if Callhomes are being transferred, but does not give XML filename, as the ConnectEMC\_email.log does

Other CallHome Information & Logs:

**/nas/opt/connectemc; ls -la poll**

```
lrwxrwxrwx 1 root root 20 Oct 16 15:51 poll -> /nas/log/ConnectHome
```

**# /nas/sbin/nas\_connecthome -service stop | start (-clear) | clear**

**# /nas/sbin/nas\_connecthome -service stop** → Pauses the delivery service for any pending events

Delivery of pending events has been paused.

**Note:** Process takes about 1 minute to stop, and XML callhome files in /nas/log/ConnectHome are removed

**# ps -eafl |grep connect** (processes that run during –service stop)

**/nas/sbin/nas\_connecthome -service stop**

```
000 S root 32690 32689 0 68 0 - 1128 nanos! 13:19 pts/0 00:00:00
```

**/usr/bin/perl /nas/opt/connectemc/.connectemc\_suspend -q -m stop -c suspend**

**# /nas/sbin/nas\_connecthome -service start** → Prompts to clear any pending events and resumes the delivery service

Do you want to clear all the pending event files?(yes/no) :yes

Any pending events have been cleared and delivery has been resumed.

**Note:** If no events are pending, just resumes delivery service

**# /nas/sbin/nas\_connecthome -service start -clear** → Clears pending events from /nas/log/ConnectHome without prompting, & resumes the delivery service [maybe there is a delay, as running this command does not immediately remove the callhome file?]

Any pending events have been cleared and delivery has been resumed.

**# /nas/sbin/nas\_connecthome -service clear** [Pauses, clears pending events, and resumes Callhome delivery service]

None exist. No pending events have been cleared.

**# /nas/sbin/nas\_connecthome -service clear**

Delivery of pending events has been paused.

Any pending events have been cleared and delivery has been resumed.

**/nas/sbin**

**nas\_connecthome** → CLI tool for the ConnectEMC feature

**connectemc** → daemon executable that monitors and delivers event files using the configured transport mechanism(s)

**Note:** Primary file is /nas/sbin/connectemc [/opt/connectemc/connectemc is a link to /nas/sbin/connectemc]

**kermit** → modem control executable

**connectemc\_starter** → process that runs everytime the connecthome service is started

**connecthome\_upgrade** → Script that performs ConnectHome upgrade during NAS Upgrades

**/nas/sys**

**connecthome.config** → Replaces callhome.config

**Note:** The /nas/sys/connecthome.config file contains Dialin modem number, Site number, Serial number, information about all the Transport methods [email, modem, FTP], & encryption status information, and replaces the /nas/sys/callhome.config. A backup copy of this file is stored in /nasmcd/CHomeFiles/connecthome.config.

**# cat connecthome.config** → Use /nas/sbin/nas\_connecthome -info for output

dialInEnabled:yes

### /nas/log

/nas/log/connecthome\_log → Log that records successful CallHome transfers & CallHome tests

# nas\_logviewer -v connecthome\_log |tail

```
logged time      = Dec 3 12:38:26 2008
creation time    = Dec 3 12:38:26 2008
slot id         =
id              = 96108609561
severity        = INFO
component       = CS_PLATFORM
facility        = ConnectHome
baseid          = 25
type            = EVENT
brief description = ConnectHome event file(s) successfully transferred
full description  = The ConnectEMC daemon succeeded in transferring the ConnectHome event file(s) to the configuration destination(s).
recommended action = For details, here are the log files:
- General : /opt/connectemc/logs/ConnectEMC
- Email : /opt/connectemc/logs/ConnectEMC_email.log
- FTP : /opt/connectemc/logs/ConnectEMC_ftp.log
- Modem : /opt/connectemc/logs/ConnectEMC_dial.log
```

**Note:** View this log using nas\_logviewer /nas/log/connecthome\_log -v option to provide verbose output

/nas/log/sys\_log → Control Station System Log showing CallHome attempts and success or failure

**Note:** Use nas\_logviewer for sys\_log and connecthome\_log with -v option to view expanded entries on CallHome events

/nas/log/ConnectHome → ConnectHome RSC xml event files

/nas/log/connectemc → symbolic link to /nas/opt/connectemc/logs [archive ConnectEMC ConnectEMC\_email.log ConnectEMC\_dial.log failed output]

### /nas/opt/connectemc

callhome.ini → Modem initialization file

connectemc.pem → RSA private encryption key

login.cmds → Modem settings in 5.5.31.6 only [changes to modem.cfg file with 5.5.32.x]

connectemc → Symbolic link to /nas/sbin/connectemc executable

connectemc.sh → Sets path to libraries [/opt/connectemc/lib]

logs → Various ConnectHome logs, see next section

rsapub1.key → Encryption key file

connectemc.cer → Certificate

curl-ca-bundle.crt

naslogger\_conduit → Logging

poll → directory containing ConnectHome xml files, but is a symbolic link to /nas/log/ConnectHome

ConnectEMC\_config.xml → Shows the type of transport service that is in effect [Email, FTP, Modem]

<ConnectConfig Type="Email">

kermit → Symbolic link to /nas/sbin/kermit executable

ConnectEMC.ini → General configuration file on log format, log names, log sizes, log archiving, log levels, polling, transport service configuration, archive options, encryption, recycle parameters, etc.

lib

Queue

recycle (directory of failed callhomes that will be retried)

recycle.log (log of retried callhomes with projected retry times)

### /nas/opt/connectemc/logs

archive (directory of ConnectEMC.archive files that captures actual content of XML Callhomes)

Example:

# view /nas/opt/connectemc/logs/archive/ConnectEMC.archive

```
-- Time : 21-10-2007 03:45:53.
-- Filename : /opt/connectemc/poll/RSC_APM00064001123_102107_034449696.xml.
-----output abridged--followed by contents of the RSC xml file---
failed (Archive directory of failed callhome files)
# ls -al /nas/opt/connectemc/logs/failed
RSC_APM00083103123_112608_141558641_ConnectEMC_config.xml
RSC_APM00083103123_112608_141558641.end
RSC_APM00083103123_112608_141558641.xml
ConnectEMC (daemon log)
ConnectEMC_email.log (record of last email attempt)
ConnectEMC_ftp.log (record of last FTP attempt)
ConnectEMC_dial.log (record of last modem attempt)
output
```

### **EXAMPLE UNSUCCESSFUL MODEM CALLHOME:**

0. /nas/sbin/kermit
1. /nas/sbin/modemtst
PENDING_CALLHOME = 0
modemtst: version 1.0
modemtst: readlink found: /dev/callhome --> /dev/ttyS0
modemtst: Current callhome port: /dev/callhome --> /dev/ttyS0
isValidPort: arg = 1
ch_port = 1 port = 1
isValidPort: arg = 1
modemtst: Modem /dev/ttyS0 OK
Port /dev/ttyS0 is valid
isValidPort: arg = 1
portIsOkay: arg = 1 port_status = 0
Port is OKAY. Good exit.
isValidPort: arg = 1
isValidPort: arg = 1
portIsOkay: arg = 1 port_status = 0
```

## **TROUBLESHOOTING MODEM USING MINICOM:**

1. Configure minicom profile for CS modem

# minicom -s

Serial port setup>A>Edit /dev/ttyS1 to read /dev/ttyS0 for the modem serial port  
Accept defaults, 38400, 8, N 1, and HW Flow Control Yes  
Save Setup as <name>

2. Connect to modem and test dial out:

# minicom <name>

atz

OK

atdt82066097

CONNECT 31200 V42bis

## **CONTROL STATION PROCESSES FOR CONNECTHOME:**

# ps -eafl |grep connect

```
140 S root 1463 1 0 69 0 - 1284 do_sel Aug27 ? 00:00:00 sendmail: accepting connections
000 S root 3531 1689 0 69 0 - 373 nanosl Aug27 ? 00:00:00 /nas/sbin/log_trimmer -n /nas/log/connecthome_log 2000 1 6 h t 10 n
000 S root 4757 1689 0 69 0 - 566 wait4 Aug27 ? 00:00:14 /bin/bash /nas/sbin/connectemc_starter
000 S root 5243 4757 0 69 0 - 1838 nanosl Aug27 ? 00:00:00 /nas/opt/connectemc/connectemc
```

**Note:** The connectemc process replaces the old ch\_monitor, while the kermit process replaces the ch\_app process

## **CONFIGURING CONNECTHOME--CELERRA MANAGER/UNISPHERE:**

**Note:** /nas/log/cel\_api.log records fact that a modification was done, and what the host IP was, but does record the actual modification

**Celerras>Support>ConnectHome tab** (Celerra Mgr)

**Unisphere > System > Service Tasks: Manage Connect Home** (Root user Scope local only!)

### **MISCELLANEOUS ITEMS:**

→Can modify Site ID, Celerra Serial Number, Enable/Disable Dial-in number, Enter/Modify Dial-in modem number, Enable or Disable Encryption, and can Test any of the ‘configured’ transport methods [needs to be configured to showup on the list]

**Note:** Missing serial number will result in UNKNOWN callhomes. Serial number is automatically detected for later NS models, but manual updates will be required for CNS, CFS, & older NS models.

### **MISC. DEFAULTS:**

Dial-in Enabled & Encryption are enabled by default—all other values blank until set

### **EMAIL ITEMS:**

→Can modify Priority (Disabled, Primary, Secondary, Tertiary) of the transport method, specify Primary & Secondary SMTP server, Subject line of email, specify multiple Recipient Address(es) with comma separation

### **EMAIL DEFAULTS:**

Default Sender is [connectemc@emc.com](mailto:connectemc@emc.com), Default Recipient is [emailalert@emc.com](mailto:emailalert@emc.com), Default Subject Line is “CallHome Alert”—all other values blank until set

### **FTP ITEMS:**

→Can modify Priority, specify Primary & Secondary FTP Server, Port to use for FTP, Username, Password, default Remote Location path, Transfer Mode (Active or Passive)

**FTP DEFAULTS:**

Default FTP user account is “onalert”, Default FTP password is “EMCCONNECT”, Default FTP destination path is “incoming”, and Default transfer mode is Active—all other values blank until set

**MODEM ITEMS:**

→Can modify Priority, specify Primary & Secondary Modem Number, Enable or Disable BT Tymnet

**MODEM DEFAULTS:**

Default setting for BT Tymnet is no—all other values blank until set

**CONFIGURING CONNECTHOME FROM CLI:**

**SETTING DIAL-IN MODEM NUMBER, SITE ID, SERIAL NUMBER, or ENCRYPTION(payload):**

# /nas/sbin/nas\_connecthome -modify -dial\_in\_number 15082498600 | -serial\_number | -site\_id | -encryption\_enabled yes | no

Ok

# /nas/sbin/nas\_connecthome -info |head

ConnectHome Configuration:

Encryption Enabled = no

Dial In :

Enabled = yes

Modem phone number = 15082498600

Site ID = s323

Serial number = APM00064001123

**ENABLING or DISABLING DIAL-IN MODEM NUMBER:**

# /nas/sbin/nas\_connecthome -modify -dial\_in\_enabled yes | no

Ok

**SETTING TRANSPORT DESTINATIONS:**

**Configuring Primary & Secondary Email Destinations:**

# /nas/sbin/nas\_connecthome -modify -email\_to

emailalert@emc.com,szg30@sun1.hosts.pvt.dns,szg30@sun2.hosts.pvt.dns -email\_from admin@emc.com

-email\_subject 'Email Callhome Alert' -email\_server sun1.hosts.pvt.dns -email\_server\_2

sun2.hosts.pvt.dns

Ok

# /nas/sbin/nas\_connecthome -info |grep -C3 Email

Email :

Priority = 1

Sender Address = [admin@emc.com](mailto:admin@emc.com) →Set using CLI only (later NAS versions can set in GUI)

Recipient Address(es) = emailalert@emc.com,szg30@sun1.hosts.pvt.dns,szg30@sun2.hosts.pvt.dns

Subject = Email Callhome Alert

Primary :

Email Server = sun1.hosts.pvt.dns

Secondary :

Email Server = sun2.hosts.pvt.dns

**Note:** Multiple email recipients allowed using comma separation between addresses, no spaces, via CLI only—EMC recommendation to keep [emailalert@emc.com](mailto:emailalert@emc.com) as the default destination address. The Callhome Email message body is Base64 encoded & is not human readable. Default Email Subject line is ‘Callhome Alert’. Default Email Sender is ‘connectemc@emc.com’. Default action is to send all email in Base 64, and encrypted. Disable encryption to decode email Base 64 messages for testing.

**Configuring Primary & Secondary FTP Server Destinations (to ESRS Gateway):** →Sets Primary FTP server & port (if specified), and Secondary FTP server & port

# /nas/sbin/nas\_connecthome -modify -ftp\_ipport 168.159.216.19 -ftp\_ipport\_2 192.1.4.248

Ok

# /nas/sbin/nas\_connecthome -info |grep -i ftp

FTP :

FTP Server = 168.159.216.19

FTP Port = 21

FTP User Name = onalert

FTP Password = \*\*\*\*\*

FTP Remote Folder = incoming

FTP Transfer Mode = active

FTP Server = 192.1.4.248

FTP Port = 21  
FTP User Name = onalert  
FTP Password = \*\*\*\*\*  
FTP Remote Folder = incoming  
FTP Transfer Mode = active

### **Modifying FTP User & Password:**

# /nas/sbin/nas\_connecthome -modify -ftp\_user anonymous -ftp\_passwd onalert@emc.com

Ok

**Note:** Default ftp user is “onalert” and default ftp password is “EMCCONNECT”

### **Configuring Primary & Secondary Modem Destinations:**

# /nas/sbin/nas\_connecthome -modify modem\_number 9,18885552222 -modem\_number\_2 9,18885553333

Ok

### **Example of EMC Destination Modem Numbers for ConnectHome Service by Country:**

|       | <b>AT&amp;T 1-800</b> | <b>AT&amp;T Local</b> | <b>Verizon</b>              | <b>BT 1-800</b> |
|-------|-----------------------|-----------------------|-----------------------------|-----------------|
| U.S.  | 866 285 3258          | 508 435 0987          | 800 626 2452 & 800 527 0941 | n/a             |
| U.K.  | 0800 028 7702         | 0203 024 4653         | 0800 169 6651               | n/a             |
| Japan | 00531 11 5188         | 035 767 9355          | 00531 12 0466               | n/a             |
| Ger   | 0800 182 7792         | 0695 170 9349         | 0800 100 9325               | n/a             |

<http://www.cs.isus.emc.com/csweb2/udh/countrytollfree.htm>

### **Setting Transport Method Priority:**

# /nas/sbin/nas\_connecthome -modify -email\_priority 1 -ftp\_priority 2 -modem\_priority 3

# /nas/sbin/nas\_connecthome -modify -ftp\_priority 2

Ok

# /nas/sbin/nas\_connecthome -info |grep -C1 FTP

FTP :

Priority = 2

# /nas/sbin/nas\_connecthome -modify -modem\_priority 2

Ok

### **Disabling Transport Method Priority:**

# /nas/sbin/nas\_connecthome -modify -ftp\_priority Disabled

Ok

# /nas/sbin/nas\_connecthome -info |grep -C1 FTP

FTP :

Priority = Disabled

# /nas/sbin/nas\_connecthome -modify -modem\_priority Disabled

### **Removing a Transport Method from the Configuration:**

# /nas/sbin/nas\_connecthome -modify -ftp\_ipport "" -ftp\_ipport\_2 ""

Ok

# /nas/sbin/nas\_connecthome -modify -ftp\_ipport ""

Error 14504231237: The Primary FTP Server cannot be unconfigured because the FTP transport is enabled.

**Note:** Must disable the transport method using -modify -ftp\_priority Disabled before the transport can be removed

# /nas/sbin/nas\_connecthome -modify -email\_server\_2 ""

# /nas/sbin/nas\_connecthome -modify -modem\_number ""

Ok

**Note:** Be aware of syntax difference between the Primary Modem number and the Secondary

# /nas/sbin/nas\_connecthome -modify -modem\_number\_2 ""

**Note:** Use double quotations in place of the FTP IP address, Email address, or Modem number that is to be removed from the configuration

### **Testing a Transport Service (Testing Celerra ConnectHome):**

# /nas/sbin/nas\_connecthome -test -email\_1 [or -ftp\_1, -modem\_1, etc.]

-----  
Reading configuration file: ConnectEMC.ini.

Run Service begin...

Test succeeded for Primary Email.

### **Logs Showing Successful ConnectHome Email Transfer:**

* Connection #0 to host 168.159.216.19 left intact
> QUIT
```

### **Testing Modem Dialout:**

1. First make sure the TTY port is functioning correctly:

```
# /nas/sbin/modemst
modemst: Modem /dev/ttys0 OK
```

2. Then test ConnectHome modem configuration:

```
# /nas/sbin/nas_connecthome -test -modem_1
```

Wed May 21 07:47:42 EDT 2008

```

Reading configuration file: ConnectEMC.ini.

Run Service begin...

Test succeeded for Primary Modem.

## **CELERRA PLATFORMS BASED ON FLEET CLARIION BACKENDS:**

**NAS FOXGLOVE (NS-960, NS-960FC, NS-G8, NS-960iS):** High-end enterprise product, GA March 2009

- Supported with NAS 5.6.43 and Flare 28++ Mira release
- Foxglove consists of the NS-G8 Gateway, the NS-960, NS-960FC, & NS-960iS Integrated models
- Foxglove is not customer installable
- Replacement for NS80, NSX, and NS80G platforms
- First NAS system to be built on both Backend and Frontend CX4-based hardware
- Integrated systems now referred to as the “Unified Storage” marketing solution
- NS-960 Integrated ships in EMC-racked configurations only, no Customer-racked systems, with 2-8 Blades, 1-2 Control Stations
- The NS-G8 Gateway ships in EMC racks or can be racked in Customer racks, 2-8 Blades, 1-2 CS
- The NS-960iS ships with 2-4 Data Movers, supporting maximum of 480 drives (not 960 drives)
- NS-960 integrated model supports 2-8 Blades, 960 drives maximum
- NS-960FC model supports 2-6 Blades, 960 drives for use with FC Hosts

**Note:** With NAS 5.6.45 and the approved upgrade to add a 5<sup>th</sup> FC IO Module to each SP, the NS-960FC can support 8 Blades and external FC Hosts

→ The Blade Wildcat-S 4U CPU Chassis, is the first CPU chassis to be used by CLARiiON, SYMMETRIX, & NAS [Symmetrix Tigon; Clariion Dreadnought; NAS Foxglove] as part of the Common SPO convergence project

→ NS-G8 & NS-960 will ship only with Wildcat-S XBlades and always with the Tornado IO SLIC annex

**Note:** The Wildcat-S Clovertown CPU chassis is being replaced by the Wildcat-S VE Harpertown board in Fall 2009 timeframe (CMR10) for both Celerra and Clariion. Board is supposed to be 100% compatible with Wildcat-S for mixed systems.

→ Foxglove as an Xblade can be used in NS80, NSX, and NS960 systems

**Note:** Xblade types cannot be mixed within the same Enclosure for NSX/NS80, just same overall Cabinet

→ For NSX, NS80/NS80G, use of Foxglove Xblade requires swap out of Enclosures and all blades to support Foxglove

→ Foxglove Blades are called X-Blades (no name assigned, though previous materials called them X-Blade90)

→ Based on CLARiiON Dreadnought hardware--follow-on product to XBlade-65 architecture based on Common SPO “Wildcat-S”

→ Replacement for NS80 & NSX models, total of 8 blades (NS-G8 replaces NSX)

→Use of IO Modules, SLICs (Small I/O Cards), with (4) SLIC slots per Blade, and an additional (2) SLIC slots per Blade in an IO Annex slot called the Tornado I/O module carrier

**Note:** At GA, only one of the two slots in the IO Annex is used for Foxglove Blades (other slot will be used later on). In each Blade enclosure, the Annex slots (4 & 5) on the lefthand side, when viewed from the rear of the cabinet, are owned by the Upper blade (blades 3, 5, 7, 9), while the Annex slots (4 & 5) on the righthand side, are owned by the Lower blade (blades 2, 4, 6, 8).

→Earthquake management switch module uses Coldfire firmware that will be upgraded by NAS, and to be backwards compatible with Typhoon and Scorpion management switches

→Foxglove NS-G8 to support up to 4-backend arrays, and supports CX300/CX400/CX500/CX600/CX700, CX3 series, CX4 series, Symm 5, DMX1-3, Tigon arrays

#### **Titan Cabinet:**

→NS-RACK-60U cabinet for single or dual 24-AMP service

→Each rack holds (4) PDU's (Power Distribution Units—similar to mounted power strips in the rack) and (4) PDP's (Power Distribution Panels—external power attaches to PDP for PDUs)

→Power cord North America PW40U-60-US (Single phase L6-30 Plug) 208V 24A

→Power cord Europe PW40U-60-IEC3 (IEC 309 332 Plug) 230V 30A

→If calculated cabinet power requirements are under 24A, connect upper PDU's to lower PDP's

→If calculated cabinet power is >than 24A, do not disconnect upper PDU's

#### **Unified Storage Configurations (NS-960; NS-960FC; NS-960iS):**

→8-Blades for NAS-only configuration (requires no external FC ports)

→6-Blades for NAS and FC configuration where (2) FC ports/SP are dedicated for external Hosts

→4 Blades for NAS and FC configuration where (4) FC ports/SP are used for external Hosts

→2 Blades for NAS and FC configuration where (6) FC ports/SP are used for external Hosts

#### **SUPPORTED STORAGE CAPACITIES:**

→896TB IP systems (7 blades \* 128TB/blade for NS-960 & NS-G8)

**Note:** Foxglove is technically limited to about 480TB support with 2TB LUNs on the Celerra. CMR7 increases LUN size support to 16TB. Currently, the CX4 platform is limited to 256 LUNs in a single Storage Group, making it possible for a system shipping with 5.6.43 to reach the LUN limit and hence not be able to use additional disks on the backend. Maximum storage capacity of the CX4-960 is currently about 760TB.

→Supports 960 drives for MPFS over FC

→Supports 480 drives for MPFS over iSCSI

#### **SUPPORTED DRIVES FOR NS-960:**

146GB 15K FC drives

300GB 15K FC drives

400GB 10K FC drives

450GB 15K FC drives

1TB 7200rpm SATA drives [1 HS per 15 drives]

1TB 5400rpm SATA drives

73GB EFD drives (max. of 30/system, 1HS for every 30 drives, no mixing of drive types, RAID5 4+1 or 8+1 for Celerra, 5.6.43)

#### **SUPPORTED RAID PROTECTION:**

##### **Fibre Channel:**

RAID1/0, 2 luns, clar\_r10

RAID5 4+1 or 8+1, 2 luns, clar\_r5\_performance & clar\_r5\_economy, respectively

RAID6 4+2 or 6+2, 2 luns, clar\_r6

RAID 6 12+2, 4 luns, clar\_r6

##### **SATA:**

RAID1/0, 2 luns, clarata\_r10

RAID5 4+1 or 6+1, 1 lun, clarata\_archive

RAID5 8+1, 2 luns, clarata\_archive

RAID6 4+2 or 6+2, 2 luns, clarata\_r6

RAID 6 12+2, 4 luns, clarata\_r6

##### **EFD:**

RAID5 4+1 or 8+1, 2 luns, clarssd\_r5

#### **FOXGLOVE BLADE SPECS:**

→Dual socket, four core Intel 2.33GHz processors with Dual 1.33GHz FSB buses

→Blades capable of 4/8/16/32GB memory, Foxglove will ship with 8GB physical RAM (but only 4GB useable by pre-Barossa NAS)

\$ server\_sysconfig server\_2 -P

Total main memory (MB) = 4090

→(4) SLIC IO slots onboard, with another two per IO Annex (only one of the two slots used at GA for Blades) Lower left Annex is for the Top blade in an enclosure (3, 5, 7, 9), while lower right Annex is for Bottom blade in the enclosure (2, 4, 6, 8).

→128TB per blade for Cognac, 256TB/Blade Barossa

→Fall 2009 the DIMM chipsets are changing from 512Mbit DDR to 1Gbit DDR, meaning that for DIMM replacements, the 1Gbit memory sticks must be replaced in pairs (replace all DIMMS with 4 pairs prior to NAS 5.6.xxx, and after 5.6.xxx, only need to replace a single pair of DIMMs)

#### **Blade Replacement Comment:**

→There are two FRU replacement parts for the Blades. The DIMMs (100-562-959), and the Blade Assembly with CPU Motherboard (103-800-002C. The latter does not come with DIMMs or SLICs. So, you would order the Blade Assembly for a CPU Module failure, then transfer DIMMs and SLIC IO modules from one Blade assembly to the other.

# /nas/sbin/enclosure\_status -e 2 -v

Failed FRU CPU Module Failed

#### **CX4-960 SP SPECS:**

→Dual quad-core Xeon 2.66GHz processors per SP using 16GB memory

→Default Read cache setting 512MB, default Write cache approx. 4.5GB per SP

→Max 4096 LUNs and 1024 Storage Groups per Array

#### **CSA COMPATIBILITY:**

→Support for Foxglove in CSA

→Support for single or dual Control Station systems

**Note:** Cable check has additional checks for secondary CS, additional Blades, additional management switches, and checks to make sure that BE and FE IO ports on the SPs match required configurations

#### **BLADE/SP SLIC IO MODULES:**

--Tomahawk [103-054-100c] is a 4-port 1/2/4Gb FC IO Module (PMC Tachyon QE4) capable of CU & Optical SFP modules

**Note:** Copper SFPs would be used for connectivity to the Backend DAEs

--Harpoon [103-053-100a] is a 2-port 1Gb iSCSI IO Module using 10/100/1000 Mbps Ethernet RJ45 connectors & HW iSCSI offload

--Thunderchild is a 4-port 10/100/1000 BaseT GbE copper

--Thunderbolt is a 4-port GbE card with (2) Optical and (2) Copper GbE ports

--Firestorm is a single port Neterion 10GbE IO card

--SLICs cannot be hot-swapped or added to the Array without SP reboots (alternating reboots per NST)

--There are a total of (5) different SLIC IO modules between the SPs and Celerra

--Tomahawk Fibre Channel module is used by both SPs and Blades

--iSCSI Harpoon module is used only by the SPs

--Thunderchild, Thunderbolt, and Firestorm Ethernet modules are used by Blades only

#### **(8) SUPPORTED SLIC CONFIGURATIONS FOR FOXGLOVE BLADE ENCLOSURES:**

→(8) Basic IO module configurations are allowed

→All Blades in the cabinet must have the same identical SLIC configuration

→Each Blade can support up to (4) IO modules in the Data Mover assembly, and an additional (2) slots per Blade in a separate IO Annex (Up to 6 total SLIC cards per Blade)

→IO Annex A & B—Tornado Annex allows two PCI-Express slots for four additional IO modules (though only one slot used at GA)

**Note:** Lower left Annex is for the Top blade in an enclosure (3, 5, 7, 9), while lower right Annex is for Bottom blade in the enclosure (2, 4, 6, 8).

→SLIC Slot\_0 will always have the 4-port FC IO card for booting the blades

→SLICs will not be recognized without a system reboot

A →Single 4-port Tomahawk card, Two 4-port Thunderchild copper GbE cards (NS960DM-8A)

A1 →Single 4-port Tomahawk card, Four 4-port Thunderchild copper GbE cards (NS960DM-8A1)

B →Single 4-port Tomahawk card, Two 4-port Thunderbolt GbE cards (4 ports optical & 4 copper) (NS960DM-8B)

B1 →Single 4-port Tomahawk card, Four 4-port Thunderbolt GbE cards (8 ports optical & 8 copper) (NS960DM-8B1)

C →Single 4-port Tomahawk card, Two single port Firestorm 10GbE cards (NS960DM-8C)

C1 →Single 4-port Tomahawk card, Four single port Firestorm 10GbE cards (NS960DM-8C1)

C3 →Single 4-port Tomahawk card, Two single port Firestorm 10GbE cards, Two Thunderbolt 4-port GbE cards (NS960DM-8C3)

C5 →Single 4-port Tomahawk card (slot\_0), Two single port Firestorm 10GbE cards (slot\_1, slot\_2), Two Thunderchild 4-port GbE cards (slot\_3, slot\_4) (NS960DM-8C5)

**Note:** Model number convention for NS-G8 the same, just substitute NSG8 for each of the 8 IO configurations

#### **BLADE IO MODULE MODEL, PART NUMBER, NAME:**

NS960DM-8A1, 103-055-100B, Thunderchild 4-port copper GbE

#### **SLIC PORT NAMING CONVENTION:**

→<port\_type> + <SLIC\_slot\_position from 1-to-r> + <port\_number\_within\_the\_slot>

→Blade SLIC slots are numbered from left-to-right: 0, 1, 2, 3, 4

#### **Examples:**

#### **SLIC Configuration “C” (Single Tomahawk (Slot 0) and Two Firestorm cards (Slots 1 & 2)):**

BE-0-0; BE-0-1; AUX-0-0; AUX-0-1 (Slot 0)

FXG-1-0 (Slot 1)

FXG-2-0 (Slot 2)

**SLIC Configuration “A” (Single Tomahawk (Slot 0) & Two Thunderchild (Slots 1 & 2)):**

BE-0-0; BE-0-1; AUX-0-0; AUX-0-1 (Slot 0)  
CGE-1-0; CGE-1-1; CGE-1-2; CGE-1-3 (Slot 1)  
CGE-2-0; CGE-2-1; CGE-2-2; CGE-2-3 (Slot 2)

**SLIC SIGNATURE DURING NAS INSTALL OR UPGRADES:**

→setup\_slot –init generates IO module signature for the Blade, stored in following files:  
/nas/server/slot\_x/device  
/nas/dos/slot\_x/boot.cfg

**Example:**

```
# cat /nas/server/slot_3/devicelgrep slic  
slicsignature validate=131585
```

**FOXGLOVE ENCLOSURES (Chassis):**

**DME0 ENCLOSURE:**

→The NAS DME Enclosure(s) will use the Wildcat-S CPU, Chassis, & midplane, (2) Power Supplies, (4) Blowers, (2) Earthquake Management switch modules, (2) Blades with various SLIC IO module configurations, and (2) Tornado Annexes  
DME0 is 100-520-839 as the FRU  
DME1 is 100-520-840 as the FRU

**Note:** Enclosure replacements will provide only the midplane chassis—all existing DME hardware will be transferred to the new chassis

→Lower lefthand LAN port on Side A Management Switch always plugs into CS Port A for ETH0 primary Internal Network LAN  
→Lower lefthand LAN port on Side B Management Switch always plugs into CS Port B for ETH2 secondary Internal Network LAN  
→Upper lefthand LAN port on DME0 Side A Management Switch is used to cross-connect to additional DMEs (lower lefthand LAN port on the A side), and then to the Upper Mgmt LAN port on SPA’s Management Switch from the last DME in the loop  
→Upper lefthand LAN port on DME0 Side B Management Switch is used to cross-connect to additional DMEs (lower lefthand LAN port on the B side), and then to the Upper Mgmt LAN port on SPB’s Management Switch from the last DME in the loop  
→Lower righthand LAN port on DME0 Side A Management Switch is used to connect to the primary internal LAN port A on CS1  
→Lower righthand LAN port on DME0 Side B Management Switch is used to connect to the secondary internal LAN port B on CS1

**NAS EARTHQUAKE MANAGEMENT MODULES:**

→Firmware upgraded during NAS upgrades, and to be backwards compatible with earlier switches  
→Enclosure ID controlled by hardware

**(3) LAN Management ports**

Lower righthand LAN port (DME0 only) would be used to connect to either A (Primary) or B (Secondary) network port on CS1  
Lower lefthand LAN port (DME0 only) would be used to connect to either A (Primary) or B (Secondary) network port on CS0  
Upper lefthand LAN port would be used to daisychain to lower lefthand port on each additional Data Mover enclosure, and then to connect from last DME to the upper LAN management port on the SPs (depending on SPA or SPB side of cabinet)

**Single Serial Maintenance port**

(1) serial mini-db9 port for maintenance

**LEDs**

Fault LED, Power LED, 7-segment display showing enclosure ID

**SPE ENCLOSURE:**

→Solar Flare Management Module: Top RJ45 LAN port is the Management LAN port; Bottom RJ45 LAN port is the Service LAN  
→Bottom mini-db9 serial port is for connectivity to SPS A or B, while top mini-db9 serial port is the Maintenance serial port  
→The CLARiiON SPE Enclosure is similar (NS-G8), but will use different SLIC IO module configurations, and a Solar Management Module for each SP

Clariion SPE is 100-562-918 Dreadnought

→The CLARiiON SPE AUX chassis (NS-960, 960FC, 960iS) is similar to the regular SPE chassis, except that it is configured for use with the Integrated Celerra systems--the RESUME prom is backed up to the PSM database, and upon Enclosure replacement, FLARE will copy the original RESUME information over the replacement chassis’s RESUME

Clariion AUX SPE is 100-520-841

**CLARiiON SOLAR FLARE MANAGEMENT MODULES:**

**LAN Ports**

(2) LAN ports: Top LAN port is the Management LAN, Bottom LAN port is the Service LAN port (laptop connection)

**Other Ports**

Bottom serial mini-db9 port used to connect to SPS A or SPS B

Top serial mini-db9 port used for maintenance

(1) USB port

**LEDs**

Fault & Power LED

## **BACKEND FC Port Rules:**

- Each Backend Loop supports up to 8 DAEs (8@15=120 drives/loop) and uses 1 FC port per SP per Loop
- NS-960 supports AUX or AUXF arrays, the latter only when no FC Enabled license is ordered
- NS-960FC supports the AUXF array, with up to 8 Backend Loops [8 DAEs/Loop =64 DAEs total, yielding 960 drives over 8 SP FC Ports], and up to (6) Blades to allow for external FC Host connectivity
- NS-960iS supports the AUXI array, with up to 4 Backend Loops @8 DAE's each=32DAE's@15drives=480 (4 FC ports/SP for 4 Loops) and 4 Blades
- Each Blade uses 1 FC port per SP (8 Blades would require 8 FC ports/SP) and plug into FC ports 2 & 3 on the SPs

## **FOXGLOVE ARRAY MODELS:**

### **ORDER ENTRY NICKNAMES:**

AUX

AUXF

AUXI

### **TRUE ARRAY SYSTEM MODEL:**

CX4-960

- There are (3) Array configurations allowed with Foxglove Integrateds: AUX, AUXF, and AUXI
- From a CLI or GUI system perspective, the array will always be seen as a “CX4-960”
- The AUX SP configuration uses (2) 4-port FC IO SLIC modules/SP, for a total of 8 FC ports/SP
- The AUXF SP configuration uses (4) 4-port FC IO SLIC modules/SP, for a total of 16 FC ports/SP
- The AUXI SP configuration uses (2) 4-port FC IO SLIC modules/SP, and (4) 2-port iSCSI IO modules/SP (two modules onboard the SP and two modules in each SP’s IO Annex), for a total of 8 FC ports/SP and 8 iSCSI ports/SP
- IO Annex slot position is 4 & 5 for each SP [An SP with all SLIC slots populated are numbered 0-5, from left-to-right]

## **FOXGLOVE PSN (PRODUCT SERIAL NUMBER):**

- The Foxglove platform uses the new PSN as the Celerra Serial Number
  - Earlier platforms used the EMC\_SERIAL\_NUMBER field from the Data Mover or Enclosure\_0 Resume to determine Celerra Serial Number
  - During factory configuration, the PSN is written to Enclosure\_0’s Resume Prom as  
EMC\_PRODUCT\_SERIAL\_NUMBER="FNM00083800203" and also to the /etc/product\_numbers.db file
- # cat /etc/product\_numbers.db  
#Product Numbers Database file  
#This file contains the Product Serial Number(PSN) and Product Part Number(PPN).  
Version=1.0

**PSN=FNM00083800203**

PPN=900-525-001

# /nas/sbin/serial

FNM00083800203

**Note:** If the PSN value was missing from the product\_numbers.db file, the serial command would use the EMC\_SERIAL\_NUMBER field, which is the physical serial number of Enclosure\_0

### **NAS INSTALLATION OF NS-960:**

- During “serialinstall” or “serialkickstart” the PSN (Product Serial Number) prompt will appear, and if the RESUME prom is properly populated from the factory, the correct PSN number will appear. If so, just accept that value as the default. If the PSN number does not correspond to the PSN from the PSNT tag, then input the correct PSN number.

## **FOXGLOVE PRODUCT PART NUMBERS (PPN, see product\_numbers.db file):**

### **FOXGLOVE PSNT (Product Serial Number Tags):**

900-525-001 (NS-960 or NS-960FC)

900-525-002 (NS-G8)

900-525-003 (NS-960iS)

→Beginning with the NS-960 release, Celerra systems will ship with a “dogtag” called the PSNT

→The PSNT consists of the Product Serial Number, Product Part Number, and Revision

→The PSNT will be used to replace the traditional 100-xxx-xxx TLA number formerly used as a placeholder for the product in CSI  
→PSNT attaches to lower righthand side of DME0’s chassis [100-520-839] on the power supply

## **FOXGLOVE NAS SYSTEM MODELS:**

NS-960

NS-960FC

NS-960iS

NS-G8

**SYSTEM MODEL COMPARISONS:**

| Celerra Mgr/<br><u>CLI Model</u> | Array<br><u>Type</u> | Navisphere/<br><u>CLI Model</u> | FC Ports/<br><u>SP</u> | Max.<br><u>Blades</u> | Max. Loops/<br><u>Max. Drives</u> | Ext. Hosts | MPFS | FC Lic. | Navi Lic. |
|----------------------------------|----------------------|---------------------------------|------------------------|-----------------------|-----------------------------------|------------|------|---------|-----------|
| NS-960                           | AUX                  | CX4-960                         | 8                      | 2-4                   | 4/480                             | no         | no   | no      | no        |
|                                  | AUXF                 | CX4-960                         | 16                     | 2-8                   | 8/960                             | no         | no   | no      | no        |
| NS-960FC                         | AUXF                 | CX4-960                         | 16                     | 2-6                   | 8/960                             | yes        | yes  | yes     | yes       |
| NS-960iS                         | AUXI                 | CX4-960                         | 8                      | 2-4                   | 4/480                             | no         | yes  | no      | no        |

**Note:** Number of Blades & Backend Loops supported are dictated by the AUX array model, which determines the number of FC BE & FE ports available per SP. Each Blade consumes one FE FC port/SP. Each BE loop consumes one BE FC port/SP. Only the NS-960FC comes with an FC and Navisphere license. The NS-960 ships with an AUXF array if configured with >than 5 Blades, and/or if configured with >than 480 Drives. Additionally, all models can be optionally configured with a 2<sup>nd</sup> Control Station. Blades can be configured with a choice of one, of the eight different IO module configurations available, but when ordered, all blades within the Celerra system must use the same IO Module configuration. Each Blade has a two-slot IO Annex for additional IO modules, though the second slot in the Annex is not currently used for any IO configurations.

**I. NS-960 INTEGRATED (AUX or AUXF array)**

- Supports 8 or 16 FC Ports/SP, depending on backend configuration
- Supports AUX or AUXF backend configuration
- Supports basic NAS IP host connectivity via NFS, CIFS, or iSCSI protocols
- Supports 1 or 2 Control Stations
- Supports 2, 3, or 4 Blades, and up to 480 drives with AUX backend
- Supports 5-8 Blades, or 481+ drives with AUXF backend
- AUX array is configured with (2) Tomahawk IO cards/SP, for a total of 8 FC ports/SP, slots 0 & 1
- AUXF array is configured with (4) Tomahawk IO cards/SP, for a total of 16 FC ports/SP, slots 0, 1, 2, 3
- Does not ship with FC License
- Does not ship with Navisphere license
- Not upgradeable to FC Enabled system at GA

**II. NS-960FC INTEGRATED (AUXF array):**

- Supports use of all 960 drives for FC Hosts
  - Supports 1 or 2 Control Stations
  - Supports 2-6 Blades, and up to 960 drives
- Note:** NAS 5.6.45 and the procedure to add a 5<sup>th</sup> FC IO Module lifts this restriction. NS-960FC can support 8 Blades and external FC Hosts if the SPs contain the 5<sup>th</sup> FC IO Module.
- Supports AUXF backend configuration only
  - Ships with four Tomahawk SLICs per SP, slots 0, 1, 2, 3
  - A 6-Blade NS-960FC would have 2 FC ports/SP available for FC Hosts
  - A 4-Blade NS-960FC would have 4 FC ports/SP available for FC Hosts
  - A 2-Blade NS-960FC would have 6 FC ports/SP available for FC Hosts
  - Ships only with the AUXF array, which means the SPs have (4) Tomahawk IO cards, or 16 total ports/SP
  - Ships only when ordered with FC License
  - Navisphere licensing levels split into 480 drives or less and 481 drives or more

**SPECIAL RULES FOR FC:**

- FC license required & is bundled with Navisphere license for 480 drives or less
- FC license required & is bundled with Navisphere license for 481-960 drives

**Note:** FLARE 28.7 NDU automatically adds the Drive Expansion enabler on the backend (though this may have started with Mira FLARE 28.5)

# /nas/sbin/navicli -h 10.241.168.151 ndu -list

Name of the software package: -960driveExpansion

Revision of the software package: -

Commit Required: NO

Revert Possible: YES

Active State: YES

Is installation completed: YES

Is this System Software: NO

**III. NS-960iS iSCSI (AUXI array):**

- Supports 1 or 2 Control Stations
- Supports 2, 3, or 4 Blades, and max 480 drives
- Supports AUXI backend configuration only
- System can be used for NAS IP Hosts and MPFS over iSCSI Hosts

→SPs ship with (2) Tomahawk FC SLICs for a total of 8 ports/SP, slots 0 & 1

→SPs ship with (2) Harpoon 2-port iSCSI SLICs, and another (2) Harpoons in the IO Annex for each SP, slots 2, 3, 4, 5

**Note:** Each IO Annex supports two SLIC modules (leftside Annex for SPB; rightside Annex for SPA)

## **IV. NS-G8 GATEWAY**

→Supports 2-8 Blades, 1-2 Control Stations

→Supports CX, CX3, CX4 arrays; Symm5, DMX1, DMX2, DMX3, & Tigon Symmetrix

→Maximum of (4) attached arrays per Celerra

## **STORAGE MANAGEMENT OPTIONS FOR FOXGLOVE:**

→NS-960 & NS-960iS systems will use CLI setup\_clariion script or Celerra Manager

→NS-960FC will use Navisphere tools

→NS-G8 uses Clariion-based tools, like Navisphere

## **FRUs/CRUs/UPGRADES:**

### **Upgrades at GA:**

Add Blades

Add Control Station

### **POST-GA Upgrades:**

Add SLIC to Blades, Dec 2009

Change FC port usages on Integrateds

Upgrading DIMMs (DIMMs or motherboard changeout)

Replace XB60 or XB65 blades with XB90 (includes swapping out Enclosure)

NS80/80G upgrade to XB90 requires all blades & enclosures be updated to XB90

NS80, NS-480 conversion to NS-960

NSX, NS80G conversion to NS-G8

NS-960 to NS-960FC Upgrade, adds (2) FC Modules to each SP, adds FC Enable license (May 2009)

NS-960 to NS-960iS Upgrade, adds (4) iSCSI Modules to each SP (May 2009)

NS-960FC AUXF Upgrade, adds a 5<sup>th</sup> FC IO module to each SP (May 2009), allowing expansion to 8 Blades/system

NS-960FC AUXF Upgrade, adds single iSCSI IO Module to each SP for MirrorView or SANCopy (May 2009)

### **CRU LIST:**

Replace Blade Enclosure Power Supply

Replace Blade SFPs

Replace Disks

Replace SPs

**Note:** Actually, you replace the SP assembly and reuse CPU, SLICs, DIMMs as needed, or replace faulty CPU, SLICs, DIMMs)

Replace SP Enclosure

Replace SP Enclosure Power Supply

Replace SLIC

Replace SPS

Replace SFP in SPE

Replace LCC in DAE

### **FRU LIST, same as above, plus:**

Replace Blades

Replace Blade enclosure

Replace Control Stations

Replace Management modules

Power Supplies DAE

Blade DIMMs

### **PUHC/PAHC CHECKS:**

→Master dog tag cache file missing (PSNT)

→Missing SLIC signature in device file

→SPA-SPB communicate check failure

→Proxy-ARP setup check on NS40, NS80, NS-960

## **FOXGLOVE ISSUES:**

### **MANAGEMENT SWITCH FIRMWARE:**

→The Coldfire firmware on the NAS “Earthquake” Management Switches in Enclosure 0 is susceptible to I2C Bus Errors

→emc215163 was created to originally track and handle the issue

→emc219555 was created to document the process for upgrading firmware to 2.98 and to resolve any current Bus Errors

### **sys log:**

CS\_PLATFORM:BoxMonitor:CRITICAL:536::::1243324284:Enclosure 0 fault occurred.

CS\_PLATFORM:BoxMonitor:CRITICAL:515::::1243324320:Enclosure 0 blade B I2C PSA bus error.

**DIMMs CHANGES (Dual In-line Memory Module):**

→Foxglove systems will be converting from an older style 1GB DIMM (8 total slots, part #100-562-959), to a newer style 1GB DIMM that will be packaged in pairs under a new part number. Until NAS firmware can support, all (8) DIMMs will need to be replaced for any DIMMs issue. With a future NAS version, only a single DIMMs pair will need to be replaced.

**DAE CABLING KITS:**

→Direct Express order entry system does not properly configure enough DAE backend cables for systems with (6) DAEs or more. To be corrected by Sept 2009

**CELERRA PLATFORM BASED ON MAMBA CLARIION BACKENDS**

**CELERRA NX4 (Wormwood):**

**FIRMWARE & SOFTWARE VERSIONS:**

NAS 5.6.39.5

FLARE 02.23.050.5.703 [ECO 67366 Flare 02.23.052.5.705; ECO 70011 Nov 2009 for patch 707]

NST 6.28.50.2.29 on Apps & Tools CD [Clariion auto-update provides 6.28.50.2.35]

FLARE 28 Navisphere and NaviExpress versions

**NX4 FACTS:**

→GA Aug 2008 NAS 5.6.39.5, lower cost model than NS20, using the Mamba AX4-5f8 array (Flare 23 Vega 02.23.050.5.703), NS40 Blades, & Maynard Control Station (no floppy) #100-520-665

→Mamba SPs can have 2-port (Clariion) and 4-port FC I/O Modules, the latter 4-port solution is the BOA card for NAS only

**Note:** NaviExpress has a feature that propagates Host data to all available FC ports—this functionality is disabled on a physical port basis. Ports 0 & 1 Fibre are for Hosts, Ports 2 & 3 AUX are for NAS Hosts only.

→A Customer installable & implementable release

→Will not support SRDF, TimeFinder, or MPFSi

→All-in-One Model only, with FC license optional--(4) FC SP ports (BOA) available for sharing array with other Hosts [two per SP]

→Optional FCOEL (FC Option Enablement License) + NaviExpress or Navisphere license

→Tiered Services--Enhanced, & Premium Support

→Support for NaviExpress (Vega Flare), RAID 1/0, SAS with new AVM profiles for R5 & R1/0, new templates for 12 drive enclosure

→New Email User notification feature configured during CSA configuration and/or Celerra Manager>Support>Email User tab

→To be shipped as EMC 40U racked or Customer-racked

→Mamba is a 2U enclosure containing (2) SPs with 4-port FC Boa (NAS-only) IO module (2 ports for Celerra; 2 ports for Windows or Unix Hosts), and (12) SAS or SATA drives

→2U Mamba DPE array with up to 12 SAS/SATA drives; (2) SPs; 4-60 disks totaling (4) expansion slots of 12 drives each

**NX4 RESTRICTIONS/LIMITATIONS:**

→MPFS/MPFSi; Timefinder; SRDF are not supported on NX4

→Celerra Manager storage related statistics will not be available since Mamba AX4-5 array does not support Java

**Note:** If customers had full Navisphere, though, and NaviAnalyzer, they could produce array statistics. Current Celerra Manager Storage System Properties displays the following message for “Front-End I/O Requests”: Data not available on this storage system model.

**FACTORY LUN CONFIGURATION ON RG0:**

→A change from the current implementation, RG0 will have all remaining space allocated to the creation of two Data LUNs

→This change will apply to NX4 and all NS20, NS40 models as of August GA

**CELERRA NX4 FOOTPRINT:**

(4) expansion DAEs of 12 SATA and/or SAS drives each [4@2U]

(1) DPE with SPs & 12 SATA drives [2U]

(1) SPS [1U] with 2<sup>nd</sup> SPS optional

(1) Control Station [1U]

(1) Blade enclosure with 2 Data Movers [1U]

**Max. footprint:** 13U

**NX4 SYSTEM HARDWARE:**

**Sledgehammer Data Movers (NS20/NS40 Blades)**

→(4) 10/100/1000 Front-End Ethernet copper ports for Blades (Broadcom cge0-cge3) as one offering, and (4) Ethernet ports with (2) Copper & (2) Optical Ports (fge0-fge1) as a different offering, with (4) FC ports (Agilent QX4) to BE array & tape drives

→Single or Dual-Blade systems, either FC-Enabled model NX4FC or Non FC-Enabled model NX4

→2.8GHz Intel P4 processors, 4GB memory, 800MHz FSB, CMB-Sledgehammer motherboard (NS40), (2) Pwr Supplies per blade

→Total storage capacity 16TB/blade for IP configurations

### **Maynard Control Station (100-520-665)**

#### **CLARiiON AX4-5F8 “Mamba” array with 4-port BOA FC IO card**

### **NX4/AX4-5F8 SYSTEM INFORMATION:**

→NX4 Platform information located on Powerlink Celerra Tools section

→Celerra does not offer Gateway support for the AX4-5 backend

→EMC Celerra NX4 System Single & Dual Blade Installation Guides (Replaces ReadMeFirst & Placemat sheet)

**Note:** Contains Wagonwheel chart, Overview of Installation steps, detailed installation section, Cabling diagrams, CSA Worksheet & information

→All NX4 systems will be factory installed and require the use of the CSA to configure during initial startup

→Minimum NAS version is 5.6.39.5, Flare version 02.23.050.5.703

→NX4 Integrated will have same physical backend (AX4-5F8), but will not be licensed as an FC model unless ordered that way

→NX4 Integrated will manage & configure additional Backend storage from Celerra Manager GUI or via Celerra CLI using setup\_backend script

→NX4FC model will use NaviExpress or Navisphere to configure and manage additional Backend storage

→NaviExpress is the default CLARiiON management tool. System can be upgraded to Navisphere, but this is a one-way upgrade.

→Flare 23 is the base flare for the AX4-5 system. Flare upgrades are not currently revertable—they are permanent—emc184109

→Default is to ship only a single Standby Power Supply (SPS A), with a 2<sup>nd</sup> SPS B optional

→All NAS systems will ship with Dual SPs to support Write Cache

→SPs and O/S first shelf drives ship within an SPE enclosure. Additional drive shelves are shipped as DAEs, up to four total

→The SP has only a single LAN Management Port, which is used to connect the Internal Management networks between SPA & DM2, and SPB & DM3 for dual blade systems. There is no 2<sup>nd</sup> LAN Service port.

→The SP has two mini-db Serial ports, but only the top port is used as the Service Port (and is marked with Wrench symbol)

→Each SP will have (4) FC Front End ports [Port 2 AUX, Port 3 AUX, Port 0 Fibre, Port 1 Fibre], and Celerra is dedicated to using the AUX ports, while additional Hosts will use only the 0 & 1 Fibre ports.

### **CONNECTING TO SP SERIAL SERVICE PORT AX4-5 (Wrench symbol):**

1. Connect using null modem serial cable between Windows workstation (db9 female) and SP top service port (mini-db9 male)  
Part #038-003-084

2. Configure HyperTerminal session [9600 baud, 8 N 1 None] using ANSIW emulation

**Note:** This connection would allow troubleshooting SP bootups, access to BIOS, or access to POST menu when using “ctrl + c” (or Esc key if that does not work) combination to let POST complete, followed by password SHIP\_it. POST model shows up as “BOOMSLANG: SAN”

### **CONNECTING DIRECTLY TO AX4-5F SP LAN PORT:**

For a factory installed AX4-5F, configure the laptop with an address of 1.1.1.2 at 255.255.255.0 mask. Connect the LAN cable from laptop to SP LAN port, open a web browser, and access the setup program using 1.1.1.1/setup. Once the setup program is available, you can then set the IP address of the SP(s) to the Celerra internal addresses of 128.221.252.200/128.221.253.201 and gateways 128.221.252.104/128.221.253.104. Repeat procedure for alternate SP, which will have the same ‘floating’ system IP of 1.1.1.1.

**Note:** Actually, for a factory fresh AX4-5 system, you may need to run a Storage System Initialization Wizard before you can assign the IP addresses for the SPs. After initialization, connect to SPA using 1.1.1.1 (SPB shows up as 0.0.0.0), assign the IP address, then connect to SPB using 1.1.1.1, and assign its IP address. With a Hub or Switch connecting to both SP LAN ports at once, you can assign both IP addresses for the SPs during the initialization process. You may also want to NDU the array to the proper flare version before doing a NAS installation.

### **NX4 CRU LIST:**

#### **NAS HEAD:**

Blades

Blade Power/Cooling Modules

SFPs on Blades

#### **ARRAY:**

SP/DAE Power/Cooling Modules

SPs

SP I/O modules

SP Memory modules

SPS

SFPs in SP

Power/Cooling Modules DAE

Drives

LCCs

### **NX4 FRU LIST:**

#### **NAS HEAD:**

Blade

SFP module Blade

Control Station [Special FRU—fault isolation checklist]

Blade Enclosure

**ARRAY:**

Power/Cooling Module SP

SP

SP I/O Module

SP Memory Module

SPS

SFP module on SPs

DPE SP/Midplane enclosure

Power/Cooling Module DPE/DAE

LCC Module

Disk

DAE Enclosure

**NX4 HW UPGRADES:**

Add Disk

Add Blade

Add SPS [Missing from documentation list]

Add DAEs

Enable FC Option

Upgrade Flare

Upgrade from NaviExpress to Navisphere via license and procedure to add the Navisphere Manager enabler [Procedure available from: <http://www.emc.com/microsites/clarion-support/ax45-install.htm>]>Upgrade to Navisphere Manager: select ‘Upgrade to Manager guide’ and download]

**NST SUPPORT NX4 or NX4FC:**

6.28.50.2.29 is the current NST version on Apps & Tools CD, Auto-update version from CLARiiON website is 6.28.50.2.35

**Hardware Registration:**

Register Storage System → Popup reports that “This feature is not supported on your Celerra integrated system.”

**Note:** Clarion perspective, this is supported on AX4 array

**Hardware Installation:**

Install Disk Array Enclosure

Install Disk

Install I/O modules and/or SFPs

→ all of these wizards report that the Storage System is not supported with these tools

**Software Assistant:**

Download and Install Hot Fix

Prepare for Installation

Install Software

Help

→ All of these wizards are supported

**Hardware Maintenance:**

Verify Storage System—supported and works

Replace Disk—not supported on AX4-5F8 system

Upgrade Disk Firmware—appears to be supported, but would use Eng. mode and Engineering>Upgrade Disk Firmware wizard

Capture SPCollect—supported and works

**NAVISPHERE EXPRESS MANAGEMENT TOOL (NaviExpress):**

→ New NaviExpress Clariion array management GUI

→ NaviExpress is an HTML web-based user interface, with HTML generated by Backend via NaviJrProvider. Client Browser sends requests via HTTP/URL to Cimom agent, which forwards to NaviJrProvider, which processes requests for HTML content, or uses get/set storage object wrappers to communicate or take action on the array

→ NaviExpress GUI consists of Main Menu frame, Header frame, and Content frame

→ All AX4-5 arrays will ship with NaviExpress installed on the array by default, though NX4 is not licensed to use it

→ A NaviExpress license comes as part of the FC Enabled license upgrade [aka NX4FC]

→ NaviExpress can be upgraded to a full Navisphere license, but no returning to NaviExpress

→ NaviExpress will be restricted to not pass Host Blob information on the NAS FC Ports [Celerra uses its own method to propagate this information]

→ NaviJr.Provider provides User interface via HTML Web Pages, Web Page classes that plug into the NaviJr Provider for NaviExpress GUI & monitors array health

**New Terminology or behavior seen in NaviExpress GUI:**

**Disk Pools** equate to Raid Groups

**Virtual Disks** equate to LUNs

Storage Groups are not visible with NaviExpress

Supports only Naviseccli

**Determining Management Tool for NX4:**

# /nas/sbin/navicli -h 192.1.4.220 managedby

Managed By: NaviExpress

**UPGRADING FROM NAVIEXPRESS TO NAVISPHERE:**

→Would need to purchase a Navisphere license

→Then download the CLARiiON procedure for upgrading

www.emc.com/ax45-support>Install>Upgrade to Navisphere: select ‘Upgrade to Manager guide’ to download

**Note:** This is a one-way upgrade only

→Download the ‘NavisphereManagerAXEnabler.ena’ file from Powerlink:

Navigator Dropdown > EMC Services Partner Web > select CLARiiON > AX4-5 Series > Softward Downloads > find the enabler

→Log into the array via NaviExpress and run the software upgrade wizard to install the enabler

**CREATING CELERRA LUNS USING NAVIEXPRESS:**

Navisphere Express>Manage>Virtual Disks (i.e., LUNs)

1. Select an available disk pool (i.e., Raid Group)
2. Enter a custom name (or keep the default name: “Virtual Disk 201”) and capacity for the new LUN, as well as how many ‘Virtual Disks’ (luns) to create
3. Assign the Virtual Disk to a Server [locate the default name used for Celerra: “Celerra\_<CS\_hostname>” in the dropdown menu]
4. Click apply to create [Flare 23 does not have Fast Bind capability]

**Comment:** LUNs created via NaviExpress automatically select the next lowest available HLU number, which in the case of Celerra, would most likely be in the Reserved HLU LUN range of 6-15 decimal. Please see emc191681 for more details, but essentially beginning with NAS 5.6.28 and above, the NAS diskmark code will automatically reassign any Reserved HLU LUN number to a valid HLU LUN number, thereby preventing assignment of Reserved LUN numbers. For Navisphere Express managed systems, the diskmark protection will be silent and will not inform the User of the change. For Reserved HLU assignments created and added to StorageGroups using Navisphere Manager, an informational message will be displayed during diskmarking to show what is being done, and the diskmark protection code will prevent an HLU from being assigned to a Celerra volume:

Info 26306752254: APM00072303347 reassigned LUN 0009 in storage group 'Celerra\_aviator' from host id 0007 to 0017

**BACKEND EVENT MONITORING:**

→Backend Event monitoring based on Storage API (Solution Enabler API) rather than Navi Agent EVMonitor [NaviExpress does not have support for Naviagent event reporting]

→To be implemented on all NAS integrated systems beginning with NX4

→Backend is polled every 5 minutes, meaning that event reporting could be delayed with NX4

→Implemented within Master Control Daemon (nas\_mcd.cfg) using a Management Daemon (mgmtd)

# ps -ef |grep mgmtd

```
root  32427 3466 0 Jul17 ?    00:00:00 /bin/sh /nas/sbin/start_sys_mgmtd
root  14956 14644 0 Jan13 ?    00:00:50 /nas/sbin/mgmtd
```

# view /nas/sys/nas\_mcd.cfg

```
daemon "System Management Daemon"
  executable  "/nas/sbin/start_sys_mgmtd"
  optional    yes
  autorestart yes
  ioaccess   no
```

**MANAGEMENT DAEMON LOGS:**

/nas/log

-rwxrwxr-x 1 nasadmin nasadmin 211083 Aug 29 10:04 nas\_log.al.mgmtd

-rw-rw-r-- 1 nasadmin nasadmin 6921 Aug 29 10:04 nas\_log.al.mgmtd.crash (Records stops and starts)

**Management Daemon Core Dumps:**

/nas/var/dump

**MINIMUM AND MAXIMUM CONFIGURATIONS:**

**Entry Configuration 5U .4TB:**

→Single DPE with dual SPs & 5@146GB SAS drives

→Single SPS

→Single Maynard Control Station

→Single Blade

**Dual Blade Configuration 13U 45TB:**

- Single DPE with dual SPs and 12@1TB SATA drives
- Single SPS
- Single Maynard Control Station
- Dual Blades
- Up to four expansion DAEs with 12@1TB SATA drives each

### **TIERED SERVICES MODEL:**

- Enhanced and Premium services (no basic)

#### **Enhanced Support:**

- Call Center 7x24, 4-hour support
- Onsite 5x9 next business day support
- CRUs to be replaced by Customer using Email Notification CCMD messaging. CRU parts shipped for next day delivery.
- FRUs will be next day EMC/Partner support
- Flare NDU can be done by customers using NST
- NAS Upgrades must be done by EMC/Partner and require software maintenance contract
- Customer installable with optional installation service

#### **Premium Support:**

- Call Center 7x24 2-hour response time support
- Onsite 7x24 4-hour response time support
- All CRU/FRUs serviced by EMC/Partner
- Flare & NAS Upgrades performed by EMC/Partner and requires software maintenance contract
- Customer installable with optional installation service

### **SELECTED NX4 HW/SW MODEL NUMBERS:**

|             |                                                                    |
|-------------|--------------------------------------------------------------------|
| NX4-1C-A    | NX4 NAS ENCLOSURE W/ ONE BLADE - FACTORY INSTALL TLA #100-520-800  |
| NX4-1C-A-FD | NX4 NAS ENCLOSURE W/ ONE BLADE - FIELD INSTALL TLA #100-520-800    |
| NX4-2C-A    | NX4 NAS ENCLOSURE W/ TWO BLADES - FACTORY INSTALL TLA #100-520-801 |
| NX4-2C-A-FD | NX4 NAS ENCLOSURE W/ TWO BLADES - FIELD INSTALL TLA #100-520-801   |

| NX4-AUXFCR  | NX4 CAPTIVE ARRAY - FIELD INSTALLED TLA #100-520-802               |
| NX4-CS      | NX4 CONTROL STATION - FACTORY INSTALLED TLA #100-520-665           |
| NX4-CS-FD   | NX4 CONTROL STATION - FIELD INSTALLED TLA #100-520-665             |
| NX4-EXPAN   | NX4 EXPANSION ENABLER SAS/SATA DRIVES                              |
| NX4-FCOPT-L | NX4 FC PORT OPTION ENABLEMENT LICENSE (includes NaviExpress)       |

### **CLARiiON ARRAY SUPPORT:**

#### **AX4-5F8 Array for Wormwood NX4:**

- To use only the 4-port Fibre Channel FE BOA I/O card on array model sold for NAS NX4 platform, with Ports 0 & 1 Fibre dedicated for shared Hosts, and Ports 2 & 3 AUX for NAS Hosts
- The “8” in AX4-5F8 represents the total of (8) FC FE ports on the array
- SP’s will not support iSCSI
- Although AX4-5 arrays allow single SP configurations, only dual SP configurations will be sold with NX4 integrateds
- Single or Dual SPS configurations provided
- Array will use only SAS or SATA drives, between 4-60 drives, with 12-drive DAE’s offered as expansion units after DPE
- Minimum configuration 4 drives [Disks 0-3 contain Vault Drives Raid5 3+1, HS optional]
- Only 4 drives used for Vault
- Array offers only SecureCLI

**Note:** Control Station will use the Flare 28 version of Naviseccli

- Array supports RAID 1/0, Raid 3, Raid 5, and Raid 6, though NAS will not support RAID 3 on this platform
- SAS & SATA drives supported within same Enclosure, but not same Raid Group
- Array will not use Navigent, so array events will be delivered via a Storage API to the Control Station Management Daemon

### **AX4-5F FLARE SOFTWARE SUPPORT:**

- Celerra NX4 GA’ed with Flare 02.23.050.5.703 [Dec 2009 introduces patch .707 for additional support]
- Flare 23 (Zeta) to support BOA FC I/O cards, full Navisphere license, upgrade to dual SPs, layered applications, some NST tool support, and Windows Server 2008 support
- Vega Flare 23 supports NaviExpress, 4-port FC I/O BOA module on SPs for NAS-only, and RAID 6 support with NaviExpress, support for AX350 array
- Flare 23 does not support Fast Bind, so LUN bind operations will take a long time
- Uses Flare 28 version of NST, NaviExpress, Navisphere & NaviCLI

### **Typical FC Port Cabling between Blade & SPs:**

- Blade 2 port BE0 → port 2 AUX on SPA
- Blade 2 port BE1 → port 2 AUX on SPB
- Blade 3 port BE0 → port 3 AUX on SPA

Blade 3 port BE1 → port 3 AUX on SPB

**DISK DRIVE SUPPORT:**

146GB 15k SAS

300GB 15k SAS

400GB 10k SAS

1TB SATA

**DAE Modules:**

(4) expansion DAEs of 12 SATA and/or SAS drives each [4@2U]

**EXPANSION TIER ENABLER RULES:**

- a) First added DAE will require an Expansion Tier enabler, which would be installed using NST
- b) Expansion DAE enabler is also required on any system with more than 12 drives
- c) Required for any system with 10 or more Hosts
- d) Required for any system using Layered Applications

**Drive Types:**

--total of 5 shelves 60 drives, with an all-SATA configuration that includes SATA vault drives; a mixed SAS + SATA drives, just not in same Raid Group; and an all-SAS configuration

--400GB 10K SAS; 146GB 15K SAS; 750GB or 1TB 7200 RPM SATA drives [mixed SAS/SATA but not in same RG]

--Supports SAS and/or SATA drives within the same Enclosure, just not within the same RAID Groups

--Supports SATA vault drives

--For Hot Sparing, could use either Drive type as a Hot Spare for both types, provided the capacity was large enough, though Eng. recommendation is to use the largest ATA drive as the Hot Spare, since the ATA drives will generally be equal to or larger than SAS

--(1) Hot Spare for every 24 drives is the rule, as minimum

**RAID Types:**

--Celerra will support RAIDs 1/0, 5, &amp; 6 on the AX4-5 array, not Raid 3

--SAS/SATA drives can be in RAID 1/0, R5, or R6 configurations

--RG0 Control LUNs can be 3+1 R5 or 4+1 R5. We will allow the 3+1 R5 only for systems that are ordered with the minimum 4-disk (no HS) or 5-disk (has HS) configurations

**SUPPORTED RAID CONFIGURATIONS:**

| RAID Type | Drive | Default LUNs | AVM Pool        |
|-----------|-------|--------------|-----------------|
| 3+1 R5    | SATA  | 2 luns       | clarata_archive |
| 4+1 R5    | SATA  | " "          | " "             |
| 5+1 R5    | " "   | " "          | " "             |
| R1/0      | " "   | " "          | clarata_r10     |
| 4+2 R6    | " "   | " "          | clarata_r6      |
| 3+1 R5    | SAS   | " "          | clarsas_archive |
| 4+1 R5    | " "   | " "          | " "             |
| 5+1 R5    | " "   | " "          | " "             |
| R1/0      | " "   | " "          | clarsas_r10     |
| 4+2 R6    | " "   | " "          | clarsas_r6      |

**Templates:**

First tray OS R5: 3+1 R5; 6+1R5; Hot Spare

Additional Trays: 4+1R5 + 6+1R5

**Note:** Many other templates being finalized**BEST FIT LUN SIZE ALGORITHM:**

NX4 introduces a new algorithm which will attempt to generate LUNs that are the same size as already existing LUNs, and also of the same Raid Type and Disk technology, regardless of the number of disks in the RG or size of the spindles. After creation of all matching sized luns, the last LUN bound would consume the leftover space in the LUN to create a single odd size LUN. One of the reasons for the “Best Fit” algorithm is to spread same size LUNs over different RAID groups in order to maximize the underlying spindle count, hence increase performance.

**Example:**

If you had 4+1R5 raid group and 5+1R5 raid group, normal AVM process would be to create two luns of the same size within each of the RGs. Best Fit would instead create two luns of the same size as existing luns across both Raid Groups. Odd remaining space is allocated to a miscellaneous sized lun. If luns of the same size cannot be created, will revert to the traditional way and create two luns of same size in each RG.

**NEW DISK TYPES:**

CLSAS

CMSAS

**New AVM Storage Pools for NX4:**

clarata\_r10 → Clariion raid 1/0 on SATA

cmata\_r10 → Mirrored Clariion Raid 1/0 on SATA

clarsas\_r10 →Clariion raid 1/0 on SAS  
cmsas\_r10 →Mirrored Clariion Raid 1/0 on SAS  
clarsas\_archive →Clariion Raid 5 on SAS  
cmsas\_archive →Mirrored Clariion raid 5 on SAS  
clarsas\_r6 →Clariion raid 6 on SAS  
cmsas\_r6 →Mirrored Clariion raid 6 on SAS

#### **NX4 BACKEND CLEANUP PROCEDURE:** emc191982

1. Log into the Control Station as nasadmin, then su to root
2. Breakdown the Proxy ARP configuration to an "unconfigured" state (if applicable):

**# /nasmcd/sbin/clariion\_mgmt -stop**

Checking if running as root...yes

Checking if model is supported...yes

Checking for integrated system...yes

Checking if interface eth3 is configured...yes

Checking if SP (192.1.4.231) is up...yes

Checking if SP (192.1.4.232) is up...yes

Step 1/12: Changing SPA IP address.

Changing SPA IP from 192.1.4.231 to 128.221.252.200 (subnetmask 255.255.255.0, gateway 128.221.252.104)-----output abridged-----

**Note:** If the command fails, run again with the following additional syntax

**# /nasmcd/sbin/clariion\_mgmt -stop -skip\_rules**

**# /nasmcd/sbin/clariion\_mgmt -info**

Error 12: Not configured

3. Unset the NAS\_DB environmental variable, and stop NAS Services:

**# unset NAS\_DB**

**# /sbin/service nas stop**

4. Destroy the Celerra array configuration [deletes RaidGroups, LUNs, StorageGroup (Removes HBA Initiator records), array security, disables AccessLogix]

**Note:** For FC Enabled systems where additional storage has been configured for Other Hosts, the nas\_raid cleanup script will not touch other Storage Groups, will leave Array Security & AccessLogix intact and enabled

**# cd /**

**# /tftpboot/setup\_backend/nas\_raid -s cleanup**

Log will be created in the current directory

System 128.221.252.200 is up

System 128.221.253.201 is up

Detecting Data Movers...2 3 Done.

Clariion Array: SL7E1080700121 Model: AX4-5F8 Memory: 1023

!!! WARNING !!!

The CLARiiON array connected to this Celerra control station

contains an existing configuration. "Celerra\_nx4"

This could include user data.

If you continue by selecting 'y' to cleanup the system at the

next prompt all existing CLARiiON configuration for Celerra\_nx4 will be destroyed and the system will have to be reinstalled.

Proceed with caution!

!!! WARNING !!!

Do you want to clean up the system [yes or no]?: yes

Cleaning Storage Group "Celerra\_nx4"

Removing LUN .....

Removing diskgroup ...

Removing initiators ....

Removing storage group "Celerra\_nx4"

Removing spares

Security domain removed

Done

**Note:** If the tftpboot directory is not present, unzip and untar from the /nas/tools directory

**# tar xvfz /nas/tools/tftpboot.tar.gz**

5. Remove the S95cable\_check file (if applicable)

**# rm -f /etc/rc3.d/S95cable\_check**

6. Insert 5.6 CD-ROM and reboot Control Station, then begin the NAS reinstall by entering "boot:serialinstall" at the prompt. Do not configure the External LAN network for the Control Station during the installation process (this will be done using the CSA wizard after the NAS reinstall completes).

7. Use CSA wizard after the reinstall to configure the Control Station, public IP addresses for the SPs, Proxy ARP, and ConnectHome/Email User features.

**MANUALLY CLEANING UP NX4 ARRAY USING NAVIEXPRESS:**

1. Configure a laptop or workstation with a valid IP address on the primary Celerra internal network (for example, IP address of 128.221.252.190 and netmask of 255.255.255.0).

**Note:** If the SPs are on a public network, configure the laptop for the same network, then connect to NaviExpress using a web browser and the IP address of SPA

2. Connect an Ethernet cable directly between the workstation and the SPA LAN port (there is only one LAN port on an AX4-5 SP).

3. Launch a web browser and enter the internal IP address for SPA (for example, 128.221.252.200).

4. Log into Navisphere Express with the appropriate username and password.

5. In the Manage>Virtual Disks>menu, select a Celerra LUN name.

a) Click checkbox to select the host connection name from which to unassign the Virtual Disk (LUN)

Connection Name

Celerra\_emcnas\_i0

b) Click apply

c) Repeat this step for all other Celerra Virtual Disks (LUNs)

6. In the Manage>Virtual Disks menu, highlight a Celerra LUN, then select Destroy Virtual Disk. Repeat this task until all Celerra LUNs (Virtual Disks) are destroyed. You can only destroy one LUN at a time.

7. From the Manage>Disk Pools> menu, select the Celerra Disk Pool (for example, Disk Pool 1), verify that the Virtual Disks listed are for Celerra, and then click on the Destroy button. Repeat this step if there are any other Disk Pools associated with the Celerra installation.

**Note:** Disk Pools are equivalent to RAID Groups, and are named differently from RAID Groups typically seen on other NAS systems. For example, there is no RG0, only "Disk Pool 1", "Disk Pool 2", and the like.

8. Remove the Data Mover Blade Initiator records from the array. From the Manage>Connections menu, select the respective "HBA Port type: Fibre Channel" Initiator records under the Server listed for Celerra, and click on the Deregister button.

9. Reset SP IP addresses to default Internal IPs for NAS Reinstall, if required, using /setup [128.221.252.200/128.221.253.201]

10. Proceed with the Factory reinstallation using a NAS 5.6 bootable CD-ROM. Specify serialinstall at the boot: prompt, and continue with the NAS installation. At the configure external LAN prompt, do not setup the external IP address or hostname for the Control Station (this will be done after the factory installation using the CSA wizard).

11. Reboot the Control Station at the end of the factory installation, then configure and register the system using the CSA Wizard.

**1U MAYNARD CONTROL STATION (Part #100-520-665):**

**Phase I:**

→GA'ed in conjunction with NX4 release, CMR3 5.6.39.5 August 22, 2008

→2 GHz Celeron Intel CPU with 800MHz FSB, 2GB memory, (1) RS232 serial port for modem access (COM1 Serial Port A), (1) USB-to-RS232 null modem RS232 serial port for Service Laptop connection (COM2 Serial Port B), Keybd, Mouse, VGA connectors, 4 ethernet ports [1 for LAN, 2 for Private Celerra networks, & 1 for IPMI Dual CS environments], 250GB SATA drive, CD/DVD-ROM, no floppy, (3) USB ports, requires minimum 5.6 NAS

**Note:** With NAS 5.6.49.3, manufacturing may start using a new 500GB SATA drive from Seagate, ST3500514NS 500GB SATA Disk Drive as an alternate HDD. TEAC DV-28S-WZ3 is also an approved/alternate DVD Reader.

→Most ports are located on the back of the unit [1-VGA, 1-keybd, 1-mouse, 4-LAN, 1-Modem Serial, 1-Serial console port, 2-USB], front has (1) USB port, Power, LEDs, DVD Drive

**Note:** All (3) USB ports will support file transfer to/from Control Station

→No reset button. You would use the power-off button to powerdown, then press again to restart the CS.

→120/240VAC, 300Watt Power Supply, 120v power cord

→Maynard supported by NAS 5.6 and above only

**# cat /proc/cpuinfo**

**# cat /proc/meminfo**

**Ports Left-to-Right on Back of CS:**

Modem serial port, eth2 Secondary network (lower left), eth1 IPMI network (upper middle), eth0 Primary network (recessed PCI card, left LAN port), eth3 Public network (recessed PCI card, right LAN port), Serial console ttyS0 (recessed PCI card, far right port)

**Phase II:**

→Support to be added for dual IPMI support [i.e., dual Control Stations, NSX, NS80]

→Support added for NS20 & NS40 platforms with CMR4 5.6.40.x

**Known Issues:**

→eth0 and eth3 ethernet ports are so far recessed into the CS assembly that a User cannot remove the cables by hand—would need a flat screwdriver to depress the rj45 latch (AR122140)

→Early prototype models had incorrect Console Port Redirection to modem serial port (Serial Port A). Correct redirection setting is for the console serial port (Serial Port B). See emc192466 for guidance on BIOS settings for Maynard.

**Note:** The Control Station part number is not visible in the properties section of the Celerra Manager>Inventory>Control Station 0>properties. Use the following Linux utility to identify Control Station part number and other information as read from BIOS.

**# /usr/sbin/dmidecode|grep Version** (or “Product Name”)

```
Specification Version: 2.0
Version: A02
Version: FRU Ver 0.04
Version: 100-520-665
Version: S3200X38.86B.00.00.0033.112120071101
Version: Intel(R) Celeron(R) CPU        440 @ 2.00GHz
```

**DELL NX4 BRANDED PRODUCT (Blackwood Project):**

→Product launch Feb 2009, with 5.6.43 CMR6

→Phase I will add the Dell Service Tag info and Dell Vendor Name to RESUME PROM, which will become part of the Registration payload, and will also be present in ConnectHome payloads. In Phase I, EMC will forward ConnectHomes to Dell, and every 2 weeks will forward Registration payloads to Dell. Dell to provide service and support. Dell to stock FRUs.

→Phase II will send ConnectHomes directly to Dell using an OEM Email Address field in the RESUME Prom to key off of when ConnectHome events are being processed. We will send Registrations directly to Dell also, and will enforce this by the Dell OEM information in the Resume, which will restrict the registration option to FTP & Email only.

**/nas/sbin/get\_service\_info** →Wrapper for the t2vpd command

**/nas/sbin/t2vpd -oem**

```
SERVICE PROVIDER="EMC"
SERVICE TAG=" "
SERVICE EMAIL="US_CONNECTHOME@DELL.COM"
Apex: US\_ConnectHome@dell.com
Cork: EMEA\_ConnectHome@dell.com
```

**CHECKING & SETTING SERVICE PROVIDER NAME AND SERVICE TAG ID (5.6.43):**

1. Checking name of Service Provider in Enclosure 0 RESUME PROM:

**# /nas/sbin/t2net\_test -GetResumeProm 2 44 100 32**

t2net\_test: Return values:

```
0000: 0x45 0x4d 0x43 0x00 0x00 0x00 0x00 0x00 0x00 0x00  E M C . . . . .
```

or

**# /nasmcd/sbin/get\_service\_info**

```
SERVICE PROVIDER="EMC"
SERVICE TAG=" "
```

2. Updating Enclosure 0 midplane RESUME PROM with Service Provider name "DELL":

**# /nas/sbin/t2net\_test -SetResumeProm 2 44 100 5 44 45 4c 4c 00**

Resume cksum for this device has been updated. New Cksum = 0x6bdf847d

**Note:** 2 44 100 are fixed values for the Service Provider field; 5 is the length of the Dell name + 1; 44 45 4c 4c are Hex characters for Service Provider name in uppercase, “DELL”; and 00 is null value at end of string.

**# /nas/sbin/t2net\_test -GetResumeProm 2 44 100 32**

t2net\_test: Return values:

```
0000: 0x44 0x45 0x4c 0x4c 0x00 0x00 0x00 0x00 0x00 0x00  D E L L . . . . .
```

**# /nasmcd/sbin/get\_service\_info**

```
SERVICE PROVIDER="DELL"
```

3. Updating RESUME PROM with original Service Tag ID:

a. Use the following command to translate Dell's Alpha-numeric Service Tag ID into Hexadecimal

**# echo <Service\_Tag> | od -t x1**

Example:

**# echo JQDK481 | od -t x1**

**0000000 4a 51 44 4b 34 38 31 0a**

0000010

**Note:** Values between 0000000 - 0a represent the Service Tag ID in Hex notation

b. Set Service Tag ID in the replacement Enclosure 0 midplane RESUME PROM:

**# /nas/sbin/t2net\_test -SetResumeProm 2 44 0b0 8 4a 51 44 4b 34 38 31 00**

Resume cksum for this device has been updated. New Cksum = 0x27d08c7c

**Note:** 2 44 0b0 are fixed values indication slot\_2, midplane, and Resume field, respectively; 8 indicates the number of characters in the Service Tag ID + 1=8; 4a 51 44 4b 34 38 31 represent the Service Tag ID; and 00 is Null at the end of the string.

c. Verify that Service Tag ID was set correctly:

**# /nas/sbin/t2net\_test -GetResumeProm 2 44 0b0 32**

t2net\_test: Return values:

0000: 0x4a 0x51 0x44 0x4b 0x34 0x38 0x31 0x00 0x00 0x00 J Q D K 4 8 1 . . .

**# /nas/sbin/get\_service\_info**

SERVICE PROVIDER="DELL"

SERVICE TAG="JQDK481"

#### **NEW SWITCH TO ALLOW DELL TO MODIFY CONNECTHOME INFO (5.6.43):**

**# /nas/sbin/nas\_connecthome -modify -service\_info**

Service Information automatically detected

Ok

APEX SYSTEMS →email\_to US\_ConnectHome@dell.com

EMEA SYSTEMS →email\_to [EMEA\\_ConnectHome@dell.com](mailto:EMEA_ConnectHome@dell.com)

**# /nas/sbin/nas\_connecthome -modify -service\_info -dial\_in\_enabled no**

**# /nas/sbin/nas\_connecthome -modify -service\_info -encryption\_enabled no**

**# /nas/sbin/nas\_connecthome -modify -service\_info -email\_to US\_ConnectHome@dell.com -email\_from ConnectHome@dell.com**

#### **DEFAULT EMAIL SETTINGS:**

**/nas/sbin/nas\_connecthome -info**

Email :

Priority = Disabled

Recipient Address(es) = US\_ConnectHome@dell.com

Subject = CallHome Alert

## ***CLARIION AX4-5 ARRAY (Mamba):*** GA January 2008

**Footprint:** 2U DPE; 2U DAE; 1U SPS

--Premium & Enhanced support, all AX4-5 arrays ship with Navisphere Express as the default, Flare 23 02.23.050.5.004 (Hercules)\*

\*Later Flare 23 releases are called Zeta [02.23.050.5.504], which offers full Navisphere support, and Vega .710

**Note:** Target Flare version for NAS products is Vega .703

--Low-end market single protocol [1GB iSCSI or 4GB FC models; Use CX3-10 when both protocols required]

--Support for Windows, Linux, NetWare, VMware, HP-UX, Sun, AIX hosts

--Scales from 4-60 drives, and supports 64 Hosts in an HA configuration, 1GB memory, single 1.66GHz processors on SPs [Single or Dual Controllers (SPs)] with 1GB memory, (4) Host FC ports per array, 45TB total storage, single SPS with dual optional, replacement for the AX150 & CX300 arrays

--Only SAS and/or SATA drives used for AX4-5 arrays

--AX4-5 supports RAID 3, 5, 1/0, & 6

--AX4-5 arrays only support SecureCLI [Classic Navi will not be available]

--Disk enclosures outside the DPE of 12 drives requires an Expansion Pack installation

--System disks are 0-3, and must be either all SAS or all SATA

--3Gbps 15K RPM SAS (Serial Attached SCSI) or SATA II disk drives, (12) drives per 2U DAE (SATA & SAS cannot be in same RG, but can share enclosure)

**Note:** With single SP systems, no SPS used. With Dual SP systems, an SP is hot-swappable

--2-port 4Gb FC FE module or (2) 1Gb/s iSCSI ports per SP, and 10/100/1000 Mgmt Ethernet port

**Note:** A special 4-port FC FE Boa I/O module is used on AX4-5f8 models used for NAS only

--AX4-5f8 array ships with SP's that use the 4-port Boa FC I/O Module [based on Tomahawk]

--Single Boomslang SP configuration allowed since 1GB flash memory available for writing dumps [but not for NAS Wormwood—require both SPs for NAS configurations]

--No Upgrade path

--Max LUNs 512, 30 RGs, 256 Luns per initiator, (4) arrays; max 64 hosts can connect via iSCSI or FC

### **SP BOOTUP INFORMATION:**

EMC BIOS Release 05.12

CPU = Intel(R) Celeron(R) CPU @ 1.66GHz

1023M System RAM Passed

1024 KB L2 Cache

-----abridged-----

Model: Boomslang: SAN

DiagName: Extended POST

DiagRev: Rev. 05.30

Build Date: Fri May 02 07:47:20 2008

StartTime: 06/05/2008 00:02:50

SaSerialNo: SL7B1080800740

### **DAEs:**

Automatic enclosure IDs

LED flashing means DAE offline

### **Power Supplies:**

Two per DPE and DAE, 550Watts

Single fan fault increases speed on others

Two fan faults will lead to array shutdown after two minutes

### **Shutting Down SPs:**

Quick push on power button leads to normal shutdown

4 sec. hold on button leads to forced shutdown

Navisphere is the preferred way to shutdown>System>Services>Shutdown

### **CLI Shutdown for AX4-5F8:**

# /nas/sbin/navicli -h 10.241.168.173 shutdown

Do you want to shutdown and power off the subsystem now (y/n)?

y

### **LED Indicators on Booting SPs:**

1/4 Hz blink = BIOS check

1 Hz blink = POST

4 Hz blink = FLARE

1-3-3-1 = DIMM failure

### **Fibre Channel Port Rules:**

Ports 0 & 1 Fibre are for non-Celerra hosts only

Ports 2 & 3 AUX on AX4-5f8 will be for NAS hosts only

### **Two Models:**

iSCSI Model with two copper 1Gbps iSCSI Front End ports/SP

FC Model with two optical 4Gbps FC Front End ports/SP

--Support for Layered Apps, AccessLogix, and Navisphere mgmt

### **Supported RAID Protection Types:**

RAID 3—five to nine disks using disk striping, single-disk parity, best suited for concurrent large I/O using 1-4 threads, read & write cache, and sequential I/O [Raid 3 NOT supported with Celerra]

RAID 1/0—groups of 2, 4, 6, 8, 10, 12, 14, or 16 disks of hardware mirror images, each image including 2-8 disks, using disk striping RAID 5—3-16 disks, disk striping, distributed parity across the disks, superb Read and good Write performance

RAID 6 (with Vega Flare)—4, 6, 8, 10, 12, 14, or 16 disk width pools allowed; RAID 6 uses two independent array positions for storing parity [Horizontal Redundancy & Diagonal Redundancy], meant to allow two adjacent data block, disk drive failures, or both

### **Supported Drive Types (GA+):**

750GB SATA II 7200rpm

400GB SAS 10K rpm

300GB SAS 15K rpm

146GB SAS 15K rpm

**Note:** SAS support requires a dual SP configuration. Drives can be mixed in same enclosure but not within the same RG. Vault drives can be all SAS or all SATA II. Hot Spare can be either SAS or SATA II.

### **Disk Shelf Rules:**

→Highest capacity drives to the left

- Then, highest speed drives to the left
- Don't mix drive types in same Raid Group

**Navisphere Express:**

All AX4-5 platforms initially ship with Navisphere Express, not Navisphere

NaviJr.Provider provides User interface via HTML Web Pages, Web Page classes that plug into the NaviJr Provider for NaviExpress GUI & monitors array health

NaviExpress will be restricted to not pass Host Blob information on the NAS FC Ports [Celerra uses its own method to propagate this information]

NaviExpress can be upgraded to full Navi with Flare 23 Zeta release

**New Terminology or behavior seen in NaviExpress GUI:**

Disk Pools equate to Raid Groups

Virtual Disks equate to LUNs

Storage Groups are not visible with NaviExpress

Supports only Naviseccli

**Determining Management Tool for NX4:**

# /nas/sbin/navicli -h 192.1.4.220 managedby

Managed By: NaviManager

# /nas/sbin/navicli -h 192.1.4.220 managedby

Managed By: NaviExpress

**March 2008 Zeta Flare Release:**

300GB SAS 15K rpm

1TB SATA II 7200 rpm

Full Navisphere support

**PERFORMING NDU FLARE UPGRADES ON AX4-5 SYSTEM:**

→There are several options for performing Flare upgrades, but note that presently, there is no way to revert back to a prior version of Flare on this platform, even if the NDU did not commit the new flare version

→Navisphere Express allows Flare NDU, and automatically commits the upgraded Flare version [Navisphere Express>System>Software>Upgrade Software]

→Secure CLI allows Flare NDU, and automatically commits the upgraded Flare version

→NST tool allows Flare NDU, with option to commit during the upgrade

**SECURE CLI NDU EXAMPLE:**

C:\Program Files\EMC\Navisphere CLI>NaviSECCLI.exe -h 128.221.252.200 ndu -install AX4-5-Bundle-02.23.050.3.728.pbu

=====

RULE NAME: Special Conditions

RULE REVISION: 6.23.3.1.2.1

RULE STATUS: Rule has warning.

RULE DESCRIPTION: This rule is a warning to check for special conditions before installing software on the storage system.

RULE RESULT: Please check for the following conditions:

1. All attached servers are running failover software.
2. All attached VMWare ESX servers running pre v2.1.0 software have I/O stopped.
3. All attached AIX servers must meet the requirements described in EMC Knowledgebase Solution ID emc67186.

**RULE INSTRUCTION:**

Item number: 0

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 02.23.050.3.728

Already Installed Revision 02.23.050.5.504

Installable YES

Disruptive upgrade: NO

Pre installation rules have been run to ensure the success of this software upgrade. One or more rules has a warning. The installation can continue with warnings.

The requested package(s) will be installed. Do you wish to proceed? : (y/n)?

y

**SHUTTING DOWN SPs FROM COMMAND LINE:**

**C:\Program Files\EMC\Navisphere CLI>NaviSECCLI.exe -h 128.221.252.200 shutdownpeersp**

This operation will shutdown and power off the SP.

Do you want to shutdown and power off the SP now? (y/n)?

y

**C:\Program Files\EMC\Navisphere CLI>NaviSECCLI.exe -h 128.221.252.200 shutdownsp**

This operation will shutdown and power off the SP.

**CONNECTING TO SP's VIA SERIAL MAINTENANCE PORT:**

1. Connect from Laptop to upper mini-db 9 serial port on SP (Maintenance port), using DB9 Female to mini-DB9 male cable [Part #038-003-084]
2. Configure HyperTerminal session using following settings:  
9600 bps; 8 data bits; None for parity; 1 Stop bits; None for Flow Control; Emulation: ANSIW
3. Use serial connection to observe bootup and to gain access to POST diagnostic menu:

Model: Boomslang: SAN

DiagName: Extended POST

*ABCab << Stopping after POST >> DEabcdegFGHabcdIJK*

- a) Press the “ctrl + c” keys here (or Esc key if that fails), which allows POST to complete, and then prints a Storage System Failure message:

\*\*\*\*\*  
\*\*\*\*\*

\* Extended POST Messages

\*\*\*\*\*  
\*\*\*\*\*

.... Storage System Failure - Contact your Service Representative ...

- b) Access POST by typing following password onscreen:

**SHIP\_it**

- c) POST Diagnostics:

Diagnostic Menu

POST 05.30

- 1) Reset Controller 11) System Test Sub-Menu
- 2) Enter Debugger 12) Image Sub-Menu
- 3) Display Warnings/Errors 13) Disk Sub-Menu
- 4) Boot OS 14) Resume PROM Sub-Menu
- 5) POST Sub-Menu 15) Power Sub-Menu
- 6) Display/Change Privilege 16) DMI Log Sub-Menu
- 7) Memory Sub-Menu 17) Information Display
- 8) Motherboard Sub-Menu 18) ICA Sub-Menu
- 9) I/O Module Sub-Menu 19) DDBS Service Sub-Menu
- 10) Enclosure Sub-Menu 20) Manufacturing Mode Sub-Menu

**SLEET NS-120/NS-480; NS-120FC/NS-480FC; NS-120iS/NS-480iS:**

→Mid-tier Integrated products, GA date December 10, 2008, NAS 5.6.41.2

- Dell will brand the NS-120 as a Dell OEM product with the 5.6.48 code release
  - Sleet 2 is the internal name for the NS-120 models, while Sleet 4 is the name for the NS-480 models
  - Blades are based on the CX3 NS40 hardware
  - Arrays are based on CX4 hardware using CX4-120 Nautilus (NS-120) and CX4-480 Trident (NS-480) backends
  - Increased system capacity and backend performance from CX4 arrays
  - Secure NaviCLI only, Flare 28
  - NST Version 28 with CRU support for Flare NDU and SLIC wizard CRU support
  - Use of Email User notification feature
  - Support for Customer provisioning and implementation, using built-in CPW in the CSA client (CPW has been delayed Q1 2009)
  - PowerPath license is included in NS-120FC model but not the NS-480FC
  - MirrorView must be part of the initial order and cannot be added after a system ships
  - EMC-racked or Customer-racked Factory installed configurations
  - Both Nautilus & Ironclad support FC & SATA drives in the same cabinet, but not within the same DAE
  - Both array types will support FC, iSCSI, and SATA technologies with the Akula Management Module
- Note:** No mixing of drive types within the same DAE. CX4-120 can use SATA in vault. Minimum configuration 5 drives + HS.
- NAS models will only support RAID 1/0, 5, & 6 [No RAID 1 or 3]
  - 4-Blade NS-484 option will be introduced in Q1 2009 [2 or 4 Blade NS-480's]
  - With the NS-480 more than 8 FC IO ports can be used, so the WWN port numbering scheme will be extended by two bits to support up to 32 FC ports
- FCP scsi-0: HBA 0: ALPA 0000ef **SP-a00:** 500601603b6002ab Class 3

## **MINIMUM SOFTWARE SUPPORT FOR SLEET:**

NAS 5.6.41.2  
FLARE 28, 04.28.000.5.009  
NST, Navisphere, and CLI based on Flare 28  
CSA 5.6.41.2

## **NAS SYSTEM MODELS:**

NS-120, NS-480 →plain Integrated model for basic NAS IP hosts  
NS-120FC, NS-480FC →Fibre Channel Enabled version supports NAS IP hosts or external FC Hosts, or MPFS over FC support  
NS-120iS, NS-480iS →iSCSI model for NAS IP hosts and external Hosts using MPFS over iSCSI

**Note:** Use the terminology “system model” to refer to the Hardware model name as indicated in Celerra Manager or from the CLI:

# /nas/sbin/model

NS-480iS

## **ARRAY MODELS:**

NS120-AUX →Factory racked NS-120, no FC or iSCSI ports for external Hosts, (1) 4-port FC card per SP  
NS120-AUXF\* →Factory racked NS-120FC, no iSCSI, (2) 4-port FC cards per SP  
NS120-AUXI →Factory racked NS-120iS, no FC, (1) 4-port FC card & (2) 2-port iSCSI per SP

**Note:** TLA for all three AUX variants is 100-520-673

NS-480-AUX →Factory racked NS-480, no FC or iSCSI ports for external Hosts, (2) 4-port FC cards per SP  
NS-480-AUXF\* →Factory racked NS-480FC, no iSCSI, configured with (3) 4-port FC cards per SP  
NS-480-AUXI →Factory racked NS-480iS, (2) 4-port FC cards & (3) 2-port iSCSI cards per SP

**Note:** TLA for all three AUX variants is 100-520-674

\*4 FC ports available for External Hosts

## **BLADE MODELS:**

→NS-120 ships with a 4-port copper Ethernet or 2-port 10GbE Optical + 2-port GbE copper Ethernet configuration  
NS121-A/FD 1-blade, 4-port Cu GbE, DME TLA part # 100-520-667  
NS121-C/FD 1-blade, 2-port 10GbE Optical/2-port 1GbE Cu Ethernet card (5.6.45)  
NS122-A/FD 2-blade, 4-port Cu GbE, DME TLA part # 100-520-668  
NS122-C/FD 2-blade, 2-port 10GbE Optical/2-port 1GbE Cu Ethernet card (5.6.45)  
NS120-AUX/CR, AUXF/CR, AUXI/CR, TLA part # 100-520-673 for all variants

**Note:** Blade FD or Array CR suffix indicates field racked system

→ NS-480 ships with either a 4-port copper or 2-port copper/2-port optical configuration  
NS482-A/FD 2-blade, 4-port Cu GbE, DME TLA part # 100-520-670  
NS482-B/FD 2-blade, 2-port Opt/2-port Cu GbE, DME TLA part #100-520-672  
NS482-C/FD 2-blade, 2-port 10GbE Optical/2-port 1GbE Cu Ethernet card (5.6.45)  
NS484-A/FD 4-blade, 4-port Cu GbE, DME TLA part # 100-520-688  
NS484-B/FD 4-blade, 2-port Opt/2-port Cu GbE, DME TLA part #100-520-689  
NS484-C/FD 4-blade, 2-port 10GbE Optical/2-port 1GbE Cu Ethernet card (5.6.45)  
NS480-AUX/CR, AUXF/CR, AUXI/CR, TLA part # 100-520-674 for all variants

**Note:** Blade FD or Array CR suffix indicates field racked system

**Product Configurations:**

The NS-120 & NS-480 will support three different configurations, which are really tied to what SLIC IO modules are resident on the SPs. The basic NAS model (NS-120/NS-480) is a traditional Integrated use for IP hosts. The NS-120FC/NS-140FC model supports IP hosts, and can support external Hosts with up to (4) Fibre Channel front-end ports that can be used for SAN-attached FC, direct-attached FC, and MPFS over FC. The NS-120iS/NS-480iS model supports IP hosts, and can support external Hosts for MPFS over iSCSI (4-ports for NS-120iS and 6-ports for NS-480-iS).

**SUPPORTED UPGRADES GA:**

DAE expansion

Adding 2<sup>nd</sup> SPS

Adding 2<sup>nd</sup> Data Mover

**POST-GA UPGRADES Q1 2009:**

FC Enable Upgrade for NS-120 & NS-480

Upgrading to a four blade Celerra NS-480 System

iSCSI Enable Upgrade (NS-120 to NS-120iS and NS-480 to NS-480iS)

Adding Blade Enclosure

Convert NS20, 120, or 40 to NS-480

Adding iSCSI modules to NS-120FC & NS-480FC for MirrorView/iSCSI support

**PRIVATE NETWORK CABLING:**

**Single Blade NS-120 (NS121-A):**

→eth0 on CS to Bottom internal LAN port on Blade 2 (mge0)

→Top internal LAN port on Blade 2 (mge1) to Top Management LAN port on SPA

→eth2 on CS to Top Management LAN port on SPB

**Dual Blade NS-120 (NS122-A) or NS-480 (NS482-A dual blade Cu Ethernet/NS482-B dual blade Cu/Optical Ethernet):**

→eth0 on CS to Bottom internal LAN port on Blade 2 (mge0)

→Top internal LAN port on Blade 2 (mge1) to Top Management LAN port on SPA

→eth2 on CS to Bottom internal LAN port on Blade 3

→Top internal LAN port on Blade 3 to Top Management LAN port on SPB

**4-Blade NS-484:** (Available with 5.6.43.8)

→eth0 on CS to Bottom internal LAN port on Blade 2 (mge0)

→Top internal LAN port on Blade 2 (mge1) to Bottom internal LAN port on Blade 4

→Top internal LAN port on Blade 4 to Top Management LAN port on SPA

→eth2 on CS to Bottom internal LAN port on Blade 3

→Top internal LAN port on Blade 3 to Bottom internal LAN port on Blade 5

→Top internal LAN port on Blade 5 to Top Management LAN port on SPB

→Initial shipments of NS-484 will share same TLA between Enclosure 0 & 1. The TLA's will be revised and become unique between enclosures beginning in April 2009

**Enclosure 0:**

100-520-670 4Cu GbE ports on blades

100-520-672 2Optical/2Cu GbE ports on blades

**Enclosure 1:**

100-520-688 4Cu GbE ports on blades

100-520-689 2Opt/2Cu ports on blades

**STORAGE MANAGEMENT:**

→Integrated and iSCSI systems will be managed completely by Celerra Manager

→FC systems will be managed by Navisphere

**DISK DRIVE SUPPORT ON CX4-120/480:**

FC (36, 73, 146, 300, 400 & 450GB)

SATA (250, 320, 500, 750GB & 1TB)

Low cost 500GB drives

**NST SUPPORT:**

→Both NS-120 & NS-480 will support all NST wizards except Register System and Post Activity SYR

**NS-120 “Sleet2” (CMR4+):**

→NS-120 integrated, NS-120FC, and NS-120iS MPFS iSCSI models (no gateway)

→Replacement for NS20 built on CX4-120 Fleet array

→“Unified Storage” marketing term for combined NAS, iSCSI, MPFS, FC solution

→Single CS only, 1-2 Data Mover Blades

→Maynard CS (100-520-665)

→NS40 Sledgehammer Data Movers, dual 2.8GHz processors, 4GB memory, 800MHz FSB, with (2) FE fibre channel ports, (1) FC port for tape connectivity, (1) management port, 4-port copper GbE Ethernet card, or 2-port 10GbE optical + 2-port copper GbE Ethernet card

→Field installed systems will be pre-configured with 8U ganged rails, which will be reused and mounted in the Customer rack

→Supports SATA & FC Drives, including SATA Vault drives

→2U Nautilus array with dual SPs 1.2GHz CPU & 3GB Memory, single SPS with optional 2<sup>nd</sup> SPS, (8) FC Ports per SP, 1-8 DAEs of 15 drives each, single BE loop for a total of 120 Fibre Channel or SATA drives

**Note:** With NAS 5.6.45, we now tolerate the array using 8Gbps FC IO Modules (Glacier)

→Nautilus 6U SPE contains SPs, DAE, and SPS

→For FC-Enabled model, up to 4 direct-attached Linux or Windows Hosts other than Celerra [FC or MPFS], or up to 120 SAN-attached Hosts [FC or MPFS]

→6-120 FC or SATA Drives [1-8 DAE's of 15 disks each]

→Max of 32TB IP storage/blade (64TB/system), or 96TB/blade for MPFS configurations

→Nautilus supports only a single BE Loop, and can have SATA drives for the Vault DAE

→Standard Integrated will ship with only a single Tomahawk FC IO module, while FC model ships with two Tomahawk FC IO modules

→No TimeFinder or SRDF support

#### **Program Purpose:**

→Introduce low-end Celerra product on CX4 Fleet array—"Technology Refresh"

→Increase storage capacity to 120 drives

→Increase performance

→Reduce service costs with enhanced user installation, implementation, and maintenance

→Use of CSA to install, factory pre-configured, EMC or Customer-racked configurations

#### **NS-120 HARDWARE CAPACITY/FOOTPRINT:**

→6-120 FC or SATA drives, maximum of 8 DAE's (cannot mix drives within same enclosure)

→32TB capacity per Blade FC or SATA, or 96TB/blade for MPFS configurations

→8U minimum footprint, max 30U footprint

→NS40 Blades built on CX4-120 Nautilus array

→Ships with single SPS (2<sup>nd</sup> SPS optional)

→NS-120 supports all 120 drives with MPFS configurations

### **THREE NS-120 MODEL OFFERINGS (NS-120; NS-120FC; NS-120iS):**

#### **NS-120 INTEGRATED CONFIGURATION (NS-120):**

→NAS IP Hosts-only configuration (CIFS, NFS, iSCSI)

→Single Maynard CS, 1-2 Data Movers, Fleet CX4-120 Nautilus

→SPs dual core CPU, 3GB memory, (1) Tomahawk 4-port FC IO modules for each SP

→Single or dual SPS

→1-8 DAEs, 6-120 FC or SATA drives (no mixing of drive types within a DAE)

→Navisphere not licensed for the backend, but NST can be used

→Maximum of 120 drives supported

→Ships with only a single 4-port FC Tomahawk IO card, no FC Enable model Upgrade at GA

#### **SP IO MODULE PORTS:**

##### **SLOT 0: Tomahawk 4-port FC IO module (A0=SPA; B0=SPB)**

Port 0 BE0→to DAE single loop

Port 1→not used

Port 2 FE0→to BE1 on DM2 SPB; to BE0 on DM2 SPA

Port 3 FE1→to BE1 on DM3 SPB; to BE0 on DM3 SPA

#### **NS-120FC CONFIGURATION:**

→NS120-FCOPT-L EMC CELERRA FIBRE CHANNEL PORT ENABLER CERTIFICATE

→Supports use of 120 drives for FC Hosts and Navisphere license

→NAS IP Hosts, external FC Hosts, or external hosts using MPFS over FC

→Two Tomahawk 4-port FC IO modules for each SP (all 4 ports 2<sup>nd</sup> Tomahawk available for MPFS or Other FC host)

→4 direct-attached FC MPFS Hosts or other FC Hosts

→128 SAN-attached FC MPFS Hosts or other FC Hosts

→Factory installed NS-120FC can support Mirrorview over FC, but FC Enabled Upgrades in the Field will not support the Mirrorview over FC option

→Navisphere licensed for this model, and required for configuring backend storage

#### **SP IO MODULE PORTS:**

##### **SLOT 0: 1<sup>st</sup> Tomahawk 4-port FC IO module (A0=SPA;B0=SPB)**

Port 0 BE0→to DAE single loop

Port 1→not used

Port 2 FE0→to BE1 on DM2 SPB; to BE0 on DM2 SPA

Port 3 FE1→to BE1 on DM3 SPB; to BE0 on DM3 SPA

#### **SLOT 2: 2<sup>nd</sup> Tomahawk 4-port FC IO module (A2=SPA; B2=SPB)**

All FC ports for Other Hosts on SPA/SPB (Port 3 would be used by Mirrorview)

#### **NS-120iS iSCSI MPFS CONFIGURATION:**

→NAS & MPFS over iSCSI configurations

→(1) 4-port FC Tomahawk I/O module on each SP (1-BE and 2-FE FC ports per SP)

→(2) 2-port Harpoon iSCSI I/O modules per SP for iSCSI MPFS hosts (all 4-ports for iSCSI MPFS Hosts)

**Note:** SP configuration based on the standard CLARiiON CX4-120 configuration

→Up to 4 direct-attached iSCSI MPFS Linux or Windows Hosts

→Up to 128 iSCSI-attached iSCSI MPFS Hosts

→During CSA configuration, a wizard walks through the setup of IP addresses for all iSCSI ports on the Array, offers to setup CHAP, and starts the MPFS service on Server\_2. Use the following command to view IP address assignments on the iSCSI ports:

**# /nas/sbin/naviseclli -h 10.241.168.182 connection -getport -sp a**

#### **SP IO MODULE PORTS:**

#### **SLOT 0: 4-port Tomahawk FC IO module (A0=SPA; B0=SPB)**

Port 0 BE0→to DAE single loop

Port 1 BE1→not used

Port 2 FE0→to BE1 on DM2 SPB; to BE0 on DM2 SPA

Port 3 FE1→to BE1 on DM3 SPB; to BE0 on DM3 SPA

#### **SLOT 1: 1<sup>st</sup> 2-port Harpoon iSCSI IO module (A1=SPA;B1=SPB)**

iSCSI 0 MPFS host

iSCSI 1 MPFS host

#### **SLOT 2: 2<sup>nd</sup> 2-port Harpoon iSCSI IO module (A2=SPA; B2=SPB)**

iSCSI 2 MPFS host

iSCSI 3 MPFS host

#### **NS-480 “Sleet4” (CMR4+):**

→Replacement for NS40 as a mid-range product, built on CX4-480 Trident Fleet array (2.2GHz 4GB memory)

→”Unified Storage” marketing term for combined NAS, iSCSI, MPFS, FC solution

→Maynard CS (100-520-665), NS40 Sledgehammer Data Movers

→Single CS only, 2 Blade system for December GA, and support for 2 or 4 Blade system with CMR6 Q1 2009 [Single or Dual DME]

**Note:** 2<sup>nd</sup> Data Mover Blade enclosure space is reserved by the configuration for expansion purposes, though the actual Enclosure itself may or may not be shipped

→NS40 Sledgehammer Data Movers, dual 2.8GHz processors, 4GB memory, 800MHz FSB, with (2) FE fibre channel ports, (2) FC port for tape connectivity, (1) management port, 4-port copper GbE Ethernet card, 2-port 1GbE optical + 2-port copper GbE card, or 2-port 10GbE optical + 2-port copper GbE Ethernet card

→Field installed systems will be pre-configured with 9U ganged rails, which will be reused and mounted in the Customer rack

→NS-480 integrated, NS-480FC, and NS-480iS MPFS iSCSI models (no gateway)

→NS-480 & NS-480FC will have a 4-blade configuration at a later release (CMR6 Q1 2009)

→2U Trident array with dual SPs, dual SPS, dual-core single 2.2GHz CPU & 4GB memory, (8) FC I/O ports per SP, 1-32 DAEs of 15 drives each, for total of 480 FC or SATA drives [FC & SATA must be in separate DAEs]

→For FC-Enabled model, up to 2 direct-attached Linux/Windows Hosts [FC MPFS or FC], or 60 SAN-attached MPFS or FC Hosts

→6-480 FC, SATA, & Flash Drives (no mixing of drives in same DAE; 1-32 DAE's of 15 disks each)

→Max IP storage 64TB/blade (128TB/system), or 128TB/Blade for MPFS configurations

**Note:** Increases to 192TB/system with Q1 2009 support for 4-Blade system

→Trident CX4-480 supports four BE Loops, and does not allow SATA drives for Vault DAE

→Standard Integrated will ship with both Tomahawk FC IO Modules, and will use Ports 0 & 1 to loop 0 & 1, resp., (dual loop), Ports 2 & 3 for DM2, DM3, respectively (2<sup>nd</sup> 4-port FC IO card will be used for Ports 0 & 1 on DM4, DM5, respectively, and other ports used for non-Celerra Hosts)

→No TimeFinder or SRDF support

#### **Program Purpose:**

→Introduce mid-range Celerra product on CX4 Fleet array—“Technology Refresh”

→Increase storage capacity to 480 drives

→Increase performance

→Introduce a 4-Blade configuration in Q1 2009

→Reduce service costs with enhanced user installation, implementation, and maintenance

→Use of CSA to install, factory pre-configured, EMC or Customer-racked configurations

## **NS-480 HARDWARE CAPACITY/FOOTPRINT:**

- 6-480 FC or SATA drives, maximum of 32 DAE's (cannot mix drives within same enclosure, nor use SATA for vault)
- 64TB capacity per Blade FC or SATA. 128TB/blade capacity for MPFS configurations.
- Note:** Max usable capacity for system would be 473TB (1<sup>st</sup> shelf 15@450GB FC drives; 465@1TB SATA drives)
- 9U minimum footprint, max 102U footprint
- NS40 Blades built on CX4-480 Trident array
- Ships with both SPS's
- Supports all 480 drives for MPFS configurations

## **THREE NS-480 MODEL OFFERINGS (NS-480; NS-480FC; NS-480iS):**

- Three NS-480 System Models
- (2) or (4) blades offered with CMR6 release

## **NS-480 INTEGRATED CONFIGURATION (NS-480):**

- NAS IP Hosts-only configuration (CIFS, NFS, iSCSI)
- Single Maynard Control Station, 2 or 4 Blades (latter offered in Q1 2009)
- Fleet Trident CX4-480 with dual core CPU, 4GB memory, and (2) Tomahawk 4-port FC IO modules for each SP
- Dual SPS
- 1-32 DAEs, 6-480 FC or SATA drives (no mixing of drives in same DAE)
- Each backend Loop represents up to 120 drives, so 4-Loops=480 drives, using 4-FC ports per SP
- Each blade uses 1-FC port per SP, 4-Blades use 4-FC ports per SP
- Ships with two Tomahawk SLICs per SP

## **SP IO MODULES for NS-480:**

### **SLOT 0: 1st 4-port Tomahawk FC IO module (A0=SPA; B0=SPB)**

- Port 0 BE0→to DAE loop 0
  - Port 1 BE1→to DAE loop 1
  - Port 2 FE0→to BE1 on DM2 SPB; to BE0 on DM2 SPA
  - Port 3 FE1→to BE1 on DM3 SPB; to BE0 on DM3 SPA
- ### **SLOT 1: 2<sup>nd</sup> 4-port Tomahawk FC IO module (A1=SPA; B1=SPB)**
- Port 0 BE2→to DAE loop 2 SPB & SPA
  - Port 1 BE3→to DAE loop 3 SPB & SPA
  - Port 2 FE2→to BE1 on DM4 SPB; to BE0 on DM4 SPA
  - Port 3 FE3→to BE1 on DM5 SPB; to BE0 on DM5 SPA

## **NS-480FC CONFIGURATION:**

- NS480-FCOPT-L EMC CELERRA FIBRE CHANNEL PORT ENABLER CERTIFICATE
- Supports use of 480 drives, but only 240 for external FC Hosts or MPFS-over-FC
- Comes with one Navisphere license for 240 or less drives, and another license for more than 240 drives
- NAS IP, FC Hosts, or MPFS over FC configurations
- (3) Tomahawk 4-port FC IO modules (3<sup>rd</sup> Tomahawk ports for MPFS or Other FC Hosts)
- (4) direct-attached FC MPFS Hosts or non-Celerra FC Hosts
- Supporting 256 SAN-attached FC MPFS or non-Celerra FC Hosts
- Factory installed NS-480FC supports Mirrorview over FC, but FC Enabled field upgrades will not support Mirrorview over FC

## **SP IO MODULES for NS-480FC:**

### **SLOT 0: 1st 4-port Tomahawk FC IO module (A0=SPA; B0=SPB)**

- Port 0 BE0→to DAE loop 0
- Port 1 BE1→to DAE loop 1
- Port 2 FE0→to BE1 on DM2 SPB; to BE0 on DM2 SPA
- Port 3 FE1→to BE1 on DM3 SPB; to BE0 on DM3 SPA

### **SLOT 1: 2<sup>nd</sup> 4-port Tomahawk FC IO module (A1=SPA; B1=SPB)**

- Port 0 BE2→to DAE loop 2 SPB & SPA
- Port 1 BE3→to DAE loop 3 SPB & SPA
- Port 2 FE2→to BE1 on DM4 SPB; to BE0 on DM4 SPA
- Port 3 FE3→to BE1 on DM5 SPB; to BE0 on DM5 SPA

### **SLOT 2: 3<sup>rd</sup> 4-port Tomahawk FC IO module (A2=SPA; B2=SPB)**

- Ports 0-3 SPA & SPB for FC Hosts (port 3 for Mirrorview if used)

## **NS-480iS iSCSI MPFS CONFIGURATION:**

- NAS or MPFS over iSCSI configurations
- (2) Tomahawk 4-port FC I/O ports
- (3) Harpoon 2-port iSCSI IO modules (all 6 ports for iSCSI MPFS Hosts)

**Note:** SP configuration based on the standard CLARiiON CX4-480 configuration

→2 Blades only for MPFS (Why? We have the FC ports available?)

→Supports up to 6 direct-attached iSCSI MPFS Hosts or 256 iSCSI-attached MPFS Hosts

→During CSA configuration, a wizard walks through the setup of IP addresses for all iSCSI ports on the Array, offers to setup CHAP, and starts the MPFS service on Server\_2. Use the following command to view IP address assignments on the iSCSI ports:

**# /nas/sbin/naviseccli -h 10.241.168.182 connection -getport -sp a**

**SP IO MODULES for NS-480iS iSCSI:**

**SLOT 0: 1st 4-port Tomahawk FC IO module (A0=SPA; B0=SPB)**

Port 0 BE0→to DAE loop 0 on SPA & SPB

Port 1 BE1→to DAE loop 1 on SPA & SPB

Port 2 FE0→to BE1 SPB on DM2; to BE0 SPA on DM2

Port 3 FE1→to BE1 SPB on DM3; to BE0 SPA on DM3

**SLOT 1: 2<sup>nd</sup> 4-port Tomahawk FC IO module (A1=SPA; B1=SPB)**

Port 0 BE2→to DAE loop 2 on SPA & SPB

Port 1 BE3→to DAE loop 3 on SPA & SPB

Port 2 FE2→to BE1 SPB on DM4; to BE0 SPA on DM4

Port 3 FE3→to BE1 SPB on DM5; to BE0 SPA on DM5

**SLOT 2: 1<sup>st</sup> Harpoon 2-port iSCSI IO module (A2=SPA; B2=SPB)**

iSCSI 0 iSCSI MPFS host

iSCSI 1 iSCSI MPFS host

**SLOT 3: 2<sup>nd</sup> Harpoon 2-port iSCSI IO module (A3=SPA; B3=SPB)**

iSCSI 2 iSCSI MPFS host

iSCSI 3 iSCSI MPFS host

**SLOT 4: 3<sup>rd</sup> Harpoon 2-port iSCSI IO module (A4=SPA; B4=SPB)**

iSCSI 4 iSCSI MPFS host

iSCSI 5 iSCSI MPFS host

**NS-120 & NS-480:**

**RAID SUPPORT:**

RAID 1/0, 5, or 6

**PRODUCT SUPPORT OPTIONS:**

Enhanced or Premium Support

**CRUs, FRUs, UPGRADES:**

SP Power/Cooling Modules

SP Management Modules

SP SFP Modules

SP Memory Modules

SP CPU Modules

SP I/O Modules

SPE Enclosure

SPS

DAE Power/Cooling Modules

LCC Modules

Disks

DAE Enclosure (Not posted on Powerlink, use CLARiiON procedure Generator)

**Upgrades:**

Add Blade (NS-120 only)

Upgrade to Mojito Blade (NS-120, NS-480, NS-G2, NX4), Q1 2010

Add SPS (NS-120 only)

Add Disk

Add DAE

FLARE upgrades

DART upgrades (EMC-only)

NS-480 to NS-480FC or NS-480iS, or adding iSCSI slic to NS-480FC Upgrade, March 2009

NS-120 to NS-120FC or NS-120iS, or adding iSCSI slic to NS-120FC Upgrade, March 2009

NS20 to NS-480 Upgrade/Conversion, Dec 2009

NS20FC to NS-480FC Upgrade/Conversion, Dec 2009

NS20 to NS-480iS Upgrade/Conversion, Dec 2009

NS20 to NS-480FC Upgrade/Conversion, Dec 2009

NS20 to NS-480iFC with iSCSI Upgrade/Conversion, Dec 2009

NS-120 to NS-480, Q4 2009

Upgrade to MPFS SW & HW support

Installing SW Enablers on Storage System

**NS-120 FACTORY INSTALL ISSUES:**

→Factory install failed with following console screen messages, even after hardware and cable swapouts

**Console Message during NAS Install:**

**Detecting Data Movers...2 3 Done.**

**Checking Data Mover to Backend fibre connectivity ...**

**Data Mover 2 Port 0 not logged in backend**

**Failed**

**Setting up Storage Groups.... Failed.**

**DEBUGGING FAILED NAS INSTALLS:**

→Above error is rather generic, so additional steps needed to isolate problem

1. Restart the Installation and configure the LAN port during the Linux Install (will need to connect via LAN later)
2. Pause at the following screen after the Linux install and reboot, and after LAN configuration and Data Mover discovery:

Celerra Install/Upgrades +-----+

```
|           |
| Please choose the Celerra System   |
| Configuration.                   |
|                               |
| +-----+ +-----+ |
| | Fibre Channel Enabled | | Integrated | |
| +-----+ +-----+ |
```

3. Use SSH and connect as root to the system

4. vi edit the following S95nas files by adding an -vx to have the Install script output verbose messages to console:

```
# /usr/bin/updatedb
```

```
# locate S95nas
```

```
# vi /etc/rc.d/rc3.d/S95nas
```

```
# vi /mnt/source/EMC/nas/S95nas
```

```
#!/bin/bash -vx
```

5. Reboot the system and set capture logging on terminal session

```
# reboot
```

6. At point of failure, review S95nas install script and find the point where it spits out the failure message, then find debug output failure and try to establish a reason for the failure.

**Root Cause:**

In this situation, when it says the Data Mover BE0 cannot log into the backend, it was true. The following CLARiiON CLI shows that the Celerra ports are not initialized, hence the install problem.

**Solution:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
The solution was to reinstall the CLARiiON FLARE on the array, which then allowed the IO ports to be properly seen by the CLARiiON.

### **VIEWING SLIC PORT INFORMATION ON CX4 ARRAYS:**

→Following output is from a CX4-120 array with only a single 4-port Tomahawk FC IO SLIC module. Note that ports 2 & 3 are dedicated for Celerra and are “Uninitialized”, an abnormal condition which will prevent successful NS-120 Factory NAS Install.

**# /tftpboot/bin/naviseclli -h 128.221.252.200 iportconfig -list**

SP ID: A

I/O Module Slot: 0

I/O Module Type: Fibre Channel

## **VIEWING iSCSI PORT INFORMATION:**

**# /nas/sbin/navisecli -h 10.241.168.182 connection -getport -sp a**

SP: A

Port ID: 7

Port WWN: iqn.1992-04.com.emc:cx.apm00083202015.a7

iSCSI Alias: 2015.a7

IP Address: 10.241.168.185

Subnet Mask: 255.255.255.0

Gateway Address: 10.241.168.128

Initiator Authentication: false

-----output abridged-----

## **EQUIVALENT VIEW FROM NAVISPHERE:**

Rightclick Array name>Port Management

→Port information is listed, including IP addresses, Port number, type, speed, and WWN/IQN

## **ADDING ULTRAFLEX SLIC IO MODULES ON CX4:**

### **Adding IO Modules to SPs:**

→Must be added to same slot on each SP

→Only safe way to add IO Modules is to use NST wizard (does healthchecks and persists the ports)

→If added via navicli, must run ioportconfig –persist and allow SPs to reboot to persist the ports on the IO card (1/2 hour)

**Note:** SPB reboots first, twice, then SPA, twice, for a total of ½ hour

**Scenario:** Adding Harpoon iSCSI IO card to CX4-480 system using NST

**Note:** This activity requires use of the NST

1. Open NST>login>Hardware Installation>Install I/O modules and/or SFPs, and follow wizard instructions

**Comments:** The wizard reboots SPB a number of times to complete the discovery & initialization of the new IO module, then does the same thing for SPA.

2. Use Celerra Manager after the NST work is completed to failback any failed over Celerra LUNs

### **BEFORE:**

**/nas/sbin/navicli -h <spa\_IP> ioportconfig -list**

SP ID: A

I/O Module Slot: 2

I/O Module Type: Fibre Channel

I/O Module State: Present

I/O Module Substate: Good

I/O Module Power state: On

I/O Carrier: No

Information about each port on this I/O module:

Physical Port ID: 0

Port Role: FE

Logical Port ID: N/A

Port Usage: Uninitialized

Port Type: Fibre Channel

Port State: Uninitialized

Port Substate: Uninitialized →See emc215363, where IO Module was added to array prior to shipment as ‘Mode 2’ system

**Is Persisted: No**

### **AFTER:**

**# /nas/sbin/navicli -h 10.241.168.179 ioportconfig -list -iomodule 2 -sp a -pportid -portrole -porttype -portstate -isportpersisted**

SP ID: A

I/O Module Slot: 2

I/O Module Type: Fibre Channel

I/O Module State: Present

I/O Module Substate: Good

I/O Module Power state: On

I/O Carrier: No

Information about each port on this I/O module:

Physical Port ID: 0

Port Role: FE

Port Type: Fibre Channel

Port State: Enabled

**Is Persisted: Yes**

### **REPLACING FAILED SLIC IO MODULE PER CPG ON CX4:**

#### **Replacing IO Modules on SPs:**

→Basic steps are to shutdown the SP with the bad SLIC, using the shutdownpeerSP CLI command, replace the SLIC, then reboot the Peer SP from the active SP

1. Shutdown the SP that requires IO card replacement from its peer SP:

**# /nas/sbin/navisecl -h <sp\_ip> -user <username> -password <password> -scope 0 shutdownpeerSP**

2. Remove faulty IO module and replace with new module

3. Reboot SP where IO card was replaced from its peer SP:

**# /nas/sbin/navisecl -h <sp\_ip> -user <username> -password <password> -scope 0 rebootpeersp**

4. Verify system from Navisphere

#### **REPLACING SFP MODULES ON SLICs:**

→Basically, SFP replacement is online (remove bad SFP and insert new SFP)

→Important to know whether SFP ports are operating with correct BE or FE designation, and are “initialized”, etc.

#### **REMOVING SLIC IO MODULES:**

→Not a supported activity (see emc215415, module removed from array)

→For End of Quarter shipments, a SLIC IO Module may have been removed from the Array backend to change the model designation from an AUXF to an AUX

→Array logs message about IO Module missing and not inserted, and ioportconfig –list shows IO Module as “Missing”

→While not a harmful message, the only real cure is to destroy the array PSM and let it rebuild, following by a factory NAS install

1. Shutdown Celerra and array

2. Remove IO Modules A2/B2 from CX4-120 system

3. Power-up array, then the Celerra, examine for error messages

→SP Event Log and getlog output says “A configured IO module is not inserted.”, and Navisphere and ioportconfig –list shows module as “Missing”.

4. Reconfigure the array (destroys PSM database):

**# /tftpboot/bin/navicli -h <sp\_ip> ioportconfig –remove**

CAUTION: Both SPs will reboot and all customer data and array configuration WILL BE DESTROYED. Do you wish to continue (y/n)? y

Error: Target system has manually registered initiators. Remove all manual initiators before attempting the command.

**Note:** You must remove all Host Initiator records from the array, unbind all LUNs, destroy all RAID Groups, and destroy the Storage Group before the –remove command will proceed with the array reconfiguration

5. Set SPA/SPB IP & gateway addresses back to Celerra defaults (128.221.252.200 [.104]/128.221.253.201 [.104]

6. Perform Factory NAS install

## **NEW HARDWARE PLATFORMS**

### **PROBES SERIES:**

→Celerra models based on the Argonaut CPU module and Blackwidow Enclosure

### **ARGONAUT FRONT-END:**

→New Blade CPU Module based on Intel Nehalem/Westmere CPUs with 6@8GB DIMM slots & 3 Channels DDR3

## **UNIFIED VCX CELERRA/CLARIION MODELS**

→Initial release called VCX 1.0 [VCX 1.1 will support File Services upgrade]

→Convergence of Clariion and Celerra models for Celerra Integrateds

→Will maintain Celerra models for Gateway environments

→Control LUNs will be factory installed on Vault space (60-90GB) for block services for potential upgrades to file services, in RAID 6 (2+2)

→DART image to be upgraded whenever Flare is upgraded

→If upgrading to File Services, DART can be kept same, or upgraded, Flare may require update depending on NAS version

→Physical space will also be reserved for adding file services

→Reservation of (2) ports on SP's for adding Celerra Blades (file services) to the configuration

→Recoverpoint to be offered as the common File/Block replication solution

→ Celerra Replication to be supported for those requiring file system replication until Recoverpoint is enhanced

→ MVView to be offered in low-end where multi-sites exist

→ NAS & CLARiiON iSCSI to be maintained for now [If >than 8 snaps per LUN is required, Celerra iSCSI can offer up to 1024 snaps, whereas Clariion iSCSI is limited to 8 snaps/lun]

#### **Internal naming convention, from low-end to high-end:**

VCX-75; VCX-125; VCX-250; VCX-500; VCX-1000

#### **Columbus (to replace NS-120):**

→ 1-2 Maynard CS, 1-2 Blades, NAS, iSCSI, & FC protocols, paired with the Hellcat Sentry-Lite array (1.86GHz Nehalem 6GB memory), max 125 drives (SAS/SATA)

→ 2.13GHz Westmere CPU, 6GB memory, 48TB/Blade, (3) SLIC slots per Blade, (4) 6Gbps SAS backend ports per DPE and (4) 8Gbps FC connections

#### **Footprint:**

→ Minimum footprint is 8U (2U DME; 3U DPE; 1U SPS; 1U CS0; 1U CS1)

#### **Huygens (introduces an NS-240):**

→ 1-2 Maynard CS, 1-3 Blades, NAS, iSCSI, MPFS, & FC protocols, using Lightning Sentry array, max 250 drives (SAS/SATA)

→ 2.13GHz Westmere CPU, 12GB memory, 64TB/Blade, (4) SLIC slots per Blade, (2) 6Gbps SAS connections and (4) 8Gbps FC connections

#### **Footprint:**

→ Minimum footprint is 8U (2U DME; 3U DPE; 1U SPS; 1U CS0; 1U CS1)

#### **DAE's:**

→ Viper 6Gbps 3U SAS DAE holding (15) 3.5" drives or (15) 2.5" drives in the 3.5" holders

→ Derringer 6Gbps 2U SAS DAE holding (25) 2.5" drives

→ Voyager D-60 6Gbps 4U SAS DAE holding (60) 2.5" drives

#### **Mariner (replacement for NS-480):**

→ 1-2 Maynard CS, 2, 3, or 4 Blades, NAS, MPFS, iSCSI, & FC protocols, using Spitfire array, max 500 drives (SAS/SATA), 128TB/Blade

→ 2.4GHz 4-core Westmere CPU Argonaut, 12GB memory, 96TB/Blade, (5) SLIC slots per Blade

→ SP's also based on Argonaut, 2.4GHz Westmere with 18GB memory

→ Viper 3U SAS 6Gb/s DAE with [15@3.5"](#) or 2.5" drives; Derringer 2U SAS 6Gb/s DAE with [25@2.5"](#) drives; Voyager D-60 4U SAS 6Gb/s DAE with [60@2.5"](#) drives

→ Total 500 drives supported [108U using 33@15 drive DAEs; 31U using 20@25 drive DAEs; 35U using 8@60 drive DAEs]; max. of 4 BE Loops, each loop can have a max. of 125 drives; Vault drives can be SAS, SATA, EFD

→ Minimum footprint 7U

→ Raid 1/0, 5, 6 for file-based luns; Raid 0, 1, 3, 1/0, 5, 6 for block-based luns

#### **Cassini (replaces NS-960):**

→ 1-2 Maynard CS, 2-8 Blades, NAS, MPFS, iSCSI, & FC protocols, using Spitfire array, max 1000 drives (SAS/SATA)

→ 2.8GHz Westmere CPU, 24GB memory, 256TB/Blade, (5) SLIC slots per Blade

#### **Footprint:**

→ Minimum 10U, maximum 208U totaling 1000 drives

#### **Drive Types:**

EFD, SAS, or SATA, with any type as Vault

#### **DAE's:**

Viper, Derringer, & Voyager

#### **APOLLO--PROPOSED NX4 REPLACEMENT 2010/2011:**

→ Single Maynard CS, 1-2 Blades, using Hellcat-Lite array using max 75 3.5" SAS/SATA/EFD or 2.5" SAS/SATA drives

→ 1.86GHz Nehalem CPU, 8GB memory, 32TB/Blade, (4) SLICs per Blade

→ Footprint: 7U minimum and 19U maximum

## **CELERRA TLC TOOLS:**

**Note:** Several tools have been developed and are now deployed on current releases of 5.4 & 5.5

### **I. Automatic Log Collection & Transfer:**

This tool is especially powerful and triggered by certain NAS Events, such as CallHomes. Its primary purpose is to run the collect\_support\_materials script at the time of the triggering event, place the tar gzip or .zip file in /nas/var/log. It also automatically extracts and gzips panic dump files, putting the header file and dumpfile in /nas/var/dump. Additionally, this feature can be manually configured to automatically transfer the Logs & Dumpfiles to an FTP Server, as defined in the /nas/site/automaticcollection.cfg file. This tool is currently being deployed as part of the Pre-Upgrade Healthcheck Script and will be automatically installed on all NAS 5.1 and higher systems that do not already have the tool installed. See emc135846. With NAS 5.5.27.5 (GNapa), the Transfer feature can be Enabled or Disabled from Celerra Manager>Support>Log Collection tab, and a Log Collection can be triggered by the "Collect" option.

## **NAS 5.6 Manual Log Collection:**

# /nas/tools/automaticcollection -getlogs

Running Master Script

collect\_support\_materials[10342]: The collection script revision 2.9.2 has started.

Collecting output from server\_log

Collecting output from internal commands

Collecting event log configuration files

Collecting files from .etc dir of each DM

Collecting Mirrorview DR logs

Collecting Backend Monitor logs

Collecting /var logs

Collecting upgrade logs

Collecting files from /etc

Collecting files from /proc

Collecting /http/logs and /tomcat/logs

Collecting Celerra Manager tasks

Collecting cron files

Collecting Control Station process information and versions

**Note:** Logs are collected in /nas/var/emcsupport

# nas\_logviewer -t /nas/log/sys\_logtail

Jun 26 02:05:54 2008:96109133825::automaticcollection[10270]: The collection script revision 2.9.2 has started.

Jun 26 02:06:09 2008:96109133826::automaticcollection[10270]: The log collection script finished successfully. A support materials file has been created in /nas/var/emcsupport.

## **II. Celerra Log Parsing Tool:**

Windows-based java application that can be used to automatically extract and present some of the Celerra Server & CS logs in a GUI window from a collect\_support\_materials.tar.gz or .zip file, and merge the contents by chronological date and time. This tool is available for download from the NAS Support website as a zip file—unzip and install using the setup.exe program—review the documentation that is also provided from the zip file to use the Parsing Tool.

## **III. Automatic Change Monitor Tool (aka Backend Monitor—see emc152661):**

A preliminary script version of this tool has been deployed on 5.4 & 5.5 systems via the Pre-Upgrade Healthcheck script. The default configuration creates a nightly Cronjob that assesses backend status and changes related to the Data Movers, and logs changes in the /Celerra/backendmonitor directory. The sys\_log also logs any Errors found and when the backend\_change\_monitor tool starts and completes. The tool is run daily via /nas/site/cron.d/nas\_sys, after each CS reboot, and when Users run # /Celerra/backendmonitor/backend\_change\_monitor.

→Output of command is logged in /celerra/backendmonitor/Program\_Logs/FEATUREOUTPUT...

→Differences between queries are logged in /celerra/backendmonitor/Diff\_Logs/DIFF...

→Errors are logged in /celerra/backendmonitor/Error\_Logs/ALERTOUTPUT...

→Connectivity Checks are run between Data Mover, Backend HBAs, and Switches (if configured)

→Zoning information can be collected from Cisco & McData currently using SNMP with EF6000 MIBs

**Note:** 5.6.38.2 incorporates this feature in NAS, with changes (see emc195237)

## **NAS 5.6 COGNAC:** 5.6.36.4 RTM March 26, 2008; Current release 5.6.50.2

### **KNOWN ISSUES:**

1. /nas/tools/nas\_summary tool in NAS 5.5 but not ported to 5.6--AR95877 (restored in 5.6.38.2)
2. /nas/sbin/cse\_recover utility, used to correct sector errors for LUN/filesystem recovery, left out of 5.6--AR114835 (5.6.37)
3. Backend events not being handled as Events by Celerra /nas/sbin/navilog\_mon script due to parsing issue--AR117752 (5.6.38).
4. Modem ConnectHome failing on 5.6 because modem not being reset as ‘data-only’ but as ‘fax-id’--AR118928 (5.6.38).
5. Foxglove I2C Error mgmt switch firmware issues—see emc219555
6. Sledgehammer & Hammerhead mgmt switch firmware issues during upgrades—see emc223234
7. Disk discovery timeout issues during NAS Upgrades or device adds (see emc222370/AR146711 5.6.44 & 5.6.45)
8. Partimage upgrade failure during first reboot to new Linux on CS for upgrades to 5.6.46—needs primus
8. Add Blade procedure for Single blade systems causes two issues: [see emc185621 for workarounds]
  - a) upgrade\_to\_dual\_intnet script truncates the /etc/modprobe.conf file (In NAS 5.5, was /etc/modules.conf)--AR117560 (5.6.38).
  - b) Add Blade procedure also causes setup\_slot -init failure because of a “dpinit” entry in the /nas/server/slot\_3/eof file, resulting in rootfs not being mounted and then extended--AR117338, emc185621 (fixed 5.6.39).

# /nas/sbin/setup\_slot -x 3 →Extends rootfs from 16MB to 256MB

Mount root filesystem root\_fs\_3 on server\_3

```
server_3 : done
server_3 : done
Extending root_fs_3 from 16 MB to 256 MB ...
c) Add Blade procedure in Cognac also fails to write slot_2's uniqueID to the /nas/server/slot_2/start file:
# /nas/bin/nas_checkup
Check Version: 5.6.39.5
```

-----Errors-----

Data Movers: Check unique id

Symptom:

\* The uniqueid reported by the Data Mover server\_2 does not match the /nas/server/slot\_2/start file.

Action : Contact EMC Customer Service and refer to EMC Knowledgebase emc146016. Include this log with your support request.

#### **PROCEDURE TO ADD UNIQUEID TO SLOT:**

```
# cat /nas/server/slot_2/start
```

```
-serial swapserial
#verify_start
flashupg post=upgrade bios=upgrade
logsys add output disk=root_log_2 bufsz=256
logsys add output event bufsz=2048
ap boot
```

```
# /nas/sbin/setup_slot -u 2
```

Upgrading server in slot 2 ...

Ping server in slot 2 ...ok

server\_2 : done

```
# cat /nas/server/slot_2/start
```

```
-serial swapserial
#verify_start
flashupg post=upgrade bios=upgrade
logsys add output disk=root_log_2 bufsz=256
logsys add output event bufsz=2048
ap boot
```

**uniqueid validate=50060160:41e0c27b**

#### **Linux Kernel Upgrade from 2.4 to 2.6:**

```
# uname -r
```

2.6.9-42.5610.EMC

#### **CREATING BOOT FLOPPY FROM NAS CD-ROM ON NAS 5.6 CONTROL STATION:**

→Floppy is only required for CFS Eagle/Hawk systems

#### **NAS 5.6 Mountpoint Changes for Media on the Control Station:**

/media/floppy

/media/cdrom [for CD-ROM drives]

/media/cdrecorder [for CD-RW drives, such as the NSX]

#### **Symptoms if using wrong mountpoints:**

```
# mount -t msdos /dev/fd0 /mnt/floppy
```

mount: mount point /mnt/floppy does not exist

```
# mount /dev/cdrom /mnt/cdrom
```

mount: mount point /mnt/cdrom does not exist

#### **NAS 5.6 Floppy Image Name Change on NAS CD-ROM:**

/mnt/cdrom/images/boot.img (NAS 5.5 or below)

/media/cdrom/images/floppy.img (NAS 5.6 and above)

#### **NAS 5.6 Boot Floppy Image:**

Since the floppy image contains no recognizable file system that Linux or Windows can detect, the only way to verify the boot floppy image is to use cksum

#### **Boot Floppy Creation & Verification Procedure:**

##### **1. Mount CD-ROM & Floppy on Control Station:**

```
# mount -r /media/cdrom
```

```
# mount -t msdos /dev/fd0 /media/floppy
```

```
# mount
```

/dev/hdd on /media/cdrom type iso9660 (ro,nosuid,nodev)

/dev/fd0 on /media/floppy type msdos (rw)

**2. Create boot floppy system disk:**

```
# dd if=/media/cdrom/images/floppy.img of=/dev/fd0 bs=1024
```

1440+0 records in

1440+0 records out

**Note:** Eventhough the command prompt returns quickly, it takes a few minutes to complete the image write to the Floppy disk

**3. Use checksum to verify the image built to floppy vs. the image on the NAS CD Media:**

```
# dd if=/dev/fd0 of=/tmp/bootflop bs=1024
```

```
# ls -la /tmp/boot*
```

```
-rw-r--r-- 1 root root 1474560 Jan 31 14:36 /tmp/bootflop
```

```
# cksum /tmp/bootflop
```

```
1683387514 1474560 /tmp/bootflop
```

```
# cksum /media/cdrom/images/floppy.img
```

```
1683387514 1474560 /media/cdrom/images/floppy.img -->Checksums match on the file named "bootflop" vs. "floppy.img"
```

**4. Unmount Media from Control Station:**

```
# umount /media/floppy
```

```
# umount /media/cdrom
```

**INSTALLATION/UPGRADE CHANGES/REQUIREMENTS 5.6:**

→Normal upgrade or install mode requires use of bootable CD-ROM

→Recommended to use a serial connection or VGA connection to perform Upgrades to Cognac

→**/EMC/nas/install\_mgr -m upgrade** script replaces traditional /EMC/nas/setup script for upgrades, except for Golden Eagle

→Boot floppy media would be required for CFS-14 Eagle and CFS-SE Hawk systems

→Golden Eagle CNS-14 would run the setup.exe program from the CD mounted to a service Laptop to perform an upgrade or to restart an upgrade, not the install\_mgr script

→In-family upgrades can be run by deploying the package to the /celerra/upgrade directory and running the upgrade from this location [create the directory if needed]

→Can only upgrade directly from NAS 5.4 or higher

→90-day Upgrade moratorium, with exceptions managed by the NAS 5.6 SafeLaunch Team

→PUHC will fail if Flare version is not Flare 24 or higher, requiring Flare upgrade to minimum Flare 24 first, then NAS Upgrade, except that Flare 19 is supported for CX600 / CX400 backends only

→NS600 or 510 Data Mover hardware are not eligible for upgrading to 5.6

→CFS/CNS platforms must have 514 Data Movers to be able to upgrade to Cognac

→Eventhough NAS 5.4 is the minimum upgrade version, an interim upgrade to 5.5.32.4 would be required in order to extend LUNs 0 & 1 if they are not already at the minimize size of 11GB, then upgrade to 5.6

→Either log into Control Station directly as Root user to mount CD-ROM and run install\_mgr –mode upgrade script, or use the steps shown below if getting the following message when logged in as nasadmin & su'd to root:

Error : You have logged in as nasadmin and su'd to root from the /nas

directory.

Action: Retry the upgrade again with the following steps:

1. Exit from the current shell.

exit

2. Change the directory to the upgrade directory.

cd /media/cdrecorder/EMC/nas

3. Obtain root privileges.

su

4. Initiate the upgrade.

./install\_mgr -m upgrade

5. If the previous steps did not solve the problem, look at the following processes list to investigate the issue.

→Upgrades will enable Replication V2 if no V1 sessions or V1 license is detected

→Upgrades are restartable from point of last completed task [e.g., CS rebooted, etc.]

→For unattended installs, can use a DOS formatted floppy for the ksnas.cfg

**Note:** Use the CD-ROM to boot the system, then at the installation prompt, insert the floppy disk that contains the ksnas.cfg file, then enter the following:

**boot:serialkickstart a:\ksnas.cfg**

→A primary CS should be upgraded first, then the Secondary CS

**Upgrade Errata:**

→For lab purposes, there is an option to upgrade to Cognac with older hardware using the following option:

**/EMC/nas/install\_mgr -mode upgrade -allow\_upgrade\_on\_obsolete\_dm**

→Emulex firmware for CFS/CNS cabinets needs to be at a 3.90a7 version for 5.6 Upgrade

**Note:** Verify firmware version using # cat /proc/scsi/lpfc/0. CNS Golden Eagle firmware & CFS-14 Eagle firmware is automatically upgraded by Cognac upgrade process, so this is no longer an open issue for GA release.

→The Floppy disk image itself contains no file system image that Linux or Windows can recognize—it just contains a bootable image called Smart Boot Manager that can then boot the CD-ROM from the CD-Drive. The boot image has been renamed from /images/boot.img to /images/floppy.img for the Cognac NAS media.

→Cognac removes support for Telnet & RSH from Linux, and SSH from Celerra Manager tools

→Rootfs increases to 256MB in size from 128MB; New installs will default back to 1inode/8k block, but upgrades will preserve 1 inode/1k block if already in use. Upgrades to Cognac will automatically extend all production Servers' rootfs, but NOT the Standby server, or any Server with rootfs already extended. Instead, the Standby rootfs would be extended if firstconfigured to be a primary (server\_setup) server, followed by setup\_slot -init. VDM rootfs will remain 128MB.

→NS/NSX platforms will increase Linux swap file from 512 to 2GB on Chivas or 1GB on Falcon Control Stations

**Note:** New swap partition is /dev/hda6 & replaces /dev/hda2

→Linux Boot partition to increase to 128MB in size for NS/NSX platforms

→Work partition magic #: 0xbef0002

### **CONTROL LUN SIZING—LUNs 0, 1, 2, 3, & 4:**

→Install LUNs 0 & 1 must be 11GB, LUNs 2-4 must be 2 GB, and LUN 5 size will be set per the following:

### **CONTROL LUN SIZING—LUN 5:**

NS20/NS40/NS-G2/NX4/NS-120/NS-480=32GB

NS80/NSX/NS-960/NS-G8=64GB

NS350/NS500/70X/CNS/CFS=2GB

→For upgrades, LUNs 0-4 are same as for new install, but LUN5 can remain 2GB

**Note:** The NS-G2 Setup Guide instructs users to create a 64GB LUN5 during the install process

### **SYMMETRIX LUN SIZING ON 5.6 NEW INSTALLS DM3/DM4:**

LUNs 0 & 1 at 12394 cylinders, which equals 11GB

LUNs 2, 3, 4 at 2216 cylinders, 2GB

### **LUN 5 will vary:**

64GB cylinders would be 2@34956 volumes for DM4, or 4@17478 cylinders for DMX3

32GB would use 1@34956 cylinders for DMX3

2GB would use 1@2216 cylinders

### **UPGRADING FROM NAS 5.5 to 5.6:**

1. Log into Control Station as root [cannot be logged in as nasadmin]

2. Mount CD-ROM and run upgrade script

**# mount /dev/cdrom /mnt/cdrom**

**#cd /mnt/cdrom/EMC/nas; ./install\_mgr –mode upgrade** [or –mode=upgrade]

**Note:** Upgrade performs setup\_enclosure –checksystem and PUHC check\_nas\_upgrade healthchecks, then recommends that the upgrade be run from the Serial Console so as to observe the progress.

3. Message comes up advising of the need to do a system reboot after the pre-install checks are completed, along with important information that a User will need to note in order to proceed

a. System will be offline for about 35 minutes while the Linux kernel upgrades and then eventually returns to a login prompt

b. Login as Root, mount CD-ROM, exit to nasadmin, cd to CD-ROM directory, su to root, run upgrade command, upgrade begins

```
$ su  
# mount -r /media/cd*  
# exit  
$ cd /media/cd*/EMC/nas  
$ su  
# ./install_mgr -m upgrade
```

4. After the upgrade/install is completed, don't forget to log out and back in as nasadmin to re-establish NASDB environment in order to run nas and server commands

### **Upgrading to Cognac ‘Console Screen Message’ after Initial Upgrade Steps:**

The Control Station must be rebooted now. After the reboot, the Control Station will remain offline while EMC Celerra Control Station Linux is upgraded. The Linux upgrade could take up to 20 minutes to complete. You will not be able to log into the Control Station during this time. After the Linux upgrade completes, the Control Station will boot back up automatically. To continue with the NAS upgrade, do the following:

1. When the Control Station finishes booting, login as "root".

2. Mount the NAS CD and make it your working directory:

```
mount -r /media/cd*  
cd /media/cd*/EMC/nas
```

3. Continue the upgrade with the command: ./install\_mgr -m upgrade

### **NAS 5.6 UPGRADE/INSTALL LOGS:**

#### **Upgrade logs:**

/var/tmp/upgrade.log [temp log during the upgrade process]

/var/tmp/upgrade\_trace.log [temp trace log during upgrade process]  
/nas/log/upgrade.<nas\_version>.<timestamp>.log [permanent and completed upgraded log]  
/nas/log/upgrade\_trace.5.6.42-5.Mar-12.log  
/nas/log/install.<nas\_version>.<timestamp>.log

→Upgrade cookies are used to track state, copied to two locations on the Control Station, and deleted after the upgrade

#### **/var/log/install\_mgr\_info**

#### **/boot/install\_mgr\_info**

### **NAS 5.6 UPGRADE RECOVERY: Rescue Mode**

→NAS CD can boot into rescue mode to run linux commands—to be used for recovery. 5.5 to 5.6 upgrade can be rolled back to state just prior to upgrade using automatic backups created by the 5.6 script

→Not to be run on CNS-14 Golden Eagle or Secondary Control Station

#### **boot: serialrescue**

Accept ‘English’, answer ‘No’ for network interface setup, select ‘Skip’ for finding Linux installation, and ‘OK’ at /mnt/sysimage mounted message. Start recovery using /recover script.

#### **REVERTING ONCE UPGRADE WAS STARTED:**

→Do not use without consultation with Support and EE, as the suggested steps are only applicable in certain situations

1. Manually mount nas partitions
2. vi edit /nas/site/motd and /etc/motd.standby files, and remove all lines with “Warning!!”

3. Rename temp logs

```
# mv /var/tmp/upgrade.log /nas/log/upgrade.<code_date>.log  
# mv /var/tmp/upgrade_trace.log /nas/log/upgrade_trace.<code_date>.log
```

4. Remove .install\_mgr\_info file

```
# rm /boot/.install_mgr_info
```

```
# rm /var/log/.install_mgr_info
```

5. vi edit /var/sadm/pkg/emcnas/pkginfo

Change version line back to code at beginning of upgrade attempt

6. Run nas\_version and make sure no warning messages are reflected

### **CELERRA LOGICAL VOLUME MANAGER (Celerra LVM) 5.6:**

→Provides logical layer between physical disk/LUN and Celerra volumes/file systems, which allows physical devices to be put into pools or “Volume Groups”. This allows Logical Volumes to span multiple physical devices.

→Allows for dynamic management of Logical Volumes

#### **LVM HEALTHCHECK TOOL:**

→Checks mount status and state of LVMs [checks for unknown or unexpected LVMs, size mismatches, missing LVMs, etc.]

#### **# /nasmcd/sbin/lvm\_checkup**

Usage:

```
lvm_checkup -check <lv | all | error> | -recover <LVMTAB_file> | -help
```

Arguments:

-check lv - Only list the status of logical volume.

error - Only list the errors in LVM health check.

all - List all information in LVM health check.

-recover <LVMTAB\_file> Recover the /etc/lvmtab with LVMTAB\_file.

-help Display the contents of this help message.

#### **# /nasmcd/sbin/lvm\_checkup -check lv**

| LOGICAL VOLUME             | DIRECTORY              | SIZE(MB) | MOUNT | LVM STATUS |
|----------------------------|------------------------|----------|-------|------------|
| emc_lv_home                | /home                  | 600      | YES   | OK         |
| emc_lv_celerra_backup      | /celerra/backup        | 840      | YES   | OK         |

| emc_lv_nas_var_backup      | /nas/var/backup        | 840      | YES   | OK         |
| emc_lv_nas_var_emcsupport  | /nas/var/emcsupport    | 560      | YES   | OK         |
| emc_lv_nas_var_log         | /nas/var/log           | 212      | YES   | OK         |
| emc_lv_celerra_backendmo.. | /celerra/backendmoni.. | 8        | YES   | OK         |

Logical Volume Summary:

- \* emc\_lv\_home is ACTIVE, Mounted, OK
- \* emc\_lv\_celerra\_backup is ACTIVE, Mounted, OK
- \* emc\_lv\_nbsnas\_jserver is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_jserver is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var\_dump is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var\_auditing is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var\_backup is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var\_emcsupport is ACTIVE, Mounted, OK
- \* emc\_lv\_nas\_var\_log is ACTIVE, Mounted, OK
- \* emc\_lv\_celerra\_backendmonitor is ACTIVE, Mounted, OK

**# /nasmcd/sbin/lvm\_checkup -check error**

No error

**Troubleshooting LVMs:**

- LVM configurations should never be changed from the install or upgrade code version defaults—use lvm\_checkup to verify
- Recommendation would be to use /nas/sbin nas stop and start to unmount and remount LVMs
- LVMs are only mounted by the Control Station acting as the Primary
- NASDB backups do capture the new LVM files show below

**Updating LVM Cache:**

```
# mv /etc/lvm.cache /etc/lvm.cache_bak
# /usr/sbin/pvscan
PV /dev/ndf  VG emc_vg_lun_5   lvm2 [32.00 GB / 30.32 GB free]
PV /dev/hda7  VG emc_vg_pri_ide lvm2 [194.35 GB / 190.93 GB free]
PV /dev/nda3  VG emc_vg_lun_0   lvm2 [5.99 GB / 2.84 GB free]
Total: 3 [232.33 GB] / in use: 3 [232.33 GB] / in no VG: 0 [0 ]
```

**/etc/lvm**

-rw----- 1 root root 1744 Oct 5 03:31 .cache

**Troubleshooting LVM Issues:****/var/log/nas\_lvm.log****Various LVM Configuration Files & Locations:****# ls -la /etc/\*lvm\***

```
-r-xr-xr-x 1 root root 6366 Nov 13 19:07 /etc/lvmtab

-----abridged-----

**List of LVMs on Celerra Control Station:**

# /usr/sbin/lvdisplay |grep "LV Name"

|         |                                                   |
|---------|---------------------------------------------------|
| LV Name | /dev/emc_vg_lun_5/emc_lv_nas_var                  |
| LV Name | /dev/emc_vg_lun_5/emc_lv_nas_var_backup           |
| LV Name | /dev/emc_vg_lun_5/emc_lv_nas_var_log              |
| LV Name | /dev/emc_vg_lun_5/emc_lv_nas_var_emcsupport       |
| LV Name | /dev/emc_vg_pri_ide/emc_lv_home                   |
| LV Name | /dev/emc_vg_pri_ide/emc_lv_nas_jserver            |
| LV Name | /dev/emc_vg_pri_ide/emc_lv_celerra_backup         |
| LV Name | /dev/emc_vg_pri_ide/emc_lv_celerra_backendmonitor |
| LV Name | /dev/emc_vg_pri_ide/emc_lv_celerra_ccc            |
| LV Name | /dev/emc_vg_lun_0/emc_lv_nas_var_dump             |
| LV Name | /dev/emc_vg_lun_0/emc_lv_nbsnas_jserver           |
| LV Name | /dev/emc_vg_lun_0/emc_lv_nas_var_auditing         |

**Above List should match what is in /dev/mapper:**

# ls -l /dev/mapper

|            |                                                                             |
|------------|-----------------------------------------------------------------------------|
| brw-rw---- | 1 root disk 253, 7 Feb 8 11:35 emc_vg_lun_0-emc_lv_nas_var_auditing         |
| brw-rw---- | 1 root disk 253, 6 Feb 8 11:35 emc_vg_lun_0-emc_lv_nas_var_dump             |
| brw-rw---- | 1 root disk 253, 1 Feb 8 11:35 emc_vg_lun_0-emc_lv_nbsnas_jserver           |
| brw-rw---- | 1 root disk 253, 5 Feb 8 11:35 emc_vg_lun_5-emc_lv_nas_var                  |
| brw-rw---- | 1 root disk 253, 8 Feb 8 11:35 emc_vg_lun_5-emc_lv_nas_var_backup           |
| brw-rw---- | 1 root disk 253, 9 Feb 8 11:35 emc_vg_lun_5-emc_lv_nas_var_emcsupport       |
| brw-rw---- | 1 root disk 253, 10 Feb 8 11:35 emc_vg_lun_5-emc_lv_nas_var_log             |
| brw-rw---- | 1 root disk 253, 3 Jan 8 16:46 emc_vg_pri_ide-emc_lv_celerra_backendmonitor |
| brw-rw---- | 1 root disk 253, 2 Jan 8 16:46 emc_vg_pri_ide-emc_lv_celerra_backup         |
| brw-rw---- | 1 root disk 253, 11 Feb 8 11:35 emc_vg_pri_ide-emc_lv_celerra_ccc           |
| brw-rw---- | 1 root disk 253, 0 Jan 8 16:46 emc_vg_pri_ide-emc_lv_home                   |
| brw-rw---- | 1 root disk 253, 4 Feb 8 11:35 emc_vg_pri_ide-emc_lv_nas_jserver            |

**LVM's are further grouped under the following:**

# /usr/sbin/vgscan

Reading all physical volumes. This may take a while...

Found volume group "emc\_vg\_lun\_5" using metadata type lvm2

Found volume group "emc\_vg\_pri\_ide" using metadata type lvm2

Found volume group "emc\_vg\_lun\_0" using metadata type lvm2

**Verify that LVMs within a Volume Group are all available:**

# /usr/sbin/lvdisplay emc\_vg\_lun\_5

```
--- Logical volume ---
LV Name          /dev/emc_vg_lun_5/emc_lv_nas_var
VG Name          emc_vg_lun_5
LV UUID          knke62-eZ9h-hPzM-gCyj-vTms-Rcm3-PPBwJo
LV Write Access   read/write
LV Status        NOT available → This should read “available” and indicates a problem
```

→ See emc206823 for more information

# /usr/sbin/vgchange -a y emc\_vg\_lun\_5

# /nas/sbin/nas\_lvm\_tool --activate-mount

**Note:** Above commands should not be run without TechSupport and/or Eng. consultation. Vgchange can add a Volume Group back to /dev/mapper directory, and nas\_lvm\_tool can mount an LVM partition, though the normal method for mounting or unmounting LVMs is through the use of NAS services.

**5.6 LINUX CONTROL STATION PARTITION & CONTROL LUN LAYOUT--NS/NSX SYSTEM:**

# df -h | df -P -l | df -l

# df -lhP

**Note:** In dual CS environments, both CS will have access to all the LVM's, but only one CS can mount.

**OTHER LUN 0 root\_disk USAGES:**

Workpart: 1MB

Dart rootFS: 16MB/DM

Dart Server Log: 4MB/DM

Partial Dump: Single dump\_slot @2MB per DM

Full Dump\_slots: 3@1.5GB shared by all DMs

LVM Reserve Pool: 2.84GB

**LUN 1 root\_Idisk USAGES:**

DART UFSLog: 64MB/DM

DART rootFS ext: 112MB \* #of DMs

DART panic handler: 8MB \* # of DMs

DART rootFS ext2: 128MB \* # of DMs

Free Space: 6.6GB

**LUN 2 Linux CS:**

Swap file: 1 or 2GB

Reserved: 384MB

LVM Reserve Pool: 27-67GB(?)

Old /boot reserved: 31MB

**LUN 5:**

Overall size will vary: For NS20/NS40 LUN 5 size will be 32GB; For NSX/NS80 systems LUN 5 size will be 64GB.

LVM Reserve Pool

# /sbin/fdisk -l /dev/hda

## NAS 5.6 COGNAC TRIVIA:

→root\_fs\_common [./etc\_common] uses root\_volume\_16 & root\_slice\_16

→Data Mover rootfs will be extended by 128MB to a new size of 256MB

Note: Upgrade will extend all Primary Server rootfs automatically, but not the Standby Server. If a Standby is converted to a Primary, its rootfs will be extended when running setup\_slot

→VDM rootfs's are not extended and remain at 128MB in size

→New install will use default 1k per 8k block inode density on rootfs

→JRE 1.5.0\_12 has been qualified for client use with Celerra manager

→Server Logs increasing to 4MB in size per DM—Block size 0x1FFF

→(3) full dump slots are 1.5GB in size—Block size 0x300004

→DM's reducing partial dump slots from (2) each to (1) partial dumpslot of 2MB for each DM—Block size 0xFFFF

→2<sup>nd</sup> copies of the NASDB backup have migrated from /home/nasadmin to /celerra/backup/

→Primary copies of NASDB Backups are still written to /nbsnas/var/backup/

→CD mountpoint now /media/cdrom

→Processes are displayed differently than the previous Linux version, as seen by NASMCD & Box Monitor processes:

# ps -ef |grep nas\_m

|      |       |   |           |          |                                                 |
|------|-------|---|-----------|----------|-------------------------------------------------|
| root | 29424 | 1 | 0 Feb21 ? | 00:00:05 | /nasmcd/nas_mcd -h /nasmcd /nas/sys/nas_mcd.cfg |
|------|-------|---|-----------|----------|-------------------------------------------------|

# ps -ef |grep boxm

|      |      |       |           |          |                                    |
|------|------|-------|-----------|----------|------------------------------------|
| root | 1970 | 29424 | 0 Feb21 ? | 00:00:27 | /nas/sbin/nas_boxmonitor /nas -i 8 |
|------|------|-------|-----------|----------|------------------------------------|

## Outputting NAS Events different in 5.6:

# nas\_event -list -c -info [Lists components]

# nas\_event -l -c DART [Lists facilities within a component]

# nas\_event -l -c DART -f DBMS [Lists events for a facility]

# nas\_event -list -a -info [List of possible actions for events]

# nas\_event -list -a callhome [List of events for a particular action]

## 5.6 Location Where Collect Support Materials & Other Log Collection Scripts are Written:

### Collect Support Materials:

→If transfer feature is not enabled, the collect\_support\_materials file is created and zipped to /nas/var/emcsupport

# pwd

/nas/var/emcsupport

# ls -la

-rw-rw-r-- 1 nasadmin nasadmin 8453115 Feb 27 08:43 support\_materials\_APM00073701085.080227\_0841.zip

# nas\_logviewer /nas/log/sys\_log |grep collect

Feb 27 08:43:52 2008:CS\_PLATFORM:LogCollect:INFO:2:::1204119832:automaticcollection[14927]: The log collection script finished successfully. A support materials file has been created in /nas/var/emcsupport.

### SPCollects:

/nas/var/log

→SPCollects gathered from /nas/tools/.get\_spcollect are written to this directory

## 5.6 NAS LOGVIEWER & SYS LOG:

### NEW FORMAT FOR SYS LOG:

The /nas/log/sys\_log is no longer a simple text file and must be viewed using a special nas\_logviewer utility

# tail /nas/log/sys\_log

120602527996108871986

120602887696108871980

120602887796108871985

120602888196108871986

# file /nas/log/eventstore/slot\_1/sys\_log →Actual location of sys\_log

/nas/log/eventstore/slot\_1/sys\_log: data

# nas\_logviewer -v /nas/log/sys\_log →Verbose mode, shows log messages in CCMD style

logged time = Mar 20 14:01:22 2008

creation time = Mar 20 14:01:22 2008

slot id =

id = 96108871986

severity = INFO

component = CS\_PLATFORM

facility = NASDB

baseid = 306

type = EVENT

brief description = nasdb\_backup: Celerra database backup done.

full description = The Celerra database backup process has created an archive of the current Celerra database files.

recommended action = No further action required.

# nas\_logviewer -t /nas/log/sys\_logmore → -t switch is terse format, more traditional sys\_log style, drops some facility and event severity info

Mar 17 14:11:27 2008:94763810819:2:The Usermapper service has been disabled.

Mar 17 14:11:32 2008:94763810820:2:The Usermapper database has been destroyed.

Mar 17 15:01:19 2008:96108871980::nasdb\_backup: NAS\_DB checkpoint is in progress.

Mar 17 15:01:20 2008:96108871985::nasdb\_backup: NAS\_DB checkpoint done.

# nas\_logviewer -f /nas/log/sys\_log →Opens log file and current events will be seen as they are entered in the log

# nas\_logviewer /nas/log/sys\_logmore →With no switches defined, adds facility & event severity information

Mar 17 14:11:27 2008:DART:USRMAP:INFO:3:Slot 2::1205777487:The Usermapper service has been disabled.

Mar 17 14:11:32 2008:DART:USRMAP:INFO:4:Slot 2::1205777492:The Usermapper database has been destroyed.

→Fortunately, the collect\_support\_materials script not only gathers up all the sys\_logs, but converts and outputs each sys\_log into a text file based on the nas\_logviewer -t terse output mode:

sys\_log.1.txt

sys\_log.2.txt

sys\_log.3.txt

sys\_log.4.txt

## LUN 0 WORKPART OVERVIEW:

Lun 0 serves as the partition table for the Workpart structure

DOS partition →11GB

Workpart → 1MB

RootFS →16@16MB

Server Log →16@4MB

Partial dumps →16 (2)MB slots, one partial per Server

Full dumps →3@1.5GB shared between all Servers

## LINUX LOCATE UTILITY:

With NAS 5.6 kernel update, the ‘locate’ utility is a symbolic link to ‘slocate’, which is more secure since it adds file permissions and ownership information to the slocate.db database, meaning that Users that do not have the permissions to access certain files will not see the files when running the “locate” utility.

### Locate and Updatedb are Symbolic Links to the Slocate Executable:

# ls -la /usr/bin/updatedb

lrwxrwxrwx 1 root slocate 7 May 6 09:10 /usr/bin/updatedb -> slocate

# ls -la /usr/bin/locate

lrwxrwxrwx 1 root slocate 7 May 6 09:10 /usr/bin/locate -> slocate

### Cognac does not create or update the slocate database automatically, as seen by a couple of different output messages:

# locate updatedb

warning: locate: warning: database /var/lib/slocate/slocate.db' is more than 8 days old

# locate pxenas

warning: locate: could not open database: /var/lib/slocate/slocate.db: No such file or directory

warning: You need to run the 'updatedb' command (as root) to create the database.

Please have a look at /etc/updatedb.conf to enable the daily cron job.

### Manually creating the slocate database:

/usr/bin/updatedb

### Location of slocate database:

/var/lib/slocate

**Location of slocate daily cron job:**

**/etc/cron.daily/slocate.cron**

**Use following workaround to setup and keep the slocate.db current:**

1. Verify the existence of the slocate database:

```
# ls -la /var/lib/slocate
```

```
-rw-r----- 1 root slocate 780388 May 19 11:56 slocate.db
```

2. If the slocate.db does not exist, create it using the following command:

```
# /usr/bin/updatedb (updatedb is a symbolic link for the slocate executable)
```

3. Edit the /etc/updatedb.conf file to activate the daily cron Job which will enable daily updates to the slocate.db database:

```
# vi /etc/updatedb.conf
```

```
# To enable the updatedb in cron, set DAILY_UPDATE to yes -->Edit this line and change no to yes to enable the daily cronjob to update the slocate.db:
```

```
DAILY_UPDATE=yes
```

```
PRUNEFS="sysfs selinuxfs usbdevfs devpts NFS nfs nfs4 afs fs proc smbfs cifs autofs auto iso9660 udf"
```

```
PRUNEPATHS="/tmp /usr/tmp /var/tmp /afs /net /fs /selinux /udev /mnt/floppy /media"
```

```
export PRUNEFS
```

```
export PRUNEPATHS
```

4. Reboot the Control Station to activate the revised cron schedule.

**Note:** /etc/cron.daily/slocate.cron job will run daily at 4:02 a.m. if the DAILY\_UPDATE is set to yes in the /etc/updatedb.conf file

**NAS 5.6 PAHC CHECKS:**

→LUN 0 & 1 11GB minimum, LUNs 2, 3, 4, 5 2GB

**# /nas/sbin/rootnas\_disk -i root\_disk**

```
id      = 1
```

```
name    = root_disk
```

```
acl     = 0
```

```
in_use  = True
```

```
size (MB) = 11263
```

**# /nas/sbin/rootnas\_volume -s root\_disk**

```
total = 11263 avail = 0 used = 11263 ( 100% ) (sizes in MB)
```

→Verify consistency of workpart

→Verify that root\_disk\_reserve is not in use by other slices and offset from partial dump matches

**# /nas/sbin/workpart -r lfgrep dump\_slices[0][0]**

```
dump_slices[0][0].lba = 0xd3800
```

**# /nas/sbin/rootnas\_volume -i root\_disk\_reserve |grep offset**

```
offset(MB) = 423
```

**Checking Offset value:** 0xd3800 / 2048 = 423

→LUNs owned by SPA

→LVM checks

**Location of CallHome Files:**

**/nas/opt/connectemc/recycle**

```
ls
```

```
RSC_APM00062405681_042007_100750260.xml
```

**Sys log viewer for new CCMD format:**

**# /nas/bin/nas\_logviewer -v /nas/log/sys\_log >system.log** (pulls all events out of the sys\_log and writes to a <filename>)

**NAS 5.6 CELERRA REPLICATOR V2 (IPREPV2):**

→RepV2 is an IP-based asynchronous remote replication utility based on Snapsure checkpoint technology

**Note:** Currently, V1-to-V2 upgrade required at 5.6.42 or higher—see CPG

→Replication can take place between File Systems, VDMs, or iSCSI LUNs

→Common base refers to base object on source or snap on destination side that matches, so that only changes need to be transmitted

→V2 replication based on Snapsure checkpoints, with each Replication session creating two internal checkpoints on the Source and on the Target systems

→RepV2 shares the same SavVol per file system as used by Snapsure for Checkpoints, etc.

→Since replication sessions flow directly between the Data Movers involved, there is no longer a “Playback Service”

**Some Terms:**

**Checkpoint**—Read-only logical point in time image of a file system—a snapshot or checkpoint

**Internal Checkpoints**—Read-only logical point in time image of a file system using a common base. Two internal checkpoints are created on the Source and two on the Destination for each replication session.

**Writable checkpoint**—Read-only checkpoint that is converted to Read-write

**Common Base**—the Internal Checkpoint common to both Source & Destination, used as a base for the next differential transfer of data from Source to Destination

**Delta**—Block changes of current internal checkpoint vs. the last replicated internal checkpoint. Replication transfers the delta over and refreshes the destination internal checkpoint.

**Differential**—difference between the common base and the changes accumulating on the source file system.

**nas\_copy**—command which copies the full checkpoint over to destination

#### **IMPORTANT REPLICATION PORTS:**

→Data Movers must have ports 8888 and 8887 available over the network

→Control Stations must have port 443 for HTTPS available over the network

#### **UPGRADING FROM V1 to V2 REPLICATION:**

##### **Reference the ‘Celerra Procedure Generator’:**

“Replicator V1 to V2 Upgrade Procedure” (See Standalone Procedures section)

##### **REP V1 to V2 UPGRADE SCRIPT:**

→Upgrades all Replication V1 file system and VDM sessions to V2, not iSCSI replication

→Can run script on Source or Destination side, but if restarting script, use same Control Station

→Must be running NAS 5.6.42 or higher

→All V1 sessions must have a valid restart checkpoint on source PFS

→Upgrade script will abort if fs\_copy is running

→Cannot run both V1 & V2 simultaneously

→Works for Local, Loopback, & Remote replication sessions, but the upgrade\_repv1\_to\_repv2 script must reside in /nas/sbin on each Control Station where RepV1 is running

**/nas/sbin/upgrade\_repv1\_to\_repv2**

**/nas/site/RepUpgradeV1V2.log**

**/nas/volume/RepUpgradeDB** →Replication database stored here, used if script needs to be restarted

##### **Restarting Script:**

If the Control Station was rebooted while the conversion was in progress, restart the script with the following option:

**/nas/sbin/upgrade\_repv1\_to\_repv2 -reboot\_recover**

##### **Basic Script Upgrade Steps:**

Basic steps are to Query for all V1 sessions first, do Verification check [e.g., ensures existence of restart checkpoints, consistent databases, minimum 5.6.38 code versions, all CS and DMs reachable, that no fs\_copy operations are running, that no Replication sessions are inactive, failed over, or suspended], verify nodes are reachable, abort the V1 sessions, deploy v2 and license, starts upgrade process, configures DART interconnects, starts Replication V2, cleans up RepV1 restart checkpoints

##### **Script can be run in Check Mode prior to maintenance window to assess replication health:**

**# /nas/sbin/upgrade\_repv1\_to\_repv2 -check**

The pre-upgrade check process has been started in background.

Script output is logged in "/nas/log/RepUpgradeV1V2.log"

**/nassbin/RepUpgradeV1V2.log**

**/nas/sbin/RepUpgradeV1V2\_Debug.log**

**/nas/sbin**

-rwxr-x--x 1 nasadmin nasadmin 101163 Jun 10 19:37 upgrade\_repv1\_to\_repv2

##### **STARTING THE V1 to V2 UPGRADE:**

**# /nas/sbin/upgrade\_repv1\_to\_repv2 -start**

**Note:** Use this command to start the V1 to V2 upgrade process

##### **RepV1 to V2 Logs:**

**# ls -la /nas/log/Rep\*** [or /nas/site directory]

-rw-r--r-- 1 root root 359 Jun 25 01:53 RepUpgradeV1V2\_Debug.log

-rw-r--r-- 1 root root 874 Jun 25 01:53 RepUpgradeV1V2.log

##### **Checking for Restart Checkpoints:**

**# nas\_fs -list |grep pfs**

pfs\_repl\_restart\_1

pfs\_repl\_restart\_2

##### **Creating Restart Checkpoints Manually:**

**Note:** Copy files to each replication file system so as to create a delta set. Create the first restart checkpoint, then copy additional files to each file system to create another delta set, then create the 2<sup>nd</sup> restart checkpoint.

**# fs\_ckpt pfs -name pfs\_repl\_restart\_1 -Create**

**# fs\_ckpt pfs -name pfs\_repl\_restart\_2 -Create**

**# fs\_ckpt virtual1 -name virtual1\_repl\_restart\_1 -Create**

```

#### Refreshing Manually Created Restart Checkpoints:

- b) Generate new files on the production file system from a Host
- c) Run /nas/sbin/refresh\_ckpt to generate dataset transfer, or fs\_replicate –refresh <name> ?
- d) After several minutes, repeat steps a & b

#### Refreshing Internal Checkpoints on Destination:

# **fs\_ckpt id=78 -refresh -ALLOW\_REP\_INT\_CKPT\_OP**

#### V1 to V2 UPGRADE PROCESS:

1. Ensure that each pfs replication session has a time-out value greater > 0

\$ **fs\_replicate –info <name>**

# **fs\_replicate –modify <name> -option to=60**

**Note:** Record the current values of the TO settings

2. Each production file system must have two restart checkpoints—manually create them if necessary:

- a) Create file system activity on each pfs before creating the restart checkpoints
- b) Create first restart checkpoint on each pfs

**# fs\_ckpt pfs1 -name pfs1\_repl\_restart\_1 -Create**

- c) Create file system activity on each pfs again by copying files, etc.
- d) Create the second restart checkpoint on each pfs

**# fs\_ckpt pfs1 -name pfs1\_repl\_restart\_2 -Create**

### 3. Run the upgrade script in Check mode:

**# /nas/sbin/upgrade\_repv1\_to\_repv2 –check**

### 4. Run upgrade script:

**# /nas/sbin/upgrade\_repv1\_to\_repv2 –start**

**Note 1:** Script queries system to find all V1 sessions, then performs a verification check for overall state, database consistency, NAS version, connectivity to CS & DMs, that restart checkpoints are present, that no fs\_copy operations are running, that no Replication sessions are Inactive, and no suspended or failed-over sessions. Script aborts V1 sessions, turns off V1 license, configures authentication and interconnects, turns on V2 license, configures V2 sessions using restart checkpoints as common base, performing differential copy.

**Note 2:** Verify success of conversion in /nas/site/RepUpgradeV1V2.log

**Upgrade For V1 -> V2 Replication Completed on System.....**

### 5. Changing time-out policy after V2 upgrade:

**\$ nas\_replicate –modify <name> -manual\_refresh**

### 6. Verifying Replication sessions:

**# nas\_replicate -list**

| Name           | Type       | Local Mover | Interconnect               | Celerra | Status |
|----------------|------------|-------------|----------------------------|---------|--------|
| Rep4_FS82_FS30 | filesystem | server_2    | -->server_2_nx4-2_s+ nx4-2 |         | OK     |
| Rep3_FS81_FS29 | filesystem | server_2    | -->server_2_nx4-2_s+ nx4-2 |         | OK     |
| Rep2_FS77_FS27 | filesystem | server_2    | -->server_2_nx4-2_s+ nx4-2 |         | OK     |
| Rep1_FS76_FS26 | filesystem | server_2    | -->server_2_nx4-2_s+ nx4-2 |         | OK     |

**Note:** Replication sessions are renamed with the file system ID of Source first, then file system ID of Destination

### **TYPES OF REPLICATION SESSIONS:**

- Loopback [same DM used as source and destination]
- Local [from one DM to another in same cabinet]
- Remote [from one DM to another DM in a remote cabinet]
- One-to-many [source file system DM replicating to up to four destination DMs]
- Cascade [from source a to destination b, from b to c]

### **Restrictions:**

- Requires V2 licensing
  - Max replication or copy sessions per DM is 1024, but max active sessions are 256
  - Max initial copies in progress at one time is 16
  - one-to-many supports up to four destinations
  - Given Source file system or iSCSI LUN can support up to four replication Sessions
  - VDMs only support one replication session, no cascading, and no one-to-many configurations
- Note:** Cascading & one-to-many are supported with 5.6.42.5 + for VDMs
- Replication must be stopped before a VDM can be unloaded
  - Max of 96 snaps per file system, with 2048 iSCSI LUN snaps allowed

### **V1 to V2 Differences:**

- V2 requires use of DM-to-DM interconnects, which are not used with V1
- V2 supports one to many different destinations and also cascading sessions [A to B to C, etc]
- nas\_replicate replaces fs\_replicate
- nas\_copy used to make one-time copy of file system, checkpoint, or iSCSI LUN vs. fs\_copy
- V2 does not use restartable checkpoints
- Auto-extend SavVol feature and no playback service used with V2
- Policy updated using –max\_time\_out\_of\_sync option with nas\_replicate, from 1-1440 minutes [No more TO & HWM in V2]
- V1 supports 24TB while V2 supports 32TB
- If using FLR-E, both Source & Destination settings must be the same
- Replication does not support the Celerra Data Deduplication until NAS version 5.6.43

### **Internal Checkpoint Nomenclature:**

**V1:** root\_restart\_ckpt, root\_suspend\_ckpt, <pfs\_name>\_repl\_restart\_1, root\_new\_ckpt, root\_restore,ckpt

**V2:** <name>\_root\_rep\_ckpt

### **Benefits of V2 vs. V1:**

- Easier to setup—can do everything from Celerra Manager wizard & GUI
- Destination file system created automatically for VDMs and regular replication sessions

--One-to-many & Cascading

--Better performance

--No restart checkpoints needed to restart replication sessions

--Beginning with 5.6.42, support for VDM cascading and VDM one-to-many replication sessions

**Note:** So now can Replicate one-to-many & cascading for File Systems, iSCSI LUNs, & VDM objects

--Beginning with 5.6.43, support for FLR & Data Deduplicated file systems (F-RDE)

## **SAVVOL INFORMATION NAS 5.6:**

→Only a single SavVol is used by Snapsure RO checkpoints, Writeable checkpoints, and Replication sessions, per production file system, and for Replication, a SavVol is also used on the Destination side

→If file system size is >than 10GB, then the default SavVol size is 10GB

→If file system size is <than 10GB, but >than 64MB, then default SavVol size will equal the production file system size

→If file system size is <than 64MB, then SavVol size will be 64MB

→Range of SavVol size can be 64MB – 16TB

→By default, the SavVol is extended by 10GB when the default HWM of 90% capacity, is reached

→If not enough space to extend by 10GB, will use remaining 10% HWM space, and if more space is needed, will then begin inactivating & deleting oldest Checkpoints first, and finally, becomes inactive if it cannot auto-extend after using all reclaimed ckpts

→A best practice recommendation is to manually create the SavVol at 10% the size of the PFS, meaning a 1TB fs would have a minimum SavVol size of 100GB [if left to the system defaults, the size would only be created as 10GB]

→Use fs\_ckpt –modify to change auto-extension HWM or total SavVol size allowed

**%full=90** [HWM range is 10-99; if set to 0, disables the auto-extension of SavVol feature]

**maxsavsize=T | G | M** →sets limit on max size in MB, GB, TB, of a given SavVol

→For Replication Sessions, autofreeze=yes | no [default] if SavVol becomes full and cannot auto-extend

→For Replication Sessions, autoro=yes | no [default] if SavVol becomes full and cannot auto-extend

## **SNAPSURE CONFIGURATION LINE:**

### **/nas/sys/nas\_param**

#### **ckpt:10:20:20**

10 = Control Station polling interval in seconds

200 = Maximum rate in MB/sec at which a file system is written to

20 = % of total system space allowed for the creation and extension of all SavVols—this value can be changed between 20-99

**Note:** The only value on this checkpoint line that should ever be changed is the % Total system space

→If the 20 percent value is reached, the following message appears in the command output, and also in the /nas/log/cmd\_log.err and /nas/log/nas\_log.al.err files:

Error 2238: Disk space: quota exceeded

Feb 1 15:20:07 2008 NASDB:6:101 CKPT volume allocation quota exceeded

### **Replication Destination SavVol Issue:**

AR113894 finds that Destination SavVol creation size will be the size of whatever data is in the Source PFS. Fixed in 5.6.37.

### **USING NAS FS QUERIES TO DISPLAY SAVVOLS IN USE ON THE CELERRA:**

# nas\_fs -query>Type=uxfs -format:"%q" -fields:Checkpoints -query:\* -format:"ID=%s, Name=%s, VolumeID=%s,

VolumeName=%s\n" -fields:ID,name,VolumeID,VolumeName

ID=26, Name=root\_rep\_ckpt\_23\_1282\_1, VolumeID=106, VolumeName=vp106

ID=27, Name=root\_rep\_ckpt\_23\_1282\_2, VolumeID=106, VolumeName=vp106

ID=31, Name=root\_rep\_ckpt\_28\_1289\_1, VolumeID=113, VolumeName=vp113

ID=32, Name=root\_rep\_ckpt\_28\_1289\_2, VolumeID=113, VolumeName=vp113

ID=33, Name=root\_rep\_ckpt\_28\_1345\_1, VolumeID=113, VolumeName=vp113

ID=34, Name=root\_rep\_ckpt\_28\_1345\_2, VolumeID=113, VolumeName=vp113

ID=37, Name=root\_rep\_ckpt\_35\_1397\_1, VolumeID=124, VolumeName=vp124

ID=38, Name=root\_rep\_ckpt\_35\_1397\_2, VolumeID=124, VolumeName=vp124

### **ENABLING V1 REPLICATION ON 5.6 FOR LEGACY ENVIRONMENTS:**

1. Check current status

# **/nas/sbin/deploy\_replication -status**

1 = V1 ready

2 = V2 ready

3 = V1 ready & licensed

4 = V2 ready & licensed

or

# **/nas/sbin/deploy\_replication -status -verbose**

'replicatorV2' license is enabled.

2. Enable V1

# **/nas/sbin/deploy\_replication -v1**

3. Check Replicator License in Celerra Manager and apply to enable

### **ENABLING V2 REPLICATION:**

1. If status 3 is returned, delete v1 license first, then enable v2

```
# nas_license --delete replicator
```

```
# /nas/sbin/deploy_replication -v2
```

### **CASCADE REPLICATION SESSIONS:**

--Defined as replicating from A-to-B, and B-to-C [C-to-D not allowed]

--Only file system and iSCSI LUN objects can use cascading sessions

--Time\_out\_of\_Sync value should be set to the same for each leg

### **ONE-to-MANY REPLICATION:**

--Defined as up to four Replication sessions originating from a Source file system to four different target file systems

--Only file system and iSCSI LUN objects can use one-to-many

### **DOWNGRADING FROM REPV2 to REPV1:**

```
1. # mv /nas/site/nas_license /nas/site/nas_license.old
```

```
2. # nas_license -init
```

```
3. # /nas/sbin/deploy_replication -v1
```

```
4. # nas_license --create replicator
```

### **Switching to V2 or V1 Replication:**

```
/nas/sbin/deploy_replication -v2 | -v1
```

```
nas_license --delete replicator | replicatorV2
```

```
nas_license --create replicatorV2 | replicator
```

→Supports (2) types of file system replication:

a.) one-time copy

b.) ongoing replication

→Supports File System, VDM, and iSCSI objects

**Note:** Replicate VDM first, then production file systems. Must have iSCSI target & LUN available at destination before replicating

→Supports Local, Loopback, and Remote directional Replication sessions

→IPREPV2 Supports (1)-to-many replications; rearchitecture; file system cascading (a-to-b-to-c, etc.); up to 1024 Sessions per DM

**Note:** This feature will be upgraded after landing on NAS 5.6, using a /nas/sbin/upgrade\_repv1\_to\_repv2 script, which logs to

```
/nas/log/RepUpgradeV1V2.log. V1 is not going to be supported past NAS 5.6
```

### **TROUBLESHOOTING IPREPV2:**

```
# .server_config server_2 -v "replicate2"
```

```
replicate2 {
```

```
    checkdb
```

```
    displayrepsnapsignatures
```

```

## **DELETING ORPHANED REPLICATION CHECKPOINT:**

**\$ /nas/sbin/rootnas\_fs -d root\_rep\_ckpt\_25\_34130\_2 -o umount=yes -ALLOW REP\_INT\_CKPT\_OP**

## **5.6 DART INTERCONNECTS (DIC):**

→NAS 5.5.19-4 rolled out Phase I of the DART Interconnect (DIC) system for local or loopback iSCSI Replication. The project goal was to allow the ability of DART Servers to intercommunicate using HTTP in a Client/Server relationship. Part of the new DIC mechanism creates system-generated passwd entries with names based on storage array back ends, and also consists of a constant UID/GID value of 9000. These new passwd entries (alias records) are used by DIC to authenticate requests between DART Servers using XML packets over HTTP. With NAS 5.6 and RepV2, the DIC interconnect is replaced with an interconnect framework, used both for authentication and throttling information between DART servers. Do not delete, or otherwise modify, these entries.

## **EXAMPLE OF SYSTEM-GENERATED PASSWD ENTRY ON DATA MOVER:**

# cat /etc/passwd

APM000716005140000\_APM000716005140000:ef0wkKxT/c0z.:9000:9000:aSGsZJrseqsu0lsa2coly5tHpX::ndmp\_md5

**VERIFYING & VALIDATING INTERCONNECTS:**

```
# nas_cel -interconnect -list
id      name      source_server destination_system destination_server
20001  loopback   server_2     sludge4       server_2
30001  loopback   server_3     sludge4       server_3
```

```
# nas_cel -interconnect -validate id=20001
```

validating...ok

**QUERYING HTTP SERVER ON DATA MOVER FOR DIC INFO:**

```
# server_http server_2 -info DIC
```

**REBUILDING THE DIC PASSWD ON DATA MOVERS:**

# nas\_cel -update id=0

operation in progress (not interruptible)...

id = 0  
name = sludge4  
owner = 0  
device =  
channel =  
net\_path = 192.1.4.218  
celerra\_id = APM000716005140000

**Note:** This command also recreated and populated server\_3 with a default passwd entry to support the DIC feature.

**REPV1 to REPV2 CONVERSION ISSUE RELATED TO DIC ENTRIES:**

If a standby server was converted to a primary while at NAS 5.5, and replication sessions were in place, and the system was subsequently upgraded to NAS 5.6, during the REPV1 to REPV2 conversion a failure occurs because the standby (now primary) server never had all the DART interconnect passwd entries required for all the remote systems. See ARs 120114 & 108256. Fix will be to run nas\_cel -update after server\_setup to ensure that DIC passwd entries are run for all systems seen by nas\_cel.

**DART INTERCONNECT TROUBLESHOOTING:**

# .server\_config server\_2 -v "dic service"

### **REPLICATION INTERCONNECTS—DART & CS:**

- DART Interconnects are required for Local & Remote Replication sessions between Data Mover pairs
- Only single interconnect built for each Data Mover pair
- Celerra Mgr wizard will create bi-directional interconnects, otherwise, the User will need to configure from Replication tab on each side of the Replication environment
- For Replication, Data Mover interconnects maintain the structure for source and destination interfaces, bandwidth information, and interface usage counts

### **UPDATING CELERRA INTERCONNECTS WITH NEW CELERRA ID (CMU):**

- 1) Edit server “start” files with correct Celerra ID or CMU (nas\_cel –list):

```
# vi /nas/server/slot_2/start
```

```
setid celerra=00019010488028CF
```

- 2) Comment out the dpinit service for each server in the “eof” file, then reboot

```
# vi /nas/server/slot_2/eof
```

```
# dpinit
```

```
# server_cpu server_2 –reboot now
```

- 3) Delete the old interconnect database

```
# server_dbms server_2 –db –delete icon_db
```

- 4) Remove comment from “eof” dpinit line and boot.cfg files, then restart dpinit service

```
# .server_config server_2 “dpinit”
```

- 5) Update the interconnects using the following:

```
# nas_cel –update id=0
```

### **5.6 NAS CEL INTERCONNECT COMMAND:**

**# nas\_cel -interconnect -create** [creates a single interconnect between two Data Movers in same or different cabinets, authentication, bandwidth throttling scheduler, & IP addresses on Source & Destination]

**-destination\_interfaces** [name of interfaces]

**-bandwidth** [can specify periods by time and bandwidth: “MoTuWeThFr07:00-18:00/2000,/8000” translates into 2000KB/sec limit from 7-6:00p.m. Mon-Friday, and 8000KB/sec at all other times]

**-modify** [can modify source & destination addresses, interconnect names, throttling, crc]

**-pause** [sets throttle value to 0, suspending transfer]

**-resume** [set throttle back to value prior to suspending]

**-delete** [deletes the interconnect configuration, but only if not being used by a Replication session]

**-info** [displays interconnect information]

**-list** [displays interconnects on entire Celerra]

**-validate** [verifies that Data Mover pairs are authenticated and validates all source and destination interface pairs]

#### **Types of Interconnects:**

- a.) Control Station interconnects, created automatically by nas\_cel
- b.) Loopback Interconnect, created automatically for each DM
- c.) Local Replication Interconnect, created between pair of DMs for source and peer sides
- d.) Remote Replication Interconnect, created between local and remote DMs

**Note:** An interconnect provides all available bandwidth for replication sessions by default

#### **Creating Interconnect Example:**

```
# /nas/sbin/nas_cel –interconnect –create ns0_dm2 –source_server server_2 –destination_system ns1_dm2 –destination_server server_2 –source_interfaces ip=192.168.10.50, 192.168.10.55 –destination_interfaces ip=192.168.10.25, 192.168.10.30 –bandwidth MoTuWe 07:00-18:00/2000, /8000 –crc yes
```

### **5.6 NAS CEL COMMAND:**

→Used to register Source and Destination Control Stations with each other, run as root, requires passphrase, run from each Control Station to register the peer CS

```
# nas_cel –create ns1 –ip 10.250.60.10 –passphrase nasadmin
```

```
# nas_cel –list [verify registrations]
```

### **5.6 NAS REPLICATE COMMAND:**

→Used to create & manage replication sessions for file systems, VDMs, and iSCSI LUNs

→DP Manager on Data Mover is used to keep source and destination objects synchronized, using HTTP over TCP/IP between Data Movers. DP Mgr also controls the replica engine, which uses RCP over TCP/IP to transmit data between Source & Target Data Movers.

→Must specify the iSCSI LUN destination for iSCSI

```
# nas_replicate –list [list of replication sessions and status]
```

```
-info [detailed information about specific replication sessions]
```

-**create** [used to create a replication session]  
-**source -fs** [source fs to replicate]  
-**destination -fs** [replication target]  
-**source\_interface** [IP address or interface name for source]  
-**destination\_interface** [IP address or interface name for destination]  
-**max\_time\_out\_of\_sync** [max time before ckpt refreshed & new delta set sent to destination; range 1-1440 minutes; default 20 min.]  
-**overwrite\_destination** [overwrite destination with changes from source]  
-**background** [run as background process and return to prompt]  
-**source -vdm** [source vdm] -**destination -vdm** [destination vdm]  
-**source -lun -target** [source iSCSI LUN & Target IQN for replication] -**destination -lun -target** [destination iSCSI LUN & Target IQN to overwrite]  
-**start** [Used to restart a replication session using differential or full copy, from source side, usually after session was stopped. Can also change interconnect and interfaces, as well as policies, during the restart]  
-**start -reverse** [restarting replication session and reversing replication direction—issued from destination side, usually after a failover or switchover has been run. VDMs need to be mounted RW & Loaded, file systems need to be RW or RO, and iSCSI LUN needs to be exported to Host as iSCSI Target. If commonbase exists, a differential copy is performed. If no commonbase exists, a full copy must be done.]  
-**reverse** [run from Source side and reverses direction of Replication without data loss]  
-**modify** [used to modify source & destination Data Mover addresses, Time Out of Sync, Name of Session, but can be run only from Source side when replication is in configured state]  
-**stop** [stops replication session] -**stop -delete** [stops replication session and deletes checkpoints & configuration]  
-**refresh** [forces update from source to target, run from source side]  
-**failover** [Used for DR failover, issued on Destination side, stops Replication session, makes destination file system RW, terminates any deltaset, makes Source RO if reachable, involves some data loss as delta sets are not transferred]  
-**switchover** [Stops replication gracefully after syncing source & destination so that no data is lost, used for testing, issued from Source side only, makes destination RW, source RO]

**Note:** V2 replication automatically creates destination file system for file system and VDM replication, and creates two checkpoints for source and destination. After first full copy, the destination ckpt1 is refreshed (ckpt2) to become the common-base for source ckpt1. Then, the source ckpt2 is refreshed to create delta between original source ckpt1 and latest copy (differential copy). Once this transfer is completed, the destination ckpt2 is used as the common base to source ckpt2

## **5.6 NAS COPY COMMAND:**

# **nas\_copy -source -fs | -source -chkt | -from\_base | -refresh | -overwrite\_destination | -full\_copy**

## **5.6 NAS TASK COMMAND:**

# **nas\_task -list | -remote\_system | -info | -abort <id> -mover -remote\_system | -delete** [used to track progress of replication commands locally and remotely, with ability to abort or delete tasks]

# **nas\_task -info xxxx -remote\_system <cs\_remote>**

**Note:** nas\_task -delete only removes task from list but does not kill the actual task itself?

## **DART TASK LIST:**

\$ .server\_config server\_2 -v “cmdSvcDisplay”

## **iSCSI LUN REPLICATION REQUIREMENTS:**

- Destination LUN needs to exist and be RO
- iSCSI LUNs are supported for Replication using one-to-many, and cascading, etc.
- Target IQNs are required for -create
- During normal iSCSI Replication, destination iSCSI LUNs are not accessible, and only becomes accessible after failover, switchover, or stop events
- During normal iSCSI Replication operation, destination LUN can be snapped with CLI, promoted, then mounted and exported for Hosts
- iSCSI snaps are crash consistent, not application consistent
- iSCSI snaps db is not stored on Control Station, only on Data Mover

## **CREATING iSCSI REPLICATION SESSION:**

# **nas\_replicate -create -iscsi1 -source -lun 0 -target iqn.1992-05.com.emc:apm0074003149000-2 -destination -lun 0 -target iqn.1992-05.com.emc:amp00071500149000-1 -interconnect ns0\_dm2**

## **SETTING UP V2 REPLICATION ON CELERRA:**

### **USING CELERRA MANAGER:**

1. Enable Replicator license: Celerra Home>Licenses>Replicator V2
2. Select Wizards>Replication>New Replication>Wizard Steps  
Select a Replication Type > File System | VDM | iSCSI LUN  
Select Destination Celerra  
Select Data Mover Interconnect  
Select Replication Sessions's Interface

Select Source

Select Destination

Update Policy

Overview/Results

3. Or use Replications tab

**FROM CLI:**

1. Setup Source &amp; Destination communication using nas\_cel -create &amp; verify using nas\_cel -list

# **nas\_cel -create cs\_source -ip 192.168.10.10 -passphrase nasadmin**# **nas\_cel -create cs\_dest -ip 192.168.10.5 -passphrase nasadmin**# **nas\_cel -list**

2. Setup DM-to-DM Source &amp; Peer Interconnects &amp; verify using nas\_cel -interconnect -validate id=&lt;interconnect\_ID&gt;

# **/nas/sbin/nas\_cel -interconnect -create cs\_source -source\_server server\_2 -destination\_system cs\_dest -destination\_server server\_3 -source\_interfaces ip=192.168.10.25, 192.168.10.30 -destination\_interfaces ip=192.168.10.50, 192.168.10.55 -bandwidth MoTuWe07:00-14:00/0800 -crc yes**# **/nas/sbin/nas\_cel -interconnect -create cs\_dest -source\_server server\_3 -destination\_system cs\_source -destination\_server server\_2 -source\_interfaces ip=192.168.10.50, 192.168.10.55 -destination\_interfaces ip=192.168.10.25, 192.168.10.30 -bandwidth MoTuWe07:00-14:00/0800 -crc yes**# **nas\_cel -interconnect -list | -modify | -pause | -resume**# **nas\_cel -interconnect -list**

| id    | name     | source_server | destination_system | destination_server |
|-------|----------|---------------|--------------------|--------------------|
| 20001 | loopback | server_2      | hammer2            | server_2           |
| 30001 | loopback | server_3      | hammer2            | server_3           |

# **nas\_cel -interconnect -validate id=20001**

validating...ok

3. Create Replication session and verify using nas\_replicate -list, -info id=x

# **nas\_replicate -create rep1 -source -fs src\_fs1 -destination -pool admin\_pool -interconnect id=200003 -max\_time\_out\_of\_sync 15****Note:** A replication session creates (4) internal checkpoints, 2 for Source, 2 for Destination, baseline and differential images

--Basically, create the Replication session from Source to Destination

--A full copy of Ckpt1 on the source fs is copied to the Destination

--After Ckpt1 is copied to the Destination, the Destination Ckpt1 is refreshed and then becomes the common base between Destination and Source file systems

--On the Source, once the common base has been established, a differential checkpoint is taken on the source fs as Ckpt2 and includes the delta of any changes--this is called the differential copy which is then transferred to the Destination.

--Once the differential has been transferred to the Destination, the Destination Ckpt2 is refreshed to become the new common base with Source Ckpt2.

--Then, in accordance with whatever update policies are in place, the cycle continues with differentials copied over and new common bases being established each time

**REFRESHING DESTINATION SESSION:**# **nas\_replicate -refresh fs1\_x -background**# **nas\_task -info <id>****DELETE REPLICATION SESSION:**# **nas\_replicate -delete <name or id=x> -mode source | destination | both****STOP REPLICATION SESSION:**# **nas\_replicate -stop fs1 -mode source | destination | both****START REPLICATION SESSION:**# **nas\_replicate -start <fs\_name or session\_id> | -interconnect <name or interconnect\_id> | -max\_time\_out\_of\_sync 10****Note:** Session can be restarted using full or differential copy, and interconnect, interfaces, and policies can be modified**STARTING A FAILED OR SWITCHED OVER REPLICATION SESSION IN REVERSE DIRECTION:**# **nas\_replicate -start <fs\_name or session\_id> -reverse -interconnect id=30000 -overwrite\_destination****REVERSING A REPLICATION SESSION:**# **nas\_replicate -reverse fs1****Note:** Run on Source side, reverses direction of replication, places source RO**MODIFY REPLICATION SESSION:**# **nas\_replicate -modify****Note:** Use modify to change name of session, source & destination interfaces, max time out of sync, run from Source**3 TYPES OF REPLICATION FAILOVER:**# **nas\_replicate -failover**

**Note:** Used in disaster scenario, issued from destination Control Station. Stops any data transfers, changes destination to RW, and performs failover. Considered a DL event since this action will incur data loss. Direction of replication not changed.

#### # nas\_replicate –switchover

**Note:** Graceful failover run from Source side, no data loss, useful when testing failover. Synchronizes Source & Destination, stops replication session, mounts Source RO, mounts Destination RW, and does not start replication. Direction of replication not changed.

#### # nas\_replicate –reverse

**Note:** Used to change direction of replication, issued from Source side, synchronizes Source & Destination, stops replication, mounts source RO, mounts destination RW, starts replication in reverse direction from differential copy.

#### TROUBLESHOOTING/LOGS:

##### SET FOLLOWING DEBUG PRIOR TO TESTING IP REPLICATION:

```
$ .server_config server_x "logsys set severity CMD=LOG_DEBUG"
$ .server_config server_2 -v "cmdSvcDisplay" [task list on Data Mover]
$ .server_config server_2 -v "cmdQueueDbTest display" → looks for any queued tasks
$ .server_config server_2 -v "testDB display" → displays dbms records related to running tasks
1249327570: CMD: 6: Displaying DBMS Records
```

```
-----  
KEY=APM000832011840000_0_2612:4294969908_Initiator  
-----abridged-----
```

```
-----  
KEY=APM000832011840000_0_2612:8589937204_Initiator
```

**Note:** Here are two DBMS records for the Task\_Id referenced above

```
$ .server_config server_2 -v "testDB delete key=APM000752005020000_0_29619:4294996915_Server"
$ .server_config server_2 -v "cmdQueueDbTest delete key=524_APM00075200502_0000_462_APM00075200501_0000"
/nas/log/nas_log.al.mgmtd [Logs communications between DART & CS]
/nas/log/sys_log & server_log
/nas/log/webui/cli.log [GUI & CLI commands recorded here]
/nas/log/webui/apl_tm.log [legacy commands if V1 is used]
```

#### CLEANING UP HUNG REPLICATION TASKS:

**Note:** Generally, hung or defunct tasks are seen during Upgrade checks. See emc204889 & emc225820 for the proper cleanup methods

1. Identify running tasks

#### # nas\_task -list

| ID   | Task State | Originator    | Start Time                   | Description             | Schedule | Remote System |
|------|------------|---------------|------------------------------|-------------------------|----------|---------------|
| 2612 | Running    | root@168.159+ | Wed Jun 10 13:00:26 EDT 2009 | Create Replication fs1. |          |               |

2. Try to abort the tasks (Source & Target Control Stations)

#### # nas\_task –abort 2612 –mover server\_2 –remote\_system <remote\_cs\_name>

3. Continue with the following actions if the tasks cannot be aborted:

- a) Delete the following DBMS records:

```
$ .server_config server_2 -v "testDB display" # Lists the testDB record.
$ .server_config server_2 -v "testDB delete key={key from display command}" # Deletes the testDB record.
$ .server_config server_2 -v "cmdQueueDbTest display" # Lists the cmdQueueDbTest record.
$ .server_config server_2 -v "cmdQueueDbTest delete key={key from display command}" # Deletes the cmdQueueDbTest record.
```

- b) Su to root user and create console tool link:

```
# cd /nas/tools
```

```
# ln -s console _console
```

- c) Run the console tool, identify and destroy tasks:

```
./_console
```

At the prompt Command {Enter "exit" to quit } **>>taskmgr.dump** # Lists the tasks.  
2250036

Command {Enter "exit" to quit} **>> taskmgr.destroy 2250036** # Deletes the task.

- d) Reboot the Data Mover(s).

- e) Continue with upgrade.

#### Some Output Examples:

#### # .server\_config server\_2 -v "cmdSvcDisplay"

1249327540: CMD: 6: CMD Context: List of all Cmd Contexts :

1249327540: CMD: 6: Task\_Id RefCount

1249327540: CMD: 6: APM000832011840000\_0\_2612:4294969908

**Note:** Here it outputs a task list, which in this case is an orphaned task on the Control Station for Replication

## # .server\_config server\_2 -v “testDB display”

1249327570: CMD: 6: Displaying DBMS Records

-----  
KEY=APM000832011840000\_0\_2612:4294969908\_Initiator

-----abridged-----

KEY=APM000832011840000\_0\_2612:8589937204\_Initiator

**Note:** Here are two DBMS records for the Task\_Id referenced above

# .server\_config server\_2 -v "testDB delete key=APM000832011840000\_0\_2612:8589937204\_Initiator"

# .server\_config server\_2 -v "testDB delete key=APM000832011840000\_0\_2612:4294969908\_Initiator"

**Note:** Above two commands deleted the dbms records seen with testDB display

## # nas\_task -delete 2612

OK

## **5.6 NDMP VBB SUPPORT:**

→NDMP 3-Way VBB support (correction to handle unexpected EOTape during restores)

## **5.6 CS SECURITY ENHANCEMENTS:**

→Various security issues; PKI (X.509 certificates from CS CLI or GUI to support Data Movers—Certificates for DM can be signed by CS or other External Host), no dynamic ports, CS Security auditing; Linux kernel upgrade from RH 7.2 to RH Enterprise Linux 4—RHEL 4; External directory support for CS authentication following EMC CAMS CSO (Common Sign-On) initiative; Support for SSL or IPSEC for Control Station commands to allow for encryption over IP; passwd management on CS; CS Security auditing

**Note:** CAMS CSO provides authentication, Role & User management, and cryptography for Celerra Manager in communications with external directory servers. The RSA Common Security Toolkit (CST) is replacing CSO in a Cognac maintenance version.

## **5.6 CELERRA PUBLIC KEY INFRASTRUCTURE (PKI—X.509 Certificates):**

→Framework for distributing & maintaining private & public keys, and digital certificates, for protecting data, authenticating users, encrypting or using digital signatures

→PKI provides authentication services for SSL [DHSM, RepV2, OpenLDAP uses SSL]

→PKI is not supported with CIFS or NFS

→Managed from Celerra Manager>Security tab>Public Key Certificates or via CLI using server\_certificate or nas\_ca\_certificate

→Public Key Certificates folder is used for certificate and public key management

→CA certificates used to verify signatures on public key certificates received

\$ server\_certificate server\_2 –ca\_certificate –import –filename /home/nasadmin/cacert.pem [Import CA]

\$ server\_certificate server\_2 –ca\_certificate –list | -info <id> | -delete <id>

→Data Movers use a ‘Persona’ as a container to have keys and certificates managed for them by the CS. Persona is used to provide private key and certificate when acting as a Server to Client connections or as a Client to another server

→Each ‘Persona’ has up to 2 sets of keys and certificates (current & next), with key sizes 2048 or 4096 bits in length

→Only a single ‘Persona’ allowed per Data Mover

\$ server\_certificate server\_2 –persona –list | -info default

\$ server\_certificate server\_2 –persona –generate default –key\_size 2048 –cn “celerra1.pvt.dns” –filename

/home/nasadmin/newcertrequest.pem [Generate keys and certificate request external CA]

\$ server\_certificate server\_2 –persona –generate default –cn “celerra1.pvt.dns” –cs\_sign\_duration 24 [CS generated key & cert]

\$ server\_certificate server\_2 –persona –import default –filename /home/nasadmin/newcert.pem [Import public key cert]

\$ server\_certificate server\_2 –persona –delete default –both [delete a persona key set]

## **DISPLAYING CONTROL STATION CERTIFICATE:**

# /nas/sbin/nas\_ca\_certificate -display

Certificate:

Data:

Version: 3 (0x2)

Serial Number: 1 (0x1)

Signature Algorithm: sha1WithRSAEncryption

Issuer: O=Celerra Certificate Authority, CN=ballpeen2

Validity

Not Before: Jan 9 13:59:09 2008 GMT

Not After : Jan 7 13:59:09 2013 GMT

Subject: O=Celerra Certificate Authority, CN=ballpeen2 -----abridged-----

## **GENERATING NEW CA FOR CONTROL STATION:**

# /nas/sbin/nas\_ca\_certificate -generate

## **USING DATA MOVER PERSONA AND CONTROL STATION AS CA FOR CERTIFICATES:**

→When using the Control Station as the CA (Certificate Authority), the Certificate Request is automatically received from the Data Mover, generated, signed, and then returned to the DM

→A Control Station cannot be used to “sign” Certificates for external Hosts

→Must specify the duration in months that the certificate is valid for a CS CA

1. Create private key and certificate for use with the Control Station as CA [Not an External CA]

# **server\_certificate server\_2 -persona -generate default -key\_size 4096 -cs\_sign\_duration 8 -cn "w2k.pvt.dns"**

server\_2 :

Starting key generation. This could take a long time...

Done

**Note:** Certificate request sent by Data Mover to Control Station, generated, signed, and returned

# **server\_certificate server\_2 -persona -list**

server\_2 :

id=1

name=default

next state=Not Available

CURRENT CERTIFICATE:

id=1

subject=CN=w2k.pvt.dns

expire=SAT JUN 5 11:23:34 PDT 2010

issuer=O=Celerra Certificate Authority;CN=emcnas\_i0

# **server\_certificate server\_2 -persona -info -all | -info default**

server\_2 :

id = 1

name = default

next state = Not Available

Current Certificate:

id = 1

subject = CN=name;CN=1.2.3.4

issuer = O=Celerra Certificate Authority;CN=ballpeen2

start date = TUE JAN 29 22:52:37 EST 2008

end date = THU SEP 25 23:52:37 EDT 2008

serial number = 03

signature alg. = sha1WithRSAEncryption

public key alg. = rsaEncryption

public key size = 4096

version = 3

### **CHECKING FOR EXPIRED KeySets:**

→Run \$ server\_certificate –persona –list and check for expired certificate date

### **CLEARING EXPIRED KeySets:**

\$ **server\_certificate server\_2 -persona -clear default -both**

### **DISPLAYING CA CERTIFICATES:**

\$ **server\_certificate server\_2 -ca\_certificate -info 2**

### **CHECKING FOR EXPIRED CERTIFICATES:**

\$ **server\_certificate server\_2 -ca\_certificate -list** (check expire= dates)

### **DELETING CA CERTIFICATES:**

\$ **server\_certificate server\_2 -ca\_certificate -delete 1**

### **USING EXTERNAL CA CERTIFICATES:**

1. Generate the Data Mover’s persona public/private key set and request that a CA sign the certificate

\$ **server\_certificate server\_2 -persona -generate default -key\_size 4096 -cn 'name;1.2.3.4'**

server\_2 :

Starting key generation. This could take a long time...

Done

\$ **server\_certificate server\_2 -persona -generate default -key\_size 4096 -cn 'name;1.2.3.4' -ou 'my.org;my dept' -organization EMC -location Hopkinton -state MA -country US -filename /tmp/server\_2.certrequest.pem**

**Note:** Example of key generation using specific DM information and writing to a file

2. Write the certificate request to a file

# **server\_certificate server\_2 -persona -info default >server\_2.certreq.pem**

server\_2 :

id = 1

name = default

next state = Request Pending → Certificate request shows pending until CA provides signed certificate

3. Send the .pem file to the External CA

4. Import the signed certificate to the Data Mover:

**\$ server\_certificate server\_2 -persona -import default**

server\_2 : Please paste certificate data. Enter a carriage return and on the new line type 'end of file' or 'eof' followed by another carriage return.

**Note:** Follow the screen instructions after pasting the certificate data onto the screen

5. Verify:

**# server\_certificate server\_2 -persona -info default**

server\_2 :

id = 1

name = default

next state=Not Available → this is the key indicator to say that the certificate was successfully imported to the Data Mover

**# server\_certificate server\_2 -ca\_certificate -list**

## **5.6 CONTROL STATION PKI MANAGEMENT:**

**# /nas/sbin/nas\_ca\_certificate -display | -generate**

Certificate:

Data:

Version: 3 (0x2)

Serial Number: 1 (0x1)

## **USE CASE:**

### **CONTROL STATION ADMIN ROLES USING LDAP OVER SSL:**

→ Normal process should be to import a Public X.509 Certificate from a CA to the Control Station using the Security>Administrators>Domain Settings tab in Celerra Manager, “Upload New SSL Certificate”

→ This should provide the Public Key which CS can use to decrypt certificates signed by the CA. With Directory Servers, the CS can then communicate to the Directory Server and receives a certificate signed by the CA, which also contains its public key, which CS can decrypt and then use to communicate with the Directory Server

→ Control Station would initiate the LDAP connection to the Directory Server, which responds with LDAP Certificate, which has been signed by the site CA Certificate, and validates the SSL handshake with LDAP. So it's the site CA certification that must be installed on the CS.

**Issues:** ARs 150154 & 155672

1) Import file must be named with ".cer" suffix and be in PEM/Base64 format

2) If a site uses multiple certs in its CA chain, than all the certificates must be aggregated in a single file, which is then used to import to the Control Station

→ This may require that AD certificates, which are in DER binary format, be converted to PEM format and concatenated into a single text file

**Converting From DER to PEM using openssl:**

**# openssl x509 -in <DER\_cert.der> -inform DER -out <PEM\_cert.pem> -outform PEM**

**Troubleshooting Control Station LDAP SSL Certificate Issues:**

**# /nas/sbin/cso\_config**

```
usage: cso_config
-create { -domain <domain name> -pServer <primary_server>
-bServer <backup_server> -port <port_num>
-sslEnabled <true/false>
-cert <certificate_path>
-type <defaultAD | customAD | other>
-bindDn <binding_address>
-name <admin_name> -password <admin_password>
-userPath <user_search_path>
-groupPath <group_search_path>
-userAttr <user_name_attribute>
-groupAttr <group_name_attribute>
-groupClass <group_class>
-groupMember <group_member>
-autoUserCreate <true/false>
| -F <config file name> -password <admin_password> }
| -test
# /nas/sbin/cso_auth -test
# /nas/sbin/cso_config --debug on | --debug off
/nas/site/CA
/nas/site/CA/ca_certificate.pem | key.pem, etc.
/nas/site/cso_cert
/nas/site/cso_auth.cfg
/nas/site/cso_auth_config.xml
```

### **OPENSSL VERSION:**

```
# rpm -qa openssl
openssl-0.9.8g-5.4.01.EMC
```

**Note:** Updated in a 5.6 maintenance release

### **5.6 SECURITY CS AUDITING:**

Audit Logs for User & Kernel space components to be written to /nasmcd/var/auditing

```
/sbin/auditctl | /sbin/ausearch (used to find audit events of interest) | /sbin/aureport | /sbin/audited | /etc/audited.conf (uses one keyword per line for configuration information) | /etc/audit.rules (rules applied on startup)
```

/sbin/audited status | -s will report on status of auditing on the Control Station

/sbin/service audited start | stop | status | restart | reload | rotate | condrestart

#### **What actions are Logged?**

Admin access of rootfs of Data Movers; Access to sensitive CS files; Changes to auditing; Users authenticating to system

→Upgrade Hardening

→FileMover improvements; Config API, HTTPS support using SSL & PKI, Retention times set by Policy Engine (creates WORM stub file)

### **5.6 CELERRA MANAGER ENHANCEMENTS:**

- Rename file system
- Rename Data Mover
- Extend Checkpoint SavVol
- Modify NetBIOS name for NT CIFS servers or Standalone CIFS servers
- Modify Alias names for W2K, W2K3, NT, or Standalone CIFS servers
- Can change CIFS server interfaces, except for the default CIFS server
- More Provision Monitoring
- Added Security & Administrative Roles

### **PROVISIONING MONITORING:**

- Celerra Manager Basic Edition only allows Event Notifications for file system usage stats
- Celerra Manager Advanced Edition allows event notifications and monitoring of file system stats, file system usage projection, storage pool management, storage projection, data mover load
- File System notifications are polled every 10 minutes, and when condition is met, notification occurs, with only one notification per 24 hour period
- Notifications are based on Storage Usage & Projections that includes file systems and storage pools, via emails, alerts, traps
- 26 weeks of historical data kept, with default 2 weeks displayed

Celerras>Storage>Pools>Usage Statistics—new tab for storage stats

Celerras>Data Movers>Server\_2>File System>renamed Statistics to “I/O Statistics” and added “Usage Statistics” tab

### **SECURITY ENHANCEMENTS CELERRA MGR:**

--Encryption, Public Key Certificates, Role-based access, Password requirements

--Group & User Management facilities

--Remote Celerra authentication & auto-user creation upon login to Celerra Mgr

**Note:** Privileges and Roles are enforced in four CLI commands: nas\_ckpt\_schedule; nas\_copy; nas\_replicate; & nas\_task

## **5.6 ADMINISTRATIVE ROLES IN CELERRA MANAGER (GUI only):**

→Roles are based on Control Station management only, not DART, and are not object specific

→Admin roles based on privileges based on job function & area of responsibility

→An admin user account is always associated with a Primary Group [Pre-defined and Custom groups, local or domain-based]

→All groups are assigned a Role, which defines the privileges of the Users assigned to the Group

→Users can belong to multiple Groups

→All admin roles have Read privileges to view objects

→Modify privileges can make changes to existing objects

→Full Control privileges can create, delete, change objects

### **(3) Levels of Access defines Privileges:**

Read, Modify, Full Control

**/nas/site/role** →Role definitions are based on ID:name:type:description:privileges

### **CELERRA MANAGER SECURITY TAB:**

#### **→Administrative Roles for Celerra Manager: Celerras>Security: Users; Groups; Roles; Domain Settings**

##### **Security>Administrators >Users:** →two default users (nasadmin & root)

nasadmin: Primary Group “nasadmin” with Operator Role, and Groups “fullnas” with Nasadmin Role

root: Primary Group root with Root Role, with Groups “bin, daemon, sys, adm, disk, wheel” with Nasadmin Role

→Users will be automatically created during login if members of defined groups

→Membership in a Primary group and up to 16 other Groups

→All custom users belong to Nasadmin group with role of ‘Operator’

→UID Mappings can be auto-selected or specified when creating, and are added to users\_db on Control Station

### **/nas/site/users\_db**

500:0:1:: →New user ‘Samuel’ added & auto-assigned first UID of 500

→User name mappings added to pst\_db after logging into Celerra Mgr for the first time

### **/nas/site/pst\_db**

samuel:Student@10.127.114.45:4

**Note:** Manually defined membership in network group, while system auto adds to nasadmin group

### **Unique Celerra Manager Logins for NASADMIN & ROOT Accounts:**

# cat /nas/site/pst\_db/cat usrenv2Id.tbl

nasadmin:unknown\_login@192.1.4.212:1

root:unknown\_login@192.1.4.212:2

nasadmin:administrator@gloria.w2k.pvt.dns:3

root:administrator@frodo.w2k.pvt.dns:5

**Security>Administrators >Groups (role) GID** →predefined groups shown—custom groups can be local or domain-based

backup (backup\_operator) 506 →access to filesystems, checkpoints, VTLUs

filemover (filemover\_application) 507 →full control filemover & tasks

fullnas (nasadmin) 503 →RW access everything except root-only functions

nasadmin (operator) 201 →RO access to everything

network (network\_admin) 501 →RO access DMs, CS, CIFS Servers; RW network devices & services

opadmin (operator) 502 →RO access to everything

root (root) 0 →RW access to everything

security (security\_operator) 504 →RW access to user & role mgmt only

service (nasadmin) 500 →RW access to everything other than root-only function

storage (storage\_admin) 505 →RO access DMs; Full access storage, volumes, pools, file systems

### **Security>Administrators >Roles:** →default system-defined roles ([/nas/site/role](#))

1:root:system-defined:System Root Role:adminDomain,adminGroup,adminRole,adminUser, etc.

2:nasadmin:system-defined:Standard EMC Administrator Role:adminDomain,adminGroup,adminRole, etc.

3:operator:system-defined:Standard EMC Operator Role:task=\*!\*=collect,download,list,ping,validate

4:security\_operator:system-defined:Security Operator...Role Management and User/Group Management, etc.

5:backup\_operator:system-defined:EMC Backup Operator Role with full access to ckpt and VTLU, etc.

6:network\_admin:system-defined:EMC Network Admin Role:device, etc.

7:storage\_admin:system-defined:EMC Storage Admin Role:alert,clarionSystem, etc.

8:filemover\_application:system-defined:FileMover Application Role:dhsmConnection, etc.

### **Security>Administrators>Domain Settings:**

→Various domain properties displayed on this page

→Allows use of Active Directory or other Directory services for remote authentication of Users logging in through Celerra Mgr

### **REMOTE CELERRA MGR AUTHENTICATION/AUTO-USER CREATION:**

--Administrative User accounts can be local or mapped to domain-based accounts

--Domain-based User accounts require access to LDAP directory server for authentication before login can be successful, and must belong to at least one of the default or custom-created Groups on Celerra Mgr

--Domain-based users that are members of custom groups created in Celerra Mgr will be auto-created when the User account logs in, provided the LDAP server is available for authentication, and User uses domain password & name

### **REQUIREMENTS FOR USING DIRECTORY SERVICES:**

--FQDN

--IP Address of AD Server

--SSL Certificates if enabled [Port 636 when enabled, otherwise port 389 used if disabled]

--Use a Directory Services server type [Default Active Directory; Custom Active Directory; Other Directory Servers]

--Username & Password [Distinguished names & search paths for OpenLDAP]

### **OTHER DIRECTORY SERVICES [OpenLDAP]:** Additional fields required when defining OpenLDAP Directory Services:

Distinguished Name: cn=administrator,cn=Users, dc=nas10, dc=emc,dc=com

User Search Path: cn=Users, dc=nas10,dc=emc,dc=com

User Name Attribute: cn

Group Search Path: cn=Users, dc=nas10,dc=emc,dc=com

Group Name Attribute: cn

Group Class: <select from dropdown>

Group Member: uniqueMember

### **CELERRA PASSWORD MANAGEMENT:**

#### **Default Password Policies:**

→Min. password length 8 characters [6-15 possible]; Max. 3 attempts to define a passwd before failing; Min. 3 characters for new password that were not in the old passwd; Min. of 1 numeral in the password; Force passwd change after expiration period

→Password settings defined in /etc/pam.d/system\_auto, using pam\_cracklib.so, but not turned on, by default. Running the nas\_config –password command enables the use of policies

**Note:** Use /nas/sbin/nas\_config –password to set & modify password policies

→Password policies turned on or modified using /nas/sbin/nas\_config –password

→Use nas\_config –password –default to reset policies to defaults

→Policies do not apply to Nasadmin & Root User accounts

→Policies do not apply to user accounts authenticated by LDAP or AD services

#### **Password Expiration Policies:**

--Not managed or enabled by nas\_config utility

--Edit /etc/login.defs to modify or update available settings

--/etc/login.defs defines auto UID/GID min & max values used by the system, as well as password aging [default=99999 days]

### **PASSWORD CHANGE ISSUE FOR NASADMIN & ROOT:**

AR117242 & emc184679 documents that if CLI # passwd nasadmin command is used to change passwords, and then CS is rebooted, the password reverts back to the original. It appears that the “shadow-“ file is being copied back over the “shadow” file that does get changed during the password change command.

### **Changing nasadmin or root passwords using Celerra Manager with NAS 5.6:**

1. Log into Celerra Manager as root user

2. Navigate to Celerras>Security>Administrators>Users>rightclick & select properties for either nasadmin or root account, then change the password in the "Password" and "Confirm Password" boxes, then click apply.

**Note:** Using Celerra Manager properly updates the password and immediately synchronizes the change to /etc/shadow and /etc/shadow- files

### **References:**

→Celerra Manager Online Help seems to be the main documentation on Administrative Roles

### **5.6 FILEMOVER ENHANCEMENTS:**

--DHSM service can be stopped & restarted without impact to CS [server\_http service –stop | -start]

--FileMover commands issued by DART to port 5080, by CS to port 5081, Policy Engine can change port

--Threads can be updated on-the-fly

--fs\_dhsm offers ability to use HTTPS for connections

### **DART provides HTTP Server:**

# server\_http server\_x –service dhsm –start

### **5.6 VERIFYING DART HTTP SERVICE:**

# server\_http server\_2 -info

server\_2 : done

DHSM FACILITY CONFIGURATION

Service name: EMC File Mover service

Comment: Service facility for getting DHSM attributes

Active: True → This output indicates DART is running the HTTP Server

## **VERIFYING HTTP CLIENTS:**

# .server\_config server\_2 -v "httpclient audit"

1211900252: HTTP\_CLIENT: 6: dump of all http client:

1211900252: HTTP\_CLIENT: 6: -----

1211900252: HTTP\_CLIENT: 6:

dump of all http peers:

1211900252: HTTP\_CLIENT: 6: -----

1211900252: HTTP\_CLIENT: 6: HTTPCLIENT audit HTTP\_STATUS:200 OK

## **Troubleshooting HTTPS:**

--Setup Null encoding to troubleshoot problems (normally encrypted)

\$server\_http server\_x -modify DHSM -sslcipher NULL [when DM is an http server]

\$server\_config server\_x -v "param ssl cipher=NULL" [when DM is an http client]

--verify that certificate is good using server\_certificate

--verify that policy engine can connect to CS port 443

--verify xml\_api service running on CS

## **5.6 WINDOWS 2008 (Longhorn) SUPPORT:**

→ Windows Longhorn compatibility (DART can co-exist as a Windows 2003 member server)

→ Compatible with Vista clients

### **Windows 2008 Features:**

Self-Healing File System—system can perform online repairs, no more chkdsk offline, etc.

Multiple Sessions with Terminal Server—allows for faster User logons

Clean Shutdown—O/S will wait to shutdown applications gracefully vs. traditional 20 second timer

Kernel Transaction Manager (KTM)—better management of threads seeking access to same resources

SMB2—better network performance and scalability

Address Space Load Randomization (ASLR)—better protection against malware by using different memory locations to run kernel programs

Windows Hardware Error Architecture (WHEA)—standardization of errors reported on HW systems

Windows Server Virtualization—some hot pluggability added in SP release for hardware components

PowerShell—scripting language

Server Core—ability to install Servers for more specialized roles, without all the other baggage that usually comes

### **SMB2 Protocol:**

Support for more concurrent open files and number of shares

Better transaction support

Client Side Encryption

Support for symbolic links

Support for compounding operations, resulting in less overhead traffic

Support for larger buffer sizes

### **Limitations:**

→ W2008 Clusters not supported [new HA Shares and cluster technology]

→ Windows 2008 domain needs to run in Windows 2003 compatibility mode if NTLM is used for authentication

→ Or a DC change can be made: Computer Configuration>Administrative Templates>System>Netlogon>Allow cryptography

algorithms compatible with Windows NT 4.0

**Note:** Registry location is HKLM>Software>Policies>Microsoft>Netlogon>Parameters>Allow NT4Crypto

→ Not compatible with Vista clients using UAC (User account Control)

→ W2008 Offline folders not supported

→ W2008 FSR (File Replication Service) not supported

→ W2008 EFS (Encrypted File Systems) not supported

→ SMB2 protocol not supported (support added with 5.6.42)

## **5.6 OPENLDAP SUPPORT:**

→ iPlanet & OpenLDAP Directory Services support using SSL (RFC 2307)

→ Extension of iPlanet LDAP support for Network Information Service per RFC 2307, expected to be a replacement for traditional NIS architecture

→ Can support only a single LDAP domain, with DM as LDAP client

→ Uses file-based configuration /etc/ldap.conf file vs. iPlanet client configuration profile [DUAConfigProfile]

### **AUTHENTICATION RULES:**

--If binddn not used & SSL disabled = Anonymous [no SSL]

--If binddn & password used, but SSL disabled = Simple [no SSL]

--If binddn not used, sselpersona not used, but SSL enabled = anonymous over SSL

--If binddn & password used, and SSL enabled = Simple over SSL

--If binddn not used, and SSL enabled, and sslpersona configured = SSL-based CA

#### **SPECIFYING SIMPLE AUTHENTICATION:**

```
$ server_ldap server_2 -set -p -domain Celerra.pvt.dns -servers 10.241.168.21 -binddn
```

```
"uid=admin,ou=Administrators,ou=TopologyManagement,o=NetscapeRoot"
```

#### **SETTING LDAP DOMAIN:**

```
$ server_ldap server_2 -set -domain celerra1.pvt.dns -servers 10.241.168.21 [Using FQDN method]
```

```
$ server_ldap server_2 -set -basedn ou=celerra1, o=pvt, c=dns -servers 10.241.168.21 [Distinguished Name Format Base DN]
```

#### **ENABLING SSL:**

Configure on LDAP server first

```
$ server_ldap server_2 -set -sslenabled y [Uses port 636 by default]
```

#### **SETTING SSL PERSONA:**

```
$ server_ldap server_2 -set -sslpersona default
```

#### **SPECIFYING CIPHER SUITE:**

```
$ server_ldap server_2 -set -sslcipher default
```

#### **NAS 5.6 IPV6 PHASE I:**

→Available via RPQ only, supporting NFSv2, v3, FTP, TFTP & NDP protocols

→CIFS & NFSv4 are not supported with the GA release of 5.6

→CLI configuration

→DNS, NIS, local file, & LDAP lookup Name Service support

→Supported with DM failover & HA networking

→Hidden support for Stateless Autoconfiguration of IPv6 addresses per Autoconfig RFC

#### **STATELESS AUTOCONFIG IPv6:**

→Mandatory part of IPv6 protocol but does not work well with CIFS applications

1. Set param and reboot Server

```
param IPv6 autoconf=1
```

2. Enable AutoConfig manually using server\_ifconfig for Linklocal Broadcast Domain or automatically after using .server\_config EUI-64 address

```
$ server_ifconfig server_2 -create -Device cge0 -name cge0 -protocol IP6 3ffe:0000:3c4d:0015:0435:0200:0300:ED20
```

```
$ server_ifconfig server_2 -create -Device cge0 -name cge0 -protocol IP6 3ffe:0000:3c4d:0015:0435:0200:0300:ED20 /48
```

**Note:** Creating interface with a different network prefix length than the default 64

```
$ server_ifconfig server_2 -all -ip6
```

```
$ .server_config server_2 -v "ifconfig cge0ll device=cge0 protocol=IP6 local=link vlan=0"
```

3. DART listens to Router Advertisements and configures Global IPv6 addresses for each Network prefix advertised

4. Names for addresses will be auto-created and assigned by DART for each device

cge0\_0\_bd= broadcast device cge0 with Vlan 0

#### **CREATING LINK LOCAL ADDRESS FOR A DEVICE:**

```
$ server_ifconfig server_2 -create -Device cge1 -name cge1 -protocol IP6 fe80::260:16ff:fe0b:1234
```

#### **NAME SERVICE INFORMATION:**

```
$ server_dns server_2 -ip6
```

```
$ server_nis server_2 -ip6 | -status
```

#### **NFS EXPORT SYNTAX:**

```
$ server_export server_2 -Protocol nfs -option ro=172.30.55.0/255.255.255.0:[ef20:4567:8900::9abc:1000] /fs1
```

**Note:** Example of access list with both IPv4 and IPv6 addresses—note the [ ] for IP6 and colon separator between addresses

#### **DAD (Duplicate Address Detection):**

a) Two Neighbor Solicitations are sent for every IP6 address when an interface is first brought online, or configured, at 200ms intervals

b) If a Neighbor Advertisement is received within 600ms, the address is marked as a Duplicate and requires User intervention

#### **DART PARAMS FOR DAD:**

param IPv6 dadtimer [time between each Neighbor Solicitation]

param IPv6 dadCount [number of NS's sent]

#### **CLEARING AUTO CONFIGURED INTERFACES:**

```
$ .server_config server_2 -v "ifconfig clearauto"
```

#### **CHECKING CONNECTIVITY:**

```
$ server_ping6 server_2 -interface cge0 3ffe:0000:3c4d:0015:0435:0200:0300:00aa
```

```
$ server_ping6 server_2 -send 3ffe:0000:3c4d:0015:0435:0200:0300:00aa
```

**Note:** Examples of pinging from cge0 to a network host and continuous pinging to a network host

#### **ENABLING VLAN ON A DEVICE:**

```
$ server_ifconfig server_2 -create -Device cge0 -name cge0 -protocol IP6 3ffe:0000:3c4d:0015:0435:0200:0300:ED20 vlan=40
```

```
$ server_ifconfig server_2 cge0 vlan=40
```

**REMOVING THE VLAN TAG FROM A DEVICE:**

```
$ server_ifconfig server_2 cge0 vlan=0
```

**NAS 5.6 GIDMAP ENHANCEMENTS:**

→gid\_map enhancements for DUDL—automatic copy of gid\_map kept, new default size 262152 bytes. Corruption of original and copy of gid\_map would still require restore from backup

**MANUALLY RECOVERING GID MAP FROM LOST+FOUND:**

- server\_mount server\_x -o gid32Ignore fs1 /tmp
- look for gid\_map in lost\_found [identify by size 262152]
- verify file \$.server\_config server\_2 -v "gidmap chkfile /tmp/lost+found/fs1"
- copy file to file system .etc directory as gid\_map
- remount file system without the gid32Ignore option

**RESOLVING GID MAP CHECKSUM ISSUES:**

- Look for checksum issue in the Server Log
- Add to /nas/server/slot\_x/param  
param ufs fixGidCorruption=1
- Reboot Data Mover and checksums should be corrected on remount
- Remove param and reboot Data Mover

**GID Map Commands:**

```
$ server_mount server_x -o gid32Ignore fs1 /tmp [mount without the gid32 function]
$ .server_config server_x -v "gidmap chkfile /tmp/<path>" [verifying a gid_map file]
$ server_file server_x -put <file> /fs1/\Vetc/gid_map [copying gid_map to a location]
$ .server_config server_x -v "gidmap resetchecksum /fs1/.etc/gid_map" [resetting checksum of gid_map]
```

→Conversion of IUsermapper, Shares, Secmap to Berkeley database (NameDB)—dbms database format

**GID MAP ISSUE DURING UPGRADES TO NAS 5.6 (emc197578):**

File Systems may not be mounted after upgrading to NAS 5.6 because the gid\_map file size has been corrupted. PreUpgrade check has been built to flag this so that corrective action can be taken prior to the upgrade, rather than recovering file systems after the upgrade. Correct size of gid\_map for NAS 5.6 is 262152.

**PreUpgrade Check:**

E000124: File system (fs01 ufs /fs01 server\_2) mounted on server\_2 gidmap file is the wrong size (524288) it should be (262144). Check Primus Solution EMC197340 for additional information.

**Recovery Steps if File Systems are unmounted:**

- Permanently unmount the affected file system.  

```
# server_umount server_X -p <fs_name>
```
- Mount the affected file system to an ALTERNATE mountpoint with rw and gid32ignore options. IMPORTANT: Make sure you an ALTERNATE mountpoint so that the file system cannot be accessed via its original exports and shares during this procedure.  

```
# server_mount server_X -o rw,id32ignore <fs_name> /<TEMP_mountpoint>
```
- Get a copy of the wrong-sized gid\_map file from the affected file system.  

```
# server_file server_X -get /<TEMP_mountpoint>\Vetc/gid_map /<workdir>/gid_map_<fs_name>
```
- Verify the wrong size, truncate the file to correct size, and verify new size.  

```
# ls -l /<workdir>/gid_map_<fs_name>
-rw-r--r-- 1 root root 524288 Sep 17 17:20 gid_map_<fs_name>
# dd if=/<workdir>/gid_map_<fs_name> of=/<workdir>/gid_map_<fs_name>_fixed bs=256k count=1
1+0 records in
1+0 records out
# ls -l /<workdir>/gid_map_<fs_name>_fixed
-rw-r--r-- 1 root root 262144 Sep 17 17:25 gid_map_<fs_name>_fixed
```
- Put the fixed gid\_map file on the affected file system.  

```
# server_file server_X -put /<workdir>/gid_map_<fs_name>_fixed /<TEMP_mountpoint>\Vetc/gid_map
```
- Permanently unmount the affected file system.  

```
# server_umount server_X -p <fs_name>
```
- Remount file system to original mountpoint making sure to specify "rw" option and any other original mount option recorded in the prestep.  

```
# server_mount server_X -o rw,<other original options> <fs_name> /<original_mountpoint>
```
- Clean-up any temporary mountpoints created during this procedure, and clean-up or save working directory files as desired.

**NAS 5.6 PERFORMANCE STATMON TOOL (server\_stats):**

→Creation of performance statistics tool for DART similar to sysstat output and Unix SAR (nas\_stat & server\_stats)  
→Serves as single interface for statistic collection for DART components CPU, CIFS, NFS, CACHES, NET, DVOL, FS VOL  
→Two types of collection: Summary and Table collections

**Note:** Data Mover will use a “statmonService” listening on port 7777, and can be disabled in /nas/server/slot\_x/eof file by commenting out:

**/nas/server[slot\_\*/eof]**

# statmonService start port=7777 allow=128.221.252.100:128.221.252.101:128.221.253.100:128.221.253.101

--Statistics will be high-level system summaries (by kibibytes = 1024 bytes), and in-depth table collections by logical unit

**\$ server\_stats**

USAGE:

server\_stats &lt;movername&gt;

[ { -summary {basic|cifs|nfs|caches} [...] ]

| -table {net|dvol|fs|voll|cifs|nfs} [...] →Table format to be used

| -table {net|dvol|fs|voll|cifs|nfs}

| -sort &lt;field\_name&gt;

| -order {asc|desc}

| -lines &lt;lines\_of\_output&gt; ] [...] ]

} [...] ]

[-count &lt;count&gt;] →Number of reports by interval period, default is 10,000

[-port &lt;port&gt;] →Default port to DMs is 7777

[-interval &lt;seconds&gt;] →Default is 15 seconds

[-terminationsummary {no|yes|only}] →Gives user choice of seeing ctrl+c termination summary message or not. ‘Only’ option suppresses time series and only reports the summary. Default is ‘yes’.

[-format {text|csv}] →Default is text

[-titles {never|once|repeat}] →Controls generation of titles for reports

**# server\_stats server\_2**

server\_2 CPU Network Network dVol dVol

Timestamp Util In Out Read Write

% KiB/s KiB/s KiB/s KiB/s

09:39:42 0 0 0 128 11

09:39:57 0 0 0 128 477

09:40:12 0 0 0 128 4

09:40:27 0 1 1 129 116

server\_2 CPU Network Network dVol dVol

Summary Util In Out Read Write

% KiB/s KiB/s KiB/s KiB/s

Minimum 0 0 0 128 4

Average 0 0 0 128 125

Maximum 0 1 1 129 477

**Note:** Default interval is 15 seconds. Stop server\_stats polling to console using ctrl + c**\$ server\_stats server\_2 -summary basic | cifs | nfs | caches****Note:** Basic provides system overview, CIFS provides cifs summary, NFS provides nfs summary, & Caches provides memory summary for DNLC, Open Files, & Buffers.**\$ server\_stats server\_2 -i 3 -c 5****Note:** Example of basic summary with 3 second interval for total of 5 counts**\$ server\_stats server\_2 -summary basic,nfs,cifs,caches -table net,dvol,fsvol,nfs,cifs -interval 10 -format csv -count - > /tmp/stats.txt****Note:** Example of a command used to investigate a performance issue with SMB2, results written to the file in 10 second increments**5.6 CCMD MESSAGES:**

→CCMD will change logging mechanisms on DART &amp; CS. LogEvent interface for DART will be enhanced to handle CCMD messages, on-disk format will be changed, and logmsg interface will be enhanced for Server Log. CS sys\_log format will be changed to CCMD, and nas\_eventcollector, nas\_eventlog, PostEvent CLI, ReportEvent API, nas\_event, etc., all will be enhanced to support.

**5.6 FILE SYSTEM FAULT CONTAINMENT/FAILOVER:**

→File System fault containment and failover to be allowed [user must initiate manual fsck]

→Auto-FSCK will not be started automatically on detection of file system corruption. Rather, the fs will fail to mount. This will allow Data Mover to come back up with all other file systems active.

→Failover from production slot to failover slot will succeed if mount fails on any file system by continuing to mount all others and completes the failover process

**# server\_param server\_2 -facility ufs -info skipFsck -v**

server\_2 :

name = skipFsck

facility\_name = ufs

default\_value = 1

current\_value = 1  
configured\_value =  
user\_action = none  
change\_effective = immediate  
range = (0,1)  
description = If enabled, fsck will not be run on a corrupted FS while booting up and FS will be left unmounted.

#### **UNCORRECTABLE SECTOR ISSUE:**

See AR114835. GA release will not have either Rvector or cse\_recover utilities for repairing Uncorrectables until Maintenance release 2, so the fallback will be to use Volcopy in the interim.

#### **5.6 DUMP ENHANCEMENTS:**

→Dump enhancement adds two new Panic Handler codes

RC\_DART\_PANIC\_HANDLER\_COMPLETE(16) →CS initiates DM failover after initial panic

RC\_DART\_PANIC\_DUMP\_COMPLETE(13)

#### **5.6 iSCSI SNAPS IMPROVEMENTS:**

→iSCSI is a network service that runs on top of TCP/IP on the Data Mover

→iSCSI snaps & replication management via CLI, iSCSI Replication integration (CLI & GUI), iSCSI AIX NACA Support (SCSI-3 error handling over full duplex and non-interlocked parallel buses; if CHECK condition is encountered, all other commands are put on hold until the condition is cleared)

→Writes are optimized since indirect block copies occur asynchronously

##### **PLU:**

Production Logical Unit—primary iSCSI object that is a file that has space persistently reserved in a file system. Space is always reported as consumed from Celerra file system perspective, but Client may only be using x\_number of actual blocks.

##### **SLU: “Snapshots”**

Snap Logical Unit—contains pointers to blocks allocated by PLU.

--Size is number of used blocks written to PLU at time of snap creation, or number of new blocks allocated since a previous snap

--Created by Host Application, Replication Manager, or now, via Celerra CLI

--Up to 2000 snaps per Data Mover

--Snapshots are crash consistent only

##### **TWS:**

Temporary Writable Snap—Becomes a Writeable version of the SLU when the SLU is promoted to an iSCSI Initiator; used during Snap Promotion and Restore. All contents deleted when a snap is demoted.

##### **Commands:**

**\$ nas\_license –create iscsi**

##### **CREATING SNAPSHOT:**

**\$ server\_iscsi server\_2 –snap –create –target ns22 –lun 0 –data “snap1” | -info** (Application label = CelerraCS for CS-created snaps) | -list | -modify | -delete | -promote <snap\_name> -initiator <initiator\_name> | -Demote <snap\_name> -Force [cmd extended to manage snaps from Dart]

##### **DELETING SNAPSHOT:**

--Must demote first

--Use -Force switch if a snapshot created by some application other than CS CLI

**# server\_iscsi server\_2 –snap –delete snap1 | -target ns22 –lun 0**

##### **RESTORING PLU FROM SNAPSHOT:**

**# server\_iscsi server\_2 –snap –restore snap1**

##### **SETTING UP ISCSI ON CELERRA:**

1. Create Target

**# server\_iscsi server\_2 –target –alias ns22 –create 1000:np=10.127.62.31**

2. Create LUN

**# server\_iscsi server\_2 –lun –number 0 –create ns22 –size 20G –fs fs\_iscsi –vp yes**

3. Set LUN Mask

**# server\_iscsi server\_2 –mask –set ns22 –initiator iqn.2006-01.com.emc.iscsi:rh-199 –grant 0**

4. Start & Verify iSCSI Service

**# server\_iscsi server\_2 –service -start**

**# server\_iscsi server\_2 –service -status**

#### **5.6 WRITEABLE SNAPS (WCKPT):**

→Writeable Snap creation—ability to turn baseline RO Snap/Checkpoint into R/W file system using Snapsure v2.5 technology

→Changed blocks are written to the SavVol [which is shared with RO checkpoints]

→Limit of (16) writeable snaps per PFS, but only one per RO baseline checkpoint snap

→Can have a total of 96 RO checkpoints, and 16 Writeable snaps, per file system

→Typically useful for backups, testing, fsck's, etc.

→Writeable snaps cannot be “scheduled” as can regular Snapsure Checkpoints, nor RO snaps if using Writeables

- Can manage Writeable snaps from GUI & CLI
- Can create, delete [must delete Writeable before baseline can be deleted], or restore Writeable snaps
- Baseline and Writeable snaps cannot be refreshed
- Deleted Writeable snaps return space to SavVol [though SavVol size never contracts and is reclaimed until all snaps deleted]
- WCKPT not visible from .ckpt directory or from Explorer
- Cannot take a Writeable Snap from Internal checkpoints

#### **BITMAP:**

Identifies the changed data blocks

#### **BLOCKMAP:**

Records addresses of saved data blocks

#### **Allowed Operations with Writeable Snaps:**

Can perform fs\_copy, nas\_copy, MPFS, nas\_fsck, NDMP, NMFS, mount & umount, export of WCKPT

#### **SavVol Full Scenario:**

- Code will automatically delete the oldest RO snaps to create enough space for expanding SavVol [inactivates Writeable if required]

#### **Creating Writeable Snap:**

**\$ fs\_ckpt fs1\_ckpt1 –Create –readonly n**

**Note:** Mounts automatically, but is not exported

#### **Default naming convention:**

**fs1\_ckpt1\_writeable1**

#### **Writeable Snap Restore—mount RO if doing manual CLI restore:**

**\$ /nas/sbin/rootfs\_ckpt fs1\_ckpt1\_writeable1 –n fs1 –Restore**

**Note:** Writeable restore from GUI remounts as RO before the Restore

#### **5.6 iSCSI LUN RECOVERY/HARDENING:**

→iSCSI LUN Recovery for data recovery and hardening (iSCSI LUNs are special files within the UxFs file system)—purpose of feature is to try and maintain LUN availability for recovery, etc.

1. First step would be to run FSCK to correct file system metadata

**Note:** Version Files are no longer truncated by nas\_fsck. Affected blocks are marked by a special -2 address. Each Version File represents a separate iSCSI LUN. File systems can contain a number of iSCSI LUNs, therefore Version Files. Version Files are presented to iSCSI Host as SCSI disk [LUN]

2. Second step would be to invoke iSCSI Host recovery application checks

**\$ server\_iscsi server\_2 –lun –info 1**

**Note:** Command summary will show lun as “Healthy” or “Corrupt”

#### **5.6 iSCSI DR ENHANCEMENTS:**

→Creation of a DR framework using Client/Server architecture

→Client agent used on iSCSI host

→Automated recovery steps and centralized recovery operations from RM GUI [Replication Manager 5.1]

#### **5.6 STORAGE HARDENING:**

→Storage Hardening: Basic Volume creation changes, maintenance states, and I/O failure handling

#### **5.6 DBCHK ENHANCEMENTS:**

→Checks DART in-memory tables against Control Station db

→Adds –local option to check db files from customer site

→DBCheck Enhancements

Checks for volume consistency between CS & DMs; checks AVM groups & profiles/storage profiles; checks Replication sessions

→Checks local and loop-back

**# /nas/tools/dbchk -**

usage: dbchk -fhlpqwxvVs

- f fast, skip long running checks
- h help, display this message
- l local, use files in current directory
- p probe, use server\_devconfig
- q quite, suppress all output and only set exit code
- v verbose, print extra information
- w warning, do additional checks for warnings
- x extra, additional long running error checks
- V Volume consistency check mode [can not be used with -l option]
- s Suggestion mode [used with (-V) option only]
- R Replication V2 consistency check mode[can not be used with -l option]

#### **5.6 NEW LOCATION FOR NASDB BACKUPS:**

**# ls -la /celerra/backup**

```
-rw-r--r-- 1 nasadmin nasadmin 326360 Jan 10 09:01 _dbms_backup.01.tar.gz

-rw-r--r-- 1 nasadmin nasadmin 2315532 Jan 9 23:01 _nasbkup.11.tar.gz
-rw-r--r-- 1 nasadmin nasadmin 2315598 Jan 10 00:01 _nasbkup.12.tar.gz
-rw-r--r-- 1 nasadmin nasadmin 3639417 Jan 10 09:01 nasdb_backup.1.tar.gz
-rw-r--r-- 1 nasadmin nasadmin 3425910 Jan 9 09:17 nasdb_backup.b.tar.gz
```

**Note:** Other location remains in /nas/var/backup—no more backups in /home/nasadmin

## NAS 5.6 DM CAPACITY INCREASES:

### DATA MOVER CAPACITY CHART FOR NAS 5.6:

|       |         |            |                                            |
|-------|---------|------------|--------------------------------------------|
| NSX   | 32TB/FC | 64TB/ATA*  | Clarion and/or Symmetrix, up to 4 backends |
| NS80  | 32TB/FC | 64TB/ATA*  | " "                                        |
| NS40  | 24TB/FC | 64TB/ATA*  | " "                                        |
| NS20  | 16TB/FC | 48TB/ATA** | ICA-only                                   |
| NS350 | 10TB/FC | 16TB/ATA   |                                            |
| NS700 | 16TB/FC | 32TB/ATA   |                                            |
| NS500 | 10TB/FC | 32TB/ATA   |                                            |
| 514   | 8TB/FC  | 32TB/ATA   |                                            |

\*64TB supported for ATA using B2D or MDL solutions [using RepV2]

\*\*48TB supported for ATA using B2D or MDL solutions [using RepV2]

## 5.6 PSEUDO IP DEVICES:

→Special Psuedo IP devices for Morgan Stanley, which will allow “pseudo” device to be created using server\_sysconfig, and management of RIP using server\_rip. Limit of one pseudo device per physical Data Mover, and no creation on VDMs. Purpose of feature is to allow for Disaster Recovery for Clients connecting to common destination IP address to access a service (NFS, CIFS, etc). RIPv2 will be supported and tunable via the server\_rip command.

## 5.6 CYCLINDER GROUP CACHE IMPROVEMENT:

→Cylinder group cache retention changes

Cylinder group cache will be periodically flushed to storage, but in-memory copies of cache are retained and apply LRU algorithms

## 5.6 AIX NACA SUPPORT:

→NACA support for AIX 5.2/5.3 O/S [Normal Auto Contingent Allegiance bit]

Error recovery feature in Unix for SCSI commands

If SCSI control byte is set for NACA=1, then a clear ACA request is needed to clear the error on the device

Celerra iSCSI targets will support Abort Task Set, Clear Task Set, and Clear ACA (new)

## SETTING UP AIX HOST FOR CELERRA iSCSI:

I. Install EMC ODM package on AIX host by copying package to /tmp directory, uncompressing, the using SMIT tool to install  
# /tmp/smit installp [Install “EMC CELERRA AIX Support Software”]

II. Configure iSCSI on AIX

- Run SMIT tool>Devices>iSCSI>iSCSI Protocol Devices>Change
- Select iscsi0 and use lsattr to get attributes and AIX Initiator Name
- Create Celerra file system(s), create target and bind to portal, then grant access rights to AIX Initiator Name
- Enter Celerra target info in /etc/iscsi/targets file on AIX host

10.169.1.10 3260 iqn.1992-05.com.emc:s2t1

e. Discover Celerra iSCSI Targets and Luns

cfgmgr -l iscsi0 | lsdev

## 5.6 CELERRA EVENT ENABLER Version 4.0.2(CELERRA CEE) [aka, CELERRA CEPA; CEPP]:

→Latest version 4.5.1

→64-bit version introduced with 4.5.0.4 July 2009

→Overall feature name is CEPA, Celerra Event Publishing Agent

→CEE stands for “Celerra Event Enabler”, which is a new framework that supports both CAVA and CEPA event publishing and processing [aka CEPP or CEPA]

→The CEPA feature is a system whereby DART CIFS servers will provide certain Event Notifications [file/directory create, open, close, delete, etc.; metadata file/directory & acl changes] via triggers and a delivery mechanism, to the CEPA Servers, which in turn directs the information to the CQM-based application for policy decisions, with CIFS Clients receiving notification from DART on whether the action was successful or has errored

→With the use of the CEPA API, 3rd Party CQM vendors can integrate with Celerra

→CEPA uses an API to support the processing and publishing of events from DART to registered applications

→CAVA is no longer referred to separately

→CQM stands for the Content/Quota Management Class of Application, which ties into the CEPA API to register, receive, and act on events taking place on Celerra CIFS Servers using IDL & XML DTD files [later rollouts will support Auditing, Indexing, & Monitoring Classes of Applications for Windows & NFS]

→The CEPA Client runs as the EMC CAVA service on a Windows Server

→CAVA has been in place for years and is the EMC agent running on a Windows system that communicates with AV engines for scanning of CIFS files

→Currently qualified vendors for CQM applications are NTP Software and Northern Parklife

→CEE is a framework to be used by CAVA and CEPA (Celerra Event Publishing Agent) facilities for CIFS protocol only, during the initial 5.6 release. Later CEPA code enhancements will provide Auditing and Event triggers for HTTP and NFS, etc.

**Note:** The CEE framework is installed using the EMC\_CEE\_Pack.exe. The Windows service that CEE runs under is the “EMC CAVA” service—‘Provides Anti-Virus and Event Publishing services for EMC NAS’. The CAVA service needs to be changed to run by a CAVA/CEE Windows Domain User account, not the default System account. Use the “Celerra Management” MMC snapin to grant the “EMC Virus Checking” & “EMC Event Notification Bypass” rights to the Domain Account used to run the “EMC CAVA” service.

→Phase I Cognac will cover the CQM Classes of Applications, which are based on Pre-Event blocking

→Phase II will add Auditing of CIFS events as a Class of Applications, using DatAdvantage (Varonis) as the 3<sup>rd</sup> party application

→CEPA is a facility within the CEE framework, responsible for processing & publishing events from DART to applications registered via the CEPA API

→CEPA API is the interface between the Windows CEPA Client and the CQM applications, using XML over RPC

→CEPA is an EMC agent running on a Windows system for providing external applications with notification and control functions regarding changes made by CIFS clients on file systems, in real time. Applications can register to receive event notifications and context (i.e., metadata) from Celerra CEPA.

### **CEPA FRAMEWORK:**

→DART contains the CAVA & CEPA functionality, called mechanisms, which consist of event triggers and a delivery method

→“CEPA functionality” is how we should refer to the Data Mover piece

→The Windows Server running the CEPA Facility is the Client API, and also runs the CAVA Facility, which runs as the EMC CAVA service

→“CEPA Client” or Server is how we should refer to the Windows API

→The CQM class of applications registers with the CEPA Client API, though all events are driven to the CQM application, not pulled

→Endpoints refers to the IP addresses of the Host that runs the CQM application, which communicates with CEPA Service via RPC

### **CEPA LIMITATIONS:**

→First release only applies to CIFS environment

→CLI interface only, no Celerra Manager functionality

→Only a single CEPA pool name is defined in the cepp.conf file (can use multiple CEPA Clients)

→CEPA Client API & CQM applications communicate using XML over RPC

→First Cognac release offers only CQM (Content/Quotas Management)

→Data Mover CEPA facility acts as the originator of the CAVA or CEPA triggers, using Pre-Event Blocking of events flagged until CQM application delivers policy decision for each event

→Data Mover as CEPA facility sends out a regular heartbeat (every 10 secs.) to registered applications, and sends events of interest to the pool via round-robin service if more than one CEPA client is defined

→By default, with CEPA facility running on Data Mover, all file systems except the rootfs are subject to the Event Notifications setup in the cepp.conf file

### **Use following command to exclude specific file systems from CEPA:**

**# server\_mount server\_2 -option nocepp fs5 /fs5**

### **CLI INTERFACE:**

**# server\_cepp server\_2 -**

**server\_2 :**

Error 2100: usage: server\_cepp { <movername> | ALL }

**-service { -start | -stop | -status | -info } | -pool { -info | -stats }**

**\$ server\_cepp server\_x -service -stop | -start | -status | -info | -pool (-info -stats)**

**Note:** Service does not run by default and requires a valid /.etc/cepp.conf file on the Data Mover

## **DART CEPA EVENT POOL & STATES:**

DART's CEPA facility will place events into a CEPA pool to maintain "state", where a default heartbeat every 60 seconds checks each event pool member. A 10-second heartbeat checks each registered application.

### **EVENT POOL STATES:**

OFFLINE—CEPA Pool member is unavailable [do not send events]

ONLINE—CEPA Pool member is available [send events]

ERROR\_CQM\_OTHER—CEPA Pool member is ready, but cannot communicate with registered consumers [do not send events]

ERROR\_CQM\_NOT\_FOUND—CEPA Pool member ready, but cannot communicate with registered applications [do not send events]

UNKNOWN ERROR

### **CEPA APPLICATION STATE:**

ONLINE—CEPA communication to at least one registered application and is "ready to go"

OFFLINE—CEPA is up but cannot communicate to any applications

UN-REGISTERED—applications are present but not yet registered with CEPA

### **SUPPORTED CEPA EVENT TRIGGERS:**

OpenFileNoAccess, OpenFileRead, OpenFileWrite

CreateFile

CreateDir

DeleteFile

DeleteDir

CloseModified, CloseUnmodified

RenameFile

RenameDir

SetAclFile

SetAclDir

## **HOW DOES CEPA WORK?**

a) Celerra CEPA facility creates an Event trigger, which trap the Event & blocks the Client's request stream

b) Event Tuple & Context is formed on DART

**Note:** An event Tuple is: Event Tuple—Event type + associated metadata

c) Event Tuple is sent to the CEPP Pool as a CEPP request (using ONC RPC interface between CEPA Server & DART) for processing by the Server

d) CEPA Client passes request to CQM application for business policy decision using the CEPA API

e) Based on CQM policy rules, a response is returned from CQM application to the CEPA Client and on to the DART CEPA facility.

**Note:** If the response is "success", client request is allowed to proceed via DART CIFS Share. If response is "failure", client request is aborted and DART provides failure or error message back to client.

### **CEPA INSTALLATION OVERVIEW:**

→Install the framework on the Windows client from the [EMC\\_CEE\\_Pack\\_4.0.2.exe](#), which installs the CEPA framework, and runs under the control of the EMC CAVA service

**Note:** If installing on a system where CAVA was previously installed,, uninstall the previous CAVA version, then install the [EMC\\_CEE\\_Pack\\_xxx.exe](#)

→CQM applications must Register with the CEPP framework

→CEPA framework user context should be Domain Users who have EMC Virus Checking & EMC Event Notification Bypass rights, with the System account in the logon properties of the SCM [Service Control Manager] changed to run by the select User account.

→CEPP is disabled by default for root file systems on DART and enabled by default on all others. To disable Event Tuple formation [CEPA event triggers] from a specific file system, use the following mount option:

**"file mount ufs rw /home 2=2 nocepp"**

## **INSTALLING THE CEE FRAMEWORK/CONFIGURING CEPA ON CELERRA & WINDOWS:**

### **OVERVIEW STEPS:**

1. Ensure that a CIFS server, with Shares, is up & running in a typical AD environment [W2k, W2k3, etc]
2. Create cepp.conf file on the Control Station and transfer the file to the Data Mover .etc directory
3. Install the CEPA Client API application on a Windows system [Celerra Event Publishing Agent]
4. Go to the "EMC CAVA" service on the Windows CEPA Client, double-click the EMC CAVA service, then assign the selected Domain User account & password to run the service
5. Using the Celerra Management MMC snapin for the CIFS Server, set the CEPA user rights for EMC Event Notification Bypass and EMC Virus Checking
6. Perform Registry Edit on CEPA Client to define CQM application(s)
7. Reboot CEPA Windows Client
8. Start the CEPA facility on the Data Mover
9. Verify CEPA environment

**1. As a prerequisite, ensure that a CIFS server, with Shares, is up & running for a typical AD environment [W2k, W2k3, etc]**

**2. Create cepp.conf file using one of the following formats as a guide, then transfer the file to the Data Mover .etc directory:****cepp.conf EXAMPLE 1**

```
cifsserver=dbms          →Name of CIFS Server running CEPA client
surveytime=90             →Heartbeat Interval between checks for CEPA Client [default 60 secs, range 5-120]
ft level=1 location=/fs1 size=5   →CMR8 fault tolerance added (0-3); location=buffer file; size=size of buffer file
msrpcuser=domain.ceeuser    →Username for CAVA service
pool name=sepapool \        →pool name on Data Mover for CEPA [only a single pool name supported]
servers=192.1.4.236 \       →IP Address of CEPA Windows Server
preevents=* \              →Max. of 13 defined events, use asterisk to include all
postevents=* \              →Max. of 13 defined events, use asterisk to include all
posterevents=* \            →Max. of 13 defined events, use asterisk to include all [min. 1 event defined on one line]
option=ignore \ or option=denied →If CEPA not available, ignore errors, or return ‘access denied’ if using ‘denied’
reqtimeout=500 \            →Timeout ms when checking/waiting for access [default 1000, range 500-5000ms]
retrytimeout=50             →Timeout ms for retrying access request to CEPA Client [default 250, range 50-5000ms,
value must be equal to or greater than Request Timeout value]
```

**Caution:** Using “option=denied” in the cepp.conf file will result in loss of ReadWrite access to CIFS shares if the CEPA Client is unavailable for any reason! See emc178796 for more information.

**SYNTAX RULES:**

First two lines of the cepp.conf file [cifsserver & surveytime] are Global Variables, and must be defined on separate lines. The remaining entries can be defined on a single text line, or separated by individual lines using a backslash “\” with a space between the \ and the last character on the line [last line of the cepp.conf would not use a slash “\”]. Events can be defined individually [each event separated by the Pipe symbol “|”] or in total by using an asterisk \* to include all thirteen events. Multiple Server IP addresses for CEPA Servers would also be separated by the | symbol.

**cepp.conf EXAMPLE 2:**

```
cifsserver=dbms
surveytime=90
pool name=sepapool servers=192.1.4.236 preevents=* postevents=* posterevents=*
option=ignore reqtimeout=500 retrytimeout=50
```

**# server\_file server\_2 -put cepp.conf cepp.conf**

**3. Install the CEPA Server application on a Windows system [Celerra Event Publishing Agent]****EMC\_CEE\_Pack\_4.0.2.exe**

**Note:** This is a 36MB file shipped with all new systems on a separate kit called “Celerra Event Enabler Software Kit”, version 4.0.2

**4. Go to the “EMC CAVA” service on the Windows CEPA Server [Start>Run: services.msc], double-click the EMC CAVA service, then assign the selected Domain User account & password to run the service [Example: cepa\_user]****5. Using the Celerra Management MMC snapin for the CIFS Server, set the CEPA user rights for EMC Event Notification Bypass and EMC Virus Checking:**

a.) Celerra Management>Data Mover Management>Data Mover Security Settings>User Rights Assignment>EMC Event Notification Bypass

b.) Celerra Management>Data Mover Management>Data Mover Security Settings>User Rights Assignment>EMC Virus Checking

**Note:** This is the same Domain User account used to run the EMC CAVA service

**6. Perform Registry Edit on CEPA Server to define CQM applications**

Start>Run: regedit>HKLM>Software>EMC>Celerra Event Enabler>CEPP>CQM>Configuration>Endpoint

a. For test environment without NTP or Northern CQM software, doubleclick “EndPoint” and type “CeppEndPoint”

b. For NTP or Northern, doubleclick “EndPoint”:

Enter “ntp” or “northern” if CQM application installed locally

Enter “ntp@xxx.xxx;xxx.xxx” or “northern@192.1.4.236;192.1.4.237” to indicate location of Remote CQM application servers

**Note:** Use semicolon to separate multiple Remote CQM application Server IP addresses

c. Reboot CEPA Server

**7. Start the CEPA facility on the Data Mover:**

**# server\_cepp server\_2 -service -start**

**# server\_cepp server\_2 -service -status**

server\_2 : CEPP Started

**8. Verify:**

**# server\_cepp server\_2 -service -info**

server\_2 :

CIFS share name = \\DBMS\CHECK\$

cifs\_server = DBMS

heartbeat\_interval = 90 seconds

|           |                 |                       |             |               |
|-----------|-----------------|-----------------------|-------------|---------------|
| pool_name | server_required | access_checks_ignored | req_timeout | retry_timeout |
| sepapool  | No              | 0                     | 500         | 50            |

# server\_cepp server\_2 -pool -info

server\_2 :

```
pool_name = sepapool
server_required = No
access_checks_ignored = 0
req_timeout = 500ms
retry_timeout = 50ms
pre_events = OpenFileNoAccess,OpenFileRead,OpenFileWrite,CreateFile,CreateDir,Dr
post_events = OpenFileNoAccess,OpenFileRead,OpenFileWrite,CreateFile,CreateDir,r
post_err_events = OpenFileNoAccess,OpenFileRead,OpenFileWrite,CreateFile,Creater
CEPP Servers:
IP = 192.1.4.236, state = ONLINE, vendor = Unknown
```

# server\_cepp server\_2 -pool -stats

server\_2 :

```
pool_name = sepapool
Event Name      Requests    Min(us)     Max(us)     Average(us)
OpenFileNoAccess 587        934        35296       2115
OpenFileRead    264        932        34790       2689
CreateFile      80         1013       9194        1901
CreateDir       24         1001       3482        1699
DeleteFile      128        1359       4231        1682
DeleteDir       35         1029       2847        1505
CloseModified   76         997        3486        1563
CloseUnmodified 856        893        34596       2370
```

Total Requests = 2050

Total Min(us) = 893

Total Max(us) = 35296

Total Average(us) = 2224

#### **TROUBLESHOOTING CEPA:**

1. Use server\_cepp command to check statistics, Cepa Client status, Cepa facility status on Data Mover, etc.
2. Set debug logging and check server\_log messages

\$ .server\_config server\_2 -v "logsys set severity CEPP=LOG\_DEBUG"

\$ .server\_config server\_2 -v "param cepp"

| Name        | Location   | Current    | Default    |
|-------------|------------|------------|------------|
| cepp.Traces | 0x026f63f8 | 0x00000000 | 0x00000000 |

\$ .server\_config server\_2 -v "param cepp Traces=1"

**Note:** With 5.6, you may need to use \$ server\_log server\_x -i option to see trace output in the server log

3. Verify CEPA Service is running and using correct User account with correctly assigned EMC rights
4. Check Windows Event Logs on CEPA Clients
5. Have customer verify CQM applications [NTP Software or Northern Parklife, etc.]
6. Check connectivity to CQM and CEPA Clients
7. Verify that CEPA facility is running on the Data Mover
8. Verify whether “option=ignore” or “option=denied” is set in the cepp.conf file, which if set to the latter may result in CIFS ReadWrite denied if the CEPA Client is not available

#### **PARAMETERS IN 5.6.46:**

# .server\_config server\_2 -v "param cepp"

| Name              | Location   | Current    | Default    |
|-------------------|------------|------------|------------|
| cepp.RPCtype      | 0x03545098 | 0x00000003 | 0x00000003 |
| cepp.Traces       | 0x03544678 | 0x00000000 | 0x00000000 |
| cepp.clientTraces | 0x03545058 | 0x00000000 | 0x00000000 |
| cepp.lowWMFTSize  | 0x035446b8 | 0x00000050 | 0x00000050 |
| cepp.maxReqTO     | 0x02867bdc | 0x00001388 | 0x00001388 |

#### **COMMON ERROR MESSAGES AND CAUSES:**

# server\_cepp server\_2 -service -info →Data Mover CEPA service down

Error 13162905619: server\_2 : The CEPP facility is stopped.

# server\_cepp server\_2 -service -status →Data Mover CEPA service down

server\_2 : CEPP Stopped

# server\_cepp server\_2 -pool -info →Data Mover CEPA service down

Error 13162905619: server\_2 : The CEPP facility is stopped.

```
# server_cepp server_2 -service -start →Syntax problem with cepp.conf file
    Error 13162905607: server_2 : No CEPP server is defined.
# server_cepp server_2 -service -start →Missing cepp.conf file in /etc
    Error 13162905622: server_2 : Cannot open '/etc/cepp.conf'.
# server_cepp server_2 -service -start →Syntax problem in cepp.conf file
    Error 13162905604: server_2 : Invalid server IP: 192.1.4.236preevents=*postevent
s=*posterevents=*option=ignorereqtimeout=500retrytimeout=50ms.
# server_cepp server_2 -pool -info →EMC CAVA service not running
CEPP Servers:
IP = 192.1.4.236, state = OFFLINE, vendor = Unknown
# server_cepp server_2 -service -start
    Error 13162905605: server_2 : Invalid pre-event list: postevents=*.  

# cat cepp.conf
preevents=\ →Missing space before "\", invalid syntax in cepp.conf file
# server_cepp server_2 -service -start
    Error 13162905613: server_2 : No CEPP pre-events / post-events defined.  

# cat cepp.conf
preevents= \
postevents= \
posterevents= \ →need at least one event listed on one of these lines
```

#### Option=ignore vs. Option=denied in cepp.conf file

→When option=ignore is set, server\_cepp –service –info shows that “server\_required” is set to “No”, and in a practical sense means that if the EMC CAVA service or CEPA Client disappears, CIFS Users will still have access to the Shares  
→When option =denied is set, the server\_cepp –service –info shows that “server\_required” is set to “Yes”, and means that if the CEPA Client or CAVA Service hung, CIFS RW access to the Shares would result in Error Deleting (or Copying) File or Folder popup message—see emc178796

Using Celerra Event Publishing Agent (CEPA), 300-006-003 A01  
Celerra Event Publishing and Processing for NAS 5.6--Engineering TTT  
Man Pages & Command Reference Guide

#### CEPA COM VENDORS:

NTP Software QFS, Northern Parklife NSS  
**FUTURES:**  
New class of application for Auditing of CIFS events, using Post\_Events, hence is not blocking—Cognac maint release  
CEE Monitor will provide centralized configuration & management of CEPA, along with a GUI display  
CEE Indexing class of application, e.g. Google Search Appliance

#### NAS 5.6 CELERRA DBMS [Database Management System] aka BDB:

With the introduction of NAS 5.6, the Celerra implements a collection of Berkeley databases that are managed under the DBMS environment (sleepycat.com). The various “applications” that use DBMS are: Usermapper, Secmap, VDMs, Celerra Replicator, and other obscure functions. One of the main purposes of this feature was to offload the nameDB databases from the rootfs, which consumed large numbers of inodes, often leading to DU events and the need to manually extend the rootfs to create more inodes.

The two features that are most affected by this new database format are Usermapper & Secmap, which are converted from the nameDB format to DBMS format during the upgrade. The conversion from nameDB to DBMS is automatic and seamless, but it is important to know that the Usermapper and Secmap databases are still managed & repaired strictly from the “application” and not through DBMS [e.g., server\_usermapper and server\_cifssupport -secmap, respectively].

#### DBMS:

→DBMS consists of a series of independent Berkeley databases to support each “application” that uses it  
→Used by Secmap, Usermapper, VDMs, Replication, NAS Events, NFSv4, & other applications  
→Comprised of a set of Base Names & Tables (databases) that are made up of rows with Primary Key values and raw data  
→Consists of Tables, Transaction Manager, Lock Manager, Record Cache Manager, and Secondary Key Tables, which are created in memory only, having Primary & Secondary Key values

#### LIMITATIONS:

--As of 5.6 GA, the ShareDB database for CIFS exports remains and has not yet been converted to DBMS format  
--Databases are not Celerra global, but managed for each Data Mover or VDM separately  
--DBMS does not automatically compensate for disk size constraints or change its default memory cache values [i.e., manual tuning]  
--DBMS maintenance would require the CIFS service or other Application [e.g., Usermapper] to be stopped to close the database, though the server\_dbms -db -check function itself is not enabled for Usermapper or Secmap in the initial Cognac release. Instead, any Usermapper or Secmap database maintenance would occur at the application level, using server\_usermapper or server\_cifssupport -secmap, as examples.

# server\_dbms server\_2 -db -check Usermapper

server\_2 :

Error 13159432299: server\_2 : Invalid checkTable action. See AR111218 for more detail.

# server\_dbms server\_2 -db -check Secmap

server\_2 :

Error 13160874015: server\_2 : Invalid checkTable action.

#### **Pre-NAS 5.6 Roots Inode Consumption & Database Types:**

Server Shares [export.shares] consume 1 inode per Share in ./etc/shares/@COMPNAME or @GLOBAL [ShareDB]

Usermapper entries consume 4 inodes for every User or Group entry [nameDB]

SecMap consumes 2 inodes for every User or Group entry added [nameDB]

#### **NAS 5.6 Roots Inode Consumption & Database Types:**

Server Shares are unchanged and still consume 1 inode for every Share created [ShareDB--convert to DBMS format in 5.6 maint.?]

Usermapper entries have been converted to dbms and inodes reclaimed by rootfs [DBMS]

SecMap entries have been converted to dbms and inodes reclaimed by rootfs {DBMS}

#### **MANAGING DBMS ON CELERRA:**

# server\_dbms server\_2

server\_2 :

Error 2100: usage: server\_dbms { <movername> | ALL }

```
-db
  -list [<db_name>]
  |-delete <db_name>
  |-compact [<db_name>]
  |-check <db_name>
  |-repair <db_name>
  |-stats [<db_name> [-table <name>]] [-reset]
  |-fullbackup -target <pathname>
  |-incrbackup -previous <pathname> -target <pathname>
  |-restore [<db_name>] -source <pathname>
  |-service -stats [transaction | memory | log | lock | mutex] [-reset]
```

# server\_dbms server\_2 -db -list|grep BASE

BASE NAME : Usermapper →Usermapper db [Tables: aliases; usrmapping; idxname; usrmapping; usrgroupmapping; usrmapping; groupmapping; usrmapping]  
BASE NAME : db\_Cmd →Stores in-progress cmds for Repl. or NAS Events [Tables: CmdTable & ConfigurationTable]  
BASE NAME : V4NameSpace →NFSv4 namespace database [Table: pseudofs]  
BASE NAME : Secmap →Secmap mapping database [Table: Mapping]  
BASE NAME : icon\_db →Interconnect records used by DART for Replication [Tables: icon\_tables & rsys\_table]  
BASE NAME : queue\_db →Stores session, task ids, operations, callers [Table: cmdQueue\_table]

**Note:** These are the various dbms databases for Cognac 5.6 release. Each database may have multiple tables.

#### **HOW CAN I DETERMINE ACTUAL SIZE OF TOTAL DBMS DATABASES:**

# server\_dbms server\_2 -db -list|grep Size [server\_dbms only gives sizes for each “BASE NAME” database—add them to see totals or run /nas/sbin/dbms\_backup –totalsize]

**Size : 1826816**

|      |   |         |
|------|---|---------|
| Size | : | 8192    |
| Size | : | 8192    |
| Size | : | 327680  |
| Size | : | 1032192 |
| Size | : | 434176  |
| Size | : | 8192    |
| Size | : | 8192    |

**Size : 24576**

|      |   |       |
|------|---|-------|
| Size | : | 16384 |
| Size | : | 8192  |

**Size : 8192**

|      |   |      |
|------|---|------|
| Size | : | 8192 |
|------|---|------|

**Size : 970752**

|      |   |        |
|------|---|--------|
| Size | : | 970752 |
|------|---|--------|

**Size : 16384**

|      |   |      |
|------|---|------|
| Size | : | 8192 |
| Size | : | 8192 |

**Size : 8192**

Size : 8192

# /nas/sbin/dbms\_backup -totalsize

2854912

# server\_dbms server\_2 -db -stats Usermapper

**Note:** Outputs stats on the various databases, but in rather obscure format that is not user-friendly. The output is segmented by various Modules: LOG; LOCK; TXN; MPOOL; MUTEX

# server\_dbms server\_2 -db -stats &lt;db\_name&gt; -table &lt;table\_name&gt;

# server\_dbms server\_2 -service -stats [appears to output similar info as -db -stats, but is likely a global output]

# server\_dbms server\_2 -db -check Usermapper

server\_2 :

Error 13159432299: server\_2 : Invalid checkTable action.

**Note:** CCMD error string is logged to Server Log, minus the actual CCMD error message number

2008-01-09 14:44:45: USRMAP: 3: Invalid checkTable action.

# nas\_message -i 13159432299

MessageID = 13159432299

BaseID = 107

Severity = ERROR

Component = DART

Facility = USRMAP

Type = STATUS

Brief\_Description = Invalid \${action,8,%s} action.

Full\_Description = Checking and Repairing Usermapper database could not be performed.

Recommended\_Action = Use server\_cifssupport -usrmap to check and repair Usermap

**Note:** Apparently, the server\_dbms db check and repair functionality does not work, and the CCMD Error message that is generated is useless since server\_cifssupport cannot be used to repair a Berkeley database.

# server\_cifssupport server\_2 -usrmap

server\_2 :

Error 2100: usage: server\_cifssupport { &lt;movername&gt; | ALL }

```

    -usrmap
    -list
        {[ -name <name> [-domain <domain_name>]
          | -domain <domain_name>

#### DBMS REFERENCES:

##### --Man Pages for server\_dbms and server\_cifssupport:

server\_dbms allows for backup and restore of the databases, as well as statistics about the db environment. Specifically, server\_dbms can perform recovery of db's from media or application corruption, as well as perform checks & fixes of the databases.

#### --Celerra Command Reference Manual

#### NAS EVENTS FOR DBMS:

**# nas\_event -l -c DART -f DBMS** → Facility ID = 122

DART(1)

|--> DBMS(122)

BaseID Severity Brief\_Description

1 ALERT(1) The environment database of the VDM might be corrupted and a recovery procedure must take place

2 CRITICAL(2) Only \${freeblocks,3,%llu} free blocks in the root file system (fsid \${fsid,2,%u}) of the VDM \${vdm,8,%s}.

3 ALERT(1) The root file system (fsid \${fsid,2,%u}) of the VDM \${vdm,8,%s} is full. There are only \${freeblocks,3,%llu} free blocks.

#### HOW TO DETERMINE IF A MIGRATION HAS OCCURRED?

**Note:** A migration occurs when upgrading from any version prior to NAS 5.6 that contains SecMap or Internal Database entries

**# server\_cifssupport server\_2 -usrmap -migration**

server\_2 : done

SECMAP MIGRATION INFORMATION → Supposed to show Usermapper migration status, but title is mislabeled

Start : Wed Jan 9 14:13:32 2008 → Time is in GMT, not local

End : Wed Jan 9 14:13:32 2008

Status : Database has been successfully migrated.

#### Server Files on Rootfs After NAS Upgrade:

```
# pwd  
/nas/quota/slot_2/.etc  
# cat secmap.migration  
1199888015  
1199888022  
# cd usrmapper;ls  
usrmapper.migration usrmap.settings  
# cat usrmap.settings  
Identity=128.221.252.2,128.221.253.2 →This is Unix epoch time in seconds since 1/1/1970, which translates to Wed, 9 Jan 2008 14:13:32 UTC  
1199888023  
# cat usrmap.settings
```

Identity=128.221.252.2,128.221.253.2 →These equate to Usermapper running on Primary & Secondary Internal networks Server\_2  
Started=on

**Server Log:** DBMS migration begins after CIFS Service is started on Server reboot during NAS Upgrade

**Usermapper Conversion Entries:**

```
2008-01-09 09:13:32: USRMAP: 6: Starting usermapper service  
2008-01-09 09:13:32: USRMAP: 6: 8: The migration of the Usermapper database to the Celerra Network Server version 5.6 format has started.  
2008-01-09 09:13:32: USRMAP: 6: The migration of the Usermapper table "aliases" has started.  
2008-01-09 09:13:32: USRMAP: 6: The migration of the Usermapper table "aliases" was successful. "0" records have been migrated.

| dbms.param.dm.txmax         | 0x02677cc0 | 0x00000014 | 0x00000014 →Max concurrent transactions, DM (20)       |
| dbms.param.vdm.cache        | 0x02677ce4 | 0x00100000 | 0x00100000                                             |
| dbms.param.vdm.lgbsize      | 0x02677ce8 | 0x00001fa4 | 0x00001fa4 →Max trans. log buffer size BDB, VDM (8kb)  |
| dbms.param.vdm.lgmax        | 0x02677cec | 0x00500000 | 0x00500000                                             |
| dbms.param.vdm.lgregionmax  | 0x02677cf0 | 0x00010000 | 0x00010000 →Max log region size BDB, VDM (65kb)        |
| dbms.param.vdm.maxlockers   | 0x02677cf4 | 0x00000064 | 0x00000064 →Max number locking entities BDB, VDM (100) |
| dbms.param.vdm.maxlocks     | 0x02677cf8 | 0x00000064 | 0x00000064 →Max number locks BDB, VDM (100)            |
| dbms.param.vdm.maxobjects   | 0x02677cfc | 0x00000064 | 0x00000064 →Max number locked objects BDB, VDM (100)   |
| dbms.param.vdm.txmax        | 0x02677ce0 | 0x00000014 | 0x00000014 →Max concurrent transactions, VDM (20)      |

### PARAMETER TUNING:

Maximum number of concurrent transactions for CIFS or VDM Server are 20 decimal (14 hex):

```
# .server_config server_2 -v "param dbms param.vdm.txmax" "param dbms param.dm.txmax"
```

dbms.param.vdm.txmax INT 0x02677ce0 20 20 (0,4294967295) FALSE REBOOT 'NA'

## **BACKUP & RESTORE OF DBMS DATABASES:**

**Note:** See AR114590 for issues with manual restores using server\_dbms

### **I. AUTOMATIC BACKUP OF DATABASES:**

→The nasdb\_backup keeps up to three dbms backups in **/nas/var/backup/**

```
-rw-r--r-- 1 nasadmin nasadmin 241856 Jan 10 07:01 _dbms_backup.01.tar.gz
```

```
-rw-r--r-- 1 nasadmin nasadmin 241856 Jan 10 08:01 _dbms_backup.02.tar.gz
```

```
-rw-r--r-- 1 nasadmin nasadmin 241856 Jan 10 08:01 _dbms_backup.OK.tar.gz
```

→Backups are automatically initiated by /nas/sbin/nasdb\_backup script, which is run as Cron job, but calls **/nas/sbin/dbms\_backup**

```
-rwxr-x--x 1 nasadmin nasadmin 13515 Dec 20 12:07 dbms_backup
```

```
# /nas/sbin/dbms_backup
```

Usage: dbms\_backup

```
-totalsize
```

```
| -backup -file <filename> [ -dir <download_directory> ] | -help
```

### **CONTENTS OF DBMS BACKUP:**

```
# tar -zvxf celerra/backup/dbms_bak.1.tar.gz →Unzips and untars to /DBMS_BACKUP.2008-01-10_09-28/server_2/
```

```
# tar -zvxf celerra/backup/_dbms_backup.02.tar.gz →Unzips & untars contents to /DBMS_BACKUP.2008-01-30_15-32
```

DBMS\_BACKUP.2008-01-30\_15-32/

DBMS\_BACKUP.2008-01-30\_15-32/dbms\_download.2008-01-30\_15-32.log

DBMS\_BACKUP.2008-01-30\_15-32/server\_2/tb.db\_Cmd.CmdTable

### **II. CREATING MANUAL DBMS DATABASE BACKUPS:**

→Creates tar.gz backup and writes to default location /celerra/backup unless a specific path is requested

#### **1. USING dbms\_backup to create dbms backup:**

```
# mkdir /celerra/backup/restore
```

```
# cd /celerra/backup/restore
```

```
# /nas/sbin/dbms_backup -backup -file /celerra/backup/restore/dbms_backup.tar.gz
```

Backup server\_2 ... Done.

Archive and compress ... Done.

Remove the temporary directory ... Done.

```
# ls -la
```

```
-rw-r--r-- 1 root root 340714 Jan 30 15:57 dbms_backup.tar.gz
```

**Note:** The backup is written to the path indicated. If no path specified, the backup is written to /celerra/backup as a tar.gz file.

#### **2. Using server\_dbms command to create manual backup:**

```
# server_dbms server_2 -db -fullbackup -target /celerra/backup/restore/db
```

server\_2 : done

```
# server_dbms server_2 -db -fullbackup -target /celerra/backup/restore
```

server\_2 :

Error 2237: server\_2 : Execution failed: system error Directory not empty (errn)

**Note:** This method of creating a backup does not use tar.gz and requires an empty directory in order to write the files. Command will create a directory if not created ahead of time.

# cd /celerra/backup/restore/db

# ls -la

```
-rw-r--r-- 1 root root 8192 Jan 30 16:08 db.db_Cmd
-rw-r--r-- 1 root root 8192 Jan 30 16:08 db.icon_db
-rw-r--r-- 1 root root 8192 Jan 30 16:08 db.queue_db
-rw-r--r-- 1 root root 8192 Jan 30 16:08 db.Secmap
-rw-r--r-- 1 root root 8192 Jan 30 16:08 db.Usermapper
-rw-r--r-- 1 root root 8192 Jan 30 16:08 sk.db_Cmd.CmdTable.parentTask
-rw-r--r-- 1 root root 364544 Jan 30 16:08 sk.Secmap.Mapping.xid
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.db_Cmd.CmdTable
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.db_Cmd.ConfigurationTable
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.icon_db.icon_table
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.icon_db.rsys_table
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.queue_db.cmdQueue_table
-rw-r--r-- 1 root root 614400 Jan 30 16:08 tb.Secmap.Mapping
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.Usermapper.aliases
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.Usermapper.groupmapnamesid
-rw-r--r-- 1 root root 385024 Jan 30 16:08 tb.Usermapper.idxname
-rw-r--r-- 1 root root 466944 Jan 30 16:08 tb.Usermapper.usrgrpmapnamesid
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.Usermapper.usrmapc
-rw-r--r-- 1 root root 8192 Jan 30 16:08 tb.Usermapper.usrmapgrpc
-rw-r--r-- 1 root root 757760 Jan 30 16:08 tb.Usermapper.usrmapsrc
```

### INCREMENTAL BACKUPS?

# server\_dbms server\_2 -db -incrbackup -previous /celerra/backup/restore/db –target /celerra/backup/restore/db/incr  
server\_2 : done

**Note:** Incremental backup creates directory, but seems to act the same as a full backup

### RESTORING DBMS DATABASES:

#### I. Catastrophic Recovery

- Entire environment needs to be restored
- Quiesce all applications first
- DM rootfs must be consistent
- Database operations for backups and restores do not appear to be logged in sys\_log or server\_log—can set “logsys set severity DBMS=LOG\_DBG3” but the server\_log entries do not explain what is taking place

# server\_dbms server\_2 -db -restore –source /celerra/backup/dbms\_bak.1.tar.gz

#### II. Application Restore

- Application must first be stopped
- Delete existing dbms Usermapper database, or overwrite the existing db via the restore process

# server\_usermapper server\_2 –disable

# server\_dbms server\_2 -db –delete Usermapper

# server\_dbms server\_2 -db -restore Usermapper –source /celerra/backup/restore/dbms\_backup.tar.gz

server\_2 :

Error 2237: server\_2 : Execution failed: system error Not a directory (errno 20)

**Note:** Cannot do individual DBMS database restore from a tar.gz backup file!

→Either unzip and untar the dbms\_backup.tar.gz file, or find a directory that contains the necessary files from a server\_dbms -db –fullbackup in order to perform the Usermapper database restore

#### Example:

# server\_dbms server\_2 -db -fullbackup -target /celerra/backup/restore/db

#### Untar & Restore Example:

# tar -zxf dbms\_backup.tar.gz

# cd /DBMS\_BACKUP.2008-01-30\_15-57/server\_2;ls -la

```
-rw-r--r-- 1 root root 8192 Jan 30 15:57 db.db_Cmd
-rw-r--r-- 1 root root 8192 Jan 30 15:57 db.icon_db
-rw-r--r-- 1 root root 8192 Jan 30 15:57 db.queue_db
-rw-r--r-- 1 root root 8192 Jan 30 15:57 db.Secmap
-rw-r--r-- 1 root root 8192 Jan 30 15:57 db.Usermapper
-rw-r--r-- 1 root root 8192 Jan 30 15:57 sk.db_Cmd.CmdTable.parentTask
-rw-r--r-- 1 root root 364544 Jan 30 15:57 sk.Secmap.Mapping.xid
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.db_Cmd.CmdTable
```

```
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.db_Cmd.ConfigurationTable  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.icon_db.icon_table  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.icon_db.rsys_table  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.queue_db.cmdQueue_table  
-rw-r--r-- 1 root root 614400 Jan 30 15:57 tb.Secmap.Mapping  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.Usermapper.aliases  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.Usermapper.groupmapnamesid  
-rw-r--r-- 1 root root 385024 Jan 30 15:57 tb.Usermapper.idxname  
-rw-r--r-- 1 root root 466944 Jan 30 15:57 tb.Usermapper.usrgrpmapnamesid  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.Usermapper.usrmapc  
-rw-r--r-- 1 root root 8192 Jan 30 15:57 tb.Usermapper.usrmapgrpc  
-rw-r--r-- 1 root root 757760 Jan 30 15:57 tb.Usermapper.usrmapusrc
```

# pwd

/celerra/backup/restore/DBMS\_BACKUP.2008-01-30\_15-57/server\_2

# server\_dbms server\_2 -db -restore Usermapper -source /celerra/backup/restore/DBMS\_BACKUP.2008-01-30\_15-57/server\_2

server\_2 : done

#### **Restart Usermapper Application & Verify Records:**

# server\_usermapper server\_2 -enable

server\_2 : done

# server\_usermapper server\_2 -Export -user users

server\_2 : done

# server\_usermapper server\_2 -Export -group groups

server\_2 : done

# wc -l users groups

5196 users

30 groups

**Note:** Same number of Users and Groups verified before and after “Restore” testing

#### **III. Application Table Restore**

→Application must first be stopped

# server\_usermapper server\_2 -disable

# server\_dbms server\_2 -db -restore Usermapper -table usrmapusrc -source /home/nasadmin/usrmap/restore

### **RESTORING USERMAPPER & SECMAP DBMS DATABASES WITHOUT DELETING DBMS DATABASE FIRST:**

#### **1. Disable the Secmap or Usermapper "application" so as to "close" the dbms database in question**

# server\_usermapper server\_2 -disable (Closes the dbms Usermapper database)

# server\_setup server\_x -P cifs -o stop (Closes the Secmap database)

#### **2. Locate an acceptable dbms backup in /celerra/backup:**

# ls -la /celerra/backup/\_dbms\*

-rw-r--r-- 1 nasadmin nasadmin 1248366 Jan 30 21:01 /celerra/backup/\_dbms\_backup.01.tar.gz

-rw-r--r-- 1 nasadmin nasadmin 1248371 Jan 30 20:01 /celerra/backup/\_dbms\_backup.02.tar.gz

-rw-r--r-- 1 nasadmin nasadmin 340742 Jan 30 16:01 /celerra/backup/\_dbms\_backup.OK.tar.gz

#### **3. Unzip and untar the selected dbms backup file:**

# tar -zvxf /celerra/backup/\_dbms\_backup.02.tar.gz

#### **4. Navigate to the directory where the dbms database files were extracted:**

# cd /celerra/backup/DBMS\_BACKUP.2008-01-30\_15-32/server\_2

#### **5. Perform the Restore of the Usermapper or Secmap database:**

**Note:** Can only perform separate database restores from extracted files, not directly from tar.gz backup archives

# server\_dbms server\_2 -db -restore Usermapper -source /celerra/backup/DBMS\_BACKUP.2008-01-30\_15-32/server\_2

# server\_dbms server\_2 -db -restore Secmap -source /celerra/backup/DBMS\_BACKUP.2008-01-30\_15-32/server\_2

#### **6. Restart the Usermapper or Secmap databases:**

# server\_usermapper server\_2 -enable (Opens the dbms Usermapper database)

# server\_setup server\_x -P cifs -o start (Opens the Secmap database)

#### **7. Verify:**

# server\_usermapper server\_2 -Export -user <filename> | -group <filename>

# server\_cifssupport server\_2 -secmap -export -file <filename>

# server\_dbms server\_2 -db -list -->Check "BASE NAME" database information for Usermapper and Secmap

### **EXAMPLE OF DELETING & RESTORING USERMAPPER DBMS DATABASE:**

# server\_dbms server\_2 -db -delete Usermapper

server\_2 :

Error 13161332737: server\_2 : The Berkeley DB function deleteTable has return with the error Permission denied .

**Note:** Above error really means that the Usermapper application must be stopped before the db can be deleted

### **1. Perform manual backup of DBMS or verify existence of good backup in /celerra/backup**

# ls -la /celerra/backup/\_dbms\*

```
-rw-r--r-- 1 nasadmin nasadmin 333185 Jan 10 13:01 /celerra/backup/_dbms_backup.01.tar.gz  
-rw-r--r-- 1 nasadmin nasadmin 166805 Jan 10 14:01 /celerra/backup/_dbms_backup.02.tar.gz  
-rw-r--r-- 1 nasadmin nasadmin 166805 Jan 10 14:01 /celerra/backup/_dbms_backup.OK.tar.gz
```

**Note:** If restoring individual databases from tar.gz backup, you must first unzip and untar the backup file and then restore from the untarred location of the database and table files

# server\_dbms server\_2 -db -fullbackup -target /home/nasadmin/usrmap/restore

### **2. Stop Usermapper Service**

# server\_usermapper server\_2 -d

server\_2 : done

### **3. Verify current Usermapper dbms size and number of User and Group entries**

# server\_dbms server\_2 -db -list

```
BASE NAME      : Usermapper  
Size          : 1642496
```

# server\_usermapper server\_2 -Export -user users | -group groups

# wc -l users groups

5194 users

24 groups

### **4. Delete the Usermapper database**

# server\_dbms server\_2 -db -delete Usermapper

server\_2 : done

# server\_dbms server\_2 -db -list |grep -i usermapper

# server\_usermapper server\_2 -Export -user users [output will be 0 byte file, db is empty]

### **5. Restore Usermapper database from good backup location**

# server\_dbms server\_2 -db -restore Usermapper -source /home/nasadmin/usrmap/restore

server\_2 : done

### **6. Restart Usermapper Application & Verify**

# server\_usermapper server\_2 -enable

server\_2 : done

# server\_dbms server\_2 -db -list |more

```
BASE NAME      : Usermapper
```

Size : 1642496

# server\_usermapper server\_2 -Export -user users.bak

server\_2 : done

# wc -l users.bak

5194 users.bak

**Note:** Cannot perform the restore to individual dbms databases with the Application started, as the following shows when Usermapper is Enabled. Corrective action would be to stop Usermapper and then perform the restore.

# server\_usermapper server\_2

server\_2 : Usrmapper service: Enabled

Service Class: Primary

# server\_dbms server\_2 -db -restore Usermapper -source /home/nasadmin/usrmap/restore

server\_2 :

Error 2237: server\_2 : Execution failed: HTTP error 409 Conflict

### **CLOSING DBMS DATABASES:**

# server\_setup server\_2 -P cifs -o stop

# server\_dbms server\_2 -db -list

```
BASE NAME      : Secmap
```

Version : 1

State : Closed

Backup enabled : YES

Comment : CIFS Secure mapping database.

**Note:** Stopping CIFS closes only the Secmap database. Use server\_usermapper server\_2 -disable to close the Usermapper database. It is not yet known how the other dbms databases are closed.

### **DBMS MAINTENANCE:**

# server\_dbms server\_2 -db -compact Usermapper

server\_2 : done

**Note:** Compact command can reduce overall size of database, but ironically, seems to use more rootfs space & inodes

**Before Compact:**

# server\_df server\_2 /

server\_2 :

| Filesystem | kbytes  | used  | avail   | capacity | Mounted on |
|------------|---------|-------|---------|----------|------------|
| root_fs_2  | 3842416 | 11312 | 3831104 | 0%       | /          |

# server\_df server\_2 -i /

server\_2 :

| Filesystem | inodes  | used | avail   | capacity | Mounted on |
|------------|---------|------|---------|----------|------------|
| root_fs_2  | 3841022 | 1522 | 3839500 | 0%       | /          |

# server\_dbms server\_2 -db -list |head -7

Size : 1900544

**After Compact:**

# server\_dbms server\_2 -db -compact Usermapper

server\_2 : done

# server\_df server\_2 /

server\_2 :

| Filesystem | kbytes  | used  | avail   | capacity | Mounted on |
|------------|---------|-------|---------|----------|------------|
| root_fs_2  | 3842416 | 16184 | 3826232 | 0%       | /          |

# server\_df server\_2 -i /

server\_2 :

| Filesystem | inodes  | used | avail   | capacity | Mounted on |
|------------|---------|------|---------|----------|------------|
| root_fs_2  | 3841022 | 1523 | 3839499 | 0%       | /          |

# server\_dbms server\_2 -db -list |head -7

Size : 1642496

**5.6 UPGRADE CONSIDERATIONS:**

Peform nameDB backup of Secmap and Usermapper

**NAS 5.6 NTXMAP FEATURE:**

→Feature allows Users that may have different names in Unix and Windows, through the use of explicit unix-to-windows or windows-to-unix name mappings (using an ntxmap.conf file), to access file systems from either protocol while maintaining proper access

→This feature is not designed for environments where explicit mappings are required for more than 1000 users, as the ntxmap.conf file must be sequentially parsed for every mapping request, which could lead to authentication latency issues, potentially impacting CIFS user login and work sessions

→A populated ntxmap.conf file, with the explicit cross-protocol name mappings, is placed in the /.etc directory of the Data Mover

→The NTXMap feature provides mappings for Windows credential mappings and Unix to Windows mappings

**Windows credential mapping mechanism:**

CIFS User connects to the Data Mover, SIDs and Names are looked up via queries to the DCs, the ntxmap.conf file is then parsed for a matching Windows user name, and Domain if defined. If a match occurs, the Windows name is then mapped to the corresponding Unix name, and a UID is assigned via the normal mapping mechanisms

**Unix to Windows mapping mechanism:**

Unix user connects to Data Mover, Unix name is parsed in ntxmap.conf file, and if matched, then maps the corresponding windows user and domain names, and SIDs are obtained through the normal mapping mechanism for a Windows user

**NTXMAP.CONF FILE:**

```
# cat ntxmap.conf
w2k:w2ku40000=:unix40000
:W2KU40006=:unix40006
*:w2ku40007=:UNIX40007
w2k:cifs=20user=:unix40008
w2k:==00fcser=:unix40009
```

**Defining the syntax for the ntxmap.conf file:**

**domain:cifs\_user=:unix\_user**

w2k = Windows domain short name, or “netbios” name, not case-sensitive, and this field can be blank or can use a wildcard \* to indicate match the name in any Domain

w2ku40000 = Windows user name, not case-sensitive, use hex ascii [=20 →space] to represent a space in the user name, use hex unicode values to represent foreign characters [==00fc ü →umlaut]

==: Colons are required on each side of the = sign, and the = sign represents bidirectional mappings, which mean that a user can be mapped from either CIFS to Unix or from Unix to CIFS

Unix40000 = Unix name, which is case sensitive

**CHECKING NTXMAP CONFIGURATION FILE:**

```
# server_checkup server_2 -test CIFS -subtest ntxmap
```

Ntxmap : Checking the ntxmap configuration file..... Pass

```
# server_checkup server_2 -test CIFS -subtest ntxmap
```

-----Checks-----

Component CIFS :

Ntxmap : Checking the ntxmap configuration file..... Fail

-----CIFS : Ntxmap Warnings-----

Warning 17457807362: server\_2 : There is a syntax error in the file /etc/ntxmap.conf at line 4. Some users of the Data Mover cannot access some of the resources.

--> Fix the syntax error of the configuration file of the Data Mover. Use the following steps: 1) Get the config. file using server\_file -get command. 2) Edit the config. file using any text editor. 3) Restore the configuration file on the Celerra using server\_file -put

```
# cat ntxmap.conf
```

```
:w2ku40003=:unix40003
w2k:w2ku40004=:unix40004
W2K:w2ku40005=:unix40005
w2k::=:unix40006
```

→Line 4 missing username

**VERIFYING SECMAP ENTRIES FOR NTXMAP:**

```
# server_cifssupport server_2 -seemap -list |grep ntxmap
UID Origin Date of creation Name SID
36970 ntxmap Sat Feb 2 05:17:33 2008 W2K\W2ku40000 S-1-5-15-242a3a09-6bc5c62-3f32a78a-2b65
36973 ntxmap Fri Feb 8 12:51:08 2008 W2K\W2ku40003 S-1-5-15-242a3a09-6bc5c62-3f32a78a-2b68
36971 ntxmap Fri Feb 8 03:39:00 2008 W2K\w2ku40005 S-1-5-15-242a3a09-6bc5c62-3f32a78a-2b6a
```

**USE CASE 1:****CIFS User accessing Share for first time [No ntxmap.conf file]:**

Usermapper=W2kU40004

Secmap=W2k\W2kU40004 from “Origin” usermapper

Ntcred=(mapped=W2kU40004.W2K) →No ntxmap file

```
# .server_config server_2 -v "usrmap dump"
```

```

## ***COGNAC MAINTENANCE RELEASE PROGRAM***

**COGNAC 5.6 MAINTENANCE RELEASE 1 CMR1:** May 2008, 5.6.37.x

→CSA enhancements, new Checklist for install issues, Popup to advise using crossover cable for discovery issues

→New NS20 (NS20 Single Blade; NS20 Dual Blade; NS20FC Single Blade; NS20FC Dual Blade) and NS40 (NS40 Single Blade; NS40 Dual Blade) Installation Guides [replacing old Placemat docs]

→Support for Symm DMX4 Enginuity 5773, with support for SSD drives (73 & 146GB) and Solutions Enabler 6.5

**Note:** Not Thin Provisioning support

→Support for MPFS Write Back (new call, FMP\_WRITE)

**SYMMETRIX EFD DRIVES (Enterprise Flash Drives using flash-based solid state drives):**

--Symm Enginuity 5773

--SSD referred to as Tier 0 storage, 10x faster response times, 30x greater IOPs, less power required

--Uses 73 & 146GB drives with Raid5 3+1 or 7+1 only, min. of 1 Hot Spare per 32 drives

--new AVM pool symm\_ssd, not greedy, allows striping and uses 32K as default stripe size

--cannot mix with other drive types, nor use for SRDF or TimeFinder

--Symm Powervault drives must be traditional HDD

**ENTERPRISE FLASH DRIVE PERFORMANCE:**

--1ms latency vs. 6-12ms latency for 15K RPM HDDs

--For random Reads, will be 10x faster and provide up to 30x greater IOPs

--20x faster destaging of data to EFDs than HDD

--5 to 8x faster for sequential Read operations

**COGNAC 5.6 MAINTENANCE RELEASE 2 (CMR2):** June 2008, 5.6.38.x

→RepV1 to V2 upgrade script [upgrade method to abort current V1 sessions and use internal restart checkpoints to upgrade to V2], and Celerra Manager GUI enhancements [rightclick fs, iSCSI lun, or VDM to create new replication session; Bandwidth Schedule function]

→Symmetrix 5773 Thin Provisioning support (ability to present more storage to application than is really allocated, until needed)

→Backend Change Monitor tool officially released with NAS code (see emc195237 for more info)

→DUDL alerts will show on Home page Celerra Mgr

### **SYMMETRIX THIN PROVISIONING:**

--Manage via CLI or Symmetrix Management Console

### **BACKEND CHANGE MONITOR:**

→Collects backend configuration information, then tracks changes via SCCS

→Feature is configured during installation or upgrade to 5.6.38.2 or higher, as seen in NAS Upgrade log output  
upgrade.5.6.38-2.Jun-05-14\16.log

```
58      Set up backend monitor tool      0
=====
```

```
15:51 [ 58/67 ] Set up backend monitor tool      1 second
```

Start at: Thu Jun 5 15:51:00 2008

Complete at: Thu Jun 5 15:51:00 2008

→Feature is automatically kicked off by the NASDB backup script once every 24 hours, relying on timestamp of /celerra/backendmonitor/tmp directory to know when the last time it ran

```
# view /nas/sbin/nasdb_backup
```

```
# run backend configuration collector
```

```
/celerra/backendmonitor/bin/backend_change_monitor -d -m queryall
```

→Feature does not log when it runs in the sys\_log or elsewhere, but does update files in /celerra/backendmonitor directory if changes are captured

→Feature may indirectly create CallHome Warnings for backend or zoning changes that are flagged during the bi-weekly PAHC checkup

→Limited to monitoring of Cisco, McData, & Brocade switches, with SNMP queries for zone info only on Cisco & McData

→SCCS is used to track configuration changes, up to 1 year only

→Feature allowed to consume only 7MB in its home directory, /celerra/backendmonitor, which is an LVM directory

→By default, feature does not monitor any Switches—must set this up via separate –addentry commands to zonemonitor.cfg file

→Live configuration file is /nas/site/zonemonitor.cfg

### **CallHome Example:**

```
# cat /nas/log/checkup-run.080415-143003.log (PAHC Log)
```

Storage System: Check if backend zone correct session

Symptom:

\* The Data Mover in slot 2 HBA 5006016039a008f5 and Symmetrix/CLARiiON

HBA 5006016039a02c85 are in different zones on switch 10.32.22.64.

Action : The zones are not configured correctly.

### **sys log entry for CallHome:**

Apr 15 14:32:00 2008:87519264790::nas\_checkup has posted a warning. See /nas/log/checkup-run.080415-143003.log for more details.

**FEATURE DOES TWO THINGS:** Data Collection and Switch zone checks

### **DATA COLLECTION:**

#### **/celerra/backendmonitor/bin/backend\_change\_monitor**

**Note:** This is run on-demand by User, or by NASDB backup script daily, tracking system configuration changes

→Script runs multiple queries

run\_query\_clariion [runs hostip port –list, storagegroup –list, and checks if Integrated or not]

run\_query\_symm [list logins symmask]

run\_query\_dm [runs fcp show and fcp bind show on Data Movers]

run\_query\_switch [does snmpwalk for Cisco and McData switches]

### **ZONE CHECKS:**

#### **/celerra/backendmonitor/bin/check\_zone**

**Note:** This is run by PUHC and/or PAHC (situational/bi-weekly), checking zoning between Blades & Backend

→Check zone parses the data collection by the collection script, looking at the following rules:

--DM WWN zone vs. Clariion/Symm WWN zone, if not in same zone, will report bad zoning configuration

--DM WWN zone vs. Clariion/Symm WWN zone, if one is in a zone but the other is not, reports bad zoning configuration

--If neither DM or Backend WWNs are in a zone, will not report anything

### **Working Directory for Backendmonitor:**

#### **/celerra/backendmonitor**

```
# ls -la
```

```

#### **Default Configuration Files:**

**/celerra/backendmonitor/etc/weekly-backendmonitor.conf**

**/celerra/backendmonitor/etc/zonemonitor.cfg**

**/nas/site/zonemonitor.cfg** [this is the real configuration file location]

```
# cat weekly-backendmonitor.conf
# rotate log files weekly
# keep 12 weeks worth of backlogs
# and compress
/celerra/backendmonitor/data/SCCS/s.*.1 {
    missingok
    nocreate
    weekly
    compress
    rotate 12
}
# cat zonemonitor.cfg
# This is the configuration file for automatic configuration change
# monitor.
# Anything after the # character is ignored. Blank lines are also ignored.
# To get back to the default configuration file, simply remove or
# rename this file and a new one will be created
# next time automatic configuration change monitor runs.
# You may change this file if you wish,
# and if you do so, it will be recreated, and
# you will not receive any updates to this file should you
# choose to upgrade your control station software later.
# The following configurations are used by SNMP query.
# Please do not modify these unless instructed by
# authorized service personnel.
# zone-snmpquery ipadd1 switch-model1 community1
# For example:
# zone-snmpquery 10.6.27.85 cisco public
```

```
# zone-snmpquery 10.6.89.81 medata public  
# zone-snmpquery 172.24.97.203 brocade public
```

#### **BACKENDMONITOR CLI COMMANDS:**

**# /celerra/backendmonitor/bin/backend\_change\_monitor -config**

The list of switches being monitored:

No switch is being monitored.

#### **MODIFYING ZONEMONITOR CONFIG FILE:**

```
# /celerra/backendmonitor/bin/backend_change_monitor -addentry 10.6.27.85 cisco public  
# /celerra/backendmonitor/bin/backend_change_monitor -addentry 10.6.89.81 medata public  
# /celerra/backendmonitor/bin/backend_change_monitor -addentry 172.24.97.203 brocade public
```

**# /celerra/backendmonitor/bin/backend\_change\_monitor -config**

The list of switches being monitored:

10.6.27.85(cisco)

10.6.89.81(medata)

172.24.97.203(brocade)

#### **REMOVING SWITCH FROM MONITORING:**

**# /celerra/backendmonitor/bin/backend\_change\_monitor –removeentry 10.6.27.85**

#### **BACKEND CHANGE MONITOR COMMAND & HELP MENU:**

**# /celerra/backendmonitor/bin/backend\_change\_monitor -help**

usage: backend\_change\_monitor

| -help

| -config

| -addentry <hostname/IP> <switch model> <SNMP community>

| -removeentry <hostname/IP>

| -mode <option>

Options:

-help - this help screen

-config - Display the current configuration

-addentry - Add a switch to be monitored. <hostname/IP>  
is the hostname or IP address of the switch,  
<switch model> is either cisco, brocade, or  
medata, and <SNMP community> is the community  
string used for SNMP query against the switch

-removeentry - Remove a switch from being monitored.  
<hostname/IP> is the hostname or IP address of  
the switch

-mode - run checks specified by <option>. The option  
is comma seperated, and it can be:  
queryall: do all query.  
queryzone: query fibre switch config.  
querydm: query DM related issue.  
queryclarion: query Clariion.  
querysymm: query Symm.

## **COGNAC 5.6.39 MAINTENANCE RELEASE 3 (CMR3):** August 22, 2008, 5.6.39.5

#### **NS20 UPDATE:**

→Increase drive capacity from 60 to 90 FC or SATA drives, based on Flare 26 Patch 012 minimum

→Ability to perform “data in place” upgrades from NS20 to NS40 (Swapout of SPs, support for 240 drives)

**Notes:** Upgrades from CX3-10 or CX3-10F to CX3-40F. No upgrade allowed if using an NS20 with SATA vault drives.

#### **Upgrade Options:**

NS20 Integrated to NS40 Integrated (NS40 with Headhunter IO card on SPs, but without the FC-Enabled option)

NS20 Integrated to NS40FC

NS20FC to NS40FC

#### **REPLICATION ENHANCEMENTS:**

→IPRepV2 internal replication checkpoints will be hidden from GUI and CLI output by default (AR116012), but there will be an option to view the internal checkpoints. \$ nas\_fs –list –all and \$ fs\_ckpt –list –all will be added to output internal checkpoints, and an option called ‘All Checkpoints Including Those Used Internally’ will be added to the GUI.

→Replication Wizard enhancements in Celerra Mgr

#### **NX4 RELEASE:**

- Release of new NSX platform and support for Maynard Control Station
- Support for new Email User notification feature (aka, Local email support)
- CSA changes to support setting up ConnectHome email and Email User notification feature
- Support for new NX4 Backend Event Reporting mechanism (not based on Naviagent; based on StorageAPI)

### **EMAIL USER NOTIFICATION FEATURE:**

- Introduced with 5.6.39 in conjunction in NX4, but will also support NS20/NS40/NS80/NSX for new installations or upgrades
- Email User feature is independent of the ConnectHome Email feature—In otherwords, you could have a system where ConnectHome was not Enabled at all and yet the Email User notification was, and email would be delivered to the Recipient defined in the Email User feature
- Email User feature absolutely requires that the Control Station be properly configured with entries that would allow proper DNS lookup and resolution of the “Recipient Email Addresses” by FQDN  
e.g., bigdog@fido.pvt.dns

#### **Example of /etc/resolv.conf:**

```
# cat /etc/resolv.conf
domain fido.pvt.dns
search fido.pvt.dns
nameserver 192.168.4.10
nameserver 192.168.5.10
```

- Email User notification feature will allow customers to receive CCMD descriptive Email alerts for all Celerra CallHome events
- CallHome Immediate or Materials triggers Email Notification
- Basic configuration during CSA setup
- More extensive configuration possible from CLI or GUI
- Based on Sendmail application and using /var/log/maillog
- Driven by same nas events engine as are ConnectHome feature
- Feature requires Recipient Email address to be enabled
- Becomes part of the DBMS BDB system
- Email Server field is truly optional, and can be blank as long as DNS is properly configured to resolve the FQDN of the Recipient email address

#### **GUI Configuration:**

- Can configure as nasadmin or root user, unlike ConnectHome, which requires root login

#### **Celerras>Support>Email User**

Service Enabled checkbox

Recipient Email Addresses:

CC Email Addresses: (Optional)

Email Server: (Optional) →Would be required if sending email external to company's DNS domain, along with proper DNS search entries in /etc/resolv.conf. Email Server entries are written to line 101 in the /etc/mail/sendmail.cf configuration file. Use /sbin/service sendmail restart to restart Sendmail program.

Subject Prefix: Celerra Notification

Sender Email Address: (Optional)

**Note:** GUI changes for most fields are put into effect immediately. If changes are made to the “Email Server” section, the entries are written to the /nas/sys/email\_user.config immediately, but are not written to /etc/mail/sendmail.cf until an event trigger for Email User is generated, at which point the sendmail.cf file will be updated with new Email Server. Email User test button in GUI should work. Alternatively, use /sbin/service sendmail restart to update file immediately. AR126368.

#### **TESTING EMAIL USER FEATURE FROM CELERRA MANAGER>SUPPORT>Email User>Test**

- Test button should display “Test Email Notification Service. OK” and send a test message to the Recipient:

#### **TEST EMAIL USER MESSAGE:**

Date: Thu, 18 Sep 2008 14:32:12 -0400

From: smiley@acme.com

To: tmatta@sun1.hosts.pvt.dns

Subject: Celerra Notification - nx4.w2k.pvt.dns, INFO, EmailUser

Event Time: Sep 18 14:32:12 2008

Brief Description: Test event for Email User.

Full Description:

Test event for Email User.

Recommended Action:

No action is required.

Celerra Name: nx4.w2k.pvt.dns (192.1.4.230)

Celerra Model: NX4FC

Celerra Serial #: APM00081800232

NAS Version: 5.6.40-2

**CLI:****# nas\_emailuser**

Error 2100: Usage:

```
nas_emailuser
  -info
  | -test
  | -modify [ -enabled { yes | no } ]
    [ -to <email_addr>[,...] ]
    [ -cc <email_addr>[,...] ]
    [ -email_server <email_server> ]
    [ -subject_prefix <email_subject> ]
    [ -from <email_addr> ]
```

| -init →Creates a configuration file if one does not exist, /nas/sys/.email\_user.config

**# nas\_emailuser -info**

Service Enabled = Yes

Recipient Address(es) = user@domain.company.xxx.com

Carbon copy Address(es) =

Email Server = 10.68.150.240

Subject Prefix = Celerra Notification

Sender Address =

**Enabling/Disabling Email User Feature:****# nas\_emailuser -modify -enabled no | yes**

OK

**Note:** The recipient email address must be configured prior to enabling email notification**# nas\_emailuser -modify -enabled yes -to smiley@acme.com**

OK

**Example When Trying to Enable Feature without Valid Recipient:****# nas\_emailuser -modify -enabled yes**

Error 13693812739: The value for attribute 'emailTo' is invalid for the requested action.

**Example of Adding Multiple Recipient Addresses:****# nas\_emailuser -modify -cc user1@acme.com,user2@acme.com**

OK

**# nas\_emailuser -info**

Carbon copy Address(es) = user1@acme.com,user2@acme.com

**Recreating Default Email Configuration:****/nas/bin/nas\_emailuser –init** [Recreates default configuration file if none exists--/nas/sys/.email\_user.config]**Email User & ConnectHome Configuration File/Ownership/Permissions:**

# ls -la /nas/sys/.email\*

```
-rw-r--r-- 1 root  root  711 Jan 16 16:30 connecthome.config
-rw-rw-r-- 1 root  fullnas 130 Jan 14 15:08 .email_user.config
-rw-r--r-- 1 nasadmin nasadmin 10 Jan 14 15:08 ..email_user.config.sig
```

**Default Emailuser configuration (/nas/sys/.email\_user.config):****# nas\_emailuser -info**

Service Enabled = No

Recipient Address(es) =

Carbon copy Address(es) =

Email Server =

Subject Prefix = Celerra Notification

Sender Address =

**Backup Copy of Email User Configuration File:**

- If the file /nas/sys/.email\_user.config gets deleted or corrupted, may see following message

**# nas\_emailuser -info**

Error 13693812737: The email user service configuration file does not exist.

**# nas\_message -info 13693812737**

MessageID = 13693812737

BaseID = 1

Severity = ERROR

Component = APL

Facility = EmailUser

Type = STATUS

Brief\_Description = The email user service configuration file does not exist.

Full\_Description = The email user service configuration file, /nas/sys/.email\_user.config, does not exist.

Recommended\_Action = Copy the backup file /nasmcd/CHomeFiles/.email\_user.config to /nas/sys/ or use -init option to create the configuration file.

2. If available, copy the /nasmcd/CHomeFiles/.email\_user.config file back to /nas/sys/

3. Or, to recreate the config file: /nas/sbin/nas\_emailuser -init

#### **Testing EmailUser Feature:**

# **nas\_emailuser -test**

OK

# **nas\_logviewer -t /nas/log/sys\_log |tail**

Aug 28 10:32:09 2008:96109330532::Test event for Email User.

#### **Rules for Recipient Email Addresses:**

The mailbox portion of the fully qualified domain name (FQDN) uses the following ASCII characters: a-z, A-Z, 0-9, !, #, \$, %, &, ` , \*, +, -, /, =, ?, ^, \_, ` , {, |, }, ., and ~. Periods cannot be the first or last character in the mailbox. The maximum number of characters, including spaces and commas, is 255. Each email address can have a maximum of 63 characters.

#### **Comments on Configuring Email User feature:**

→ Set the sender email so that bounced emails go back to the Administrator

→ Sender email may be required for some email servers, depending on Customer's environment

→ If emails are sent external from Customer's network, then the Email Server field must be filled in with an Email Server that has access to the external network, along with configured DNS entries in /etc/resolv.conf for the external network

→ If the email send fails at the first email server, then sendmail will continue to retry for a few times, then gives up

→ CSA Wizard will be used to configure both ConnectHome email, and Email User notification

Issue with Email User Feature with NAS Upgrades:

→ During an upgrade to 5.6.39.5 or higher, the Email User feature must be initialized with its default /nas/sys/.email\_user.config configuration file. However, there are certain DNS misconfigurations on the Control Station that can cause the System Management service to take a long time to complete its initialization during the Upgrade process, and in turn may cause a Task 65 failure when trying to setup the email user feature:

**/install\_mgr -m upgrade**

=====Tasks=====

13:26 [ 65/68 ] Initial emailuser 15 seconds

Waiting for mgmtd to complete the initialization ...

nas\_emailuser failed to initialize: Error 13958709250: No response from Celerra

Manager for task Init Email Notification Service..

Error : Failed to initialize the emailuser feature.

Result: Failure

=====Task [65/68] "Initial emailuser" has failed.

#### **Workaround:**

1. Stop the System Management daemon on the Control Station:

# killall mgmtd

2. Tail log and wait for the Management Daemon to complete its restart:

# tail -f /nas/log/nas\_log.al.mgmtd

2008-11-17 12:50:32.409: INIT: 1: MGMTD initialization complete:

3. Initialize the default Email User configuration:

# /nas/bin/nas\_emailuser -init

OK

4. Start the NAS Upgrade

#### **Default contents of the hidden .email\_user.config file:**

# **/nbsnas/bin/nas\_emailuser -info**

Service Enabled = No

Recipient Address(es) =

Carbon copy Address(es) =

Email Server =

Subject Prefix = Celerra Notification

Sender Address =

#### **SCSI-3 PERSISTENT RESERVATION SUPPORT:**

→ Celerra now supports SCSI-3 Persistent LUN Reservations for Celerra iSCSI Targets (restrict or share access to SCSI LUNs)

→ SPC-3, SBC-2, & SAM-3 are used for this implementation

→Main purpose is for iSCSI target & cluster support for W2K8 & MS 2008 iSCSI Failover Clusters

**Note:** Client nodes will be able to register and reserve disk access rights as an I/O fencing mechanism for iSCSI luns where disks may be shared, as in Clusters. Persistent reservations are managed by the SCSI (SPC-3) subsystem

→Reservations are persistent through I\_T nexus loss, target resets, LUN resets, & power loss

→Cannot use both SCSI-2 Reserve/Release and SCSI-3 PR at the same time

#### **Configuring PR with MS Windows 2008 Clusters:**

1. Connect all hosts in the cluster for the Celerra iSCSI target

2. From MS GUI Failover Cluster Manager, create cluster

3. Optionally configure MPIO and add Celerra as “EMC Celerra” with five spaces between EMC and Celerra

#### **Server Log Example for code prior to Support with Windows 2008 iSCSI Clusters:**

2008-08-04 12:11:55: VLU: 3: SCSI op code 5e not supported

2008-08-04 12:11:58: VLU: 3: SCSI op code 5f not supported

#### **Persistent Reservation OpCode Commands:**

0x5E →Persistent Reservation In OpCode (Host cluster queries access rights db for SCSI LUNs from iSCSI targets)

0x5F →Persistent Reservation Out OpCode (Host cluster registers or reserve access rights to SCSI LUNs)

#### **PERSISTENT RESERVATION OUT SERVICE ACTIONS:**

REGISTER | RESERVE | RELEASE | CLEAR | PREEMPT | PREEMPT AND ABORT | REGISTER AND IGNORE EXISTING KEY | REGISTER AND MOVE

#### **PERSISTENT RESERVATION IN SERVICE ACTIONS:**

READ KEYS | READ RESERVATION | REPORT CAPABILITIES | READ FULL STATUS

#### **Configuring APTPL:**

→Purpose of APTPL is to be able to recover all PR information and state after power loss

→Disabled by default on Celerra

→Celerra can store PR information on disk if Hosts are configured and have requested this (APTPL—Activate Persist Through Power Loss—this can be enabled via Celerra parameter)

→MS Windows 2008 does not use the APTPL feature, though other Host Cluster implementations do

#### **# server\_param server\_2 -facility iscsi -info EnableAptpl**

server\_2 :

```
name      = EnableAptpl
facility_name = iscsi
default_value = 0
current_value = 0
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range     = (0,1)
description = Support PR Persist Through Power Loss
```

#### **# server\_param server\_2 -facility iscsi -modify EnableAptpl -value 1**

server\_2 : done

Warning 17716815750: server\_2 : You must reboot server\_2 for EnableAptpl changes to take effect.

#### **SCSI-3 Persistent Reservation Issue Resulting in Long Data Mover Failover Times--AR124930:**

→NAS 5.6.39, 5.6.40, & 5.6.41 exhibit long Server failover times if iSCSI LUNs are in use

#### **Workaround:**

Disable following parameter and reboot the Data Mover

#### **# server\_param server\_x -f iscsi -modify EnableAptpl -value 1**

#### **CLARIION LUN RENAME FEATURE (emc192005):**

→Celerra LUN rename feature for Clariion systems [Default CLARIION behavior is to name a LUN as “LUN 1”, etc., with Navisphere, and “Virtual Disk 201”, etc., with NaviExpress

#### **DEFAULT CLARIION LUN NAMES:**

→If Navisphere is used as the management tool, LUNs that belong to Storage Groups are labeled “LUN 6”, etc.

→If NavisphereExpress is used as the management tool, LUNs are known as “Virtual Disks” and default to names such as “Virtual Disk 201”, etc.

#### **FEATURE RULES:**

→Celerra LUNs will automatically be renamed during the diskmarking process or Celerra Manager Rescan

→Celerra LUNs, Storagegroup name, and Initiator Records, are renamed if Control Station Hostname is renamed via Celerra Mgr or CSA process

→Default Storage Group name

#### **Celerra\_<CS\_hostname>**

```
# /nas/sbin/navicli -h 10.241.168.188 storagegroup -list |grep "Group Name"
```

**Storage Group Name:** Celerra\_sludge4

→Default Server Initiator Record name will be the same as the Storage Group name, per the following format

**Celerra\_<CS\_hostname>**

**Example:**

```
# /nas/sbin/navicli -h 10.241.168.188 port -list |grep Server
```

**Server Name:** Celerra\_sludge4

Server IP Address: 10.241.168.187

**LUNs are renamed using the following convention, with Control LUNs appended with (NAS/OS):**

**Celerra\_<CS\_Hostname>\_<LUN\_ID>\_<dVolume>**

```
# /nas/sbin/navicli -h 10.241.168.188 getlun 16 -name
```

Name Celerra\_sludge4\_16\_d7

**For example, on a factory system where Control Station uses default name, “emcnas\_i0”:**

Celerra\_emcnas\_i0\_0\_root\_disk (NAS/OS)

Celerra\_emcnas\_i0\_8\_d9

→If the Control Station hostname is changed via the CSA process or when using Celerra Manager, a special

/nas/http/webui/bin/hostname.pl script is run that Updates Hostname; Runs nas\_cel –update; Restarts JServer; starts background job to run setup\_clariion –check\_and\_update –all, which updates Celerra Storage Group & Initiator Records names with the updated Hostname info, and finally, calls nas\_diskmark, which updates the LUNs with the new Hostname info

→If a LUN name is manually renamed or customized using Navisphere or NaviExpress, then the LUN will not be renamed during next nas\_diskmark/server\_devconfig -create operation

→If nas\_disk –rename is used to rename a dvolume ID number, the corresponding information is updated in the LUN name

→If nas\_disk –delete is used to remove a dvolume from the Celerra database, the LUN is renamed to the default CLARiiON LUN naming convention (e.g., LUN 6)

→Feature can be disabled by editing /nas/sys/nas\_param file

→Celerra Control LUNs are easily identified by the “(NAS/OS)” label after the name

→LUNs deleted from NAS DB will always revert back to the “LUN x” naming convention

**CONTROL STATION HOSTNAME RENAME WEBUI SCRIPT:**

**# /nas/http/webui/bin/hostname –s <new\_hostname>**

**Note:** This should be equivalent to changing Control Station Hostname from Celerra Mgr, from the CLI

**COMMANDS THAT UPDATE LUN NAMES:**

**nas\_disk –delete** →In this case, restores to the default CLARiiON “LUN x” name

**nas\_disk –rename** →Updates dvolume ID (e.g., d10 to d20), and updates dvolume ID info in LUN name

**nas\_diskmark –mark –all** →Diskmarks any new volumes and renames with new Celerra LUN name

**server\_devconfig –create** →Diskmarks any new volumes and renames with new Celerra LUN name

**WHAT THE VARIOUS SCRIPTS DO FOR THIS FEATURE:**

**/nas/sbin/setup\_clariion –check\_and\_update –all**

→Updates Storage Group and Celerra Initiator Names, if required

→Calls nas\_diskmark script, which then updates LUN names if required

**/nas/bin/nas\_diskmark**

→If called separately, will rename any Celerra-owned lun from its default CLARiiON name [e.g., LUN 20, Virtual Disk 201, etc] to the new Celerra\_cshostname\_lunid\_dvolume naming convention

→Otherwise, nas\_diskmark is called by the setup\_clariion –check\_and\_update –all script to update LUN names

**LUNs REVERT TO DEFAULT CLARIION NAMES IF DVOLUMES DELETED FROM CELERRA DB:**

**# /nas/sbin/navicli -h 192.1.4.231 getlun -name**

LOGICAL UNIT NUMBER 6

Name Celerra\_nx4\_6\_d11

**# nas\_disk -d d11 -perm**

**# /nas/sbin/navicli -h 192.1.4.231 getlun -name**

LOGICAL UNIT NUMBER 6

Name LUN 6 →This was d11 as shown above

**Note:** Does not get renamed back to default NaviExpress names, which are ‘Virtual Disk xxx’ etc.

**DISABLING LUN RENAME FEATURE:**

→By default, the feature is enabled, but can be easily disabled by editing the /nas/sys/nas\_param file to change the clar\_rename\_luns from true to false:

**# cat /nas/sys/nas\_param**

#clar\_rename\_luns:<true|false>

clar\_rename\_luns:true

**PERMANENTLY DISABLING LUN RENAME FEATURE:**

**Note:** Ordinarily, any changes made to the /nas/site/nas\_param file are reset to code defaults, say after a NAS Upgrade. In order to disable the LUN Rename feature persistently, make the following edit to the /nas/site/nas\_param file:

```
# vi /nas/site/nas_param
```

```
#clar_rename_luns:<true/false>
```

#### **LUN RENAME LOGGING:**

→See /nas/log/symapi.log for entries related to LUN renaming

|                         |      |                  |                |                                  |
|-------------------------|------|------------------|----------------|----------------------------------|
| 2008-07-01 06:43:07.590 | 7788 | 1 EMC:Celerra CS | User Generated | Renamed LUN SL7E1080700121 00006 |
|-------------------------|------|------------------|----------------|----------------------------------|

#### **Celerra\_emcnas\_i0\_6\_d12**

|                         |       |                  |                |                                  |
|-------------------------|-------|------------------|----------------|----------------------------------|
| 2008-07-01 06:45:30.883 | 10369 | 1 EMC:Celerra CS | User Generated | Renamed LUN SL7E1080700121 00006 |
|-------------------------|-------|------------------|----------------|----------------------------------|

#### **LUN 6**

### **TCP/IP LARGE RECEIVE OFFLOAD (LRO) FEATURE:**

→TCP/IP Large Receive Offload (LRO) [aggregation of multiple incoming packets into fewer, larger, packets to reduce CPU load]

→DART implements in software at Data-Link network layer

→Feature will be disabled by default

#### **Enabling/Disabling LRO:**

```
# .server_config server_2 -v "param tcp lro=1" and add param to /nas/server/slot_x/param file
```

```
# .server_config server_2 -v "param tcp lro=0"
```

#### **Displaying and Clearing LRO Stats:**

```
# .server_config server_2 -v "bcm cge0 displayLroStat" "bcm cge0 clearLroStat"
```

### **WINDOWS IDENTITY MANAGEMENT FOR UNIX FEATURE (IMU or IdMU):**

→Windows IdMU allows DART to use AD as the single naming service source for both NFS & CIFS protocols

→IdMU is an enhancement to retrieve Users and Groups from AD using LDAP and MS-IdMU schema (RFC2307)

→Only a single domain is support

→DART uses Bind + Password or Bind SSL to connect to AD server when using LDAP protocol

→IdMU provides a NIS Server to NFS clients and supports Unix Netgroups [i.e., a NIS replacement in multi-protocol environment]

→IdMU supported with Windows Server 2003 R2 and newer

→No Kerberos support for IdMU yet (NAS 6.0)

→Requires Celerra configuration for “ldap” in /etc/nsswitch.conf file for Users/Groups/Netgroups (and Hosts if not using DNS), and AD Servers supporting IMU Schema

→Group accounts can be Local or Domain-mapped from entries in /etc/group file on the Control Station (GID for Domain-mapped groups is needed only for use on the Control Station)

→User accounts are also Local or Domain-mapped from entries in /etc/passwd file on the Control Station (UID for Domain users needed on Control Station and controls client access privileges)

→Domain User accounts must also have membership in at least one Domain-mapped Group in order to login to the CS

#### **Default Windows Template Configuration Files:**

```
# ls -la /etc/ldap*
```

```
-rw-r--r-- 1 root bin 1814 Aug 13 10:24 /etc/ldap.conf.idmu_template_v1 (SFU3.5 Schema Windows 2003 R1)
```

```
-rw-r--r-- 1 root bin 2007 Aug 13 10:24 /etc/ldap.conf.sfu35_template_v1 (IMU Schema Windows 2003 R2)
```

#### **Configuring IdMU for Celerra:**

1. Set LDAP as a resolver in /etc/nsswitch.conf file for Users, Groups, Netgroups

2. Set param cifs resolver=1 on Data Mover

**Note:** IdmU feature only supports single Windows Domain

3. Disable Secmap on Data Mover (only done if UID/GIDs will be changing)

**Note:** When using LDAP cache, all Users must be authenticated by AD—Secmap is not queried for the LDAP function

4. Disable Usermapper on Data Mover

5. Copy modified Template file as /etc/ldap.conf file

6. Edit /etc/ldap.conf file ‘Containers’ section to reflect AD domain information

```
nss_base_passwd cn=Users,dc=eng-domfsu,dc=lcsc?one
```

```
nss_base_group cn=Users,dc=eng-domfsu,dc=lcsc?one
```

```
nss_base_hosts cn=Computers,dc=eng-domfsu,dc=lcsc?one
```

```
nss_base_netgroup cn=netgroup,cn=eng-domfsu,cn=DefaultMigrationContainer30,dc=eng-domfsu,dc=lcsc?one
```

7. Set the LDAP Client for AD on DART using one of the two possible authentication methods

```
# server_ldap server_2 -set -p -basedn dc=emc,dc=com -binddn cn=administrator,cn=Users,dc=emc,dc=com -servers
```

```
10.240.80.200
```

```
# server_ldap server_2 -set -p -basedn dc=emc,dc=com -binddn cn=administrator,cn=Users,dc=emc,dc=com =servers
```

```
10.240.80.200 -sslEnabled y
```

#### **Migrating NIS Database to AD using “Microsoft Identity Management for UNIX” Snapin:**

→Use “NIS Data Migration Wizard” to migrate NIS maps to AD (maps are passwd, group, hosts, netgroup)

→Create NIS maps on UNIX NIS Server using # ypcat passwd >passwd, # ypcat group > group, etc.

→Create UNIX users manually using ADUC>Users>username>Properties>UNIX Attributes tab

#### **How IdMU Would Work for CIFS User:**

1. CIFS Server would get Windows credentials for User [User SID + Group SIDs]
2. CIFS Server would build credentials
  - a. Query secmap for UID/GID for User SID
  - b. If not found, queries AD for username of SID
  - c. If nsswitch.conf configured with LDAP, uses username to obtain UID/GIDs
  - d. If Usermapper configured and above fails, will create UID/GID

#### **Troubleshooting/Configuring LDAP:**

```
# server_ldap server_x -info -v | -clear | -set | -lookup -user <username> or -group, -hostbyname, -netgroup
```

```
# .server_config server_x -v "logsys set severity LDAP=LOG_DBG2"
```

```
# server_param server_2 -facility ldap -list
```

server\_2 :

|                   |          |         |         |                                                                       |
|-------------------|----------|---------|---------|-----------------------------------------------------------------------|
| param_name        | facility | default | current | configured                                                            |

| change_effective     | = reboot DataMover                                          |
| range                | = (0,2)                                                     |
| description          | = Switches off/on the ldap cache and optional offline mode. |
| detailed_description |                                                             |

Switches off/on the ldap cache and optional offline mode. It may be useful to disable the cache for testing. The offline mode means that in the case of a cache hit with an expired entry, if we cannot update the entry because none of the ldap servers are available, then the ldap service will report the expired entry. This feature may be disabled to enhance the security, by setting the cache-only mode 1.

#### **OTHER FEATURES 5.6.39:**

→Support for Celerra Servers as a Host in Navisphere, NST, or NaviExpress wizards, using CS IP address and name as default

→CSA support for MPFS iSCSI systems

**Note:** NS40 and NS40FC for MPFS will use CSA to do normal factory-install configuration of Celerra. CSA can configure back-end iSCSI ports, CHAP, and start MPFS service on Server. Powerlink Landing Page and Installation Guide will be provided.

→Celerra Gateway support for Fleet Arrays (Proteus Flare 28)

→Java JRE 1.5.12 Upgrade (Clients that connect to Celerra Manager will need to upgrade to 1.5 JRE before using)

→Updated Celerra Simulator (Blackbird)

#### **COGNAC 5.6 MAINTENANCE RELEASE 4 (CMR4):** Oct 15, 2008, 5.6.40.3

→Support for 128TB capacities on Blades (qualification effort, no code changes required)

#### **STIG HARDENING:**

→STIG hardening script for CS security for DISA, DLA Federal agencies (once released, can be applied to any 5.5/5.6 version)

**Note:** Script used on CS is “nas\_stig –on | -off” and can be applied to harden security. Backported to 5.5.36, RPQ only.]

```
# /nas/tools/nas_stig
```

nas\_stig

```
-on  
| -off  
| -status  
| -verify  
| -version
```

**Note:** Once implemented, a /etc/nas\_stig.state file is created, and actions logged in /nas/log/nas\_stig.log

**# /nas/tools/nas\_stig -status**

STIG hardening has never been performed on this system (state file is not present)

**ORACLE DNFS SUPPORT:**

→Oracle 11g dNFS support (Oracle NFSv3 client) in order to mitigate an NFSv3 weakness related to data integrity in XID generation by the client. Feature implements a checksum of first 200 bytes of each NFS operation to guarantee data integrity. Feature disabled by default since it incurs an NFS performance hit:

**# server\_param server\_2 -facility nfs -info transChecksum -v**

server\_2 :

```
name      = transChecksum
facility_name = nfs
default_value = 0
current_value = 0
configured_value =
user_action = none
change_effective = immediate
range     = (0,1)
description = NFS Request Checksum
detailed_description
```

Dart-wide param indicating whether NFS request CRC should be calculated.

**# .server\_config server\_2 -v "xidcachestats dump"**

Xid Cache Statistics: Total lookups = 11959

inProg Hits 0, resend reply 0, drop 0, redos 0, drops 0, misses 11959, reforward 0 inProg counts 0 forward Counts 0, CRC

**mismatches 0**

1220455722: ADMIN: 6: Command succeeded: xidcachestats dump

→Maynard CS support for NS20/40 systems

→Multi-byte support for share names, share comments, tree quota path & comments in GUI only [allows native language inputs in support of internationalization efforts]

→FileMover reading of archived data block retrieval enhancement for pass-thru from 8k to 32k (see AR75700)

**Note:** This is a Read Buffer Size enhancement from 8k to 32k

→Replication V2 enhancements (hide option for internal checkpoints; GUI enhancements)

**Note:** Internal checkpoints are exposed in CLI and GUI with 5.6. This enhancement will allow an option to hide the internal checkpoints from view in GUI

**COGNAC 5.6 MAINTENANCE RELEASE 4+ (CMR4+ 5.6.41.2) Dec 2008:**

→NS-120/NS-480 Sleet release support, nasStorageAPI-7.0-12

**Note:** This code will only ship for the Sleet platforms and is not to be used in CCA or for any other hardware platform installs or upgrades

→MPFS support for Sleet hardware and integration into CSA

**Note:** CSA should be able to start the MPFS service on the Data Mover, create the Storage Group, configure iSCSI IP addresses on backend, and set CHAP authentication. Both NS-120 & NS-480 platforms will use FC Enabled option when configuring MPFS over Fibre Channel, and iSCSI option when configuring MPFS over iSCSI.

**COGNAC 5.6 MAINTENANCE RELEASE 5 (CMR5 5.6.42) Dec 2008:**

→Secure FTP using SSL

→Support for SMB2

→System Management performance improvements

→Statistics enhancements

→Cascade replication support on VDMs—up to 4 sessions from Source to Targets; Adds support for two-hop Cascading for RepV2

→Multi-byte support for share names, share comments, tree quota path, tree quota comments

→CSA/CPW qualification for NX4, NS20, NS40, Sleet2, Sleet4

→Dual Maynard CS support NSX/NS80

→64-bit Support for MS VSS Provider for iSCSI for Windows 2003/2008—runs as a Windows service interfacing between Volume Shadow Copy Service and Celerra iSCSI Snapshots. Allows VSS-Enabled backup applications to make shadow copies of iSCSI luns.

**Feature Specifics:**

**DART FTP SECURE (FTPS):**

→Sends FTP traffic over SSL for encryption and authentication (Keys & Certificates managed by PKI)

**Note:** Secure FTP would use SSH to tunnel the FTP session over the connection

→ftp daemon to run during boot.cfg time (ftpd)

→Configuration stored in XML file (/etc/ftpd/conf/ftpd.xml)

- Administered via server\_ftp commands
- Supports new commands (AUTH—Authentication/Security Mechanism; PROT—Data Channel Protection Level; PBSZ—Protection Buffer Size; and CCC—Clear Command Channel)
- Follows RFC959, RFC2228, and RFC4217
- Clients using SSL to Port 990 can use this feature for secure authentication and data transfer on Celerra (control (Port 990) & data channel (Port 9890 SSL encoded))

**\$ server\_ftp –service | -start | -stop | -stats | -server –status**

**\$ server\_ftp server\_x –info | -modify**

**\$ server\_certificate server\_x**

**# server\_ftp server\_2**

```
-info  
| -service {-status | -start | -stop }  
| -service -stats [-full | -reset]  
| -modify  
  [-controlport <port>]  
  [-dataport <port>]  
  [-defaultdir <path>]  
  [-homedir {enable|disable}]  
  [-keepalive <period>]  
  [-highwatermark <threshold>]  
  [-lowwatermark <threshold>]  
  [-deniedusers <path>]  
  [-welcome <path>]  
  [-motd <path>]  
  [-timeout <length>]  
  [-maxtimeout <length>]  
  [-readsize <size>]  
  [-writesize <size>]  
  [-umask <mask>]  
  [-maxcnx <number>]  
  [-sslcontrol {disable|allow|require|requireforauth}]  
  [-ssldata {disable|allow|require}]  
  [-sslpersona {anonymous|default|<name>}]  
  [-sslprotocol {default|ssl3|tls1|all}]  
  [-sslcipher {default|<list>}]  
  [-sslcontrolport {port}]  
  [-ssldataport {port}]
```

**Note:** Must create certificate on DART and import to the client for FTP Secure SSL feature

## **SMB2 SUPPORT:**

### New features:

#### **Command Crediting**

→Client requests simultaneous operations; Server grants based on resources--protects against replay attacks & number of outstanding requests; Server can set Client credit to 0 to preserve resources; credits allow parallel operations such as copy chunk on Server side

#### **Asynchronous Command Processing**

→Server can send asynchronous response if an operation will take a long time, client can opt out. Async operations are SMB2\_NOTIFY, SMB2\_CREATE, SMB2\_LOCK

#### **Command Compounding of related operations**

→bunching of client requests in single transport message; performs more extended processing per roundtrip; server also bundles responses in transport message

→Examples of compounding are Create + Query Info; Create + Query Dir + Query Dir + Close; Create + Change Notify

#### **Durable Handle**

→allows for clients to be able to sustain temporary disconnections, only granted for exclusive access to a file; cached for 16 minutes after client disconnect; tunable via DART parameter

#### **Symbolic Links**

→clients can create symbolic links similar to UNIX; target can be a file or directory, relative or absolute UNC path; but feature is disabled by default on Vista & 2008 clients, and requires Administrative privileges; stored as uxfs symbolic link on Celerra, hence can be traversed by NFS clients; deletion of a symbolic link deletes the link, not the target

#### **Server Side Copy Chunk**

→client does data copy on same server without pulling data back to client; copy data from one file system to another if on same Data Mover; Copy, Xcopy, and Robocopy will use without the backup privilege set; EMCopy will use copy chunk with backup privilege, which overrides access rights checking on sources and resources Security Descriptors

#### **Other Information:**

--Improved performance and Unicode 3.0 command set support

--Used on Vista and Windows 2008 systems, Ports 445 & 139

--Only NTSTATUS codes returned, no SMB errors

--Simplies CIFS command set from 113 to 19 commands

--Will be disabled by default, used on Netbios, Standalone, or Compnames

**\$ server\_cifs server\_x –add security=NT,dialect=SMB2 | SMB2only** (type NT1 to disable once enabled)

--One of the main features is that the use of UNIX-like symbolic links will be supported in CIFS

--Server\_cifs and server\_cifs –o audit output the best way to ID a system running SMB2

Max protocol = SMB2

--\$server\_stats server\_x –table cifs –i 3 –terminationsummary no

--SMB2 supports larger buffer sizes and can send multiple commands within the same packet

--SMB2 uses strong hash using HMAC-SHA256 (vs. MD5 used in SMB) and signs session keys of User sending packet

#### **Typical SMB2 Dialog:**

SMB2\_SESSION\_SETUP (NTLMSPP negotiate msg, using SMB1)

SMB2\_SESSION\_SETUP (NTLMSPP response)

SMB2\_SESSION\_SETUP (NTLMSPP authenticate)

SMB2\_SESSION\_SETUP (NTLMSPP response)

SMB2\_TREE\_CONNECT

SMB2\_TREE\_CONNECT (response)

SMB2\_CREATE

SMB2\_CREATE (response)

SMB2\_READ

SMB2\_READ (response)

SMB2\_CLOSE

SMB2\_CLOSE (response)

SMB2\_TREE\_DISCONNECT

SMB2\_TREE\_DISCONNECT (response)

### **SYSTEM MANAGEMENT PERFORMANCE IMPROVEMENTS:**

New objects added to cache (interface, CIFS server, device)

Prefetching to occur for cached object data, but only for User nasadmin (Mover, VDM, File System, Migration File System, Checkpoint, Volume, Share, Export, Mount)

#### **STATISTICS ENHANCEMENTS:**

Celerra Statistics Framework (perfStats) provides common API for developers, built into standard kernel, and are accessible via server\_stats command; most common type of stats are counters and facts

Four new statistics types [MinMaxAvg; Stopwatch; MinMaxAvgSw; SStopwatch]

Counters are reported in terms of rate change per second

Facts are reported as point-in-time value

#### **Default setting is for server stats to show rate of change since previous sample:**

**\$ server\_stats server\_x –su basic –i 2 –c 5 –type rate**

#### **To see just the change in value since last sample:**

**\$ server\_stats server\_x –su basic –i 2 –c 5 –type diff**

#### **To see overall change since initial sample:**

**\$ server\_stats server\_x –su basic –i 2 –c 5 –type accu**

#### **REPv2 ENHANCEMENTS:**

One-to-many replications now supported for VDM Source to (4) VDM Destinations

VDM Cascading for two hops now supported, with each session independent of the other (limit is not enforced)

Source VDM can be in loaded or mounted State (but only one specific VDM in loaded state for Replication environment)

Option to disable CRC checking for Replication sessions has been removed

#### **MULTI-BYTE SUPPORT:**

Celerra Manager supports input of native languages for Shares & Comments, Tree quota paths & Comments, supporting Unicode 3.0

#### **Supported Multi-byte interfaces:**

MMC, APL, Dart, Celerra Mgr, Command Service, CBM DLL, SMI-S/CIM-NAS, CIC, SNMP, MAC XML, MAC RPC, NMI Handling, DART AV, CAVA API, CAVA Engine, CIFS API, CBM API, NDMP, DHSM API, DVT, XML-API

Supports multi-byte data in CLI, XML-API, CCMD, and Logs

## **COGNAC 5.6 MAINTENANCE RELEASE 6 (CMR6 5.6.43.8) Feb 23 2009:**

### **Foxglove release: NS-960 Integrated, NS-960FC, NS-960iS, and NS-G8**

XBlade based on Wildcat-S architecture. First Celerra platform to use CX4 hardware for Blades, as well as the SLIC Ultraflex IO modules. Blades are dual socket, 4-core Intel 2.33GHz processors with 1.33GHz dual-buses and quad channel memory, shipping with 8GB memory, though only 4GB is usable prior to Barossa release. A DME will consist of 1-2 Blades, 2 Earthquake management switches, and 4 Power Supplies. Foxglove will support 2-4 DMEs with 1-2 Blades each, and 1-2 Control Stations.

### **NS-960 product can have 2-8 Blades, but depends on model:**

NS-960 2-4 Blades and maximum of 480 drives

NS-960FC 2-6 Blades and maximum of 960 drives for use with FC Hosts

NS-960iS supports 480 drives

NS-G8 supports 2-8 Blades

### **NS480-4 Support (4-Blade Support)**

#### **FLR Compliance (FLR-C)**

#### **FILE LEVEL RETENTION: (aka FLR-E, FLR-C, CWORM)**

**Purpose:** FLR-E currently protects against file changes from NFS, CIFS, or FTP clients, but does not prevent administrative meddling of the file system, deletion of the file system, or tampering of the system clock, hence FLR-C. Intent is to meet Storage compliance regulations, as put forth by the SEC Rule 17a-4(f). Storage characteristics should have Non-rewriteable, non-erasable format; automatic storage media recording verification for quality and accuracy; serialized original and duplicate units of storage media, with time-date stamp; capacity to download indexes and records; testimony from 3<sup>rd</sup> party vendor that storage meets the FLR compliance standards. A FLR-C compliant file system will support NFS, CIFS, and FTP access. FLR Enterprise (i.e., CWORM feature) currently supports three file states—CLEAN, WORM, EXPIRED, and FLR-C adds a fourth, APPEND\_ONLY. All files start in a CLEAN state, and ordinarily progress to WORM, then EXPIRED, though files can go from EXPIRED back to WORM when clients extend the retention life of a file. APPEND\_ONLY allows a file to transition between CLEAN and WORM states, depending on whether it is Read-Only or Writeable. WORM state can be determined by the DHSM API.

#### **FLR-C LIMITATIONS:**

→NDMP backups do not preserve the FLR attributes. Restore to a file system with file-level retention enabled. If restoring expired files, will have infinite retention date. If necessary to retain file expiration status, restore to non-FLR file system, then copy to FLR file system.

#### **FLR FILE STATES:**

CLEAN—normal file state

APPEND\_ONLY—files cannot be deleted or renamed—existing data cannot be modified, but new data can be added to a file

WORM—files cannot be deleted, renamed, modified, or appended to

EXPIRED—files cannot be renamed, modified, or appended to, but can be deleted

#### **File Level Retention (FLR) COMPLIANCE:**

--FLR will now require license activation in Celerra Manager

--FLR has four possible states: CLEAN, WORM, EXPIRED, APPEND\_ONLY

--FLR will use a new FLR software clock to prevent administrators from tampering with system clock to change FLR status

**Note:** Software clock ticks only when file system is mounted RW. Will catch-up with system time through slow adjustments.

--FLR protection to be enhanced so as to prevent administrators from destroying and restoring FLR file systems

--FLR data integrity verifies that stored data can be read back (all writes verified by reading back data)

**Note:** This can be disabled via param as it is an expensive operation

--Soft infinite retention period (means retention period can be increased) is now a hard infinite period that cannot be changed

#### **FLR-C Features:**

Tamper Proof Clock—use of a software clock vs. hardware system clock to prevent administrator tampering

**Note:** If FLR clock is behind system clock, will advance up to 138 seconds per hour

File System Protection—intended to prevent administrators from destroying protected files in a FLR-C file system

**Note:** File System contents cannot be modified or deleted by Clients, Users, Administrators when set to FLR-C

Data Verification—to provide data integrity for data written to storage by doing read back from storage—DM will panic when a failure of this integrity check occurs after two retries

Default Infinite Retention period—if specific retention time is not set, a file will get the default retention period, which is not changeable for FLR-C

Activity Logging—logging of file actions taken to a FLR\_logs directory

Append\_only Files—ability to append to a file without changing existing data. File can be WORM or APPEND\_ONLY state.

#### **Creating FLR-C or FLR-E File System from CLI (Can also do from GUI):**

\$ nas\_fs –name flr\_1 –type uxfs –create size=10G pool=id=3 storage=SINGLE worm=compliance (enterprise) –option slice=y, mover=server\_2

#### **FLR Parameters:**

# server\_param server\_2 -facility FLRCCompliance -list

server\_2 :

param\_name facility default current configured

ActivityLogRP FLRCompliance 7 7

writeverify FLRCompliance 0 0

**\$ server\_param server\_2 –facility FLRCompliance –modify –value writeverify 1** (1 Enables Write Verify, default is off, 0)

#### Verifying File System FLR-C:

# nas\_fs -i file5

id = 28

name = file5

acl = 0

in\_use = True

type = udfs

**worm = compliance with no protected files**

worm\_clock= Fri Nov 13 10:45:33 EST 2009

worm Max Retention Date= No protected files created

**# /nas/tools/\_fs\_db server\_2 readsb 97 psb**

About to read superblock from volume 97 and sector 16

ncyl=263

magic=**0xdcbaabc** →This magic value means that the file system is set to FLR-C mode

#### Restoring Checkpoint to FLR-E File System:

**\$ /nas/sbin/rootfs\_ckpt flr1\_ckpt1 -name flr1\_ckpt2 -Restore -Force**

#### FLR Toolkit Version 3.0:

--A windows application that can be used to monitor, query, report, and verify status of FLR file systems

Dashboard—snapshot of CIFS share with report, charts, and showing when files will expire

Report Generator—detailed reports on CIFS Shares

Query Builder—searching for files on CIFS Shares

Monitor Service—monitor pathnames and auto set retention dates in directories

--can use CLI to apply retention dates or query files from CIFS shares

#### FLR Toolkit Version 3.4:

→Available from Powerlink Celerra Tools page as an installable: EMC\_FLR\_Toolkit\_v3.4.0.zip

→Windows utility designed to manage and report on Celerra File Retention at file system, directory, & file levels

→Explorer-based monitoring and reporting capability, and some CLI querying and management capability as well

→Toolkit does not support Append-only files, or FLR-C file systems

→Program Files\EMC\FLRToolkit\FLRService\FLRMonitorService.log

#### Flare 28 Mira Support:

EFD solid state drive support will be on Trident & Dreadnought arrays only, for 73GB 520BPS 4GB FC interfaces; support for 400GB EFD drive. New AVM pool, clarssd\_r5 with new disk type “CLSSD” configured in RAID 5 4+1 or 8+1

**Note:** AVM rules do not allow mixing disk types in a pool or extending file systems from one pool to a different pool type

#### General SSD Rules:

--Used only in RAID 5 4+1 or 8+1 configurations

--Not used as Vault drives

--Not recommended for use as Celerra Control LUNs in case of Gateway systems

--Drive type cannot be mixed within same DAE or within a RAID group

--Hot Spare can only be SSD for SSD

--SSD drives are valid for CX4-960 and CX4-480 arrays

--one Hot Spare recommended for every 30 drives

**Note:** No mention at all about best practice cache settings Celerra (write enabled, read disabled) vs. Clariion (both write & read cache disabled)

#### Celerra Data Deduplication/File-level Dedup and Compression (Celerra F-RDE; Celerra Dedupe, etc.):

##### “File Level Deduplication (single instancing) and File Compression”

→Key attributes of Celerra Deduplication are ‘single file instancing’ and ‘file compression’

##### Purpose:

File Level Redundant Data Elimination (F-RDE) seeks to eliminate duplicate file instances and performs compression (50%), providing for storage efficiency. For example, 70 file copies will have 70 inodes with metadata, but the actual file data will be a single file. Since this feature will have a performance impact, the targeted files will be those that are relatively inactive, with an access age threshold.

##### Operation:

Based on last access time and modification times, DART will scan file systems for eligible files and then perform the R-RDE function by putting file data in hidden F-RDE store (EDRS store) as a stub file using FileMover technology. The “name” of a deduped file is not hidden and looks online to the User (hence de-duplicated). Hidden deduped files are placed in the slash etc store of the file system and are not visible to Clients. The data is “compressed” on the way into the ‘store’ and “uncompressed” on the way out of the ‘store’.

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Reads are done in pass-through mode without recalling the data, while writes and other administrative actions will perform the recall of data.

#### **DEDUPLICATION FEATURE:**

- File Level Deduplication does not require a lot of CPU or Memory, and provides about 10% space savings, while the compression component requires lots of CPU, but improves space savings by up to 50%
  - Note:** This is because deduplication uses a background, asynchronous operation that operations on inactive files
  - Files are selected based on Size and Age (accessTime & modificationTime)
  - Deduplication uses an internal policy engine, a Compression engine based on EMC RecoverPoint, and a Deduplication engine based on EMC Avamar hashing
  - Deduplication is based on file data, NOT metadata
  - On average, compression offers a 50% space savings
  - Policy Engine on Data Mover scans file system for de-dupe candidates (up to a million files in 3 minutes using 5% CPU) as a background asynchronous operation
  - Policy Engine uses 1 thread for deduplication and 1 thread for reduplication (recall)
  - Policy Engine logs exceptions and deduplication completion in Server Log under DEDUPE facility
  - Dedupe candidates are sent to the EDRS store for deduplication, compressed, then given a unique handle for each file stored
  - Policy Engine puts the file offline using FileMover and the unique file handle—original file replaced with stub file that references the data in the EDRS store
- Note:** RDE stub files will not display in CIFS as offline (until NAS 5.6.47)
- Dedupe works with Replication V2 file systems
  - Single file instancing (deduplication) can be disabled by changing the param singleInstancingEnabled to 0, which allows the compression feature to continue to run
  - From Celerra Manager, turn Deduplication On, Off, or Suspended, see Status, and see Statistics for deduplication (all other tasks require CLI)
  - Reduplication is the process of recalling deduplicated files from the EDRS store, such as when turning “Off” dedupe, but command will not execute unless the file system has enough space to allow. Or, if a client modifies or writes to a file, that file will be reduplicated and uncompressed
  - With the original Phase I version (5.6.43) of Deduplication, write operations to a deduplicated file leads to a full recall of the file, and write latency

#### **How Does Single File Instancing Work?**

→ When files are compressed, a hash is derived and applied to the file data, then compared to the existing hidden Data Store. For those files where the contents are identical, the hash will be the same. So, if the hash is found to already exist in the Data Store, a Stub file is placed in the file system to replace the data, hence we get “single file instancing” [aka, ‘file level deduplication’] of files with the same exact data content.

#### **Celerra Manager Deduplication Properties:**

Files scanned: 70  
Files deduped: 70 (100% of total files)  
Original data size: 503 MB (102% of current file system capacity)  
Space saved: 428 MB (85% of original data size)

#### **F-RDE LIMITATIONS:**

- Replication V1 not supported with deduplicated file systems
  - File systems running 5.6.47 deduplication cannot be mounted on pre-5.6.47 code due to a magic number change
  - Deduplication will not occur on paths >than 1024 bytes in length, creating errors [See emc231579—to be fixed 5.6.49]
  - 2010-01-08 15:23:43: DEDUPE: 3: 2: Deduplication of file system id 846 was aborted after 10 failure(s), 121571720 KB available on FS. Last reported error was: NameTooLong.
  - Files 24K and below are not deduplicated or compressed by default, though lower values can be specified via param
  - By default, system will abort dedupe rather than extend SavVol for Snapsure
  - By default, files >than 200MB will not be deduplicated for CIFS timeout reasons
  - iSCSI LUNs cannot be deduplicated
  - The F-RDE deduplication feature can be run in conjunction with Celerra FileMover
  - Writes to de-duped files initiates recall
  - NDMP (NVB) volume-based backups are supported, but only with full restores
- Note:** Downside here is that single file restores are not supported from NVB. Instead, for single file backup and restores, use Checkpoints.
- PAX NDMP & Network backups will reduplicate & uncompress the files for the backup application, though the files themselves are left deduplicated & compressed on the Celerra file system. Because of this, backup performance will be impacted. Also, restoring files from regular NDMP or Network backups will be restored in a non-deduplicated state (overwrites what might be deduplicated files?).
  - Over 64k instances of the same file will not be deduped, but will be compressed
  - FSCK cannot detect/repair stub files for RDE store

→For MPFS file systems, IO to any files in the RDE store will revert to NFS or CIFS

→Does not support Writeable Checkpoint feature

→Deduplicated blocks are not counted in Quotas (recommendation to use ‘File Size’ Quotas)

→Does not support CDMS mgfs file systems

→Deduplication scanning will abort after (10) errors are encountered. This is default behavior and the error thresholding can be increased to a max of 1000 errors:

### **param dedupe peMaxErrors=1000**

#### **THREE STATES FOR DEDUPLICATION:**

on (deduplication on for a file system)

off (deduplication turned off and file system undo’s any deduplicated files—called “reduplication”)

suspended (deduplication suspended)

#### **Commands:**

**# fs\_dedupe -list | -info | -all | <fs\_name> or <fs\_id>| -modify | -state {off | suspended | on}**

**Note:** Setting state to on implements Policy Engine. Setting state off recalls all files in RDE store. Setting state to suspended means Policy Engine will not look for dedupe candidates on the file system

**# fs\_dedupe -modify fs5 -state suspended**

Done

**Note:** Use the following command to force dedupe suspension, as in a situation where the dedupe task may not be suspended and the file system is unmounted:

**# .server\_config server\_2 -v "pe action=disable fsid=<file system ID>"**

**# fs\_dedupe -info fs5**

Id = 29

Name = fs5

Deduplication = Suspended

As of the last file system scan (Mon Feb 16 13:19:15 EST 2009):

Files scanned = 70

Files deduped = 0 (0%)

File system capacity = 1008 MB

Original data size = 646 MB (64% of current file system capacity)

Space saved = 0 MB (0% of original data size)

**# fs\_dedupe -info fs5**

Id = 29

Name = fs5

Deduplication = Off

**# fs\_dedupe -modify fs5 -state on**

Done

**# fs\_dedupe -list**

| id | name | state | status | time_of_last_scan            | original_data_size | usage | space_saved |
|----|------|-------|--------|------------------------------|--------------------|-------|-------------|
| 29 | fs5  | On    | Idle   | Mon Feb 16 13:19:15 EST 2009 | 646 MB             | 64%   | 0 MB (0%)   |

**# fs\_dedupe -info fs5**

Id = 29

Name = fs5

Deduplication = On

Status = Idle

As of the last file system scan (Mon Feb 16 13:19:15 EST 2009):

Files scanned = 70

Files deduped = 0 (0%)

File system capacity = 1008 MB

Original data size = 646 MB (64% of current file system capacity)

Space saved = 0 MB (0% of original data size)

#### **TURNING DEDUPLICATION OFF RE-DUPLICATES ALL FILES:**

**Note:** But only if there is room to do so, as seen in the following—had to extend the file system to turn it off

**# fs\_dedupe -modify cifs1 -state off**

Error 12048: Additional space 57 MB needed on this file system to perform this operation.

**# fs\_dedupe -modify cifs1 -state off**

Done

**# fs\_dedupe -info cifs1**

Id = 32

Name = cifs1  
 Deduplication = Off  
 Status = Re-duplicating(28% complete)

### **DEDUPLICATION STATUS:**

→Using fs\_dedupe -info, the various states for dedupe are Status = Scanning; Status = Idle; State = Reduplicating

#### **# server\_param server\_2 -facility dedupe -list**

server\_2 :

| param_name               | facility | default | current | configured                                                                                                |
|--------------------------|----------|---------|---------|-----------------------------------------------------------------------------------------------------------|
| fileExtensionExcludeList | dedupe   | "       | "       |                                                                                                           |
| singleInstancingEnabled  | dedupe   | 1       | 1       |                                                                                                           |
| minimumSize              | dedupe   | 24      | 24      | →Min size that file will be deduped & compressed, default is 24k                                          |
| savVolThreshold          | dedupe   | 90      | 90      |                                                                                                           |
| accessTime               | dedupe   | 30      | 30      | →Files accessed within this number of days will not be deduplicated                                       |
| maximumSize              | dedupe   | 200     | 200     | →largest file size in MB that will be deduplicated, default is 200MB to avoid CIFS write timeout failures |
| caseSensitive            | dedupe   | 0       | 0       |                                                                                                           |
| throttle.cpuLowTrigger   | dedupe   | 40      | 40      |                                                                                                           |
| throttle.cpuHighTrigger  | dedupe   | 75      | 75      |                                                                                                           |
| minimumScanInterval      | dedupe   | 7       | 7       | →number days between scans, default 7 days                                                                |
| modificationTime         | dedupe   | 60      | 60      | →Number of days before file will be deduplicated without mod. time change                                 |

### **TESTING DEDUPLICATION MANUALLY (Single file instancing and compression):**

**Note:** With the default parameter settings, the first time any files would be deduped on a file system would be during the first scan that occurs after the 30 day accessTime setting, and then only if the file had not been accessed within the 30 day accessTime, or modified within the 60 day modificationTime window. In order to test this feature, we will temporarily disable the accessTime and modificationTime parameters.

1. Create a CIFS Server, and a file system with Shares that are accessible from a Windows client on the domain
2. From the Windows client, copy a set of identical files to multiple directories on the Celerra file system
3. For NAS Versions 5.6.43 to 5.6.46, use the server\_param facility to disable the AccessTime & ModificationTime on a Data Mover basis by setting each param to 0:

| param_name       | facility | default | current | configured |
|------------------|----------|---------|---------|------------|
| accessTime       | dedupe   | 30      | 30      | 0          |
| modificationTime | dedupe   | 60      | 60      | 0          |

**Example:**

#### **# server\_param server\_2 -facility dedupe -modify modificationTime -value 0**

server\_2 : done

#### **# server\_param server\_2 -facility dedupe -modify accessTime -value 0**

server\_2 : done

**Verify changes:**

#### **# server\_param server\_2 -facility dedupe -list|grep Time**

|                  |        |    |   |
|------------------|--------|----|---|
| accessTime       | dedupe | 30 | 0 |
| modificationTime | dedupe | 60 | 0 |

4. With NAS 5.6.47 and later, change the parameter values on a per file system basis (i.e., only on the file system used for the testing):

#### **# fs\_dedupe -modify file2 -access\_time 0**

#### **# fs\_dedupe -modify file2 -modification\_time 0**

**Verify changes:**

#### **# fs\_dedupe -info file2**

5. Verify file system usage prior to turning Deduplication scanning on:

#### **# server\_df server\_2 file2**

server\_2 :

|            |         |         |        |          |            |
|------------|---------|---------|--------|----------|------------|
| Filesystem | kbytes  | used    | avail  | capacity | Mounted on |
| file2      | 2519984 | 2199880 | 320104 | 87%      | /file2     |

6. To turn deduplication on, or to initiate a new scan immediately, use the "# fs\_dedupe -modify file2 -state on" CLI command. From Celerra Manager, you would first "Suspend" and then turn back "On" deduplication in order to initiate a new scan, or just "On" if deduplication was never turned on:

**Note:** Scanning will take place and deduplication and compression of qualified files will occur

#### **# fs\_dedupe -modify file2 -state on**

Done

7. Use fs\_dedupe to monitor the progress of the file system deduplication scan operation:

**# fs\_dedupe -info file2**

```
Id          = 25
Name        = file2
Deduplication = On
Status      = Scanning (0% complete)
```

As of the last file system scan (N/A):

```
Files scanned    = 113
Files deduped   = 83 (0% of total files)
File system capacity = 0 MB
Original data size = 476 MB (0% of current file system capacity)
Space saved     = 0 MB (0% of original data size)
```

-----output abbreviated-----

8. When the fs\_dedupe -info reports the deduplication scan status as "Idle", deduplication scanning has completed. Review the results using server\_df and fs\_dedupe:

**# server\_df server\_2 file2**

server\_2 :

| Filesystem | kbytes  | used           | avail          | capacity   | Mounted on |
|------------|---------|----------------|----------------|------------|------------|
| file2      | 2519984 | <b>1135984</b> | <b>1384000</b> | <b>45%</b> | /file2     |

**# fs\_dedupe -info file2**

```
Id          = 25
Name        = file2
Deduplication = On
Status      = Idle
```

As of the last file system scan (Wed Dec 2 16:22:59 EST 2009):

```
Files scanned    = 265
Files deduped   = 200 (75% of total files)
File system capacity = 2460 MB
Original data size = 2143 MB (87% of current file system capacity)
Space saved     = 1034 MB (48% of original data size)
```

-----output abbreviated-----

9. After testing has been completed, you can restore the accessTime and modificationTime parameters to the default values, 30 days &amp; 60 days, respectively, or to whatever other value is desired.

**DISABLING SINGLE FILE INSTANCING (Deduplication):****Note:** This disables “deduplication” but still allows “compression” to work**# server\_param server\_2 -facility dedupe -info singleInstancingEnabled**

server\_2 :

```
name        = singleInstancingEnabled
facility_name = dedupe
default_value = 1
current_value = 1
configured_value =
user_action  = none
change_effective = immediate
range       = (0,1)
```

description = This parameter is used to enable or disable single instancing capabilities of the Celerra deduplication feature.

→Set singleInstancingEnabled to 0 to disable this feature, while retaining the compression feature

**REDUPLICATING FILES:**

→Files are reduplicated if Clients modify or write to them

→Also, turning the dedupe feature “Off” will reduplicate all files to the file system, but requires enough space to do so

**# fs\_dedupe -modify cifs1 -state off**

Error 12048: Additional space 78 MB needed on this file system to perform this operation.

**WHAT HAPPENS TO DEDUPLICATION IF FILE SYSTEM FULL?**

→Cannot turn off deduplication feature

→Cannot duplicate anymore files

→Deduplication feature remains set to “on” for the file system, but is “Idle”. Further scanning will not occur until file system space is provided.

### Server Log:

2009-07-07 12:56:25: DEDUPE: 3: PE: ProcessFile failed on file /cifs1/deduped/dir3/DX9-10-06/Apr2006\_d3dx9\_30\_x86.cab with error: NoSpace  
2009-07-07 12:56:25: DEDUPE: 3: 2: Deduplication of file system id 32 was aborted after 10 failure(s), 88 KB available on FS. Last reported error was: NoSpace.

2009-07-07 12:56:25: DEDUPE: 6: PE: Task 1 aborted scan on fsid 32, duration: 0 seconds

2009-07-07 12:56:25: DEDUPE: 6: 5: The deduplication scan on file system id 32 has just completed.

**Note:** Ironically, the Log says the scan completed, but in reality, it has been aborted.

### Celerra Manager records Error:

X Slot 2: Deduplication of file system id 32 was aborted after 10 failure(s), 88 KB available on FS. Last reported error was: NoSpace.

### Resolution:

1. Clicked on “Auto Extend Enabled” in Celerra Manager for the file system (or manually extend the file system)
2. From Celerra Manager file system properties page, under the ‘Deduplication’ section, click on “Suspended”, “apply”, then click on “On”, then ‘apply’. From the CLI, issue the following command:

# **fs\_dedupe -modify cifs1 -state on**

Done

**Note:** This will initiate a new scan of the file system

# **fs\_dedupe -info cifs1**

|               |                           |
|---------------|---------------------------|
| Id            | = 32                      |

| Id            | = 32    |
| Name          | = cifs1 |
| Deduplication | = On    |
| Status        | = Idle  |

As of the last file system scan (Tue Jul 7 13:09:12 EDT 2009):

|                      |                                                |
|----------------------|------------------------------------------------|
| Files scanned        | = 188                                          |
| Files deduped        | = 188 (78% of total files)                     |
| File system capacity | = 984 MB                                       |
| Original data size   | = 920 MB (93% of current file system capacity) |
| Space saved          | = 741 MB (80% of original data size)           |

## **FILTERING USING EXCLUSIONS:**

### Excluding File Extension Types:

\$ **server\_param server\_x -facility dedupe -modify fileExtensionExcludeList -value .mp3**

### Excluding Directories:

\$ **server\_param server\_x -facility dedupe -modify dirExcludeList -value temp\_dir**

### Disabling Single File Instancing:

\$ **server\_param server\_x -facility dedupe -modify singleInstancingEnabled -value 0** (default is 1)

### Hidden Parameters:

dedupe rdeLoggingEnabled →Controls logging of RDE stub file events to /.etc/dhsm.log

dedupe fileExtensionIncludeList →Can dedupe specific file extensions via colon delimited list

### For Client IO Errors when accessing deduped files?

--Users will need to restore from backup

--Recovery Tool can generate list of files that need to be restored from backup and also to verify status of deduped files in file system

**Note:** Need to obtain RecoveryTool from engineering (CHECK\_DEDUP)

# **.server\_config server\_2 -v "sspeache"**

## **CONTROLLING WHEN DEDUPLICATION OCCURS:**

1. Deduplication will occur when first enabling the system for deduplication (if timestamps and rules allow), and thereafter, as per the Rules of the Policy Engine
2. If deduplication scanning is occurring during a bad timeframe (middle of working day), simply turn on the dedupe session again for the file system at the desired timeframe (-modify -state on)

## **TROUBLESHOOTING DEDUPLICATION:**

**# .server\_config server\_2 -v "pe action=**

```
action=enable fsid=n
action=disable fsid=n
action=off fsid=n
action=start fsid=n
action=stop fsid=n
action=pause fsid=n
action=resume fsid=n
action=status fsid=n
action=free fsid=n
action=trav fsid=n
action=rmdb fsid=n
action=listfs
```

**# .server\_config server\_2 -v "pe action=listfs"**

```

**DEDUPE SAVVOL FULL ISSUE:** emc210954

→By default, deduplication is set to stop when 90% of the SavVol has been consumed, but in practice, deduplication may stop just before the 90% threshold is reached.

→The SavVol parameter “savVolThreshold” may need to be revised to 100% or turned off (set to 0) if the intent is to keep deduplication active without concern for the SavVol capacity.

# server\_param server\_2 -facility dedupe -modify savVolThreshold -value 100

# fs\_ckpt id=29 -l  
id ckpt\_name creation\_time inuse fullmark total\_savvol\_used ckpt\_usage\_on\_savvol  
32 checkpoints1 04/01/2009-22:47:46-EDT y 90% 89% 0%

**Server Log:**

DEDUPE: 3: 2: Deduplication of file system id 29 was aborted after 10 failure(s), 2653147840 KB available on FS.

Last reported error was:SavVolAtCapacity.

DEDUPE: 6: PE: Task 1 aborted scan on fsid 29, duration: 98 seconds

**ROUTINE SERVER LOG ENTRIES:**

2009-07-06 16:08:00: DEDUPE: 6: PE: Task 1 starting scan on fsid 32

2009-07-06 16:08:00: DEDUPE: 6: StoreHost: Created repository root on file system 32

2009-07-06 16:08:01: DEDUPE: 6: Domain not found for fsid 32, creating.

2009-07-06 16:08:01: DEDUPE: 6: Domain initialized for fsid 32

2009-07-06 16:08:07: DEDUPE: 6: PE: Task 1 finished scan on fsid 32, duration: 7 seconds

2009-07-06 16:08:17: DEDUPE: 6: 5: The deduplication scan on file system id 32 has just completed.

**Using Celerra Data Deduplication Tech Module:**

‘By default the system is configured to abort deduplication operations on a file system before it causes the SavVol to extend. This avoids the SavVol expanding due to deduplication activity.’

**Hiding NFS Exports:**

--Ability to hide exports from clients via export process (see param mount.forceFullShowmount)

--Client that tries to access a hidden export that they do not have export access for will see “does not exist”

**DHSM Enhancement:**

--Scripts enhanced to handle file names with ampersand, >, <, and apostrophe characters

## **Increased UNIX Group Support:**

--Group support increased to 128 UNIX groups for O/S types, such as AIX and Redhat, that can support more than 16 UNIX groups in the RPC credential (NFS uses AUTH\_UNIX authentication mechanism, traditionally set at 16 groups maximum)

--Celerra now can store up to 128 UNIX groups, but requires setting the maxgroups param

# **mount -o maxgroups=64 server\_2:/mntpoint /fs1**

**Note:** Mount example from AIX client

# .server\_config server\_2 -v “param security maxgroups” (maxgroups=128 to change to 128 group support)

security.maxgroups INT 0x02dbd738 16 16 (16,128) TRUE REBOOT ‘Define the max number of extra group in Unix credential’

# **server\_param server\_2 -facility security -info maxgroups -v**

server\_2 :

```
name      = maxgroups
facility_name = security
default_value = 16
current_value = 16
configured_value =
user_action = reboot DataMover
change_effective = reboot DataMover
range     = (16,128)
description = Define the max number of extra group in Unix credential
detailed_description
```

In Unix a user can belongs to many groups, when a user is authenticated a credential is created, where this information is stored. By default Celerra is supporting only 16 groups stored in the credential for authentication. This parameter allows to extend the number of groups we are storing to 128. This is also impacting the credential passed to Celerra in NFS requests in the RPC. Bumping this parameter is allowing to support clients able to set more than 16 groups in the RPC credential, like AIX or RedHat.

## **SYR Enhancements:**

--A new script to Data Mover system usage patterns on customer boxes has been added to /nas/tools/.sys\_stats

--Purpose is to collect CPU & Memory statistics and deliver via the Monthly SYR callhome when log\_config is run. Log\_config converts the histogram data into XML format

**Note:** .syr\_stats is not intended to be run manually, just by Cron Jobs and when log\_config runs monthly

# **/nas/tools/.syr\_stats -report**

usage: /nas/tools/.syr\_stats [ -update | -init | -report [cpulmemorycacheduncachederrors] | -help ]

This script is used by SYR to collect statistical data and should not be run manually

--There is also a new cron job to collect CPU & Memory utilization on Data Movers every 5 minutes. The information collected by the .syr\_stats -update Cron is placed in a histogram file stored in the /nas/var/log directory:

### **Histogram File:**

**/nas/var/log/syr\_stats**

### **Cron Job:**

/nas/site/cron.d/nas\_sys

**0-59/5 \* \* \* \* root /nas/tools/.syr\_stats -update > /dev/null 2>&1**

--Feature is enabled on new installations when log\_config -start is called, which creates the Cron Job

--For NAS Upgrades, log\_config -status checks to see if CallHome & the Cron Job for log\_config is configured. If configured, then the SYR collection is considered “Enabled”, and log\_config will restart to enable the new stats collection tool

**41 3 2 \* \* \* root /nas/sbin/log\_config -d -c >/dev/null 2>&1**

### **How the svr\_stats script is setup during Install or Upgrades:**

# **/nas/sbin/log\_config -start -all**

Adding entry to /etc/cron.d/nas\_sys

41 3 2 \* \* \* root /nas/sbin/log\_config -d -c >/dev/null 2>&1

Adding stats entry to /etc/cron.d/nas\_sys

0-59/5 \* \* \* \* root /nas/tools/.syr\_stats -update > /dev/null 2>&1

Creating Data Mover stats log file

### **Symptom when log\_config & sys\_stats CRON Jobs are not present:**

# **/nas/sbin/log\_config -status**

disabled

### **PUHC Warning—emc231857:**

Data Movers : Checking for excessive memory utilization..... Warn

Data Movers: Check for excessive memory utilization

Symptom: The script /nas/tools/.syr\_stats cannot be found on  
the system.

### **PAHC or Post-Install Warning—emc232647:**

Data Movers: Check for excessive memory utilization

Symptom: Cannot determine the memory usage status.

Action : Run "/nas/tools/.syr\_stats -report cached" manually to investigate further.(abridged)

## **COGNAC 5.6 MAINTENANCE RELEASE 7 (CMR7 5.6.44.4) Mar 2009**

### **DYNAMIC SRDF:**

→Allows DR site to mirror with Source after failover, with the idea to prevent long down-time during restore operations (due to synchronization between RDF volumes) and to provide better disaster protection in case DR site experiences failure while in an activated state

→Bin file changes: Enable RDF dynamic mode; Set Dynamic RDF flag on Celerra Volumes

**# /nas/sbin/nas\_rdf –activate -reverse**

**Note:** So, after failover, data is being mirrored from the R2 side to the R1 side. As data blocks are written to the R2, they are also synchronized back to the original source, or R1 side

### **> 2TB LUN SUPPORT:**

→Support for LUNs greater than 2TB on NS-960 and Gateways, which translates into 16TB luns

→Celerra Integrated NS-960 platforms create only a single LUN per Raid Group if using the setup\_clariion script

**Note:** With NAS 5.6.45, the Celerra Manager Provisioning Wizard is also capable of creating >than 2TB LUNS on ATA drives

→All other Integrateds will fallback to creation of dual luns per RG and <than 2TB luns when using setup\_clariion. You must specify a storage profile when using setup\_clariion that will be capable of creating large luns, such as the following example:

**# /nas/sbin/setup\_clariion -init**

The following 7 template(s) available:

1. ATA\_RAID5\_HS\_6+1\_6+1

2. ATA\_RAID5\_HS\_4+1\_4+1\_HS\_HS\_HS\_HS

3. ATA\_RAID5\_HS\_4+1\_8+1

4. ATA\_RAID10\_HS\_R10\_R10\_R10\_R10\_R10\_R10\_R10\_R10

5. ATA\_RAID6\_HS\_4+2\_6+2

6. ATA\_RAID6\_HS\_12+2 →This template yields a 10.7TB LUN from a shelf of 1TB SATA drives

Enclosure 1\_0.

Created disk group 8, luns 17

**Note:** I created a 5TB file system on the 10.7TB LUN, and it took 50 minutes until the file system was converted from rawfs and became mounted on the Server

→Gateways will support >than 2TB luns

### **POST & BIOS UPDATE:**

→NS-960 Integrated & Gateway will flash new firmware during NAS Upgrade or Install: POST 7.30 & BIOS 4.60

**Note:** emc208053 documents an issue with firmware in which the Blade may fail to boot (AR137603—fixed with BIOS 4.60 POST 7.30). If this happens when running the CSA, the error seen would be 1004021000 for Blade 2 (Blade 2 is booting up (rc=0), 1004031000 for Blade 3, etc.

Workaround: Reseat the Blade, but first make sure that the white “hand” LED is not lit, which would indicate an unsafe condition, with the blade doing a firmware update, etc.

### **SAVVol:**

SavVol default extension & creation size increased to 20GB

## **COGNAC 5.6 MAINTENANCE RELEASE 8 (CMR8 5.6.45)—July 2009**

→NS-960 CSA Provisioning Support will be available with a later NAS release

→Dell NX4 OEM Phase II support

→Celerra Gateway qualification for Tigon Symmetrix backend (V-Max hardware), but not for any new features it may present, with support for microcode 5874.1xx

→Support for Libra FLARE (04.28.000.5.704) for Gateway and Integrateds

### **CSA PROVISIONING WIZARD (CSA CPW):**

→The CPW functionality has been around for some time now, but has been restricted to EMC and Partner use only, and made available via a separate Powerlink download

→With NAS 5.6.45.5, the CSA with the Provisioning Wizard functionality becomes part of the mainstream NAS code release, and will be made generally available for customers

→The platforms where the CSA with CPW functionality has been qualified, are the NX4, NS20, NS40, NS-120, NS-480, NS-960

**Note:** You can also use the Celerra Manager Provisioning Wizard functionality to accomplish the same storage provisioning as that found in the CSA utility. Also note that >than 2TB LUNs is capable for NS-960 platforms when using Celerra Mgr provisioning.

### **MODEL ORDERING CHANGES:**

**Interim Model Ordering System--July:**

→In July, the Order Entry system for NS-480/NS-960 platforms will present one base array model, dropping the original AUXF & AUXI names: **NS480-AUX or NS960-AUX**

→Customers would add FC or iSCSI slices, to get the desired configuration

#### **New Model Ordering System:**

→In August, the Order Entry system for the NS-960 will have two base models:

**NS-960AUX or NS-960AUX8** (AUX8 indicates the use of the new 8Gbps Glacier FC IO Module)

#### **NS-960 Rules:**

→One Base AUX array will have (2) 4-port 4Gbps Tomahawk FC IO Module

→Another Base AUX array will have (2) 4-port 8Gbps Glacier FC IO Module

→Mfg or Upgrade can add (1) or (2) 4Gbps FC IO Modules to the array

→Mfg or Upgrade can add (1) or (2) 8Gbps FC IO Modules to the array, in lowest available slot position before 4Gbps cards

→Mfg or Upgrade can add (1) or (2) 10Gbps iSCSI Poseidon IO Module, in lowest available slot position before 1Gbps iSCSI cards

→Mfg or Upgrade can add 1-4 1Gbps iSCSI IO Modules

→960 Drive models can add an additional 4Gbps FC IO Module for BE connectivity

SP slot 0 & 1 must be all 4Gbps FC (AUX) or all 8Gbps FC (AUX8), and are always populated

SP slot 2 can be empty, be 4Gbps FC (when requiring >than 480 drives), or be 1/10Gbps iSCSI

SP slot 3 can be empty, be 4/8Gbps FC (for FC or MPFS over FC), or be 1/10Gbps iSCSI

SP slot 4 can be empty, be 4/8Gbps FC (5th FC for 8 Blades & more FC hosts), or be 1/10Gbps iSCSI (Mview or MPFS over iSCSI)

SP slot 5 can be empty, or have 1/10Gbps iSCSI (Mview or MPFS over iSCSI)

If MPFS over iSCSI selected, slots 2, 3, 4, & 5 would be 1/10Gbps iSCSI

#### **NS-960 SP Configurations (up to 4-Blade & 480 Drives):**

(2) FC SLICs, slots 0 & 1

(2) FC SLICs, slots 0 & 1, and (4) iSCSI SLICs, slots 2, 3, 4, 5

#### **NS-960 SP Configurations (>4-Blades or >than 480 Drives):**

(4) FC SLICs, slots 0, 1, 2, 3

(4) FC SLICs, slots 0, 1, 2, 3, and (1) iSCSI SLIC, slot 4

(5) FC SLICs, slots 0, 1, 2, 3, 4

(5) FC SLICs, slots 0, 1, 2, 3, 4, and (1) iSCSI SLIC, slot 5

**Note:** Customers select AUX or AUX8, then add additional slices per the above rules, to create the desired configuration.

→Fibre Channel Tomahawk SLIC is 4Gbps 4-port card

→Fibre Channel Glacier SLIC is 8Gbps 4-port card

→iSCSI Harpoon SLIC is 1Gbps 2-port card

→iSCSI Poseidon SLIC is 10Gbps 2-port card (Requires Taurus Flare 29)

#### **NS-480 Rules: NS480-AUX; NS480-AUX8**

→Base AUX array will have (2) 4-port 4Gbps Tomahawk FC IO Module (no 8Gbps Glacier)

→Mfg or Upgrade can add (1) 4Gbps FC IO Module to the array

→Mfg or Upgrade can add (1) 8Gbps FC IO Module to the array, in lowest available slot position before any 4Gbps FC cards

→Mfg or Upgrade can add (1) or (2) 10Gbps iSCSI Poseidon IO Module, in lowest available slot position before 1Gbps iSCSI cards

→Mfg or Upgrade can add (1), (2), or (3) 1Gbps iSCSI IO Modules

SP slot 0 & 1 can only be 4Gbps FC (AUX), and are always populated

SP slot 2 is either empty or populated with 1 or 10Gbps iSCSI

SP slot 3 can be empty, or be 4/8Gbps FC, or be 1/10Gbps iSCSI

SP slot 4 can be empty, or be 1/10Gbps iSCSI

If FC or MPFS over FC selected, slot\_2 is empty, and slot\_3 is 4 or 8Gbps FC

If FC or MPFS over FC selected, & Mirrorview over iSCSI is selected, slot\_2 will have an iSCSI slice, & slot\_3 is a 4 or 8Gbps FC slice

If MPFS over iSCSI selected, slots 2, 3, & 4 are iSCSI

#### **NS-480 SP Configurations:**

(2) FC SLICs, slots 0 & 1

(2) FC SLICs, slots 0 & 1, and (3) iSCSI, slots 2, 3, 4

(3) FC SLICs, slots 0, 1, 3

(3) FC SLICs, slots 0, 1, 3, and (1) iSCSI, slot 2

#### **NS-120 Rules: NS120-AUX, NS120-AUXF; NS120-AUXF8**

→Base AUX array will have (1) 4-port 4Gbps Tomahawk FC IO Module (no 8Gbps Glacier)

→Mfg or Upgrade can add (1) 4Gbps FC IO Module to the array

→Mfg or Upgrade can add (1) 8Gbps FC IO Module to the array, in lowest available slot position before any 4Gbps FC cards

→Mfg or Upgrade can add (1) 10Gbps iSCSI Poseidon IO Module, in lowest available slot position before any 1Gbps iSCSI cards

→Mfg or Upgrade can add (1) or (2) 1Gbps iSCSI IO Module

→NS-120 is handled differently & will use AUX, AUXF8, or AUXF in the order entry system, dropping the AUXI designation

SP slot 0 will have 4Gbps FC (AUX), and is always populated

SP slot 1 can be empty, or be 1/10Gbps iSCSI

SP slot 2 can be empty, or be 4/8Gbps FC, or be 1/10Gbps iSCSI

SP slots 3 & 4 are not used

#### **NS-120 SP Configurations:**

(1) FC SLIC, slot 0 (Port 1 empty, not used)

(2) FC SLICs, slot 0 & 2

(1) FC SLIC, slot 0, (2) iSCSI SLICs, slots 1 & 2 for MPFS over iSCSI

(2) FC SLICs, slots 0 & 2, (1) iSCSI SLIC, slot 1 for Mview over iSCSI

#### **GLACIER 8Gbps FC IO MODULE:**

→Libra Flare 28.7 introduces support for 8Gbps FC IO module

→Support for new 4-port Glacier 8Gbps FC SLIC on SPs for Gateways and the NS-120, NS-480 & NS-960 platforms (Aug 2009)

**Note:** NS-120 & NS-480 arrays supporting FC will add only a single Glacier card per SP, which will be used to support 4 or 8Gbps Host access. All FC IO cards on the NS-960 arrays, however, will support the Glacier IO module.

→Arrays using Glacier card will use a new CLARiiON model name:

#### **CX4-120C8, CX4-240C8, CX4-480C8, CX4-960C8**

→Glacier is a 8Gbps replacement to the 4Gbps Tomahawk FC IO Module, and is RoHS 6 compliant

→For new installs and array upgrades—can only add 8Gbps FC modules to existing array, not replace 4Gbps with 8 Gbps

→Currently, neither Blades nor SPs themselves support 8Gbps internally on the array—would only be used by external Hosts

→5.6.45 qualifies support for the 8Gbps FC IO Cards (Glacier) in the NS-960/NS-G8 Blades, though they will not begin shipping until November 2009

→8Gbps FC support will be added for NS-960/G8 Blade IO Modules in the future

**Note:** NS-120 & NS-480 Blades are not capable of running 8Gbps

→8Gbps FC uses optical SFP+ transceivers and LC connectors, with OM2 or OM3 cables (10/150 meter distance, respectively)

#### **MOJITO 10GbE/1GbE ETHERNET MODULE:**

→Support for the Mojito FrontEnd Ethernet IO card for NX4, NS-120, NS-480, & NS-G2 platforms, Q1 2010

**Note:** Mojito consists of 2-ports 10GbE with optical SFPs (will not support 1GbE speeds) and 2-ports 1GbE copper with RJ45 connectors. The 10GbE interface will support FSN failover from 10G-to-1G; 10G-to-10G; & 10G-to-LACP 1G ports

→Blade part number 100-520-066

#### **# server\_sysconfig server\_2 -pci |tail**

Broadcom 10 Gigabit Ethernet Controller

0: fxg0 IRQ: 24

txflowctl=disable rxflowctl=disable

0: fxg1 IRQ: 25

txflowctl=disable rxflowctl=disable

#### **# cat data\_mover\_resume.server\_2.xml**

<?xml version="1.0"?>

<DataMoverResume Host="server\_2">

  <RESUME\_INFORMATION\_BLADE

**EMC\_PART\_NUMBER="100-520-066"**

    EMC\_ARTWORK\_REVISION=" "

    EMC\_ASSEMBLY\_REVISION="A03"

    EMC\_SERIAL\_NUMBER="CF21B091200008 "

    VENDOR\_NAME="CELESTICA "

    LOCATION\_OF\_MANUFACTURE="THAILAND "

    YEAR\_OF\_MANUFACTURE="2009"

    MONTH\_OF\_MANUFACTURE="4 "

    DAY\_OF\_MONTH\_OF\_MANUFACTURE="10"

    ASSEMBLY\_NAME="**Mojito NS3-40 Dual 10G NAS** "

#### **Troubleshooting Mojito 10GbE:**

**\$ .server\_config server\_x -v "xena fxg0 stat"** [Viewing port statistics on the 10GbE interface]

**\$ .server\_config server\_x -v "xena fxg0 macstats"**

#### **DUAL CONTROL STATION DLm 2.0:**

→Dual Control Station for DLm product (includes NS-120 & NS-960)

→Achieved through use of existing DLm external switch for connecting the 2<sup>nd</sup> Control Station

→Control Station used as management station for the DLm, and is used to pass SNMP traps, deliver ConnectEMC callhomes, and to provide for ESRS connectivity to DLm

#### **MAC OS 10.5 SUPPORT:**

→Support for MAC 10.5 as NFSv3 client

→Support for SMB1 CIFS protocol

#### **PROVISIONING WIZARD for CELERRA MANAGER (aka, UMPW--Unified Manager Provisioning Wizard):**

→Celerra Manager Provisioning Wizard, new naming convention

→This wizard allows users to provision storage for Integrated and FC enabled systems from Celerra Manager, which is a big change from past versions, where only the pure Integrated system was allowed to use Celerra Manager

**Note:** With the advent of this capability, the Celerras>Storage>Systems>array\_name>Configure option is no longer presented

→For NX4, NS20, NS40, NS-120, NS-480, & NS-960 systems

→Celerra Manager “Provision Storage” wizard is available by rightclicking array (Celerras>Storage>Systems>array) or from Wizards>Provisioning>Provision Storage

**Note:** Provisioning capabilities presented are the same as found in the CPW utility. Only a single RAID type can be specified with the provisioning tool at a time, meaning that setup\_clariion may configure a shelf of disks differently because it uses multiple RAID type templates.

→For De-provisioning, Celerra Manager allows the deletion of Hot Spares, and unused Disk Groups (Raid Groups), which is similar to the CLI nas\_disk –delete –perm –unbind, which removes from the Celerra DB and from the array backend (cannot remove individual dvolumes from Celerra Manager as can be done with nas\_disk –delete)

**nas\_storage -delete id=x -spare <spindle\_ID> | -group <diskgroup\_ID>** →Equivalent functionality as with Celerra Mgr

**Note:** As a feature, Deprovisioning was actually included with 5.6.42, which also allowed delete of dvolumes (since removed)

#### **CLARiiON VIRTUAL PROVISIONING SUPPORT:**

→Mira FLARE (.504) introduced Virtual Provisioning Phase I, and Libra FLARE (.704) expands with Phase II

→CLARiiON Virtual Provisioning is a concept whereby more storage can be presented to an application than is physically available. The idea is to be able to increase capacity utilization on the array, simplify storage management, and reduce application downtime.

→Virtual Provisioning groups a collection of physical disks into “Thin Pools”, which are nested under the “Storage Pools” icon in Navisphere, along with traditional LUN RAID Groups. “Thin LUNs” are created within the “Thin Pools” and then added to a Storage Group.

→Main difference between Thin and Thick LUNs is that the former uses less actual physical space—space is only allocated from the Thin Pool when an application uses it

→Celerra supports this feature on Gateway and FC Enabled systems only (since Navisphere must be used and licensed)

→Celerra supports the use of CLARiiON Virtual Provisioning in the creation of file systems or iSCSI LUNs—Thin LUNs are added to the Celerra Storage Group, and diskmarked for use on the Celerra

→Celerra creates a “Storage Pool” for AVM based on the name of the Thin Pool, as created by Navisphere, and creates a separate “Storage Pool Profile” for each corresponding “Thin Pool” where “Thin Luns” are added to the Celerra Storage Group, as shown below:

#### **# nas\_pool -list**

```
id    inuse  acl   name
40    n      0     Thin Pool 0_FNM00083800203
41    y      0     Thin Pool 1_FNM00083800203
```

**Note:** Each time new Thin Luns are added to the Celerra that originate from different CLARiiON Thin Pools, a new Storage Profile Name is assigned and added to the ‘pools’ file

#### **# cat /nas/volume/pools|tail**

```
40:Thin Pool 0_FNM00083800203:0:Thin Pool Thin Pool 0 on FNM00083800203:1:1:y:n:n:80:y:y:
41:Thin Pool 1_FNM00083800203:0:Thin Pool Thin Pool 1 on FNM00083800203:1:1:y:n:n:82:y:y:
```

#### **# nas\_disk -info d9**

```
id      = 9
name    = d9
acl     = 0
in_use  = True
pool    = Thin Pool 0_FNM00083800203
size (MB) = 51199
type    = CLSTD
protection= RAID5(2+1)
stor_id  = FNM00083800203
stor_dev = 0006
volume_name = d9
storage_profiles = Thin Pool 0_FNM00083800203
virtually_provisioned = True
```

→Celerra does not rename Thin LUNs, but does adjust the HLU value to a legal Celerra data lun value

#### **USING NAVICLI:**

**# /nas/sbin/navicli -h 10.241.168.150 storagepool -list**

**# /nas/sbin/navicli -h 10.241.168.150 thinlun -list**

**# /nas/sbin/naviseccli -h 10.241.168.179 -user nasadmin -password nasadmin -scope 0 thinlun -create -type Thin -capacity 5 -sq gb -poolId 2 -sp a**

#### **CLARiiON VIRTUAL PROVISIONING RULES:**

→Not supported with Vault drives or Celerra Control LUNs

- Not supported with CPW or UMPW
  - Not supported with MirrorView or SAN Copy
  - Not supported with Reserved LUN pools, clone Private LUNs, or as a component of a metaLUN
  - Cannot use Celerra VP with CLARiiON VP for the same LUNs
  - Best Practice to not mix virtual and dense LUNs, mix Disk Technology, or Disk sizes, within a pool
  - Best not to use Thin LUNs for high performance applications
  - Thin LUN size limited from 1GB to 14TB
  - For VMWare configurations, setup VMWare virtual disks as “zeroedthick”—storage is reserved in the Datastore, but the VMWare kernel does not initialize all the blocks until the guest O/S begins writing to uninitialized blocks
  - Do not create sparse iSCSI luns from file systems that are built on CLARiiON Thin Luns
  - Feature requires installation of the VirtualProvisioningEnabler on the array (CLARiiON Support Site)
- Note:** Download from CLARiiON Support Site: [VirtualProvisioningEnabler-01.01.5.001-fleet64\\_free.ena](#)
- Feature requires configuration of Thin Pools and Thin LUNs via CLI, or Navisphere, either via the Storage Provisioning Wizard, by Thin Pools icon under Storage Pools>Create Thin Pool, or by rightclicking Array\_name or Storage Pool icon > Storage Pool Operations >Create Storage Pool>Storage Pool Type:
    - o RAID Group    o Thin Pool
      - Thin Pools can be expanded via Navisphere/CLI by adding disk drives to the pool
      - When Thin LUNs are deleted, space is reclaimed in the Thin Pool by ‘Consumed Capacity’
      - CLARiiON Thin Pools are supported with FC, SATA, or EFD drives in R5 & R6 configurations

**Note:** RAID 5 is the default selection when creating Thin Pools and is recommended--when expanding a R5 Thin Pool, add disks in multiples of 5, minimum of 3 disks. RAID 6 can be used, and is recommended for SATA drives--add disks to R6 Thin Pools in multiples of 8 drives, minimum of 4 disks.

- Supported with IP Replication (configure virtual provisioning on Source only, Destination will synchronize automatically)
- Not supported on NX4 since it's based on Flare 23

### **THIN POOL TERMINOLOGY:**

- Thin Pool ‘User Capacity’ is the total raw capacity of the drives, less the overhead associated with the RAID protection, that can be used by all Thin LUNs in the pool
- ‘Consumed Capacity’ is what is actually allocated from the total ‘User Capacity’, and includes Array overhead in building a Thin LUN (requires minimum of 2GB per Thin Lun), and Host file systems created
- ‘Total Subscribed Capacity’ is the total capacity used by the Host(s) (file systems, iSCSI LUNs, etc.)
- ‘Percent Subscribed’ is derived from Total Subscribed Capacity divided by User Capacity \* 100
- % Full Threshold (Consumed Capacity / User Capacity) is an alert monitoring mechanism on the array that issues a Warning when the threshold is crossed, and a Critical alert when pool usage crosses 85%. By default, Thin Pools are created with a 70% threshold value.
- ‘Oversubscribed by’ is when ‘Total Subscribed Capacity’ exceeds the ‘User Capacity’ of the Thin Pool

### **NS-G2 REBRANDING of NS40G:**

- Rebranding the NS40G as the NS-G2 product. /nas/sbin/model will show the system as an NS-G2 based on new TLA part number from manufacturing. Upgraded systems will not change and will remain NS-40G.
- Differences between NS-G2 and NS40G is that NS-G2 will support the Mojito Ethernet card, Maynard CS only, provides 3-year warranty, offers Enhanced support, and recommends additional 1U space by Control Station for access

### **/nas/sbin/t2vpd**

**Note:** Parses for known NS-G2 TLA numbers from resume, & use nas\_xml command to set model to NS-G2 vs. NS40G

### **NS-G2 Enclosure TLA's/Models (Single & Dual-blade systems):**

Factory model NSG2-1A/2A

100-520-679, 100-520-680 for Single & Dual Blade enclosure, 4-port Cu 1GbE Ethernet card

Factory model NSG2-1B/2B

100-520-681, 100-520-685 for Single & Dual Blade enclosure, 2-port Optical 1GbE, 2-port Cu 1GbE Ethernet card

Factory model NSG2-1C/2C

100-520-686, 100-520-687 for Single & Dual Blade enclosure, 2-port 10GbE Optical, 2-port 1GbE Cu Mojito Ethernet card

**Note:** FRUs & CRUs will be the same as presented for front-end on NS-120/NS-480 Celerra

### **Hardware Commands:**

# **/nas/sbin/t2vpd -s 2** →Blade & SFP info from RESUME PROM

# **/nas/sbin/t2vpd -e 0** →Enclosure TLA information

### **64-BIT CEE SUPPORT:** CEE Version 4.5.0.4

→64-bit Windows application for 64-bit Operating Systems

→64-bit CEE offers IPv6 runtime support and replaces ONC/XDR [ONC/RPC] protocol communications with MS-RPC using XML payloads (eliminates need to continue licensing the 32-bit ONC product from Distinct)

→Both 32-bit and 64-bit CEE kits will be maintained

EMC\_CEE\_Pack\_Win32\_4.5.0.4 (32-bit version)

EMC\_CEE\_Pack\_x64\_4.5.0.4 (64-bit version)

→New CEE version backwards compatible with ONC protocol if NAS is down-rev

→Adds new fault tolerance feature

→Adds Auditing class support based on DatAdvantage from Varonis

#### **Upgrading from 32-bit to 64-bit CEE:**

1) Would require uninstall of existing CEE or CAVA package, followed by installation of the 64-bit version

2) viruschecker.conf & cepp.conf files would require editing to add IPv6 addresses

addr=192.16.20.15:192.16.20.16:[001:0db8:85a3:0000:0000:8a2e:0370:7334]

3) Edit cepp.conf file to add new fault tolerance level line & msrpcuser=<cee\_username> line

#### **CEPA AUDITING CLASS SUPPORT:**

→CEPA Phase 2 Auditing class application support [DatAdvantage—from Varonis]

→Adds two new events for auditing: OpenDir and CloseDir

**Note:** Auditing clients will register with CEPA API and use “post-event” reporting from Celerra to gather auditing events without blocking CIFS calls. CEPA API uses an IDL & XML DTD file to interact with the application host (XML over RPC). Application could be co-resident within the CEE framework using local RPC calls, or remote using MS-RPC calls. Windows clients that perform file or directory create, open, close, close after modification, rename, delete, set acl functions can be audited. CEPA will gather events and context to create the tuple that is delivered with the CEPA API to registered applications. “Context” consists of event type, UNC, NetBIOS name of server, File owner SID, File user SID, file size, dwDesiredAccess, dsCreationDisposition.

#### **New Lines for Cepp.conf file:**

**ft level=0** →Fault Tolerance feature

**msrpcuser=domain.ceeuser** (domain name used to run CAVA service on CEE system)

#### **New Fault Tolerance Capability:**

ft level=0 location=/fs1 size=5 →with loss of CEPA heartbeat, continue and tolerate lost events (default setting)

ft level=1 →with loss of CEPA heartbeat, continue and use a persistent buffer file as a circular event buffer for lost events (once buffer is full, events will be overwritten)

ft level=2 →with loss of CEPA heartbeat, continue and use a circular event buffer file until buffer is full, then stop CIFS

ft level=3 →with loss of CEPA heartbeat, stop CIFS

**Note:** Without location specified, circular event buffer file is written to root; without size specified, default is 1MB for persistent buffer file.

**# server\_cepp server\_x –pool –stats –all** (to observe auditing statistics)

#### **MSRPC VC/CEPP ISSUE:**

→If CEPP cannot perform a reverse DNS lookup of the IP Address to a Name, the Server Logs will become flooded with the following entries, because it tries to use MSRPC, which will fail: See AR149912.

2009-07-21 09:16:54: 26041909248: SMB: 6: netbios session request failed return type 83 error 82 (see rfc 1002) on server 198 with client FILESRV01AVBK with port 139

#### **Workaround:**

→Set “param cepp RPCtype=1” to disable MSRPC protocol for VirusChecker and CEPA and to use ONC-RPC

1= ONCRPC

2= MSRPC

3= both (default)

#### **CST 1.1 TOOLKIT:**

→Replacing Control Station CAMS Common Sign-On (CSO) module with the RSA Common Security Toolkit (CST) module—this is used for communications & authentication with external directory servers

→Allows sharing of encryption keys, such as for dual CS environments

#### **SYMMETRIX V-MAX TOLERANCE:**

→Support for V-Max backends, using SymAPI version V7.0.0.0-914 or higher

→Minimum microcode level that supports Solutions Enabler 7.0 (i.e., SymAPI 7.0) is 5671

→NAS upgrades to 5.6.45 or higher will be blocked if any backends are detected as Symm 5 or older, or if the Symm Microcode level is below 5671

#### **SYMMETRIX SUPPORT:**

→Symm 5 & 5.5 are not be supported with 5.6.45 because the Solutions Enabler SymAPI version is V7.0

Symm Family: 5.0 & 5.5; Model 81xx, 84xx, 87xx (Microcode 5566, 5567, 5568), & 82xx, 85xx, 88xx (5567, 5568)

→Also, DMX & DMX2 are not supported unless running microcode 5671 or higher

#### **8K TREE QUOTAS:**

→Support for 8K tree quotas per file system (from 2048 to 8096 tree quotas per file system)

### **COGNAC 5.6 MAINTENANCE RELEASE 9 (CMR9 5.6.46)—RFE Aug 2009**

→CPW integration into DART release cycle was scheduled, but is now postponed. Instead, a separate CPW version will be posted on Powerlink.

### **COGNAC 5.6 MAINTENANCE RELEASE 10 (CMR10 5.6.47) GA Dec 2009:**

**CELERRA PANIC CALLHOME/LOGGING ENHANCEMENTS—See emc227235:**

- Serviceability feature for providing system ‘snapshot’ & panic header info in the CDATA section of the CallHome payload for all Blade Panics (<than 100kb)
- When triggered, the /nas/tools/.status\_check script runs a series of commands to gather a Snapshot of the system state, along with the panic header file, and inserts the information into the CDATA CalHome XML file as plain text. The contents of another new feature, the /nas/log/inventory\_status file are also delivered, but for all CallHomes (and not just panics)
- Useful for initial triage as it does not require Support to dial back into the system to determine panic header and whether system failed over properly or not
- Script basically collects panic header, failover status, NAS information, Array information, and snippets from sys\_log, server\_log, SP logs, etc.

**New BoxMonitor Panic Events:****BoxMonitor:CRITICAL:802 to 815** (slots 2-14)

- Original BoxMonitor Panic Event IDs (BoxMonitor:CRITICAL:302 to 315) are kept to record actual panic time, but by themselves, no longer call home

**How does the new feature work?**

- A Panic triggers Event 302-315, logs to sys\_log, calls recover\_slot, which calls .status\_check, then Event 802-815 fires & sends XML CallHome with payload
- Goal is to run .status\_check within 30 seconds, with a hard cutoff at 2 minutes, at which point the script will send whatever it has collected, in the CallHome
- Panic CallHomes are limited by System to once every 24 hours per Blade

**/nas/sys/nas\_eventlog.cfg file**

```
disposition range=802-802 threshold=1 rearm=1000 resetafter=86400, callhome plaintext
```

**BoxMonitor sys log events for slot\_3 panic with old & new event ID:**

- ```
Nov 5 12:25:18 2009:CS_PLATFORM:BoxMonitor:CRITICAL:303:::1257441918:Slot 3 has panicked.
Nov 5 12:25:25 2009:CS_PLATFORM:BoxMonitor:DEBUG:905:::1257441925:Slot 3 recover_slot /nas 3 has started.
Nov 5 12:29:20 2009:CS_PLATFORM:BoxMonitor:CRITICAL:803:::1257442160:Slot 3 has panicked - post panic logging complete: >>PANIC in file: ../../dskdump.cxx at line: 1836 : for new panic event test. Dump information can be found in /nas/log/post_panic_info_2009_11_05_12:29:03_EST_slot_3.log.
```

**Script & Input file:****/nas/tools/.status\_check** → Main script for this new feature

- Gathers panic header; failover recovery status; NAS version; model info; log collection status; getreason codes; sys\_log, cmd\_log, cmd\_log.err, /var/log/messages info; FCP info; server version and info; NAS Cel list; exports; NFS & CIFS Stats; storage list; Navicli getagent, getcrus, getcache, getdisk, getlun –trespass, getlog -50

**/nas/tools/.status\_checks.csv** → Editable input file to .status\_check for commands to run with .status\_check**Log Files:****Post Panic Info Log:****/nas/log/post\_panic\_info\_<date>\_slot\_x.log**

```
-rw-r--r-- 1 root root 70515 Nov 10 11:27 post_panic_info_2009_11_10_11:26:59_EST_slot_2.log
-rw-r--r-- 1 root root 2454 Nov 10 11:27 panic_headers.log
```

- The post\_panic\_info\_<timestamp>\_<slot\_x>.log holds system summary info from .status\_check, with up to (14) unique post\_panic\_info log files kept

**Panic Headers Log:****/nas/log/panic\_headers.log**

- This file holds up to 2000 lines of panic header info, trimmed back to 2000 lines daily, as needed, via log trimmer in /nas/sys/nas\_mcd.cfg

**Log Trimmer:****/nas/sys/nas\_mcd.cfg**

- This is where the Panic Headers log Trimmer lives

```
daemon "Paniclog Trimmer"
  executable  "/nas/sbin/log_trimmer"
  optional    no
  autorestart yes
  ioaccess    no
  cmdline     "-n /nas/log/panic_headers.log 2000 1 24 h t 2 n"
```

**Can run the .status check script manually:****# /nas/tools/.status\_check -showAll** (hidden switch)

```
.status_check: -slot <slot_num> [ -f <csv_input_file> ] [ -quiet ] [ -verbose ] [ -timeout ]
               | -csv_op [ check | clean ] [ -f <csv_input_file> ]
```

-slot: Mandatory argument. Information will be collected with regards to the server in this slot.

-quiet: Operation will display no output. | -verbose: Operation will display detailed process information.  
-f: Absolute path to custom CSV file  
-timeout: Overwrite the default timeout given for this operation to complete (default 120 secs)  
-csv\_op: Mandatory argument. Followed up by either check or clean  
check: Check if the file is sane and not malformed.  
clean: Make CSV file user readable and properly justified

## # /nas/tools/.status\_check -s 2

Spawning worker threads to collect information...done  
Waiting for jobs to finish.....done  
Collection log saved to: /tmp/.system\_status\_slot\_2.txt → Information saved here when .status\_check run manually

### NAS Event Information:

#### # nas\_event -list -action callhome|grep -i 802

802 CRITICAL(2) Slot \${SLOT},24,%u} has panicked - post panic logging complete: \${PANIC\_INFO},8,%s}. Dump information can be found in \${src\_file\_path},8,%s}.

#### /nas/sys/nas\_eventlog.cfg file contents

```
disposition range=802-802 threshold=1 rearm=1000 resetafter=86400, mail user
    disposition range=803-803 threshold=1 rearm=1000 resetafter=86400, mail user
    disposition range=804-804 threshold=1 rearm=1000 resetafter=86400, mail user
disposition range=802-802 threshold=1 rearm=1000 resetafter=86400, callhome plaintext
    disposition range=803-803 threshold=1 rearm=1000 resetafter=86400, callhome plaintext
    disposition range=804-804 threshold=1 rearm=1000 resetafter=86400, callhome plaintext
```

**Note:** The 86400 = seconds, which translates into once every 24 hours

### Contents of Post Panic Info File:

<![CDATA[CCMD ID: 78928610082

Brief Description: Slot 2 has panicked - post panic logging complete: >>PANIC in file: ./dskdump.cxx at line: 1836 : testing new panic handling feature. Dump information can be found in /nas/log/post\_panic\_info\_2009\_11\_10\_11:26:59\_EST\_slot\_2.log.

Full Description: The DART OS running on the Data Mover slot has panicked. The specified dump information that describes this error can be found in the dump log.

Recommended Actions: To resolve this problem, perform the following: To resolve this problem, perform the following:

1. Using the CLI, log in as nasadmin (or as a user with NAS administrative privileges) and "su" to root (requires the root password).
2. To check for the existence of the logs, run the "cd /nas/var/emcsupport" command and then the "ls" command to see if the log collection file exists.
  - \* An example file is support\_materials\_APM00073701085.080206\_1401.zip.
3. To check for the existence of the dump and header files, run the "cd /nas/var/dump" command and then the "ls" command to see if the dump files exist.
  - \* Example dump files are dump\_APM00073701085.080206\_1411.dump.gz and header\_APM00073701085.080206\_1411.txt.
4. If the Data Mover continues to be unresponsive or for assistance, search the Knowledgebase on Powerlink as follows:
  - a. Log in to <http://powerlink.emc.com> and go to Support > Knowledgebase Search > Support Solutions Search.
  - b. Use the message ID or text from the error message's brief description to search.

A list of all dump headers can be found by performing the following actions:

1. To view the post\_panic\_info file, run the "cd /nas/log/" command and then run "cat post\_panic\_info | less" and look at the specified dump information.

System Configuration Snapshot: Tue Nov 10 11:15:02 EST 2009

Control Station Slot No: 0

#--Panic header--##

DART time of dump: Tue Nov 10 08:13:48 2009 UTC

Product: EMC Celerra File Server

Uptime: 010 days, 22:24:16

Version: T5.6.47.6

IP Address: 128.221.252.2

Host Name: server\_2

COMPRESSED = YES

DART panic/fault message:

>>PANIC in file: ./dskdump.cxx at line: 1836 :

testing new panic handling feature

-----output abridged-----

#--Failover / recovery status--##

Status\_check collection script version: 1.0

Time on Control Station: Tue Nov 10 11:27:00 EST 2009

Information being collected for slot: 2

Standby slot for this slot is: 3

Failover status: SUCCESS

Recovery status: SUCCESS

#--NAS Version--##

5.6.47-6

##--Model--##

NS-960

##--Automatic Collection Status--##

Current configuration:

The automatic collection feature is enabled and the automatic transfer feature is disabled

Maximum number of dumps allowed in /nas/var/dump: 2

##--Reason Codes--##

10 - slot\_0 primary control station

4 - slot\_2 configured(Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c ; Slic Code = 33686017)

5 - slot\_3 contacted(Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c ; Slic Code = 33686017)

##==sys\_log Info==##

Nov 9 10:01:13 2009:CS\_PLATFORM:NASDB:INFO:306:::1257778873:nasdb\_backup: Celerra database backup done.

Nov 9 11:01:08 2009:CS\_PLATFORM:NASDB:INFO:300:::1257782468:nasdb\_backup: NAS\_DB checkpoint is in progress.

-----output abridged-----

##==Status Report==#

Collection status: SUCCESS

The overall execution time for this collection was: 16 seconds

**Panic still triggers Auto Log Collect Script Feature, which is independent of the Panic Enhancement feature:**

→Auto Log Collection & Dump collection still takes place independently

**/nas/var/emcsupport**

-rw-rw-r-- 1 nasadmin nasadmin 2527422 Nov 5 12:32 support\_materials\_FNM00083800203.091105\_1229.zip

**/nas/var/dump**

-rw-rw-r-- 1 nasadmin nasadmin 28059525 Nov 5 12:29 dump\_FNM00083800203.091105\_1229.dump.gz

**UNIFIED BLOCK STORAGE EXPERIENCE (UBSE):**

→New Marketing characterization for Celerra Integrated offerings

→Unified Block Storage the new Integrated terminology

→A major goal of this initiative is to support all CLARiiON CX4 SP I/O Modules configurations on Celerra Unified models (e.g., 8Gbps FC; 10Gbps iSCSI)

→Allows for Native Block CLARiiON FC & iSCSI support--LUN can be presented via FC or iSCSI to Hosts, and can support all the CLARiiON Layered Applications

→A supporting goal is to shift to “Base Models” in the Order Entry process—customers order a ‘Base NS-480’, ‘Base NS-960’, etc., then add whatever legal combinations of SLICs are allowed for the SPs, along with a choice of MPFS over iSCSI/FC, or native CLARiiON iSCSI/FC licenses

→Marks the transition from Celerra iSCSI as a product, to CLARiiON iSCSI, phasing out the former

→However, for the time-being, the /nas/sbin/model command will still display the three variants that we know today (e.g., NS-120, NS-120iS, NS-120FC), but will transition next year to only a single /nas/sbin/model name per Celerra platform (e.g., NS-120 only)

→Be advised that the Install Guides, and other formal documentation, have already removed the use of the “FC” and “iS” terms

→A related nas\_inventory feature was introduced to assist providers in Remote System identification (nas\_inventory will be discussed in detail in next Topic)

→/nas/sbin/model can no longer be used alone to define the actual system ‘type’

→/nas/sbin/model expanded with “–option –list” to show license option for a particular system (read from /etc/be\_sg\_info file)

→/nas/sbin/nas\_hw\_upgrade expanded to allow Mfg or Field to enable or disable license flag options depending on Customer Sales Order for the Unified models, used during Installs and HW Upgrades

→During factory installation, either the “FC Enabled” or “Integrated” option is selected, then after installation, the has\_hw\_upgrade script is run, with appropriate switches selected based on Licenses and Physical SLICs ordered

→/nas/log/nas\_xml.xml contains model name used for display purposes

**Protocol Licenses available when ordering:**

NS120/480/960-NBOPTUL MPFS over FC →MPFS FC (mpfsfc flag)

NS120/480/960-NBOPTUL MPFS over iSCSI →MPFS iSCSI (mpfssi flag)

NS120/480/960-NBOPTUL CLARiiON FC →CLARiiON FC (clarionfc flag)

NS120/480/960-NBOPTUL CLARiiON iSCSI →CLARiiON iSCSI (clarionis flag)

**Note:** CLARiiON FC or ISCSI is referred to as Native Block storage (NB)

**Protocol License Flags/Options:**

→License “flags” are added or deleted by using nas\_hw\_upgrade script

→License “flags” are written to /etc/be\_sg\_info file

→License “flags” are displayed via /nas/sbin/model –option –list

**License Flag Translation Table:**

**/nas/sbin/model –option –list**

**tail /etc/be\_sg\_info**

**/nas/sbin/nas\_hw\_upgrade**

|                                |                       |                             |
|--------------------------------|-----------------------|-----------------------------|
| OPTION ENABLED: MPFS FC        | MPFSF_ENABLED=YES     | -option -enable -mpfsfc     |
| OPTION ENABLED: MPFS iSCSI     | MPFSI_ENABLED=YES     | -option -enable -mpfsis     |
| OPTION ENABLED: CLARIION FC    | CLARIIONF_ENABLED=YES | -option -enable -clariionfc |
| OPTION ENABLED: CLARIION iSCSI | CLARIIONI_ENABLED=YES | -option -enable -clariionis |
| OPTION ENABLED: SAN            | FC_ENABLED=YES        | -fc_option -enable          |

**Note:** Each line represents a protocol license option and the different way it's displayed, depending on what's being looked at

**Manufacturing Rules:**

→If MPFS over FC and/or MPFS iSCSI, system installed as an “Integrated”

→If CLARiiON FC and/or CLARiiON iSCSI, system installed as an “FC Enabled”

→Specific license “flags” are written to /etc/be\_sg\_info file during installation when /nas/sbin/nas\_hw\_upgrade script is run

**Upgrade/Reinstall Rules:**

→Field will be expected to update license flags per the upgrade procedures or during system reinstalls—for Upgrades, the Field may need to refer to the Sales Order for licensing & SLIC HW info

**Special Installation Note:**

→During fresh NAS installs, the system gives an option for “FC Enabled” or “Integrated”. You would select “FC Enabled” if the “CLARiiON FC” or “CLARiiON iSCSI” options were ordered, otherwise “Integrated”.

→Display model name is a function of Install choice, the nas\_hw\_upgrade flags enabled, and actual HW I/O modules used

**NAS HW UPGRADE FLAG OPTIONS:**

# **/nas/sbin/nas\_hw\_upgrade** →Used to add, remove, or list protocol Flag options, writes to be\_sg\_info file

```
nas_hw_upgrade -fc_option {-enable|-disable}  
nas_hw_upgrade -option {-enable|-disable} {-mpfsfc -mpfsis -clariionfc -clariionis}  
nas_hw_upgrade -option -list {-mpfsfc -mpfsis -mpfs -clariionfc -clariionis -clariion -san}
```

**/nas/log/nas\_hw\_upgrade.log**

→Logs upgrade and license flag option activities

# **tail /etc/be\_sg\_info**

# **/nas/sbin/model -option -list** →Output of this command reads from /etc/be\_sg\_info file

```
OPTION ENABLED: MPFS FC  
OPTION ENABLED: MPFS iSCSI  
OPTION ENABLED: CLARIION FC  
OPTION ENABLED: CLARIION iSCSI  
OPTION ENABLED: SAN
```

**Translating upgrade licenses into flag options (i.e., MPFS over FC, MPFS over iSCSI, CLARiiON FC, CLARiiON iSCSI):**

→Based on CPQO rules, customer orders SLIC upgrades per rules established by CLARiiON, for the CX4 system that they have, and order appropriate protocol licenses, resulting in the Sales Order

→Field/Support may need to establish if any of the applicable licenses are on the Sales Order

→Use the SLIC I/O Upgrade procedures to help translate what licenses apply to which nas\_hw\_upgrade flag option (Celerra Procedure Generator)

**UBSE System Model Display Rules:**

→If the MPFSIS flag is set during install, system reports as “iS” model

→If MPFSIS flag is set, and the MPFSFC flag, system still reports as “iS” model

→If MPFSFC flag is set, or no flags are set, system reports as plain Integrated model (NS-960)

→If CLARiiON iSCSI, CLARiiON FC, or FC Enabled option during install are set (alone or in combination with each other), then system reports as an “FC” model, with SAN flag option and FC Enabled=Yes flag set

→NAS Upgrades to 5.6.47 will not change display model output

→During factory build-to-ship, system model display is reflected by FC Enabled vs. Integrated choice, and the flag options selected when using the nas\_hw\_upgrade script

→In the field, system model display and options will be changed or updated based on the use of the nas\_hw\_upgrade script, presumably in conjunction with hardware and license upgrade activities

→/nas/log/nas\_xml.xml file contains the displayed model name based on install and flag options used during install/upgrade

**CSA SETUP MPFS RULE:**

→CSA will only offer “Setup MPFS” configuration option if MPFS FC and/or MPFS iSCSI flags are enabled

**EXAMPLES OF SYSTEM MODELS:**

**Base NS-120 Example for CLARiiON iSCSI:**

→A base NS-120 is ordered with a Clariion iSCSI license and physical iSCSI I/O modules for the array

→Clariion iSCSI or Clariion FC automatically means the system is installed with the “FC Enabled” option

→It shows up at CSA configuration time as an “NS-120FC” with the “SAN” option enabled, and the factory used the nas\_hw\_upgrade command to set the -clariionis Flag

# **/nas/sbin/model**

NS-120FC

# **/nas/sbin/model -option -list**

OPTION ENABLED: CLARIION iSCSI

OPTION ENABLED: SAN

# /nas/sbin/nas\_hw\_upgrade -option -enable -clarionis (Flag applies if iSCSI modules ordered with the NS-120 system)

**Base Model without any License Flags Ordered:**

# /nas/sbin/model -option -list

OPTION ENABLED: NOT AVAILABLE  No Flag options are set

# /nas/sbin/model

NS-960

**Example output when only FC Flag set:**

# /nas/sbin/nas\_hw\_upgrade -fc\_option -enable

# /nas/sbin/model

NS-960FC

# cat /etc/be\_sg\_info | grep FC

FC\_ENABLED=YES

# /nas/sbin/model -option -list

OPTION ENABLED: SAN

**Example output when only MPFSIS Flag is set:**

# /nas/sbin/nas\_hw\_upgrade -option -enable -mpfsis

# /nas/sbin/model

NS-960iS

# /nas/sbin/model -option -list

OPTION ENABLED: MPFS iSCSI

# tail /etc/be\_sg\_info

FC\_ENABLED=NO

MPFSI\_ENABLED=YES

**Note:** iS designation used only if the MPFSI Flag is enabled (and the MPFSF Flag can be enabled), but no FC Enabled, no Clariion iSCSI, or no Clariion FC enabled flags are set

**Example output when MPFSIS flag is set, and either Clariion iSCSI or Clariion FC flags are set:**

→ Always results in FC Model + SAN flag, or both, results in FC Model & SAN Flag also set

# /nas/sbin/nas\_hw\_upgrade -option -enable -clarionfc -clarionis

# /nas/sbin/model

NS-960FC

# /nas/sbin/model -option -list

OPTION ENABLED: MPFS iSCSI

OPTION ENABLED: CLARIION FC

OPTION ENABLED: CLARIION iSCSI

OPTION ENABLED: SAN

# tail -4 /etc/be\_sg\_info

MPFSI\_ENABLED=YES

CLARIIONF\_ENABLED=YES

CLARIIONI\_ENABLED=YES

FC\_ENABLED=YES

**UNIFIED STORAGE MODELS:**

**NS-120 Model:**

Base NS-120 offers 2 blades, 120 drives, NAS only (i.e., no licenses)

Array models are AUX, AUXF, & AUXF8

**NS-480 Model:**

Base NS-480 offers 4 blades, 480 drives, NAS only (i.e., no licenses)

Array models are AUX

**NS-960 Model:**

Base NS-960 offers 4 blades, 480 drives, NAS only (no licenses), and 4 or 8Gbps FC Modules on the SPs slots 0 & 1

Array models are AUX and AUX8

**NS-120 UNIFIED MODELS:**

**NS-120 Base NS120-AUX (1) 4-port 4Gbps FC card (slot 0)**

slot\_1 → Can have (1) 2-port 1Gbps iSCSI card or (1) 2-port 10Gbps iSCSI card

slot\_2 → Can have (1) 4-port 4Gbps FC card, or (1) 4-port 8Gbps FC card, or (1) 2-port 1Gbps iSCSI card

**Note:** Single BE port slot\_0 port 0 for DAE's

**NS-120FC Base NS120-AUXF (1) 4-port 4Gbps FC card (slot 0)**

slot\_1 → Can have (1) 2-port 1Gbps iSCSI card or (1) 2-port 10Gbps iSCSI card

slot\_2 → Can have (1) 4-port 4Gbps FC card

**Note1:** Single BE port slot\_0 port 0 for DAE's

**Note2:** The AUXF variant is phased out in Q3 2010

**NS-120FC Base NS120-AUXF8 (1) 4-port 4Gbps FC card (slot\_0)**

slot\_1 → Can have (1) 2-port 1Gbps iSCSI card or (1) 2-port 10Gbps iSCSI card

slot\_2 → Can have (1) 4-port 8Gbps FC card

**Note1:** Single BE port slot\_0 port 0 for DAEs

**Note2:** The AUXF8 variant will go away Q3 2010

**NS-120 SLIC SLOT RULES:**

→ If 10Gbps iSCSI card selected, must go in lowest eligible slot, which is slot\_1

→ Only a single 10Gbps iSCSI card allowed per SP on the NS-120

→ If 8Gbps FC card selected, must go in lowest eligible slot, which is slot\_2

**NS-480 UNIFIED MODELS:**

**NS-480 Base NS480-AUX (2) 4-port 4Gbps FC cards (slot\_0 & 1)**

slot\_2 → Can have (1) 2-port 1Gbps iSCSI card or (1) 2-port 10Gbps iSCSI card

slot\_3 → Can have (1) 4-port 4Gbps FC card, or (1) 2-port 1Gbps iSCSI card, or (1) 4-port 8Gbps FC, or (1) 2-port 10Gbps iSCSI

slot\_4 → Can have (1) 2-port 1Gbps iSCSI card

**Note:** Two BE ports slot\_0 & slot\_1 ports 0 & 1 for DAEs

**NS-480 SLIC SLOT RULES:**

→ If 10Gbps iSCSI card selected, must go in lowest eligible slots, starting with slot\_2 and/or slot\_3

→ Add any 1Gbps iSCSI to the right of 10Gbps iSCSI slots

→ If 8Gbps FC card selected, must go in slot\_3

→ Only (2) 10Gbps iSCSI cards allowed per SP on NS-480

**NS-960 UNIFIED MODELS:**

**NS-960 Base1 NS960-AUX (2) 4-port 4Gbps FC cards (slot\_0 & 1)**

**NS-960 Base2 NS960-AUX (2) 4-port 8Gbps FC cards (slot\_0 & 1)**

slot\_2 → Can have (1) 4-port 4Gbps, or (1) 2-port 1Gbps iSCSI, or (1) 4-port 8Gbps FC, or (1) 2-port 10Gbps iSCSI (FC can be used for Host, Blade, or Backend connectivity)

slot\_3 → Can have (1) 4-port 4Gbps, or (1) 2-port 1Gbps iSCSI, or (1) 4-port 8Gbps FC, or (1) 2-port 10Gbps iSCSI (FC for Host or Blade connectivity)

slot\_4 → Can have (1) 4-port 4Gbps, or (1) 2-port 1Gbps iSCSI, or (1) 4-port 8Gbps FC, or (1) 2-port 10Gbps iSCSI (FC Host connectivity)

slot\_5 → Can have (1) 2-port 1Gbps iSCSI card, or (1) 2-port 10Gbps iSCSI card, or (1) 4-port 4Gbps FC, or (1) 4-port 8Gbps FC (FC Host connectivity)

**Note:** Two BE ports slot\_0 & slot\_1 ports 0 & 1 for DAEs, plus optional (4) BE ports if FC card added to slot\_2

**NS-960 SLIC SLOT RULES:**

→ If >than 480 drives needed, add a 4Gbps FC card in slot\_2 for BE DAEs

→ If 10Gbps iSCSI card selected, must go in lowest eligible slots, starting with slot\_2, slot\_3, slot\_4, or slot\_5, but only a max of (20 of these to a configuration

→ Max. of (2) 10Gbps iSCSI cards per SP

→ Add any 1Gbps iSCSI to the right of 10Gbps iSCSI slots

→ If 8Gbps FC card selected, goes in lowest eligible slot, starting with slot\_2, 3, or 4

→ Add any 4Gbps FC cards to the right of 8Gbps FC cards, for max. of (2)/configuration

**AUX ARRAY MODELS:**

NS120-AUX → NS-120 with 4Gb FC slot\_0 only

NS120-AUXF → NS-120 with 4Gb FC slot\_0 & slot\_2

NS120-AUXF8 → NS-120 with 4Gb FC slot\_0 & 8Gb FC slot\_2

NS480-AUX → NS-480 with 4Gb FC slot\_0 & slot\_1

NS960-AUX → NS-960 with 4Gb FC slot\_0 & slot\_1

NS960-AUX8 → NS-960 with 8Gb FC slot\_0 & slot\_1

**Additional SLIC Models:**

AUX-M4GF-FE-A = 4Gb FC

AUX-M8GF-FE-A = 8 Gb FC

AUX-M1GI-A = 1Gb iSCSI

AUX-MXGI-A = 10Gb iSCSI

AUX-M4GF-BE-A = 4Gb FC for BE (Backend)

**LICENSE MODELS WITH TRANSLATIONS:**

NS120-NBOPTL + NAV-NS120 → Native FC/iSCSI license + Navisphere lic.

NS480-NBOPTL + NAV-NS480 → Native FC/iSCSI license + Navisphere lic.

NS96-NBNV480L → Native FC/iSCSI license for < than 480 drives, with Navisphere

NS96-NBNV960L → Native FC/iSCSI license for > than 480 drives, with Navisphere

**Note:** Existing rules apply if ordering MPFS over FC or MPFS over iSCSI

**Example MPFS over FC (Linux, 1 Host, 2 CPUs):**

MPFS-CPU-LIC + MPFS-CPU-T1 (qty 2) + MPFS-LNX-DCD

**EXAMPLE OF HOW TO CHANGE MODEL DISPLAY:**

**Scenario:**

# /nas/sbin/model

NS-960

# cat /etc/be\_sg\_info

--edited for brevity----

MPFSF\_ENABLED=YES

# /nas/sbin/model -option -list

OPTION ENABLED: MPFS FC

**Changing from NS-960 to NS-960iS Model:**

# /nas/sbin/nas\_hw\_upgrade -option -enable -mpfsis

Checking if running on primary CS...yes

Checking if running as root...yes

Checking for integrated system...yes

Checking if model is supported...yes

Checking if backend is supported...yes

Options enabled:

MPFSI\_ENABLED=YES

Model: NS-960iS

Command succeeded

# /nas/sbin/model

NS-960iS

# tail /etc/be\_sg\_info

-----edited for brevity-----

MPFSF\_ENABLED=YES

MPFSI\_ENABLED=YES

# /nas/sbin/model -option -list

OPTION ENABLED: MPFS FC

OPTION ENABLED: MPFS iSCSI

**USE CASE: NS-960 SP IO MODULE UPGRADE 5.6.47**

**Note:** Started with simple NS-960 system, with only (2) FC IO Modules per SP, in slots\_0 & 1. Used the NST tool to add a single 2-port iSCSI IO Module to SPs in Slot\_2 (A2 & B2).

**Current System configuration before licensing update:**

# /nas/sbin/model

NS-960

# /nas/sbin/model -option -list

OPTION ENABLED: NOT AVAILABLE

**Updating Hardware Licensing per procedure:**

# /nas/sbin/nas\_hw\_upgrade -option -enable -mpfsis -clarionis

Checking if running on primary CS...yes

Checking if running as root...yes

Checking for integrated system...yes

Checking if model is supported...yes

Checking if backend is supported...yes

Options enabled:

MPFSI\_ENABLED=YES

CLARIIONI\_ENABLED=YES

FC\_ENABLED=YES → This equals the OPTION ENABLED: SAN seen in model -option -list output

Model: NS-960FC

Command succeeded

**Note:** Creates /etc/be\_sg\_info.orig backup file, then adds the new licensing options to the /etc/be\_sg\_info file. All nas\_hw\_upgrade activity is captured in the /nas/log/nas\_hw\_upgrade.log file.

/nas/log/nas\_hw\_upgrade.log

**Results:**

# /nas/sbin/model

NS-960FC

# /nas/sbin/model -option -list

OPTION ENABLED: MPFS iSCSI

OPTION ENABLED: CLARIION iSCSI

OPTION ENABLED: SAN

# tail /etc/be\_sg\_info → HW Upgrade added following lines to the be\_sg\_info file, read by the model –option –list command

MPFSI\_ENABLED=YES

CLARIIONI\_ENABLED=YES

FC\_ENABLED=YES

**Note:** Running the nas\_hw\_upgrade –option –disable command will reverse the upgrade

**USE CASE: MPFSFC OPTION**

# /nas/sbin/nas\_hw\_upgrade –option -enable -mpfsfc

Checking if running on primary CS...yes

Checking if running as root...yes

Checking for integrated system...yes

Checking if model is supported...yes

Checking if backend is supported...yes

Options enabled:

MPFSF\_ENABLED=YES

Model: NS-960

Command succeeded

# /nas/sbin/model

NS-960

# /nas/sbin/model –option -list

OPTION ENABLED: MPFS FC

# tail /etc/be\_sg\_info

-----edited-----

MPFSF\_ENABLED=YES

**IDENTIFYING CELERRA SYSTEM REMOTELY:**

→ New Serviceability feature ‘nas\_inventory’ allows for remote identification of hardware configurations on the Celerra & Array

→ Consists of Collection Script, Cron Job, nas\_inventory command, and Inventory Cache file for CallHome delivery

→ Overall, the Cron Job uses /nas/sbin/collect\_inventory to maintain a system inventory cache, written and updated to the /nas/log/inventory\_status file, and is delivered in the XML payload for all CallHome events & Email User notifications

→ nas\_inventory command takes what already existed in the Celerra Manager Inventory tab and converts to CLI output

**NAS Inventory CLI:**

# nas\_inventory –list –location –info –all | –tree | –report –fields –noheader

# nas\_inventory –report –fields location, status

-list switch outputs all components by Name, Type, Status, and System ID

-location switch shows component locations & how the location is defined, which can then be used with -info

-tree switch lists the components in a Tree hierarchy

-info displays details of all components; specify component by “ “ location field to output details of that component, similar to output seen in RESUME

-report switch is hidden, displays information on components, such as part #'s

**Collect Inventory Script:**

/nas/sbin/collect\_inventory

→ collect\_inventory Cron is run 15 minutes past the hour, whenever NAS is started, or manually by a User, and calls nas\_inventory and /nas/sbin/model –option –list commands to create the inventory\_status file

**Cron Job:**

/nbsnas/site/cron.d/nas\_sys

15 \* \* \* \* nasadmin /nas/sbin/collect\_inventory > /dev/null 2>&1 (15 minutes past every hour)

**Inventory Cache File:**

/nas/log/inventory\_status

→ Cron Job creates & then updates the status of system components in a /nas/log/inventory\_status cache file

→ The inventory\_status file maintains most recent output from the collect\_inventory script, which in turn calls /nas/bin/nas\_inventory & /nas/sbin/model –option –list. Only the most recent nas\_inventory & model –list outputs are maintained in the inventory-status file.

/nas/sbin/model –option -list

/nas/bin/nas\_inventory -list

# cat /nas/log/inventory\_status

System Configuration Snapshot: Thu Nov 12 09:15:01 EST 2009

Control Station Slot No: 0

/nas/sbin/model -option -list:

OPTION ENABLED: CLARIION iSCSI

OPTION ENABLED: SAN (output abbreviated)

**CallHomes/Email Notifications:**

→The “inventory\_status” cache file is delivered as a “System Configuration Snapshot” with every CallHome event and is parsed into the CDATA XML section of the CallHome payload

**Relevant Troubleshooting Logs:**</nas/log/webui/cli.log></nas/log/apl/tm.log>**Sample Outputs:**# [nas\\_inventory -list](#)

## **CELERRA DEDUPLICATION PHASE 2 (Celerra F-RDE):**

- Celerra Deduplication feature was introduced with NAS 5.6.43
- Deduplication is file compression and single-file instancing of identical data files
- Celerra “compresses” files for file system space savings (estimated average 50% savings), & “single instances” identical files by keeping a hashed copy of the data in the hidden data store, while stub files are kept for all inodes that reference the same content in the file system
- Celerra uses EMC RecoverPoint technology for file compression
- Celerra uses EMC Avamar hashing technology for single file instancing
- Celerra Deduplicatiion differs from Data Domain deduplication in that the former is an inline dedupe for backup to disk, while Celerra supports production & archival file dedupe

### **5.6.47 introduces a number of major enhancements:**

- Sparse write capability, the ability to write to existing deduplicated files without having to “recall” or “rehydrate” the file while writes take place (use of migration inode in the stub file with updated block addresses)
- Sparse write also allows deduplication of file sizes up to 8TB now without CIFS client timeouts (writes directed to migration inode blocks in stub files)
- If deduplicated files are modified so that size of changed blocks plus total number of blocks is larger than logical size by 10%, then deduplication of the file will be dynamically done, as opposed to waiting for next deduplication scan
- Support for VMWare in NFS environments for duplication of large VMDK files
- Support for large files without rehydration
- Ability to deduplicate “active” files, not just “inactive” ones
- NDMP PAX Backups/Restores preserves “compressed” file sizes, but not “single instanced” files since NDMP requires all instances of file in stream
- Ability to apply deduplication parameters to specific file systems [i.e., on a per file system basis vs. parameters that applied to the whole Data Mover only]
- Ability for CIFS clients to see & change compression attributes on files/folders
- Prior to 5.6.47, dedupe parameters were applied using server\_param –facility dedupe command. With 5.6.47 and above, we now use the fs\_dedupe command to change param values at a file system or Data Mover level.
- Feature does not support block-level deduplication, such as for iSCSI Luns

### **What can CIFS Clients do?**

#### **CIFS CLIENT COMPRESSION BEHAVIOR:**

- >CIFS clients can view compression attributes on files & folders, as well as manipulate them, but only on a file system with Deduplication enabled, and with the cifs\_compression\_enabled attribute turned on (which it is by default)
  - Use Explorer>Properties to see the true file ‘Size’ vs. “Size on disk” (the latter of which is the compressed size)
  - Use Explorer>select file or folder >Properties>Advanced> \_\_Compress contents to save disk space
  - When selecting a directory to compress, the CIFS client can elect to compress just that folder, or all subfolders and files
- Note:** The technical materials refers to the Client action as bypassing the dedupe policies, since the client can compress any file or folder that it chooses, and the Celerra dedupe engine does not compress folders
- By default, once deduplication has been turned on for a file system, the cifs\_compression\_enabled attribute is enabled by default
  - Only files meeting the minimum size requirements are compressed by Celerra deduplication during scanning
  - Folders are not automatically compressed by Dedupe, only by Client action using Explorer
  - For a compressed folder, any uncompressed files that are copied to it, will be compressed
  - For an uncompressed folder, any compressed files that are copied to it, will be uncompressed
  - CIFS client can compress entire file system by selecting toplevel folder and selecting Advanced, then box to “Compress contents to save disk space” and then “\*Apply changes to this folder, subfolders and files”

**Note:** One of the effects of this is that all files, regardless of size, show as compressed.

→Turning off the cifs\_compression\_enabled attribute for a particular file system will uncompress all files and folders that may have been previously compressed, either by dedupe or CIFS client

→Explorer popup error seen if trying to compress files or folders without deduplication enabled on the Celerra file system

#### **“Error Applying Attributes:**

#### **An error occurred applying attributes to the file.”**

#### **Behavior when turning on or off the cifs compression enabled parameter on a file system:**

- If cifs compression is set to no, all files that were compressed per the deduplication engine on Celerra, will show as uncompressed on the clientside. However, the system “remembers” what the previously compressed files were, because once you restore the cifs compression param to yes, all originally compressed files will again show as compressed.
- Similar behavior is seen when Client forces compression of all folders and files. If compression is disabled, then all files & folders show up as uncompressed. However, once cifs compression is re-enabled, the system remembers and all files and folders that were specifically compressed before, will show that attribute again.

#### **DEDUPLICATION UPGRADE STORY WITH 5.6.47:**

- See emc223821 for some background

→If Deduplication is not enabled on any file systems prior to 5.6.47, then the NAS 5.6.47 upgrade has zero impact and is a non-issue  
→If Deduplication is enabled prior to 5.6.47, the Upgrade to 5.6.47 will not impact anything, but any deduplicated files that are subsequently written to “after” the upgrade, will cause the file system to be updated with a new ‘magic’ number 0xdbadface (pre 5.6.47 magic number is 0xbadface)

→Engineering’s recommendation is to backup any file systems that have deduplication enabled prior to upgrading to 5.6.47  
→Once a file system running 5.6.47 has had the Magic number updated, then that file system becomes unmountable on any earlier NAS versions

→The 5.6.47 Upgrade code itself requires a mandatory reboot of the Standby Server, the idea being that if a problem occurs on a Primary server and it fails over, then the file systems will be able to remount, whereas if the Standby was still running a previous NAS version, it might not be able to mount the file systems

**Note:** Lab testing would indicate in practice that this situation would not really happen, since you need to be able to mount the file system first at 5.6.47, then have a User write to a “deduplicated” file, before the magic number would be updated, and since the server would thus already be running 5.6.47, the purported problem would not exist

#### **What happens to pre-5.6.47 file systems running Deduplication, once upgraded to 5.6.47?**

→After the upgrade to 5.6.47, the file system Magic number would be updated either after new files were deduplicated, or whenever the first pre-existing deduplicated file was written to

#### **Server log:**

2010-01-20 09:41:55: DEDUPE: 4: last message repeated 1 times

2010-01-20 09:41:55: DEDUPE: 6: Domain initialized for fsid 28

2010-01-20 09:53:18: DEDUPE: 6: Replacing magic number 0xbadface(195951310) with RDE magic number 0xdbadface

2010-01-20 09:53:18: DEDUPE: 6: Updated on-disk super blocks with RDE magic number change

# /nas/tools/\_fs\_db server\_2 readsb 102 psb |grep magic

About to read superblock from volume 102 and sector 16

magic=0xdbadface

#### **Trying to mount 5.6.47 deduplication file system with NAS Versions prior to 5.6.47:**

→As long as the magic number was not updated on the file system running Deduplication, it could still be mounted on pre-5.6.47 NAS code

→For 5.6.47 systems where the file system magic number has been updated to 0xdbadface, the file systems would be unmountable by any pre-5.6.47 code

#### **Trying to mount 5.6.47 file system with new magic number on 5.6.46 Server:**

# server\_mount server\_2

file2 on /file2 ufs,perm,rw,<unmounted>,<corrupt>

#### **Server log:**

2010-01-20 10:17:18: UFS: 6: Volume name:102

2010-01-20 10:17:18: UFS: 3: invalid superblock 0xd45a4000:

magic 0xdbadface, bsize 0x2000, ssize 0x2000

should be 0x11954 or 0xbadface, 0x2000, 0x2000, <= 0x2000

2010-01-20 10:17:18: UFS: 4: 7: File system 28 is corrupted and will remain unmounted.

2010-01-20 10:17:18: UFS: 3: initFS failed, initRootNode returned status DirtyFileSystem

2010-01-20 10:17:18: ADMIN: 3: Command failed: file mount ufs rw /file2 102=28 rw

2010-01-20 10:17:18: ADMIN: 3: Command failed: export "/file2"

**Note:** Despite the log entries above, the file system isn’t really corrupted at all and can be mounted on 5.6.47 DART

→Support for Thin file cloning, which are writeable snapshots of files (up to 2000 clones). Useful in VMWare environments where VMDK can be distributed to multiple users

#### **UPGRADE ISSUE FOR IP REPLICATION:**

**Note:** If you upgrade the Source side to 5.6.47, but Destination is running 5.6.43, etc., the destination file systems will show up as unmounted and corrupt. From this actual case, the recommendation was to stop the replication sessions until the destination could be upgraded to 5.6.47, at which point Replication should be able to be restarted. See emc230290.

fs01 on /fs01 ufs,perm,ro,<unmounted>,<corrupt>

fs02 on /fs02 ufs,perm,ro,<unmounted>,<corrupt>

#### **MODIFYING DEDUPLICATION PARAMS:**

##### **Setting Deduplication Values from Celerra Manager:**

→Can turn on deduplication when creating new file system

→File Systems tab ‘Deduplication Settings’ section, used to modify params globally or per file system

→No separate License required for deduplication

→Can also fine-tune duplication from CLI using fs\_dedupe

##### **Modifying Deduplication Parameters via CLI:**

→Use the server\_param facility prior to 5.6.47. After 5.6.47, use the fs\_dedupe facility to change params on a per file system basis, or for changing global Data Mover parameter values.

# server\_param server\_2 -facility dedupe -list

**Note:** Only outputs global parameter values that have been changed from the defaults

**Use fs\_dedupe to tune deduplication parameters on a file system basis:**

**# fs\_dedupe -modify fs1 -access\_time 0**

**# fs\_dedupe -modify fs1 -modification\_time 0**

**Use fs\_dedupe to list, modify, or clear (back to default) deduplication parameter settings on a Server basis:**

**# fs\_dedupe -default -set server\_2 -access\_time 0** →Changes global default values on the Server

→Changes global default values on a Server basis. All file systems created and enabled for deduplication will inherit the global Server values.

**RESTORING DEFAULTS GLOBALLY & PER FILE SYSTEM:**

**Setting Deduplication Values back to default values on a Server Basis:**

**# fs\_dedupe -default -clear server\_2**

→Resets the Server back to its original code default values

**Setting Deduplication Values back to default values on a File System:**

**# fs\_dedupe -clear file6**

→You can also reset or change default values for individual params on a file system

**VERIFYING PARAM VALUES GLOBALLY AND PER FILE SYSTEM:**

**Verifying Current Global Server Dedupe Values:**

**# fs\_dedupe -default -info server\_2**

Server parameters:

server\_2

|                             |   |
|-----------------------------|---|

Cifs Compression Enabled = yes

Pathname Exclude List =

### When are Files Reduplicated?

--when deduplication is turned off

--when CIFS client decompresses a file

--when DHSM API reduplicates a file

--when sum of written blocks + size in EDRS store is greater than logical file system by 10%

### Exposing the EDRS File Store on a given file system (Do not expose the store without Eng. involvement):

# .server\_config server\_2 -v "storeHost exposeRepository /file3"

1258129678: DEDUPE: 6: Throttle running in Full mode (1% busy)

1258129678: UFS: 7: inc ino blk cache count: nInoAllocs 2: inoBlk 202df904

1258129678: DEDUPE: 6: StoreHost: ExposeRepository succeeded

/nasmed/quota/slot\_2/file3/etc

# ls -la

total 288

dr-xr-xr-x 3 root bin 80 Nov 13 11:27 .

drwxr-xr-x 7 root root 1024 Nov 13 11:08 ..

**drwx----- 5 root bin 1024 Nov 13 11:27 EDRS\_v1**

-r--r--r-- 1 root bin 262152 Nov 12 13:22 gid\_map

# cd EDRS\_v1;ls -la

drwx----- 12 root bin 1024 Nov 13 11:21 AQAAAAA

drwx----- 2 root bin 1024 Nov 12 14:57 Q09ORg

drwx----- 2 root bin 1024 Nov 13 11:21 VEVNUAABAAAAA

### Hiding the EDRS Store:

# .server\_config server\_2 -v "storeHost hideRepository /file3"

1258130068: DEDUPE: 6: Throttle running in Full mode (1% busy)

1258130068: UFS: 7: inc ino blk cache count: nInoAllocs 2: inoBlk 202df904

1258130068: DEDUPE: 6: StoreHost: HideRepository succeeded

### SavVolAtCapacity Behavior (emc229138):

→ Deduplication scanning will abort if Snapsure checkpoints are in use, and the SavVol usage is at 81% capacity or higher (though param suggests that it should not abort until 90% of SavVol is used)

**Note:** Eng. explanation is that the dedupe value represents 90% of the SavVol HWM, which by default is 90%. So, 90% of 90 is 81.

→ See Server Log messages and Celerra Manager alerts

→ This is the design behavior for Deduplication—don't want to have deduplication extending SavVol by default

### Workarounds:

--See emc229138 for all the workarounds and details

--Extend SavVol on the file system using Celerra Manager > File Systems > rightclick file system name > Checkpoints > Extend Checkpoint Storage

--Or, disable the “Savevol Threshold” deduplication param by setting to 0

# fs\_dedupe -modify file1 –savvol\_threshold 0

### FEATURE INTEROPERABILITY WITH DEDUPE:

--NDMP PAX backup/restore supports compressed files, but not ‘single instance’ files

--NDMP VBB backup/restore supported, but not single file or file-by-file restore

--Block Quota policy (size on disk) is affected by deduplication, but not File Size Quota policy, which relates to logical file sizes

--Snapsure can increase SavVol space used when using deduplication (changes)

--MPFS clients will fallback to NFS/CIFS when accessing deduplicated files

--ReplicationV2 supports deduplication

--Replication V1 is not supported—See emc242296:

1) In the case of an existing file system with deduplication already enabled, if you attempt to setup Replication V1, all the steps will succeed without error, yet the Replication Session itself does not get established.

### Example:

# cat /nas/log/cmd\_loggrep dupe1

2010-05-27 16:35:46.307 db:0:12778:S: fs\_copy -start dupe1\_ckpt2 dupe1\_dest:cel=nx4-2 -fromfs dupe1\_ckpt1 -option monitor=off

2010-05-27 16:35:56.864 db:0:12778:E: fs\_copy -start dupe1\_ckpt2 dupe1\_dest:cel=nx4-2 -fromfs dupe1\_ckpt1 -option monitor=off

**Note:** So, even though all commands succeeded, including the above incremental for the 2<sup>nd</sup> checkpoint, no RepV1 session actually started

2) In the case where Replication V1 is already established, the commandline will provide an Error 12050 when trying to turn on deduplication, preventing deduplication from being started.

### Example:

# fs\_dedupe -modify dupe2 -state on

Error 12050: The file system contains Replicator V1 sessions.

## **EMC CELERRA FAST SOLUTION (Fully Automated Storage Tiering):**

→Search for “EMC CELERRA FAST” for a complete description of the solution

### **TOP TALKERS FEATURE (5.6.47) [-top replaced in 6.0]:**

→Feature to help customers identify NFS/CIFS clients consuming the most resources, and to assist with identifying storage problems

→Server\_stats and counters have been enhanced to identify NFS/CIFS Clients

→CLI version only with this release, no GUI support

→Default list of TopTalkers is for 20 systems, but is customizable

# server\_param server\_2 -facility statmon -list|grep top

```
top.updateInterval      statmon      0      0
top.maxClients         statmon      20     20
```

\$ server\_param server\_2 -facility statmon -modify toptalker.maxClients (default client list is 20, editable from 1-256 max)

\$ server\_param server\_2 -facility statmon -modify toptalker.updateInterval -value xx (off by default, 0-86400 seconds)

→Update interval off by default (configure from 0-86400 secs.), recommendation to use 600 secs to minimize DART resource impact

→Update interval defines frequency that DART polls network connections to build top talkers list—runs internally

#### **Turning Feature On:**

# server\_stats server\_2 -top cifs

ERROR (13421969432): The top collection options are currently disabled on the server\_2 Data Mover.

# server\_param server\_2 -facility statmon -modify top.updateInterval -value 5

server\_2 : done

**Note:** Must set an updateInterval value to begin gathering Top Talker statistics

#### **Example Commands:**

# server\_stats server\_2 -top

```
[{ -summary {basiclcifslnfslcaches}{...}
  | -table {netldvollfs vollcifslnfs}{...} | -table {netldvollfs vollcifslnfs}
    | -sort <field_name> [-order {asc|desc}] [-lines <lines_of_output>]
    | -count <count> [-port <port>] [-interval <seconds>]
    | -terminationsummary {no|yes|only} [-format {text|csv}]
    | -type {ratelendifflaccu} [-titles {never|once|repeat}]}
```

# server\_stats server\_2 -top cifs -te no -i 5

# server\_stats server\_2 -top cifs | nfs

# .server\_config server\_2 -v "topTalker" "topTalker cifs" "topTalker nfs"

## **FAST UNMOUNT AND FAST MOUNT ON REBOOT OR FAILOVER:**

→Feature designed to improve reboot and failover/fallback times

→Focus is on improving file system unmounting and mounting

→Mount begin & end commands are executed in parallel (async mounts)

→Unmount time reduced by multi-threading vnode & data flush operations

**Note:** From a global freelist traversal of each file system to a multi-threaded single traversal of the global freelist

→For Failover, CS sends bulk request to Data Mover to mount file systems, file systems mounted one by one by DART, but mount end is sent back to CS after all are mounted

→For Reboots, unmount and remount operations are done using boot.cfg order

→Mount requests are queued and handled by a default group of 64 threads

# .server\_config server\_2 -v "param cfs" | grep Parallel

```
cfs.maxParallelMount 0x01fb1edc 0x00000040 0x00000040
```

**Note:** 40 hex = 64 decimal

## **BOOT.CFG & SERVER LOG ENTRIES:**

### **Pre-5.6.47 mount entries:**

mount begin

file mount udfs rw / 12=2 rw

----edited----

file mount udfs rw /CSAShare 184=54 rw

mount end

### **New Fastmount entries in 5.6.47:**

mount fastmount

mount begin

file mount udfs rw / 12=2 rw

----edited----

file mount udfs rw /file5 97=28 rw

mount end

# server\_log server\_2 -s |grep mount

2009-11-12 22:58:14: ADMIN: 6: Command succeeded: mount fastmount

2009-11-12 22:58:14: ADMIN: 6: Command succeeded: mount begin

-----edited----

2009-11-12 22:58:14: ADMIN: 6: Command succeeded: mount end

#### **Fast Mount Issue with NMFS:**

→See emc233009 to disable the ‘Fast Mount’ feature if using NMFS

#### **CELERRA SRDF HEALTHCHECK HARDENING:**

→Purpose of this feature is to verify SRDF state and configuration

→Healthchecks are run at end of nas\_rdf –init and –localinit

→Healthchecks are run at beginning of nas\_rdf –activate & -restore

→These healthchecks are not built into the PUHC

→When problems noted, an appropriate CCMD error message with recommended action is printed to screen and to the /nas/log/nas\_rdf.log

#### **(6) Warning Messages Available:**

##### **MessageID = 17726767122**

--Destination Standby slots do not matchup with Source slots

--Run nas\_rdf –init on the destination system to fix

--Message can be generated at nas\_rdf –activate or after –init

##### **MessageID = 13431799813**

--Checks if Source R1’s are RW mounted and Destination R2’s

--Log into Source to verify if file systems mounted and Data Movers restored

--Issue nas\_rdf –restore on Source if necessary

--Message can be generated before nas\_rdf –restore operation

##### **MessageID = 17726767105/13431799811**

--Checks if all devices synchronized between Source and Destination

--Check devices on each side and determine action required

--Message can be generated before –init, before –activate, before –restore

##### **MessageID = 17726767117**

--Device Group configuration check

--Compare symrdf list of devices to symrdf –g device group devices, and add missing devices to appropriate device groups

--Message can be generated after –init, after –localinit, before –active, and before –restore

##### **MessageID = 17726767118**

--Match devices via probe to those in device groups

--Add missing devices

--Message can be generated after –localinit or –init, before –activate or –restore

##### **MessageID = 17726767119**

--Display failed or degraded backend devices (symdev list –service\_state notnormal)

--Verify devices and escalate to Service Provider if required

--Message can be generated after –localinit & -init, and before –activate & -restore

#### **FLARE 29 TAURUS SUPPORT (04.29.000.5.003):**

→5.6.47 introduces Integrated & Gateway support for Flare 29

→With Flare 29, SPs no longer require rebooting for changing IP addresses (Feature added by CLARiiON per NAS request due to Proxy Arp requirements). For Celerra Integrateds, make sure to use the clarion\_mgmt –modify –spa\_ip –spb\_ip when changing IP addresses on the SPs.

→Flare 29 introduces CLARiiON LUN shrink, but only for Windows 2008 Server Host LUNs with this initial Flare release (Basic & Dynamic disk volumes)

→Total LUNs per Storagegroup increases to 1024 for CX4-480, CX4-960 (Gateways & NS-480/960)

→Total LUNs per Storagegroup increases to 512 for CX4-120 backends (Gateways & NS-120)

**Note:** setup\_clariion & CPW updated

→Support for 2TB SATA drives (low power 5400rpm drives)

→Flare 29 provides support for 2-port Ultraflex 10Gbps iSCSI ‘Poseidon’ modules with optical SFPs on the array [10Gbps iSCSI can be used as Native iSCSI solution, MirrorView solution, or MPFS over iSCSI solution]

→Flare 29 NDU’s have a “Celerra Compatibility Check” screen where the user must select a box certifying that the NAS Version is compatible with the FLARE version

#### **CLARiiON DISK POWER SAVINGS FEATURE:**

Celerra supports file systems hosted on SATA II disks in Raid Groups (Storage pools) using the Flare 29 power management spindown capability after an established idle I/O period (CLARiiON default is 30 minutes)—Celerra will tolerate spinups after an I/O request is generated

**Note:** Initial testing did not show that 5.6.47 worked, but did at 5.6.48.

#### **Enabling Power Savings on Array and on Raid Groups for SATA II Drives:**

- 1) Rightclick Array serial > Power Savings > Select checkbox to “Enable Storage System Power Savings”, and checkboxes for desired RAID Groups to “Allow Power Savings”  
> Click on “Allow Power Savings” for qualified Raid Groups under “Storage System Pool Settings”
- 2) Rightclick Raid Group > Power Savings > Click on “click here to enable”

#### Using CLI to set Power Savings Globally on the Array:

# /nas/sbin/navicli -h 10.241.168.150 powersaving -globalsettings on

Turning Global Power Saving settings on will spin down all eligible unused disks and all Power Saving settings on Storage Pools will take effect. Do you want to proceed?(y/n) y

#### Verifying Power Savings Mode from GUI:

Rightclick Raid Group > Power Savings > Click on Disks tab and look at “State” column

Or, expand the Physical >Enclosure > Disks display in Navisphere, and observe the drive power state

**Note:** When actually in Power Savings mode, the GUI will show Disk Drives or Raid Group disk drives in the “Low Power” state

#### Verifying Power Savings Mode Enabled on Array from CLI:

# /nas/sbin/navicli -h 10.241.168.150 powersaving -info

System Idle Time: 30 minutes

Global Power Saving Settings: ON

#### Verifying Power Savings Mode Enabled on specific Raid Group:

# /nas/sbin/navicli -h 10.241.168.150 getrg 8 -all |grep Power

Power Savings Setting: ON

RAID GROUP Power Savings Eligible: YES

Is RAID GROUP in Power Savings Mode: NO

**Note:** The ‘Is RAID GROUP in Power Savings Mode: NO’ line indicates that the disks are not in “Low Power” savings mode

#### Example when Disks are in Power Savings Mode YES:

# /nas/sbin/navicli -h 10.241.168.150 getrg 8 -all |grep Power

Power Savings Setting: ON

RAID GROUP Power Savings Eligible: YES

Is RAID GROUP in Power Savings Mode: YES

#### ADDITIONAL POWER SAVINGS MODE INFO:

→From Navisphere, Disk State shows up as “Low Power” in Raid Group > Power Savings > Disks properties (Low Power)

→Also, all unbound SATA drives will also automatically go into Power Saving mode (Low Power)

→On the DAE itself with SATA drives, each Drive that is in Power Saving mode will flash the Green Power LED once every second

→Testing access to CIFS files on a file system hosted on SATA II drives in “Low Power” mode took less than 30 seconds to power-up drives and display files

#### CLARiiON NATIVE iSCSI/10Gbps SUPPORT:

→Flare 29 Arrays support 2-port 1Gbps iSCSI and/or 2-port 10Gbps iSCSI Ultraflex IO modules in various configurations

→Celerra has qualified the use of 10Gbps “Poseidon” iSCSI for NS-120, 480, & 960 arrays, as well as all Gateway platforms

→Poseidon replaces the 1Gbps iSCSI Harpoon module, and requires FLARE 29

→With the introduction of the 10Gbps iSCSI I/O module, Celerra supports CLARiiON Native iSCSI (not NX4), and also marks the beginning of the transition from file-based iSCSI Celerra support to CLARiiON native iSCSI lun support

**Note:** Integrated Arrays now support Host—attached iSCSI luns or FC luns

→Celerra Integrated supports ‘native’ CLARiiON iSCSI, and traditional Celerra MPFS over iSCSI

→Native Block License (NBOPT-L), for either iSCSI/FC, replaces FCOPT license

→Part of the benefit of ‘native’ CLARiiON iSCSI is that LUNs can be presented to either FC or iSCSI without data migration

NS-120 arrays can have up to (4) iSCSI modules, (2) of which can be 10Gbps

NS-480 arrays can have up to (6) iSCSI modules, (4) of which can be 10Gbps

NS-960 arrays can have up to (8) iSCSI modules, (4) of which can be 10Gbps

#### CLARiiON NATIVE vs. CELERRA iSCSI:

→CLARiiON native iSCSI support offers unlimited LUN size (>2TB)

→CLARiiON iSCSI can use CLARiiON & Navi features

→CLARiiON iSCSI luns support drive spin down feature

→CLARiiON iSCSI luns support PowerPath encryption

→Celerra file-based iSCSI luns support Netware & IP NAS mgmt

→Celerra file-based iSCSI luns are still limited to 1MB under 2TB

→Celerra iSCSI does not support Navi software features

→Celerra iSCSI does not support drive spin down feature of Flare29

→Native CLARiiON iSCSI for Celerra platforms require purchase of Native Block Option (right to use FC or iSCSI on the array) and Navisphere [NSxxx-NBOPTL]

→NS-960 platform, however, has Navisphere bundled with the NativeBlock License

**Note:** Celerra FCOPT license will no longer be offered

#### 8Gbps FC SLIC SUPPORT FOR NS-960/NS-G8 BLADES:

→NS-960/G8 Blades now support the ‘Glacier’ 8Gbps Fiber Channel I/O modules for connectivity between Blades and SPs, though backend buses & DAE’s still only operate at 4Gbps

**Note:** Celerra AUX arrays [NS-120/480/960] have supported 8Gbps FC I/O modules since NAS 5.6.42

→Sold only with new Installations at this time (no upgrade path yet)

→Auto-negotiates 2/4/8Gbps

→8Gbps SFP is different than 4Gbps

→Allowed in any SLIC slot where a FC I/O Module is allowed

→Backend array models offered for NS-960 will be NS960-AUX (4Gbps FC) and NS960-AUX8 (8Gbps FC)

### **EFD ENHANCEMENTS:**

→Flash Drives have been supported on CX4-480/960 since NAS 5.6.43

→In broad terms, about 10-30x faster than high-speed FC drives

→Best when used for random I/O workloads

→Adds Raid 1/0 support [min. 3 drives for HS]

**Note:** Clariion EFD luns are configured with Write & Read cache disabled, while Celerra best practices dictates that EFD Celerra LUNs be configured with Write cache enabled and Read cache disabled.

### **Restrictions:**

Celerra does not currently support having mixed FC & EFD drives in the same enclosure

### **Supported EFD Raid Types:**

#### **Raid1/0 1+1, Raid5 4+1, Raid5 8+1**

**Note:** Pools are clarefd\_r10 & clarefd\_r5, respectively

→Raid 1/0 1+1 & Raid5 4+1 will create four SP-balanced & equal sized LUNs per RG (setup\_clariion)

→Raid5 8+1 will create eight SP-balanced & equal sized LUNs per RG (setup\_clariion)

**Note:** Multiple Luns & threads are required to leverage EFD high performance

→Naming convention changed from “SSD” to “EFD”, hence AVM pool name clarssd\_r5 becomes clarefd\_r5, clarefd\_r10, etc., default 256K stripe size

→Cannot add EFD drives to empty slots in a DAE with FC drives

**Note:** In practice, setup\_clariion (and Provisioning wizard from Celerra Manager) fails when there are FC & EFD drives in the same enclosure. The NAS Support Matrix has a note that says though Clariion supports mixed FC & EFD drives in the same Enclosure, Celerra does not.

→Celerra FAST would be one example of a NAS solution using EFD, CLARiiON FAST another example, and next year, CLARiiON will introduce an extension to CLARiiON Write Cache using EFD drives

→Striping used whenever 2 or more luns available, otherwise concatenated

→EFD uses 16 internal channels, services 16 simultaneous I/Os vs. FC 1 I/O

→CLARiiON LUNs have queue depth of 12, therefore we need multiple LUNs per RG to have enough queued I/O to satisfy the EFD drives 16 channels

→At the same time, using multiple luns per RG yields multiple striped dVolumes on Celerra, which increases I/O queue depth

**Note:** Celerra has a normal queue depth of 8 I/O’s per dvol

### **Setup clarion EFD Templates:**

4+1 R5, HS, 1+1 R1/0, 1+1 R1/0, 4+1 R5

4+1 R5, HS, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, HS

HS, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0, 1+1 R1/0

### **Example Output of EFD Drive:**

# /nas/sbin/navicli -h 128.221.252.200 getdisk 0\_0\_11

Bus 0 Enclosure 0 Disk 11

Vendor Id: STEC

Product Id: ZIV2A210 CLAR200

Product Revision: 100H

Lun: Unbound

Type: N/A

State: Unbound

Hot Spare: NO

Prct Rebuilt: Unbound

Prct Bound: Unbound

Serial Number: STM000100300

Drive Type: FC SSD  
Clariion TLA Part Number: 005048998  
User Capacity: 0  
Idle Ticks: 5288  
Busy Ticks: 188  
Current Speed: 4Gbps  
Maximum Speed: 4Gbps

### **2TB SATA DRIVE SUPPORT:**

→Support for 2TB 5400rpm drives for NS-960, NS-G8, NS-480, NS-120, NS-G2, & NX4  
→2TB drives can be used within the same enclosure with other SATA drives (not vault)  
→NS-960 would support 896TB usable capacity with 2TB drives

### **LARGE LUN SUPPORT:**

→Large LUN support for up to 16TB luns is extended to NS-120/480  
**Note:** Previously limited to Gateways & NS-960 platform (5.6.44)  
→Large LUN support affects setup\_clarion and CPW/UMPW utilities, which will now allow the creation of up to 16TB luns for NS-960, NS-480, & NS-120  
**Note:** Only the NS-960, using the R6 12+2 template would reach the 16TB LUN limit because it also enforces the single LUN per RG rule (useOneLUN)

### **MirrorView/S GA:**

→MView/S for Celerra has been supported via RPQ since 5.5.23  
→MView/S is now a “GA” offering  
→Number of luns in Consistency Group increases from 16 with Flare 28 to 32 with Flare 29 for NS-120  
→Number of luns in Consistency Group increases from 32 with Flare 28 to 64 with Flare 29 for NS-480 & NS-960  
→Overall, MView/S seen as a more viable Disaster Recovery solution than before

### **SMB 2.1 SUPPORT:**

→SMB 2.02 protocol supported for Vista and Windows 2008 R1 since NAS 5.6.42  
→Support now extended to SMB 2.1, used by Windows 7, Vista SP2, and Windows 2008 R2, SMB2 leases and Unbuffered writes  
→SMB2.1 enhancements are all related to increasing CIFS performance by reducing network traffic overhead  
→SMB2 leverages Client “leases” for better data cache and synching with Server vs. SMB1 Opportunistic Locks  
→With SMB 2.1 leases, Client lease can span multiple opens and multiple connections  
→New param cifs smb2.capabilities, set to 0x00000003 by default, supports SMB2\_CAP\_GLOBAL\_DFS & SMB2\_CAP\_GLOBAL\_LEASING, but not Global Large MTU feature (later release)

### **Three Types of SMB2 Leases:**

Read-Caching Lease—multiple clients (or same) can cache read the same file(s)  
Write-Caching Lease—Only single client can write cache, using byte-range lock  
Handle-Caching Lease—multiple clients (or same) can cache open file handles

### **Unbuffered writes—FILE FLAG WRITE THROUGH:**

→Clients can perform synchronous Write-through operations to Server (no server-side buffering), regardless of how file was opened  
→Clients can do synchronous & asynchronous writes for same File Handle, and keep data cache synchronized with server for longer periods

### **Large MTU:**

→SMB2 large MTU capability is not supported with this release

### **Enable SMB2 on Celerra via server cifs cmd:**

# server\_cifs server\_2 -add security=NT,dialect=SMB2 | SMB2only

**Before:**

# server\_cifs server\_2

Max protocol = NT1

**After:**

# server\_cifs server\_2

Max protocol = SMB2

**Use server\_cifs audit to determine SMB protocol version/Leases:**

# server\_cifs server\_2 -o audit fullgrep "ProtoFid"

```
| Proto=SMB2.10, Arch=Win2K8, RemBufsz=0xffff, LocBufsz=0xffff, popupMsg=1  
| Fid=87, FNN=0x1bafe850(FREE,0x00000000,0), FOF=0x00000000 Lease=RHW FILE=/foo.txt
```

**Note:** RHW=Read Handle Write caching lease

**MPFS SMB 2.02 SUPPORT:**

→ 5.6.47 qualifies SMB2.02 on Vista SP1 and Windows 2008 MPFS Clients

→ Clients will send 0x293 Server Capability during FMP Session create to indicate ability to do SMB2

**WINDOWS RESTRICTED GROUP GPO SUPPORT:**

→ Restricted Groups allow system administrators to define & control membership for security-sensitive groups

→ Restricted Groups support Local Users, Domain Users, and Domain Groups

→ Restricted Groups GPO updated every 90 minutes, whenever CIFS is started, or manually when using server\_security –update –policy gpo

→ Usually applied to the Local Groups on Workstations or member Servers (e.g., CIFS Server)

→ A Restricted Groups domain policy can define which Users or Groups are members of a Restricted Group, and also which groups the Restricted Groups can belong to

→ For DART, this becomes a new way to define and enforce Local Groups content

→ Restricted Groups 'Members' property page defines who is a direct member of the group

→ Restricted Groups 'Memberof' property page defines Restricted Group membership in other Groups

# server\_log server\_2 -s → Example of GPO update every 90 minutes

2009-11-20 04:09:46: LGDB: 6: Restricted Groups enforced for deduper

2009-11-20 05:39:50: LGDB: 6: Restricted Groups enforced for deduper

**MULTI-BYTE CHARACTER SUPPORT FOR CELERRA INTERFACES:**

→ Feature allows ability to input, store, and display multi-byte characters using Celerra management interfaces (e.g., CLI server\_cifs, fs\_dhsm, server\_cdms; MMC snapins; XML-API; & Celerra Manager), such as for local languages

→ While not true Internationalization or Localization, this is a step towards it

→ 5.6.47 extends multi-byte support from CIFS Sharename & Tree Quota fields introduced with 5.6.40, to many other fields [CIFS Compname, Netbios, or Alias names; CIFS Comments; Domain or Workgroup names; OU name; User name for User Quotas; Mountpoint & File System names; Checkpoint name; CDMS source share and export names & paths; DFS Root name]

→ Requires Unicode setting for the Data Mover

→ Follows Unicode 3.0 standard, default encoding HTML, XML (ISO/IEC 10646)

→ Browsers and Host OS's must support UTF-8 (variable length character encoding for Unicode, ranging from 1-4bytes, U+0000 to U+10FFFF)

→ UTF-8 can encode any valid Unicode character using multiple bytes (1-4 bytes)

**Issues—See emc229599:**

Known problem with ECC, which does not support multi-byte characters. Issue is currently understood to have the following potential impact to ECC when inputting Celerra Object names using non-ASCII characters, for any of several available interfaces [e.g., Celerra Manager, MMC Snap-in, CLI, etc]:

--With NAS 5.6.40, Celerra supports multi-byte characters in CIFS Share names. As such, if Share names use >than 63 non-ASCII characters, then ECC may fail to properly discover the Celerra.

--With NAS 5.6.47, Celerra extended multi-byte characters support to include File System, Mountpoint, NFS Export, and Quota User names (among several other Object name fields not used by ECC). As such, for any of the Object name fields listed in the next bullet, ECC may fail to discover the Celerra if the stated Fields use >than 63 non-ASCII characters. Additionally, if the stated Fields contain any non-ASCII characters, the non-ASCII characters themselves will be garbled in the XHMP summary collected by the ECC engine, but for any ASCII characters used within the same object name, these will be displayed correctly. The underlying data and names themselves on the Celerra system are not impacted. This is solely a Discovery/Display issue with ECC.

**List of Celerra Object Field Names that are used by ECC:**

[Fields which Celerra supports for non-ASCII characters, and are therefore susceptible to the Discovery/Display issue]

File System Names → Supported with 5.6.47

Mountpoint Names → Supported with 5.6.47

CIFS Share Names → Supported with 5.6.40

NFS Export Names → Supported with 5.6.47

Quota User Names → Supported with 5.6.47

→These names can cause ECC Celerra Discovery failures if using >than 63 Unicode characters in the object names

→In addition, Object names collected by ECC will be garbled in the ECC report for any names that use Unicode characters

#### **Suggested Workarounds:**

1) Use only ASCII characters in the above listed Object Field Names when using ECC for Celerra discovery.

2) If Unicode characters must be used, in order to successfully "discover" the Celerra, keep all applicable Object Field names under 64 characters, but also be aware that if any on-ASCII values are used in the above named fields, the non-ASCII characters will appear garbled in the ECC summary.

#### **OUT OF FAMILY REPLICATION V1 SUPPORT (5.5 to 5.6):**

→Goal of this feature is to provide customers a more manageable method for updating replication infrastructure by supporting the upgrade of target systems to 5.6.47 while source systems are running a minimum revision of 5.5.39

**Note:** check\_nas\_upgrade checks were put into place that requires any 5.5 V1 environment to have the Source side at 5.5.39 before upgrading the environment to NAS 5.6. See AR165855.

→Upgrade methodology would be to leave the 5.5 source site replication sessions running while upgrading target sites to 5.6 (Do not suspend sessions)

→Important to know that “management” of the replication environment is limited while running dissimilar code families on source vs. targets [i.e., cannot start new sessions; cannot restart suspended or inactive sessions; cannot reverse or suspend sessions; cannot do fs\_copy; cannot resync failed over sessions]

→Customers can failover from the 5.5 source to 5.6 target, but cannot fallback until source is upgraded to 5.6

→File System copies, restarts, or creating new sessions will fail when the sites are at dissimilar code versions

→Attempted upgrades to 5.6.47 on source with destinations running 5.5 will PUHC fail; PUHC fail if fs\_copy is running; PUHC fail if source is less than 5.5.39

#### **Upgrading Bi-Directional Replication-Example:**

→Situation where each side of replication is both a Source and Target

Source1 (Target2) ↔ Source2 (Target1)

→Suspend replication sessions from Source2 to Source1 to break the bi-directional dependency

→Upgrade Source2 to 5.6.47, then Source1 to 5.6.47, then restart replication sessions from Source2 to Source1

#### **OUT OF FAMILY REPLICATION V2 SUPPORT:**

→Goal of this feature is to be able to support out-of-family V2 replication for any version 5.6.47 or higher, with NAS 6.0

→ReplicationV2 will be compatible with full management capability across the CLI & GUI

→The only caveat here is that both Source & Target sides must be running at least 5.6.47 or later, meaning that the Source could be running 6.0 while the Target runs 5.6.47, or vice versa—the order would not matter

→All the commands and functionality would be available

→One caveat is that there is no guarantee that some new feature or functionality might not affect this strategy, and the exceptions will be handled as they occur

→One example of interoperability issues with GUI's is that a system running 5.6 would have to use the Celerra Manager interface, while a system running 6.0.xx would use the new Unisphere GUI framework (GUI that will be used to manage both CLARiiON and Celerra)

#### **CSA ENHANCEMENTS:**

→Prior to 5.6.47, CSA could only configure Server\_2—now, can configure all Primary Servers [i.e., DNS, NTP, Unicode, Timezones]

→Prior to 5.6.47, CSA(CPW) could not configure LACP or Ethernet Channel on some newer network device names [e.g., fxg0, cge-3-0, etc.]—it only recognized devices named cge0 – cge3. Now, CSA wizards will be able to display & use all available network devices on the Blades

→From “Attach an iSCSI LUN” GUI screen, the “Local Host IP Address” will now display all bound IP addresses

→Warning message will be displayed if trying to mount an iSCSI LUN on the local Host when it has already been assigned to another initiator

→For Dell NX4 systems only, a unique IQN will be created for each new target based on IQN string plus unique target name assigned

#### **Multiple Connections per iSCSI session:**

--Ability to create up to (10) internet IP address connections per iSCSI session [will use Local Host IP addresses instead of 0.0.0.0 for target login]—user will be able to select which IP address to use for a particular session connection login

--If no existing connection between Host and iSCSI Target, will create iSCSI session and the connection between source portal and Target (iscsicli logintarget)

--If connection between Host & Target already exists, will allow adding new connection (iscsicli addconnection)

#### **CPW/CSA SUPPORT FOR MPFS:**

→With 5.6.47, the CSA/CPW will present a wizard to configure MPFS for the Celerra and for Linux clients using Best Practice guidelines for FC & iSCSI, the goal being ready for MPFS I/O at the end of configuration

→MPFS Setup wizard can also be used to ‘reconfigure’ an existing MPFS setup

→Builds FC environment or iSCSI environment as needed on Celerra & Hosts

→MCM tool being removed from Powerlink (CSA capability replaces)

→'Setup MPFS' wizard discovery will generate an error if at least 4-8 equal sized luns are not available for Raid5

(clar\_r5\_performance), Raid6 (clar\_r6), or Raid 1/0 (clar\_r10)

→Users should go back to the "Select a Wizard" page and select "Provision unused disks", select Custom mode, and as an example for Raid 1/0, select 4 disks for Raid 1/0 to create a Raid Group with 4 luns, and then repeat again to create another RG with 4 luns

**The 'Welcome to the CSA' screen will only present the 'Setup MPFS' button under the following rules:**

→If model is NS40-AUX-C, 'Setup MPFS' will display for MPFS over iSCSI

→If model is NS20/40FC, 'Setup MPFS' will display for MPFS over FC

→If model is NS-120, 480, or 960, the /nas/sbin/model -option -list command is run to check whether any MPFS flags are enabled

--If only MPFS iSCSI flag is set, 'Setup MPFS' will display for MPFS over iSCSI

--If only MPFS FC flag is set, 'Setup MPFS' will display for MPFS over FC

--If both MPFS iSCSI & FC flags are set, 'Setup MPFS' will display for mixed environment for MPFS over iSCSI and MPFS over FC

**MPFS Setup Chronology:**

CSA > 'Select a wizard' > 'Setup MPFS' (Presented only if Wizard detects an MPFS-enabled Celerra /etc/be\_sg\_info)

--MPFS discovery occurs for MPFS over iSCSI, MPFS over FC, or both, checks to make sure a Storagepool is available with LUNs, and also offers the option of setting up just the Celerra, or both Celerra & MPFS Hosts

--If MPFS already configured, User presented option to reconfigure

--If applicable, User is prompted to setup/verify IP's on iSCSI ports on SPs

--Setup CHAP

--Create>Select MPFS StoragePool and number of members to stripe at 256KB

--Wizard configures backend [Setup iSCSI ports, Create MPFS StorageGroup, Create/Extend MPFS StoragePool, Add LUNs to MPFS Storage Group, Start MPFS Service on Data Mover]

--Add Hosts screen [enter Username, Password, & IP address], with option to use an Import Host List

--Install MPFS Client Software [Linux version 5.0.31.7]

--Set iSCSI parameters using Best Practices or Custom options for Host

--Set sysctl parameters

--Create/Mount MPFS enabled NFS Exports [If creating export, select the mpfs\_r10\_pool, name the export, and give a size to file system]

--Add export to Host

--Host Configuration Summary displays

--Host Configuration Status

--Verify MPFS exports and luns on the Host using # mpfsinq

**OTHER CELERRA MPFS ENHANCEMENTS:**

→SMB 2.0.2 support for Vista SP1 & Windows 2008 MPFS clients

→Support for CentOS 5.3, AIX 6.1, and Windows 2008 (but not R2)

→Windows 2008 (x64 &x86) support for MPFS over FC/iSCSI

→RHEL 4.8 & 5.3 (32 & 64-bit) support for MPFS over FC/iSCSI

→Support for 10Gbps iSCSI I/O modules on CLARiiON SPs

→Increased Host support on FC or iSCSI Ports for Arrays running Flare 29

| CX4 Models                        | 120 | 240  | 480  | 960  |
|-----------------------------------|-----|------|------|------|
| Max Initiators FC ports           | 256 | 256  | 256  | 512  |
| Max Initiators 1Gbps iSCSI ports  | 256 | 256  | 256  | 256  |
| Max Initiators 10Gbps iSCSI ports | 256 | 512  | 1024 | 1024 |
| Max Initiators/SP                 | 256 | 512  | 1024 | 4096 |
| Max Initiators/Array              | 512 | 1024 | 2048 | 8096 |

**WILDCAT-S VE HARPERTOWN CPU MODULE:**

→Introduction of a new motherboard for NS-960/G8, Harpertown Wildcat-S VE (original motherboard Clovertown Wildcat-S)

→Actual shipments expected January 2010 using Coldfire management firmware version v2.99. Earlier mgmt firmware versions do not support Harpertown.

**IOMEGA CIFS COPY SUPPORT TO CELERRA SHARES:**

→CIFS copy support from Iomega ix4-200d StorCenter device to Celerra

**AVM CHANGE:**

→AVM auto-extend default change from 10GB to 20GB, meaning that file system <than 20GB will auto-extend by the original size of the file system, and one >than 20GB will auto-extend by 5% of its size, or by 20GB, whichever is larger

**COGNAC 5.6 MAINTENANCE RELEASE 11 (CMR11 5.6.48.7 Patch 705):**

→Tolerance for Symmetrix Madeira 5874.207 release (Symm released in Jan 2010) for all Gateways

→Tolerance for Symmetrix FAST v1 solution for non-Celerra hosts

→Dell OEM NS-120/480/960 support

- Support for NS-480 and NS-960 Dense Storage products
- Porting the CCC (Celerra Configuration Collector) to the Control Station—enhances Collect Support Materials
- Celerra Event Enabler (CEE) version 4.5.2.2
- Support for RHEL 5.0 update 4 for MPFS Linux clients
- DART support VMWare plugin (see below)

**Note:** In order to “Add a Celerra” using the plug-in, it will check to make sure that the correct NAS version is on the Celerra

## **CELERRA CONFIGURATION COLLECTOR:**

→Basically, the CCC is a java collection tool to gather configuration details from the Celerra system, and is outputted to a raw XML file that is only used by the NSD [Network Solution Designer] application (at this time)

### **When does the CCC information get collected?**

- 1) Automatically whenever the automatic log collection script runs

**Note:** Default behavior, though you could comment out the “GetCCC” option in the /nas/site/automaticcollection.cfg file

- 2) Manually if invoked using /nas/tools/automaticcollection –getlogs or /nas/tools/collect\_support\_materials -CCC

- 3) Or manually if invoked from Celerra Manager > Support > Log Collection > Collect

### **Scripts called by the Log Collection utilities:**

/nas/tools/automaticcollection –getlogs →Automatically or manually started, calls collect\_support\_materials

/nas/tools/collect\_support\_materials -CCC or -CCC-quota →Main collection script with CCC options

/nas/tools/collect\_config →Called by log collection script, in turn calls java –jar /nas/tools/ccc.jar \$1\$2

**Note:** -symmdisks is automatically added as a variable whenever symm backend is seen. –quota option is added when specifying –CCC-quota flag manually

/nas/tools/monitor\_collect\_script →script started by collect\_support\_materials to monitor processes once every 60 seconds, and kills any processes that last 15 minutes

### **Configuration Files:**

/nas/site/automaticcollection.cfg →GetCCC option enabled by default

/nas/tools/CCC.cfg →Change “Timeout 300” to a different value

### **Logs:**

# ls -la /nas/log/ccc.log\*

```
-rwxrwxrwx 1 nasadmin nasadmin 621251 Mar 2 13:49 ccc.log
-rwxrwxrwx 1 nasadmin nasadmin 143979 Mar 1 17:38 ccc.log.1.gz

-----abridged-----

## **EMC Celerra Plug-in for VMware Version 1.0.7 ('Nimitz' release): Requires 5.6.48.701 patch!**

### **FEATURES:**

→NFS Datastore Provisioning

→VM Full Clone

→VM Fast Clone

→VM Compression

**Overall Plug-in Purpose:**

NFS Datastore Provisioning; Array-based compression & cloning of VMs

**Note:** Celerra creates ufs file system from array and presents to VMware ESX servers via NFS Export, and vSphere plug-in creates the NFS Datastore presentation, from which the VMDK Snaps (Fast Clone) or VMDK Copies (Full Clone) are made for VMs

**VMware PLUG-IN CAPABILITIES:**

--View Celerra properties for VMs, NFS Datastores, etc via the Plugin

**1) Provision or Extend Storage for NFS Datastores:**

--Create & mount NFS Datastores on ESX Servers via Celerra file systems (or use existing)

--Filesystems created with Virtual Provisioning and Auto-extend enabled

--NFS Exports use best practice mount options

--Extends existing Celerra NFS Datastores storage (aka file systems, max. size of 16TB Celerra limitation)

**2) Optimize Storage using Compression (aka Celerra Dedupe):**

--Ability to compress or uncompress VMs that reside on Celerra NFS Datastores

**3) Create VM Clones as Full Copies or Fast Snap Copies:**

--Ability to “clone” VMs that reside in Celerra NFS Datastores

--Fast clone support – VM .vmdk files are “snap” copies, limited to the same Datastore file system where the VM is stored

--Full clone support – VM .vmdk files are full copies, limited to Datastore file systems on the same physical Data Mover

**Plug-in Specifics:**

→The plug-in is a Windows executable that installs on the Virtual Center vCenter 4.0 or VMWare vSphere 4.0 Client system

→Properties are available by rightclicking objects in vSphere [VMs; Hosts; Clusters; Datacenters; Folders; Datastores]

→ESX data path plugin, vStorage API integration for NFS—better integration between storage platforms and ESX server

**Note:** vCenter plug-in will allow an admin to make a copy of a VM as a full clone or fast (thin) clone

→Qualified with ESX 3.5 and 4.0 Hosts

→Plug-in is designed to simplify management of virtual infrastructure on NFS Data Stores

→Plug-in provides storage optimization by offering compression of VM’s & associated VMDK files (via NAS Deduplication code)

a) Reads only uncompress the portion of the file requested

b) Writes go to a set-aside file for background compression

→Replication Manager snap management & recovery [Celerra Snapshot checkpoints of NFS datastore; SRM integration]

a) Snap management initiated via RM v5.2

b) VMSnap executes on all VMs within the datastore (application consistent copies)

c) Celerra Snapshot creates copies of VMs in the NFS Datastore

d) Restores of individual VMs or entire Datastore

e) Can perform offline backups

→VMware Site Recovery Manager (SRM 4.0) Integration

a) Celerra Replicator management by SRM with NFS Storage Replication Adapter (Replication between Celerras)

b) Celerra supports SRM failover and fallback (with NFS Failback plug-in)

**MANAGING CELERRAS FROM PLUG-IN:**

[View > Home > Solutions and Applications: EMC Celerra](#)

**PROVISION OR EXTEND STORAGE:**

→Provision Storage wizard allows creation of the NFS Datastore on a particular Control Station and Data Mover, using either a new NFS Export (new file system with Virtual Provisioning enabled by default) or an existing NFS export

→Default Celerra best practice settings for the NFS Export is to mount with “uncached” & “noscan” options

→Add the Celerra to the VM Infrastructure using the “Provision Storage” dialog, or if a VM operation for cloning or compressing is done on a VM to which the Celerra has not yet been added

→Can extend the file system using the “Extend Storage” wizard, which extends the presented NFS Datastore

**Note:** Max size is 16TB per Celerra file system limit

**VM FULL CLONE:**

→Rightclick VM > EMC Celerra > Full Clone or Fast Clone

→Creates full & separate copy of a VM (vmx & vmdk files) in the NFS Datastore using Celerra DHSM full clone api

→Limited to the NFS Datastore on the same Data Mover

→Maximum clone count is based on number of CPU cores in Datacenter Cluster or ESX Host

**VM FAST CLONE:**

→Creates file level snap of a VM’s vmdk file and a full clone of a VM’s vmx file

→Limited to the NFS Datastore of the parent VM

→Maximum clone count based on the number of CPU cores in the Cluster or ESX Host

→Initial fast clone snap size is only 32kb, but expands after the VM’s are powered on, and depends on guest O/S size

→Fast clone properties will list the parent

→Fast Clones can only be made on VMs on the same file system

→VM’s with a Fast Clone cannot be deleted (leaves .vmdk file)

→Fast Clones cannot be compressed

#### **STORAGE OPTIMIZATION: COMPRESS/DECOMPRESS**

→Compression (Celerra Deduplicatiion) is not enabled by default when creating the NFS Datastore, but can be configured via Advanced Options during creation, or via Properties dialog box after creation of the Datastore

**Note:** Setting compression automatically enables deduplication on the underlying Celerra file system, but shows up as “suspended”. The Deduplication API is called whenever plug-in actions are taken.

→Compress or decompress VMs, approximately 30-50% (rightclick VM > EMC Celerra > Compress/Decompress)

→Compression properties will show compression characteristics

→Compression not allowed on Branch File (Fast clone) or Version File [a base file (aka VM) with fast clones]

→Plug-in does not support NMFS

→Plug-in does not support Compression or Fast Clones when using VMware Fault Tolerance feature

#### **PREREQUISITES FOR USING CELERRA VMWARE PLUGIN:**

--NAS 5.6.48.7 + 701 patch

--ESX Server 3.5 or 4.0

--vCenter Server 4.0

--vSphere Client 4.0

--NFS license enabled on Celerra

--Network connectivity between Data Mover, Control Station, ESX server, vSphere client

--DHSM enabled and configured on Celerra for CS & vSphere Client access (cloning & compression)

--EMC Celerra Plug-in for VMware installed on vSphere client

--Available Storage Pools on Celerra for automatic creation of NFS file system and export for NFS Datastore

#### **Current Limitations:**

→Deduplication does not work for version files, which are fast clones

→No way to monitor progress of deduplication for full clones, or failure message from client

#### **USING THE CELERRA VMWARE PLUGIN:**

##### **I. Install the EMC Celerra Plug-in for VMware on the vSphere Client Server**

##### **II. Setup the DHSM User and Service on the Data Mover:**

**Note:** The DHSM setup will be required if using the Plug-in to compress or uncompress VMs in the NFS Datastore, or cloning or viewing properties.

###### **a) Create DHSM User on the Data Mover(s)**

```
# /nas/sbin/server_user ALL -add -md5 -passwd dhsm_user
```

Creating new user dhsm\_user

User ID: 525

Group ID: 525

Home directory:

Changing password for user dhsm\_user

New passwd:

Retype new passwd:

###### **b) Enable digest Authentication**

```
# /nas/bin/server_http ALL -modify dhsm -authentication digest -users dhsm_user
```

server\_2 :

#### DHSM FACILITY CONFIGURATION

Service name : EMC File Mover service

Comment : Service facility for getting DHSM attributes

Active : False

Port : 5080

Threads : 16

Max requests : 300

Timeout : 60 seconds

#### ACCESS CONTROL

Allowed IPs : any

Authentication : digest ,Realm : DHSM\_Authorization

Allowed user : dhsm\_user

#### SSL CONFIGURATION

Mode : OFF

Persona : default

Protocol : default

Cipher : default

###### **c) Start DHSM Service on Data Movers**

```
# /nas/bin/server_http ALL -service dhsm -start
```

server\_2 : done

#### DHSM FACILITY CONFIGURATION

Service name : EMC File Mover service  
Comment : Service facility for getting DHSM attributes  
Active : True

#### d) Add vSphere Client IP & Control Station IP to DHSM access list

# /nas/bin/server\_http ALL -append dhsm -hosts 10.250.148.134

-----abridged-----

#### ACCESS CONTROL

Allowed IPs : 10.250.148.134,10.250.148.184

**Note:** Add the IP address of the Control Station in order to view get\_attributes, or to manually test compressing, decompressing, cloning, etc., but using the tools found in the /nas/tools/dhsm directory

#### III. Add the Celerra Control Station to the vSphere Plug-in:

[View > Home > Solutions and Applications: EMC Celerra > Add](#)

Add Celerra – EMC Celerra Plug-in

Celerra Control Station Hostname / IP: 10.250.148.184

Celerra Control Station Username: nasadmin

Celerra Control Station Password: passwd

DHSM Username: dhsm\_user

DHSM Password: passwd

**Note:** Observe the Recent Tasks section at the bottom of the vSphere screen to monitor success or failure of the Add operation

#### IV. Create a new NFS Datastore:

[Datacenter > rightclick, EMC Celerra > Provision Storage](#)

**Note:** Enter Datastore name, Control Station, Data Mover, Data Mover interface, Storage Pool, then enter details for new or existing NFS export, as well as any advanced properties (e.g., Virtual Provisioning; Enable Compression (dedupe), etc)

→ NFS Datastore created at Datacenter level is visible to all ESX Server Hosts, while NFS Datastore created at Host level is visible to that Host only

→ When creating from existing NFS Export, best practice popups recommends Virtual Provisioning, and mount options nocache, and uncached

→ Plugin should provide popup error if there was a problem during the NAS Storage Provisioning operation, though a provisioning error will not stop the Celerra from creating and exporting the NFS file system (so you may need to cleanup exports and file systems once the datastore issue has been figured out)

#### EXAMPLE OF SUCCESSFUL NAS NFS DATASTORE CREATION USING PLUGIN:

# server\_mount server\_2 |grep uncached

fs1 on /fs1 udfs,perm,rw,noscan,uncached

Dstore1\_184 on /Dstore1\_184 udfs,perm,rw,noscan,uncached

datastore2\_184 on /datastore2\_184 udfs,perm,rw,**noscan,uncached**

# server\_export server\_2

server\_2 :

export "/dstore\_225" root=192.1.8.229 access=192.1.8.229 → VMKernel IP address on the ESX Host Server

#### EMC NFS Plugin.log:

Issuing command to Celerra:

https://10.241.168.30/servlets/wizards?object=filesystem&command=new&properties=name=Dstore1\$storageMB=10240\$type=uxfs\$rwMover=server\_2\$storagePool=36\$thinProvisioningEnabled=True\$flrState=off\$autoExtendEnabled=True\$autoExtendMaxMB=20480\$rdeState=off\$autoExtendHWM=90

DEBUG 2010-03-03 11:22:16 [com.emc.celerra.tools.engine.apl.HttpsConnection]: Issuing command to Celerra:

https://10.241.168.30/servlets/wizards?object=export&command=new&properties=path=/Dstore1\$mover=server\_2\$rootHosts=192.1.8.227\$accessHosts=192.1.8.227

DEBUG 2010-03-03 11:22:17 [com.emc.celerra.vmware.nfs.engine.CloneController]: mount NFS Datastore Dstore1 on Host 192.1.8.225 by using NFS Export /Dstore1 and Datamover interface 192.1.8.241

#### vSphere Client Plugin:

View > Inventory > Datastores > Dstore1: rightclick and “Browse Datastore...” or go to “EMC Celerra > Properties” to see properties of the Datastore [Shows VMs in the Datastore; Compression is not enabled by default]

#### vSphere Client plug-in GUI:

#### Plug-in Properties for Datacenter, Cluster, and ESX Host objects:

EMC Celerra > Compress; Decompress; Provision Storage; Properties; Help

#### Plug-in Properties for VMs:

EMC Celerra > Compress; Decompress; Full Clone; Fast Clone; Properties; Help

→ For “Provision Storage”, you create an NFS Data Store based on a new or existing NFS Export, after logging into the Celerra with username and password, and providing a dhsm username and password

→Rightclick VM > EMC Celerra > Properties | Full Clone | Fast Clone | Compress | Decompress

→Once created, you can rightclick the NFS Datastore, select EMC Celerra>then go to “Compress; Decompress; Extend Storage; or Properties”

**Note:** You must setup a DHSM user account and service on the Data Movers that are hosting the VMware NFS Datastores, and then add the vSphere Host to the DHSM access list. This is necessary because VM properties, cloning, and compression cannot be done without the Celerra’s DHSM api.

#### Troubleshooting Plug-in:

→Plug-in activities are logged on the Windows Client

**Program Files>VMWare>Infrastructure>Virtual Infrastructure Client>Plugins>EMC Celerra>log>EMC\_NFS\_Plugin.log**

#### USING DHSM TOOLS FROM CONTROL STATION TO TEST PLUGIN:

##### Viewing attributes of objects in the NFS Datastore:

```
# /nas/tools/dhsm/get_attributes -u dhsm_user -p nasadmin -d 192.1.8.241 nfs:/dstore4/2k3_cloned/2k3_cloned.vmdk
<DHSM_GET_ATTRS PATH="nfs:/dstore4/2k3_cloned/2k3_cloned.vmdk" DEDUPE="True"/>
```

##### Compressing Single File in Datastore:

```
# /nas/tools/dhsm/dedupe_file -u dhsm_user -p nasadmin 192.1.8.241 nfs:/dstore4/Win2k3157/Win2k3157.vmdk
<DHSM_DEDUPE_FILE PATH="nfs:/dstore4/Win2k3157/Win2k3157.vmdk"
```

```
# /nas/tools/dhsm/get_attributes -u dhsm_user -p nasadmin -d 192.1.8.241 nfs:/dstore4/Win2k3157/Win2k3157.vmdk
<OFFLINE_ATTRS
```

OFFLINE\_PATH="dart://rde/AQAAAAA/1e1/c2/AQm8fBIIINUL69uSy4DMQHkYwfhQUAAAAAAAAAAAAAAwAAAAAA  
AAACAw;338b91b1" →This line indicates that the file is compressed

##### Uncompressing Single File in Datastore:

```
# /nas/tools/dhsm/redupe_file -u dhsm_user -p nasadmin 192.1.8.241 nfs:/dstore4/Win2k3157/Win2k3157.vmdk
<DHSM_REDUPFILE PATH="nfs:/dstore4/Win2k3157/Win2k3157.vmdk"
```

##### Creating a Full Clone of VMDK File:

```
# /nas/tools/dhsm/clone_file -f -u dhsm_user -p nasadmin 192.1.8.241 nfs:/dstore4/Win2k3157/Win2k3157.vmdk
nfs:/dstore4/Win2k3157/w2k3_cl.vmdk
```

<DHSM\_CLONE\_FILE PATH="nfs:/dstore4/Win2k3157/Win2k3157.vmdk"

CLONE\_PATH="nfs:/dstore4/Win2k3157/w2k3\_cl.vmdk" CLONE\_TYPE="Full"

##### Creating a Fast Clone of VMDK File:

→Difference from previous command is to drop the “-f” from the commandline syntax

#### EMC CELERRA PLUGIN FOR VMWARE Version 1.1.9 (Eisenhower release): June 2010

→Enhancement to the initial Version 1.0.7 Celerra VMware plugin release

#### PRACTICAL INFORMATION ON THE PLUG-IN:

--The initial plug-in release for Celerra was version 1.0.7, March 2010

--A new and enhanced plug-in was GA’ed in June 2010, version 1.1.9

--The plug-in setup.exe is downloadable from Powerlink

--The plug-in installs on Windows 2003 running VMware vSphere 4.0

--The vSphere communicates to the Celerra using HTTPS

--Celerra Screenshot is one of several DART features that are leveraged in the creation of fast clones for VMs

--When you create the DHSM connections, make sure that the ESX Host VMkernel IPs, and Control Station IP, are added to the DHSM connection (dhsmsetup.pl script does not necessarily advise you to do this otherwise)

--The Celerra DHSM API is used for Cloning, Compression, & Viewing of properties within the vSphere 4.0 Client

--VMs are seen as a ‘Regular file’ from within the vSphere GUI properties

#### Datastores:

--Supports only NFS Datastores, not FC or iSCSI block Datastores

--Datastores are built on Celerra file systems and are intended to be dedicated for ESX Server use only, using the vSphere plug-in functionality, and not for general use by other NFS or CIFS Hosts

--Datastores are created by default with Celerra Virtual Provisioning and file system auto-extend enabled

--Datastores are used as a container for Virtual Machines, including Full or Fast clones of Virtual Machines

#### Compression:

--Optimizes storage through the use of Celerra deduplication for compression of VMs

--Overall performance of VMs is said to be within 10% of uncompressed VMs

--However, compression is never automatically applied and must be manually initiated by the vSphere Client (using the plug-in capability), and applies only to VMs within datastores

--You can initiate ‘compression’ from various object levels (Datacenter, Datastore, ESX Host, individual VM, etc.)

--Be aware that having ‘Compression Enabled’ on a datastore does not automatically compress VMs or Clones that get added to (or created in) the datastore—the User must manually initiate an operation to compress any new VMs or Clones added to a datastore

--Compression attributes and space savings on VMs can be seen via ‘Properties’ from the plug-in

--Compression information is not visible from the Celerra CLI

#### Compression Error Examples—Product Functioning as designed:

**Action:**

Try to compress a Virtual Machine that already has Fast Clones created underneath (aka, Version file, or Base VM with Fast Clones)

**Result:** The action taken is not allowed, no popup, just results in a Task Error

“Compress vm184-2 Error Unable to compress a version file(Base VM with Fast Clones). This operation is not allowed.”

**Action:**

Try to compress a Fast Clone

**Result:** The action taken is not allowed, no popup, just results in a Task Error

“Compress vm184-2clone1 Error Unable to compress a branch file(Fast Clone). This operation is not allowed.”

**VM Properties using Plug-in:**

--A Virtual Machine is seen as a ‘Regular file’ from within the context of the vSphere plug-in properties

**VM path is:**

**/dstore184-3/w2k3-184**

**Full Clones:**

--Full clones are complete copies of a VM, and can reside on the original datastore file system, or other datastore file systems, provided it is on the same Celerra Data Mover

--Full clones are seen as Regular files in vSphere properties

--Full clones hang off the root of the datastore file system to which they are copied, and under a full\_clones subdirectory

**Full Clone of ‘w2k3-184’ in datastore ‘dstore184-3’:**

**# ls -la dstore184-3/full\_clones**

drwxr-xr-x 2 root root 1024 Jun 30 13:27 clone00001

**Note:** In this example, clone00001 is ‘w2k3-184-clone1’ in vSphere

**Properties of Full Clone using Plug-in:**

--Full clone of VM ‘w2k3-184’ is a complete & independent copy

--Like VMs, Full clones are also ‘Regular files’

--You can create multiple clones using ‘Clone Count’ field, and assign your own naming convention with ‘Clone Name’ field, Power On automatically, Integrate with VMware View

**Full clone path:**

**/dstore184-3/full\_clones/clone0001**

**Fast Clones (aka Branch file):**

--Fast clones are snapped copies of a VM, and can only reside on the original file system datastore where the parent VM resides. In otherwords, the Fast Clone is a child of the parent VM and lives in a sub-directory on the parent file system.

--A VM that has a child Fast Clone is called a ‘Base VM’, or ‘Version file’

**Fast Clone from parent VM ‘vm184-2’ in datastore ‘dstore184-3’:**

**# ls dstore184-3/vm184-2 |grep clone\***

clone00001

clone00002

**Properties of Fast Clone using Plug-in:**

--Fast clone of ‘vm184-2’

--Fast clones are called Branch files, or thin clones of a Base file (the parent VM)

--You can create multiple clones using ‘Clone Count’ field, and assign your own naming convention with ‘Clone Name’ field, Power On automatically, Integrate with VMware View

**Fast Clone Path:**

**/dstore184-3/vm184-2/clone0001**

**CREATING A VIRTUAL MACHINE USING vSPHERE:**

--The following steps provide an overview of how you might create a VM on a newly created Celerra NFS datastore, and is strictly a function of the vSphere Client and not the Celerra plug-in

**Steps for Creating a Virtual Machine on a Celerra datastore:**

1. Create an NFS datastore using the plug-in
2. Create the VM by rightclicking the Datacenter object in vSphere
  - a.) Highlight Datacenter name > New Virtual Machine > Create New Virtual Machine
  - b.) Choose a name for the VM, Datacenter/ESX Host, and datastore to host the VM
  - c.) Select a desired Operating System from the list (e.g., Windows 2003)
  - d.) Proceed through the ‘Create a Disk’ and ‘Ready to Complete’ screens and the VM gets created
3. After creating the VM, you must then actually ‘install’ the O/S
  - a.) Rightclick the new VM > Edit Settings
  - b.) Upload a Windows 2003 ISO image file to a datastore location using the “Browse Datastore” and ‘Upload’ functionality within vSphere
    - c.) Select “CD/DVD Drive 1” from hardware list, then select “Datastore ISO File” and browse to the previously uploaded ISO file, and finally, check the box at the top of the screen for “Connect at power on”
    - d.) Highlight the VM name, and click on the “Console” tab located on the righthand side of the vSphere screen

e.) Click the green triangle button at the top of the screen to power on the VM, and install the Windows O/S within the context of the ‘Console’ screen display

**PLUG-IN PRE-REQUISITES:**

- Minimum NAS 5.6.48.7 + 701 patch
- ESX Server 3.5 or 4.0
- vCenter Server 4.0
- vSphere Client 4.0
- VMware View Manager 4.0
- NFS license enabled on Celerra
- Network connectivity between Data Mover, Control Station, ESX server, vSphere client, VMware View client
- DHSM enabled and configured on Celerra for Control Station & vSphere Client access
- EMC Celerra Plug-in for VMware installed on vSphere Client
- Available Storage Pools on Celerra for the automatic creation of NFS file systems and exports (for NFS Datastores)

**PLUG-IN FEATURES FOR 1.1.9:**

**VMware View 4.0 integration:**

- VMware View is integrated to VSphere using an ‘Add’ dialogue option in the plug-in
- ‘Refresh Desktops’ applies to Fast Clones only—refreshing a Fast Clone Desktop deletes the existing Fast Clone, creates a new Fast Clone with the same name from the ‘base’ VM, then places new Clone back in the VMware View Pool as a ‘refreshed’ Desktop
- Full and Fast clone integration into VMware View
- Allows for automatic registration of Fast clones in VMware View

**No Scan Mount Option for disabling CAVA scanning:**

- By default, Celerra file systems will mount with the “noscan” option so as to disable CAVA virus scanning on the NFS datastores

**Script Setup of DHSM on Celerra:**

- DHSM script sets up the DHSM user, service, & connection to the Celerra and the vSphere VMkernel [previously, all manual steps]
  - a) Upload dhsmsetup.pl perl script to any location on the Control Station, using a program such as WinSCP3
  - b) As Root user, execute the script & answer the prompts for UID, GID, etc:  
**# perl dhsmsetup.pl <Data Mover name> <dhsm\_user> <vSphere\_host IP>**
  - c) Append the CS IP address to DHSM connection if you want to use the Control Station DHSM troubleshooting utilities

**Users can view Space Savings after running compression:**

- Before and after space savings are now displayed in GUI properties for a compressed object

**CONFIGURING THE CELERRA PLUG-IN ENVIRONMENT:**

**I. Download the EMC Celerra Plug-in for VMware from Powerlink and install on the vSphere Client**

**II. Setup the DHSM User, Service, and Connection(s) on the Data Mover:**

**Note:** The DHSM setup is required for using Compression, Cloning, or to View properties of objects within the plug-in

**a) Create DHSM User on the Data Mover(s)**

**# /nas/sbin/server\_user ALL -add -md5 -passwd dhsm\_user**

Creating new user dhsm\_user

User ID: 525

Group ID: 525

Home directory:

Changing password for user dhsm\_user

New passwd:

Retype new passwd:

**b) Enable digest Authentication**

**# /nas/bin/server\_http ALL -modify dhsm -authentication digest -users dhsm\_user**

server\_2 :

**DHSM FACILITY CONFIGURATION**

Service name : EMC File Mover service

Comment : Service facility for getting DHSM attributes

Active : False

Port : 5080

Threads : 16

Max requests : 300

Timeout : 60 seconds

**ACCESS CONTROL**

Allowed IPs : any

Authentication : digest ,Realm : DHSM\_Authorization

Allowed user : dhsm\_user

**SSL CONFIGURATION**

Mode : OFF

Persona : default  
Protocol : default  
Cipher : default

**c) Start DHSM Service on Data Movers**

```
# /nas/bin/server_http ALL -service dhsm -start
DHSM FACILITY CONFIGURATION
Service name : EMC File Mover service
Comment : Service facility for getting DHSM attributes
Active : True
-----abridged-----
Allowed IPs : 10.250.148.134,10.250.148.184
```

**Note:** Add the IP address of the Control Station in order to view get\_attributes, or to manually test compressing, decompressing, cloning, etc., using the tools found in the /nas/tools/dhsm directory

**e) Verify DHSM Service:**

```
# server_http server_2 -info
DHSM FACILITY CONFIGURATION
Active : True
ACCESS CONTROL
Allowed IPs : 10.241.168.134,10.241.168.184,192.1.4.195
Allowed user : dhsm_user,dhsm_user1
```

**III. Add the Celerra Control Station to the vSphere Plug-in:**

**View > Home > Solutions and Applications: EMC Celerra > Add > EMC Celerra**

|  |   |
|--|---|
| Celerra Control Station Hostname / IP: | 10.250.148.184  |
| Celerra Control Station Username:      | nasadmin  |
| Celerra Control Station Password:      | *****<br>DHSM Username: dhsm_user<br>DHSM Password: ***** |

**Note:** See ‘Recent Tasks’ section in vSphere screen to monitor success or failure of actions

**IV. Integrate VMware View into the vSphere environment:**

**a. Install and configure View Manager on a Windows system**

- (1) Install VMware View Agent 4.0.1
- (2) Install VMware View Connection Server 4.0.1

**Installed Services:**

VMware View Connection Server—VMware View service

VMwareVDMDS—VMware LDAP directory services

- (3) All Programs > VMware > View Administrator Console
- (4) Click Configuration > Add license details
- (5) Click ‘Servers’ and add the vSphere/vCenter Server IP, username, and password to register

**b. Add View Manager to vSphere**

- (1) View > Home > Solutions and Applications: EMC Celerra > Add > VMware View Manager
- Vmware View Manager Server:

Username:

Password:

**PERFORMING PLUG-IN TASKS:**

**PROVISIONING NFS DATASTORES:** Provision Storage by creating new file system or using existing NFS export

**Datacenter > rightclick, EMC Celerra > Provision Storage**

--Virtual Provisioning (with file system auto-extend) is selected by default

--Manually type the ‘Initial Capacity’ & ‘Max Capacity’ values, or else the “OK” button will not enable itself! AR371466

**Advanced Options:**

- High Water Mark=file system extend threshold, default 90% full (50-99% avail.)
- ‘Uncached’ mount option is a default (NFS best practice)—NFS writes are not cached on the Server, are written straight through to storage disks
- No Prefetch unchecked means Read ahead Prefetch on large files is used
- Enable Compression not a default—when checked Dedupe is in ‘suspended’ state on file system, giving ability= to compress VMs within the Datastore
- Celerra AntiVirus Scanning--unchecked = “noscan” mount option NFS BP
- Export to Subnet--allows datastore export to a subnet

**ESX Settings:**

- Set Timeout Settings--based on best practice NFS heartbeat settings for ESX Server exports
- HostHeartbeat=12
- HostHeartbeatMaxFailures=10
- HostHeartbeatDelta=5
- HostHeartbeatTimeout=5
- See Program Files\Vmware\Virtual Infrastructure Client\Plugins\EMC Celerra\cfg\vmware\_nfs.ini file for many more ESX Export settings
- See the EMC Celerra Plug-in for VMware Troubleshooting Checklist for definitions of all the ESX Server parameters

#### **DATASTORE EXAMPLE--Celerra File System Properties for ‘dstore184-3’:**

# nas\_fs -info dstore184-3

```
name    = dstore184-3
auto_ext = hwm=90%,max_size=12288M,virtual_provision=yes
deduplication = Suspended (When Compression selected during creation)
```

**Note:** Compression was selected during “dstore184-1” creation, represented by deduplication = Suspended

# server\_mount server\_2

```
dstore184-3 on /dstore184-3 ufs,perm,rw,noscan,uncached
```

# server\_export server\_2

```
export "/dstore184-3" root=192.1.8.229:192.1.8.216 access=192.1.8.229:192.1.8.216 (ESX Server VMkernel IP addresses)
```

#### **What Happens during NFS Datastore creation?**

- a) Celerra file system created from selected Storage Pool (1fs per NFS datastore)
- b) File system mounted based on selected/default options
- c) File system exported for NFS root access to ESX Server VMkernel IP addresses
- d) NFS Datastore created in vSphere for selected ESX Hosts
- e) NFS export options are updated on ESX Hosts

#### **OPTIMIZING STORAGE:**

- Compresses or decompresses VMs (at Cluster, Datacenter, Datastore, ESX Host, Folder, or VM object level)
- Compression not enabled by default
- Compression sets file system deduplication into “suspended” state, and plug-in actions will be able to automatically compress or decompress
- Compression not allowed on Fast Clones (aka Branch Files), which are snapshots of the parent VM, and referenced back to the parent VM
- Compression not allowed on a VM (Version file, base file) that has had Fast Clones created
- Compression typically yields 30-50% space savings

#### **CLONING VIRTUAL MACHINES (VMs):**

- Can create Full independent copies of VMs or Fast clone snaps of VMs
- Total number of clones allowed varies with the number of CPU cores in the ESX Cluster or destination ESX Host
- Full clones are full and independent copies of a VM
- Full clones can be made from one datastore to another as long as the datastores reside on the same physical Data Mover
- Fast clones are file-based snapshots of VMs, with relationship to parent
- Fast clone destinations limited to the same NFS Datastore as parent VM
- Multiple clones can be created by incrementing “Clone Count” field
- Fast clones cannot be compressed
- VMs with associated Fast clones cannot be deleted
- Fast clone snap size is only 32kb, but expands to size of O/S after Fast clone VM is powered on

#### **VMware VIEW INTEGRATION:**

- Full/Fast clone integration with VMware View
- One difference between Full and Fast clone is that you do not choose a Destination NFS Datastore (can only snap to the same Dst ore as the parent VM)
- Add View Manager to vSphere and vSphere to View Manager
- View allows Fast clones to be automatically registered
- View allows refreshing of Desktop VMs on Fast clones only, within View Pools

#### **EXAMPLE--Refreshing “view1\_fast1” Fast clone:**

- a) Select a new or existing View Pool to add the clones
- b) Create full clone pool ID and name
- c) Full clone Pool desktop settings
- d) View Pools and Desktop view of clones integrated with VMware View
- e) Refresh Desktop using plug-in & View integration

#### **Refresh performs the following steps, as seen below:**

- 1) Fast clone ‘view1\_fast1’ is powered off
- 2) Fast clone is then deleted

- 3) A clone directory is created in the Datastore
- 4) A new Fast clone of the base VM ‘View1’ is created
- 5) The Fast clone is registered as a VM in the Datacenter
- 6) Refreshed Fast clone ‘view1\_fast1’ is reconfigured

#### **EXTENDING STORAGE:**

--Extending the NFS Datastore means extending the underlying Celerra file system (hence the default file system auto-extend value)  
--From example below, the (Max: 100.05GB) is the total available space in the Storage Pool on the Celerra

#### **USING CELERRA DHSM TOOLS:**

--Provided the dhsm\_user, service, and connection are setup properly, the Celerra Control Station can use CLI to perform many similar functions as done directly by the plug-in  
--Refer to the Troubleshooting Checklist document on the Partners Web site, for dhsm tool examples

#### **# ls /nas/tools/dhsm**

clone\_file → Use to create Full or Fast clones  
get\_attributes or set\_attributes → Use to view or set attributes on objects in the datastore  
dedupe\_file → Compressing files  
redupe\_file → Uncompressing files

#### **CELLERRA PLUG-IN LIMITATIONS:**

--Plug-in does not support Celerra NMFS  
--Plug-in does not support compression or fast cloning when using VMware Fault Tolerance  
--Compression not allowed on Fast clone or base VM with Fast clones  
--Deduplication does not work for ‘version files’, aka ‘fast clones’  
--The plug-in requires that Data Movers in the same Celerra cabinet have the same DHSM username and password

#### **TROUBLESHOOTING/PRIMUS SOLUTIONS:**

##### **Key Log on vSphere Client (EMC NFS Plugin.log):**

Program Files > VMWare > Infrastructure > Virtual Infrastructure Client > Plugins > EMC Celerra > **EMC\_NFS\_Plugin.log**

##### **Plug-in Configuration File (vmware\_nfs.ini):**

→Based on key parameters & best practices for ESX  
Program Files > VMWare > Infrastructure > Virtual Infrastructure Client > Plugins > EMC Celerra > cfg > **vmware\_nfs.ini** [See Online Help for details; To change logging levels from LogLevel=Info (default), set LogLevel=Error, or LogLevel=Debug]  
→See Program Files\VMware\Virtual Infrastructure Client\Plugins\EMC Celerra\cfg\vmware\_nfs.ini file for many more ESX Export settings  
→See the ‘Troubleshooting Checklist’ reference for complete definitions of all the parameters in the vmware\_nfs.ini file

##### **vSphere Task & Events--Recent Tasks:**

Use the Task & Events section to troubleshoot and observe plugin actions, at Datacenter, Datastore, ESX Host, VM level, etc.

##### **DHSM Verification on Data Mover:**

##### **# server\_http server\_2 -info | grep Active**

Active : True

##### **Knowledgebase Solutions:**

emc235511 Invalid NAS version detected by plugin  
emc235510 Celerra...not found—need to register CS with plugin  
emc234921 Error...creating datastore—needs IP configured on VMkernel  
emc235684 Cannot view properties of VM...None of Data Movers interfaces are reachable from vCenter—DHSM not setup & enabled

##### **REFERENCES:**

##### **GA release typically contains the following reference materials:**

EMC Celerra Plug-in for VMware Read Me First\*  
EMC Celerra Plug-in for VMware Release Notes\*  
EMC Celerra Plug-in for VMware Solution Guide\*+  
EMC Celerra Plug-in for VMware.zip setup.exe file\* (plug-in installable)  
EMC Celerra Plug-in for VMware Troubleshooting Checklist\*\*

\*\*Located at EMC Services Partner Web > Celerra > Celerra Plug-in for VMware Troubleshooting Checklist

+An updated Solution Guide to be posted soon

##### **Powerlink:**

Powerlink > Support > SW Downloads and Licensing > Downloads A-B > Adapters for Third Party Applications  
Celerra Plug-in for VMware  
Celerra Plug-in for VMware 1.1.9 Read-Me  
Celerra Plug-in for VMware 1.1.9 (.zip file with Read-Me; Release Notes; DHSM Script Setup instructions; dhsmsetup.pl Perl script; setup.exe)

#### **EMC CELERRA PLUGIN FOR VMWARE Version 1.1.20 (Aug 2010):**

→No new features with this release, just bug fixes

#### **FUTURE CELERRA VMWARE PLUGIN SUPPORT:**

- Support for FC/iSCSI LUN block provisioning of VMFS Datastores on CLARiiON luns from VI client
- Data restore from Celerra Checkpoints
  - a) Granular file restores to VM from available checkpoints  
Rightclick VM > EMC Celerra > Recover Files
  - b) Virtual Machine restores from Celerra Checkpoints  
Rightclick VM > EMC Celerra > Recover VM [Replace Active VM with recovery VM or Convert recovery VM to new VM]
- VDI Enhanced View Support

#### **COGNAC 5.6 MAINTENANCE RELEASE 12 (CMR12 5.6.49.3)**

- Mfg will begin using 500GB HDD for Maynard
- Mfg will begin using Flare 29 Patch 006 for NS-120, NS-480, & NS-960 platforms
- No new features in this release

#### **COGNAC CMR13 5.6.50 MAINTENANCE RELEASE:**

- Tolerance for Flare 30 Zeus, similar to NAS 6.0

#### **COGNAC CMR14 5.6.51 MAINTENANCE RELEASE:**

- Will tolerate arrays that use FCoE I/O modules for other Hosts, and supports Flare 30.5 Jupiter release, which introduces the FCoE I/O modules on the array
- Tolerance for Symmetrix Danube microcode on Gateways

#### **CELLERRA DENSE RACK SOLUTIONS (Yields 30 drives per 3U space vs. 15 drives):**

- GA June 2010, NOT customer installable
- NS-480 & NS-960 will introduce an Integrated factory-built option for a 42U Dense rack solution (No field installed to cust. Racks)
- Design allows for the installation of two 3U D15 DAE's in each rack row through the use of tandem rails, which will double the number of drives stored from 15 to 30 per tier (CTA Cable Track Assembly & CMA Cable Management Arm)

**Note:** Uses 3U & 6U rail adapters

- New CTA FC coupler with use of smaller 28gauge HSSDC2 cables
- SATA & EFD drives only for both solutions (except Vault will remain FC R5 4+1 + HS)

**Note:** Thermal design prevents use of FC drives in anything other than the Vault location

- NS-960 will ship with Dense racks to support up to 960 drives

- NS-960 will use a unique NS-42URK16DAE (NS system + 16 DAEs) rack for system, then an NS-42 12-tray rack for add-on DAEs & DMEs [NS-42URK24DAE—24 DAEs]

#### **NS-480 Dense Rack Product [NSD-480]:**

- NS-480 is offered with only a single 42U dense rack, max. 24 DAE's in 12 tandem drawers, totaling 360 drives
- NS-480 will use the 12-tray NS-42URK24DAE rack
- Single Control Station, 2 or 4 Blades, 1-12 tandem drawers for DAE's

→SP's can ship with 2-3 FC IO Modules, and, 2-3 iSCSI IO Modules, for a total of (5) IO modules max

#### **NS-960 Dense Rack Product [NSD-960]:**

- Min. config with single 42U rack, max. config with (3) 42U dense racks (8 DAE's in 1<sup>st</sup> rack, 12 DAE's in next two racks)

#### **Dense Rack Restrictions:**

- 2 & 5 meter cables are 100 Ohm
- Only vault drives can be FC, all other drives would be either SATA and/or EFD
- No data-in-place upgrades for Clariion
- Not sold as field installable, only factory-racked and pre-configured
- Clariion 480 and 960 models only [Flare 28.003, or 28.704, or 29.001]

#### **BAROSSA (NAS 6.0.36.4)** GA September 2, 2010

→Customer installable [Only for Integrateds, using CSA. Gateways require EMC/Partner installation.]

→Customer upgradeable [Using USM—Unisphere Service Manager and Celerra Upgrade Tool wizards, but Integrateds only)

#### **Location of NAS 6.0 Code on Powerlink:**

Software > Software Downloads and Licensing > Downloads C > Celerra Software

**Note:** Includes Apps & Tools CD, Customer Documentation set, Release Notes, Install CD's and DVD images, Upgrade CD's and DVD images, tar.gz package and CD1.iso file required to run the CUT tool manually.

**Location of Customer Service and Customer Documentation Sets on Powerlink:**

Support > Technical Documentation and Advisories > Hardware/Platforms Documentation > Celerra Network Server > General Reference

- Celerra Network Server Documentation (User Edition)
- Celerra Network Server Documentation (Customer Service Edition)

**UNSUPPORTED HARDWARE:**

CNS-14, CFS-14, 507, 514, 517, 518 Data Movers; NS350, 500, 700 [these platforms cannot support 64-bit O/S]

**UNSUPPORTED FEATURES:**

**Replication V1:**

→ A series of PUHC checks will check for Replicator V1 license, sessions, checkpoints, or fs\_copy sessions, and fail the upgrade  
Error HC\_CS\_1620181221: Celerra Replicator (V1) sessions or checkpoints

Error HC\_CS\_1620181222: fs\_copy sessions

Error HC\_CS\_1620181223: Celerra Replicator (V1) license on

**Note:** Must either delete and remove all vestiges of RepV1 & license from system, or convert from V1 to V2 first (min. of 5.6.42 to convert), then upgrade to 6.0

**VG2/VG8 GALILEO GATEWAY MODELS:**

→ Galileo models are based on the Argonaut hardware, Westmere Intel CPU's for Blades, and Blackwidow Blade enclosure

→ No Prequalifier required for Installation, but is not customer installable—requires EMC or Partner Service installation

→ Installation is defined as Racking, Cabling, NAS installation, and System Registration

→ CSA & CPW are not supported on the Gateways, but the Registration Wizard will be supported

→ Ships in a basic EMC 40U rack from factory, or is available for field installation in a customer rack

→ HW warranty 3 years with Enhanced or Premium maintenance

→ SW warranty 90 days, beyond requires SW maintenance contract

→ Systems are upgradeable using USM Celerra Upgrade Tool (NAS 6.0) [Gateways are not yet officially customer upgradeable]

→ Common front-end hardware based on Argonaut (Westmere processor) and Blackwidow enclosure (Chassis, Power Supplies, Management modules)

→ FSB is replaced with a QPI (Quick Path Interconnect) which runs at 4.8Gbps

→ Maynard Control Station

→ Replaces NS-G2 & NS-G8

→ Based on Barossa 6.0 NAS release & Flare 30 Zeus

→ Factory or Customer-racked models

**EMC Celerra VG2 (Galileo A)—mid-range system replacement for NS-G2:**

→ 4-core 2.4GHz Westmere CPU, 3@2GB DIMMs totaling 6GB, 800Mhz DDR3 SDRAM memory, 1-2 blades, 1-2 Control Stations, and using only (4) IO slots/blade (5<sup>th</sup> slot is not used)

→ The VG2 can be direct-connected to a single storage backend, or attached to a max. of (4) backends via Fabric Switch

→ VG2 supports 64TB/blade

**EMC Celerra VG8 (Galileo B)—high-end system replacement for NS-G8:**

→ 6-core 2.8GHz Westmere CPU, 24GB memory (6@4GB DIMMs) 1066 MHz DDR3 memory, 2-8 blades, 1-2 Control Stations, and using (5) IO slots/blade

→ The VG8 can be direct-connected to a single storage backend, or attached to a max. of (4) backends via Fabric Switch

→ Supports 128TB/Blade, with Marketing leeway to bump this up to 256TB if necessary

**I/O MODULE TYPES:**

**FIBRE CHANNEL:**

→ Both systems will ship with the 4-port 8Gb FC I/O by default, though customers can select the 4-port 4Gb FC I/O module

**Note:** 4Gb card supports 1/2/4Gbps speeds, while 8Gb card supports 2/4/8Gbps speeds

4-port 8Gbps FC I/O Module (303-092-102B)--Glacier

4-port 4Gbps FC I/O Module (103-054-100C)--Tomahawk

→ Both systems can support up to (3) different Ethernet I/O modules

**ETHERNET:**

4-port 1GbE copper I/O module (303-121-100A)

2-port 1GbE copper + 2-port 1GbE optical Quad module (303-122-100A)

2-port 10GbE optical--max. of two per blade (303-081-103B)

**POST GA Q4 2010 HEATWAVE FCoE IO MODULE:**

→ Celerra VG2/VG8 blades will support FCoE IO for backend connectivity, either one or two FCoE SLICs, or mixed with FC

→ FCoE SLIC is Qlogic EP8112 10GbE Enhanced Ethernet

**Note:** Initial use on blades only for FCoE backend connectivity, not 10GbE frontend ethernet connectivity

→ Blades can support both FCoE & FC SLICs

→FCoE must be in slot\_0 if expected to boot from Backend via these connections [BE0, BE1]

→Otherwise, backend connections by FCoE in slot\_1 is possible [BE2/AUX2, BE3/AUX3]

→Example switch support would be Cisco Nexus 5010/5020 or Brocade 8000

#### **I/O MODULE RULES:**

→Single FC I/O module, default order entry is for 8GB FC 2/4/8Gbps, in slot\_0 only [4GB FC 1/2/4Gbps card optional]

→8Gb FC card uses SFP+ optical connectors, while the 4Gb FC card uses SFP optical connectors

→VG8 FC card comes with all (4) SFP's in the ports (2 ports to SPs; 2 ports for Tape drives)

→VG2 FC card comes with only (3) SFP's, but a 4<sup>th</sup> can be ordered (2 ports to SPs; 2 ports for Tape drives)

→Systems must use same hardware I/O module configuration, slot-for-slot, for all Blades

→Maximum of (2) 10GbE optical I/O modules per Blade

→Both Blades have (5) I/O slots, but VG2 only uses (4), while VG8 can use all (5)

→When adding I/O modules, must not skip slots, from left-to-right

→General rule-of-thumb, if adding multiple Ethernet card types, add 10GbE to leftmost open slot, then the 2portCU 1GbE/2portOpt 1GbE card, and then the 4-port CU 1GbE card

#### **SFP PART NUMBERS & DESCRIPTIONS:**

##### **019-078-032:**

→Standard multimode optical Fibre Channel SFP for 4Gbps FC IO Modules, supporting 1/2/4/GB (CX4, NS-120, NS40, etc)

##### **019-078-042:**

→Standard multimode optical Fibre Channel SFP+ for 8Gbps FC IO Modules, supporting 2/4/8Gbps CX4, Galileo Blades, etc

##### **019-078-041:**

→Standard multimode optical 10GbE SFP+ iSCSI or Ethernet, supporting Clariion 10GbE iSCSI or Celerra 10GbE Ethernet

#### **HARDWARE FOOTPRINT:**

VG2 Gateway footprint is 4U (2U blade enclosure, & 1U for each CS—1U space if CS1 is not ordered)

VG8 Gateway will have a footprint from 4U-10U maximum (2U @ four enclosures, 1U for each CS)

#### **I/O MODULE SUPPORT:**

##### **(2) different Fibre Channel I/O SLIC modules offered:**

--Default FC I/O SLIC module is the 8GB Glacier (2/4/8Gbps) with SFP+ connectors, though customers can still select the 4GB Tomahawk (1/2/4Gbps) FC I/O module when ordering (SFP connectors)

--Only (3) of the FC ports will be populated with SFPs (a 4th SFP can be ordered) on the VG2 [All ports have SFPs for VG8]

##### **(3) different Ethernet I/O SLIC modules offered:**

4-port 1GbE copper (303-121-100A) Thunderchild Broadcom 5715 controller

2-port 1GbE copper & 2-port 1GbE optical card (303-122-100A) Thunderbolt Broadcom 5715 controller

2-port 10GbE optical (303-081-103B) Poseidon Broadcom 5771 controller

→IO module slots are based on PCI-Express Gen 2 bus

→IO Modules used will be Tomahawk (4Gbps FC), Thunderchild, Thunderbolt, Poseidon I Broadcom 57710 controller (2-port 10Gbps), Glacier (8Gbps FC), and FCoE Heatware module, with PCI-Express Gen 2, post-GA release

**Note:** FC IO module on blades can be either 4Gbps or 8Gbps, but can only have (1) FC card, and in slot\_0

#### **IO Module Port Numbering:**

##### **FC Card:**

BE-0-0, BE-0-1, AUX-0-0, AUX-0-1

##### **Slot 1 Card:**

cge-1-0, cge-1-1, fge-1-0, fge-1-1 (Example)

##### **Slot 4 Card:**

cge-4-0, cge-4-1, fge-4-0, fge-4-1 (Example)

#### **DETERMINING PLATFORM/MODEL INFORMATION—EXAMPLE VG8:**

# /nas/sbin/model

VG8

# /nas/sbin/serial

FNM00101600060

# /nas/sbin/t2cab

3 - CELERRA IP CABINET

The Cabinet child is : 14 - a CELERRA ARGONAUT

# /nas/sbin/t2vpd -m

Argonaut\_B

# server\_sysconfig server\_2 -P

server\_2 :

Processor = Intel Six Core Westmere

Processor speed (MHz) = 2800

Total main memory (MB) = 24576

Model = VG8

QPI speed (MHz) = 6400  
 Bios Version = 04.73  
 Post Version = Rev. 24.20  
 Firmware Version = Rev. 10.50  
 Family ID = 0x0012  
 FRU ID = 0x000c

#### # nas\_inventory -list head

| Component                      | Type    | Status | System ID                      |
|--------------------------------|---------|--------|--------------------------------|
| Celerra VG8 APM000832011840000 | Celerra | OK     | Celerra VG8 APM000832011840000 |

→GUI also displays model name

#### **DART CONSOLE/T2CAP FACILITY:**

→New tier2 utility using a t2console/t2cap listener that will continually record management switch information (from Coldfire firmware) into separate files for each Data Mover in the /var/log/t2cap\_slot\_x.log

→Only available with Celerra Argonaut systems (VG2/VG8, etc.)

→Each mgmt switch is responsible for reporting console information for its blades to the Control Station

#### # /nasmcd/sbin/t2cap

T2cap - Version 1.0 - 11/24/09

usage: t2cap <slot> -f

<slot>: Sends console output to the screen.

-f : Writes console output to a file of the form /var/log/t2cap\_slot\_\*

Source revision 5.2.0.1 - 06/12/03

#### /var/log/t2cap\_slot\_2.log

-rw-r--r-- 1 root root 20325 Jun 14 21:28 t2cap\_slot\_2.log

**Note:** The t2cap logs record POST and bootup messages, as well as fibre channel login and normal server log boot.cfg tasks

#### Verifying that T2cap is running?

#### # ls -la /var/run |grep t2cap

```

-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_2.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_3.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_4.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_5.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_6.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_7.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_8.pid
-rw-r--r-- 1 root root 4 Aug 6 10:36 t2cap_slot_9.pid

```

#### # ps -ef |grep t2cap

```

root 4066 3489 0 Aug06 ? 00:00:01 /nasmcd/sbin/t2cap 2 -f
root 4067 3489 0 Aug06 ? 00:00:01 /nasmcd/sbin/t2cap 3 -f
root 4068 3489 0 Aug06 ? 00:00:00 /nasmcd/sbin/t2cap 4 -f
root 4069 3489 0 Aug06 ? 00:00:01 /nasmcd/sbin/t2cap 5 -f
root 4070 3489 0 Aug06 ? 00:00:00 /nasmcd/sbin/t2cap 6 -f
root 4071 3489 0 Aug06 ? 00:00:00 /nasmcd/sbin/t2cap 7 -f
root 4072 3489 0 Aug06 ? 00:00:00 /nasmcd/sbin/t2cap 8 -f
root 4073 3489 0 Aug06 ? 00:00:00 /nasmcd/sbin/t2cap 9 -f

```

#### **VG2/VG8 PRODUCT SERIAL NUMBER & PART NUMBERS:**

##### Product Part Numbers (PPN):

**900-567-004** (VG2 Galileo A)

**900-567-005** (VG8 Galileo B)

→The intentions are that the PSN & PPN will be persistent for enclosure replacements

#### # cat /etc/product\_numbers.db

#Product Numbers Database file

#This file contains the Product Serial Number(PSN) and Product Part Number(PPN).

Version=1.0

PSN=FNM00101600060

PPN=900-567-005

#### # tail /var/log/serial.log

---

Completed -- serial -set -psn FNM00101600060 -ppn 900-567-005 -force

Mon Jun 14 11:04:27 EDT 2010

---

#### Changing PPN Number:

→Use command: # /nas/sbin/serial -set -psn FNM00101600060 -ppn 900-567-005 –force

→Connect to Blade in enclosure, access POST Resume information, set PPN, reboot

#### **DME0 ENCLOSURE RESUME INFORMATION VG8:**

# cat /nas/log/enclosure\_resume.enclosure\_0.xml

```
<?xml version="1.0"?>
<EnclosureResume EnclosureID="0">
  <RESUME_INFORMATION_MIDPLANE>

#### **VG2/VG8 FRU/CRU INFORMATION:**

→Nimitz mgmt switch reports on most system FRUs except for SFPs & DIMMs, which DART reports on

→Coldfire mgmt switch firmware is flashed during upgrades, and setup\_enclosure determines the correct enclosure switch type in order to select the correct mgmtfirmware\_nm.s19 firmware & bootblock\_nm.s19 package for the system

#### **CRUs:**

Blade Encl Pwr Supply  
Blade I/O modules  
Blade SFPs  
Blade Management modules

#### **FRUs:**

Control Station  
Blade DIMMs  
Blade Assembly (Includes motherboard, not DIMMs—called a “CPU Module”)  
Blade Enclosure

#### **GALILEO HARDWARE UPGRADES AT GA:**

##### **Customer/EMC/Partners:**

Add SFP for 2<sup>nd</sup> tape connection VG2 only  
Add Blades VG2/VG8  
Add Blade I/O modules

##### **EMC/Partners only:**

Add 2<sup>nd</sup> Control Station VG2/VG8  
Add Blade Enclosure VG8 only  
Change I/O module for upgrade of same type module

#### **GALILEO BACKEND STORAGE SUPPORT:**

→VG2 supports direct connect (single CLARiiON only) or fabric switch connect to CLARiiON or Symmetrix (up to four arrays)  
→VG8 supports direct connect (single CLARiiON only) or fabric switch connect to CLARiiON or Symmetrix (up to four arrays)

#### **CLARiiON:**

CX300, 500, 700 [Flare 19, 24, 26]  
CX3-10, -20, -40, -80 [Flare 22, 24, 26]  
CX4-120, 240, 480, 960 [Flare 28, 29]

#### **SYMMETRIX:**

DMX1, 2, 3, 4  
VMAX, VMAX-SE

**Note:** Galileo also supports VMAX using 8GB FC with Enginuity 5874.207.168

#### **INCREASED STORAGE CAPACITY:**

→256TB/Blade on NS-960/NS-G8 architecture (file system still limited to 16TB)  
→iSCSI LUNs increased to 16TB

#### **DART 64-BIT OPERATING SYSTEM:**

- DART uses a 64-bit O/S, which allows for use of larger memory structures & addresses, increasing performance
- 64-bit DART does NOT mean 64-bit file systems [still 32-bit only]
- 4GB Memory systems will see a 10% performance penalty when upgraded to 64-bit
- Upgraded 6.0 systems will automatically use all physical memory (e.g., NS-960/NS-G8 will use all 8GB, whereas only 4GB used with 5.6)
- Control Station Linux remains 32-bit
- DART file systems remain 32-bit
- Ability to address >than 4GB memory
- Obsolete Hardware that does not support 64-bit instructions:  
510 DM, NS350, NS500, NS600, NS700, NS704; 507, 514, 517, 518 DMs, CNS14, CFS14

# **server\_sysconfig server\_2 -P**

server\_2 :

Processor = Intel Six Core Westmere  
Processor speed (MHz) = 2800  
Total main memory (MB) = 24576  
Model = VG8

## **6.0 ZEUS FLARE 30 (CX4-only) TOLERANCE:**

- Celerra will tolerate CX4 arrays running Flare 30, but many specific R30 features are not supported for use by Celerra
- Celerra does not support Auto-Tiering (CLARiiON FAST) policy
- Celerra does not support LUN Compression
- Celerra does not support DLU Fully Provisioned pool LUNs
- Celerra does not support mixed drive types in enclosure or Storage Pools

**See emc241591—nas diskmark -m -a:**

Warning 17717198855: FAST device 0033 on APM00083201184 was not marked because FAST is not supported in this release.

Warning 17717198861: Fully provisioned CLARiiON pool device 0065 on APM00083201184 was not marked because it is not supported in this release.

Warning 17717198863: CLARiiON pool device 000B on APM00083201184 was not marked because compression is not supported in this release.

→Zeus supports SATA EFD drives. SATA EFD & FC EFD drives are treated as the same drive types by Celerra (e.g., clarefd/clefd pools)

**Note:** SATA EFD drives are expected to be 100-200GB Samsung drives using Chariot paddle card

→Unlike CLARiiON, Celerra does not support the use of mixed drive technologies in the same Enclosure or Pool (Regular SATA, FC, EFD), will produce diskmark errors

**emc242009 examples:**

- Mixed drives in enclosure will show CPW GUI Error: ‘No provisioning can be done’
- nas\_diskmark -m -a: ‘Warning...Device...not marked...cannot contain mixed disk drive types.’
- setup\_clariion -init: ‘...disk devices can’t be configured...’

**nas diskmark:**

Warning 17717198856: Device 000B on APM00083201184 was not marked because a single CLARiiON device cannot contain mixed disk drive types.

**Setup clariion -init** script complains that it has no matching template for a Shelf with mixed drives:

*16 disk devices can't be configured using User Defined.*

*Configuration template doesn't completely match hardware.*

*Some disks may need to be relocated to fully configure the selected template.*

**EMC FAST Cache (EFD Drives):**

- FAST caching extends the arrays caching capability by mapping frequently accessed data to Flash drives, dramatically increasing the scale of caching [73GB – 2TB], as well as increasing system performance—DRAM cache cannot be scaled the same on a cost effective basis
- FAST Cache is created in RAID1 mirrored Read/Write mode, using a Policy engine and 64KB memory map strategy
- Requires FAST Cache enabler on SPs, and SP reboot
- Configurable on RAID Group and Pool-based luns via Unisphere
- Once installed FAST Cache is enabled by default on newly created Pool or RAID luns
- FAST Cache is non-volatile, meaning that data is preserved on power loss
- FAST Cache is not used on Vault drives
- Celerra CSA/CPW allows user to skip configuration of EFD drives to allow for FAST Cache configuration first
- FastCache can be enabled on individual RAID Group luns
- FastCache is enabled at the Storage Pool level only, meaning all luns within a pool will have the capability
- Luns and Pools created after installing the FASTCacheEnabler will be enabled by default
- Once enabled, applications can experience performance improvements as frequently accessed chunks of data are copied to FastCache, and demoted when usage falls

→FASTCache works with extents of 64KB (DRAM works at 2-16KB), operating at millisecond to microsecond speeds

→FASTCache uses a Policy engine (manages IO flow into and out of cache) and Memory map of 64KB chunks of storage, with a memory map copy stored in array DRAM

#### Creating FAST Cache from CLI:

# /nas/sbin/navicli -h 10.250.40.25 cache -type efd -create disks <disknames> -mode ro | rw -raidtype <rtype>

# /nas/sbin/navicli -h 10.250.40.25 cache -type efd -info | -stats | -status | -disks

#### Creating FAST Cache from Unisphere:

→Unisphere > System > Manage Cache

#### STORAGE POOL ENHANCEMENTS FLARE 30:

→Support for RAID 5, 6, & 1/0 for Pools, though any given pool can only be one RAID type

→Support for mixed drive types within Pools, but not for RAID Groups (this is how FAST works, by using different drive types for tiering within a single pool of luns)

→Support for up to three different drive types (FC, SATA, EFD) per pool (though Celerra does not support different drive types)

→CLARiiON Best Practice with Flare 30 is to have heterogeneous pools of mixed disk types, to support FAST Tiering

**Note:** Hetero pools support EFD, SATA, FC three tiers, and a single RAID protection type, and should be the same size

→Max number of drives 955 per Storage Pool on CX4-960 (RAID Groups limited to 16)

→Added support for DLU fully provisioned luns in Storage pools (previously just Thin luns in pools)

**Note:** DLU Thick LUNs cannot be used as WIL luns or Clone Private luns (CPL)

→CLARiiON now supports 14TB lun size

→Thin LUNs can now be expanded (both thick and thin luns can be expanded)

→Pool luns can now be shrunk (but only with Windows 2008 hosts)

#### LUN shrink:

a) Windows 2008 Server only, use Disk Mgmt to shrink a file system

b) Use Diskraaid utility from VDS provider in EMC Solutions Enabler to shrink pool LUN

c) Array background process migrates the Flare, Thick, or Thin LUN to a new Thin Lun, returning 8k chunks to the Storage Pool

#### CLARiiON LUN TYPES:

FLU Flare luns are traditional RAID Group luns, and are not TLU or DLU luns, and are supported by Celerra 6.0

TLU Thin luns are not fully provisioned pool luns, and are supported by Celerra 6.0

DLU Thick luns are fully provisioned pool luns, and not supported by Celerra 6.0

#### FLARE LUNs vs. THICK LUNs vs. THIN LUNs:

→Flare & Thick lun performance is best, Thin lun performance not as good

→Flare lun Raid Group disks limited to 16, while Thick & Thin Storage Pool disk limit is 955 disks

→Flare luns support all RAID protection types, Thick & Thin support only R5, R6, and R1/0

→Flare luns are expanded using Metaluns, Thick & Thin luns do not use Metaluns for expansion

→Compression converts Flare and Thick luns into Thin luns

→Flare luns do not support Auto-Tiering (FAST), while Thick & Thin luns do

→Flare luns support disk spin-down, Thick & Thin luns in Storage Pools do not

→Flare & Thick luns support RLP (Reserve Lun Pool), while Thin luns do not

→Flare luns support WIL (Write Intent Log) & CPL (Clone Private Lun), while Thick & Thin luns do not

#### CLARiiON LUN CONCEPTS & CELERRA SUPPORT:

→FLU ‘Flare’ Luns are traditional CLARiiON LUNs created in RAID Groups and are not TLU or DLU luns, and 6.0 supports

→TLU ‘Thin’ Luns are created in “Pools”, and are supported by 6.0

→DLU ‘Direct’ Luns are also created in “Pools”, but are NOT supported by 6.0

→Auto-tiering, or CLARiiON FAST, can only be set on Luns created from “Pools”, and is NOT supported by 6.0

→CLARiiON LUN compression is NOT supported by 6.0

→Enclosures with mixed disk technologies is supported by CLARiiON, but is NOT supported by 6.0 and diskmarking will fail

#### CLARiiON VIRTUAL PROVISIONING:

→Much has changed since VP was introduced with Flare 28. The concept of ‘Thin Pools’ no longer exists. You must create a ‘Pool’ under the Unisphere > Pools/RAID Groups section, then create LUNs and check the box for “Thin” if you want thin LUNs. The default would be to create Thick Direct LUNs (aka, fully provisioned)

→VirtualProvisioning enabler requires SP reboot

→Thin Luns in the Pools are also called TLU’s, whereas fully provisioned luns in the Pools are called DLU’s

→Celerra supports Clariion Thin Luns, but only if Auto-tiering policy is not set

Unisphere > Storage > LUNS > LUN 22 >properties > Tiering tab > Set the “Tiering Policy” to “\*No Data Movement”

#### Celerra will diskmark TLU Thin Luns if Auto-Tiering is turned off:

# nas\_diskmark -m -a

Discovering storage (may take several minutes)

done

Info 26306752254: APM00083201184 reassigned LUN 0022 in storage group 'Celerra\_sleet-120' from host id 0008 to 0024

Info 26306752254: APM00083201184 reassigned LUN 0023 in storage group 'Celerra\_sleet-120' from host id 0006 to 0025

**Celerra will not diskmark DLU pool luns, as they are not supported:**

# **nas\_diskmark -m -a**

Discovering storage (may take several minutes)

done

Warning 17717198861: Fully provisioned CLARiiON pool device 0065 on APM00083201184 was not marked because it is not supported in this release.

Warning 17717198861: Fully provisioned CLARiiON pool device 0064 on APM00083201184 was not marked because it is not supported in this release.

**Celerra will not diskmark LUNs that have a CLARiiON FAST Tiering Policy Set:**

# **nas\_diskmark -m -a**

Discovering storage (may take several minutes)

done

Warning 17717198855: FAST device 0033 on APM00083201184 was not marked because FAST is not supported in this release.

Warning 17717198855: FAST device 0032 on APM00083201184 was not marked because FAST is not supported in this release.

**FAST (Auto-Tiering):**

- Via policy on a per-lun basis, dynamically moves ‘hot’ data to higher performing drives, and ‘cold’ data to lower performing drives
- Requires Virtual Provisioning and AutoTiering enablers
- Once installed, all Pool luns will have AutoTiering enabled by default
- With Flare 30, CLARiiON FAST is now a two-way data relocation solution, with a flexible scheduler
- Tiering is now based on drive speed and capacity, within a Storage Pool
- Lun properties, “Tiering” tab, set each LUN to “No Data Movement” to disable auto-tiering

Name of the software package: -AutoTiering

**Note:** Installing AutoTiering enabler does not require SP reboots

→ Tiering requires that the User set the Tiering Policy and the Data Relocation Scheduler

**Celerra will not diskmark LUNs that have Compression set:**

# **nas\_diskmark -m -a**

Discovering storage (may take several minutes)

done

Warning 17717198863: CLARiiON pool device 000B on APM00083201184 was not marked because compression is not supported in this release.

→ You can uncompress the LUN under properties “Compression” tab

**Note:** You cannot compress DLU luns until after the LUN has been written to. You cannot compress RAID Group FLU luns without migrating the existing data to a Pool first. You can compress TLU thin luns without having any data in them.

**CLARiiON LUN COMPRESSION:**

- Ability to take a source fully provisioned Pool lun (DLU), or regular FLARE Raid Group lun (FLU), and migrate the lun to a new destination lun (pool) that then becomes “thin” (TLU), and after migration the original Flare or Thick lun is deleted, and the Thin lun is renamed with the original LUN number
- As mentioned earlier, Celerra does not support, though if you compress a Celerra Lun, the data is still available, but Celerra storage health checks and associated backend operations will subsequently fail
- Turning off LUN Compression changes the lun from Thin to Thick (aka, Fully provisioned DLU)
- Compression Enabler requires SP reboot
- So, compression can be applied to any Lun, and the results will be a new Thin Lun
- For Celerra, if you turn on compression, even though the data is migrated to a Thin lun and is still available to Clients, we will not be able to make any further changes to storage because health checks will fail diskmarking operations because of the compressed lun
- You cannot turn off LUN compression and migrate back to a RAID Group, it must remain in a Pool
- Stopping a Flare or Thick lun compression operation will make the Lun Thick (i.e., fully provisioned)

**Viewing Compression Attributes from CLI:**

# **/nas/sbin/navicli -h 10.241.168.179 compression -list**

Compression Feature State: On

LOGICAL UNIT NUMBER: 25

Name: Celerra\_sleet-120\_25\_d24

UID: 60:06:01:60:67:80:21:00:EC:8F:5D:49:0F:65:DF:11

Destination Pool ID: N/A

Current State: Compressed

Status: OK(0x0)

Percent Complete: 100

Rate: Medium

Total Capacity (Blocks): 281406912

Total Capacity (GBs): 134.185

Consumed Capacity (Blocks): 8389120

**Turning on LUN Compression via CLI for Flare LUN:**

# /nas/sbin/navicli -h 10.241.168.179 compression -on -l 23 -destPoolId 2 -rate high

**Turning on LUN Compression via CLI for Thick or Thin LUN:**

# /nas/sbin/navicli -h 10.241.168.179 compression -on -l 24

**CLARiiON SUPPORT FOR MIXED DRIVES WITHIN SAME “POOL”:**

→CLARiiON still does not support the used of mixed drive types within a RAID Group

→However, with Flare 30, CLARiiON does support the use of mixed drive types within a “Pool”

→Celerra does not support this, as demonstrated by the following

# nas\_diskmark -m -a →Message output below is inaccurate for CLARiiON, though the point is Celerra still does not support Discovering storage (may take several minutes)

done

Warning 17717198856: Device 000B on APM00083201184 was not marked because a single CLARiiON device cannot contain mixed disk drive types.

**CELERRA CLARiiON PUSH REGISTRATION:**

→Celerra will be able to provide CS Hostname, IP Address, Vendor string, and Unique ID for Blade registrations with the Array, thereby allowing for host-based protections of LUNs used by Celerra (to be implemented with Flare 31)

→Celerra upgrades where the Celerra Host initiator naming convention is not in use will not use this feature

**Sample Output navicli port -list:**

# /nas/sbin/navicli -h 10.241.168.179 port -list

Information about each HBA:

HBA UID: 50:06:01:60:C1:E0:D9:54:50:06:01:68:41:E0:D9:54

Server Name: sleet-120

Server IP Address: 10.241.168.178

HBA Model Description:

**HBA Vendor Description: EMC Celerra File Server 6.0** →New with 6.0

HBA Device Driver Name:

Information about each port of this HBA:

SP Name: SP A

SP Port ID: 1

**HBA Devicename: server\_3:scsi-0** →New with 6.0

Trusted: NO

Logged In: YES

Source ID: 1

Defined: YES

Initiator Type: 3

StorageGroup Name: Celerra\_sleet-120

**6.0 NEW LINUX KERNEL RHEL 5.2:**

→Based on Red Hat Enterprise Linux 5 (RHEL5)

→Kernel upgraded from 5.6 2.6.9 to 6.0 2.6.18

→Required for IPv6 support

→Required for additional security improvements

→Will not support CNS, CFS, NS350, NS500, NS600, or NS700 platforms

→Adds ipv6calc tool

→Will change ProxyARP to ProxyND service for the IPv6 support

# uname -r

2.6.18-128.1.1.6005.EMC

**STORAGE API VERSION 6.0.36-4:**

# rpm -qa |grep -i nasStorage

nasStorageAPI-8.2-12

**NEW CONTROL STATION PARTITIONS WITH 6.0:**

/celerra/audit →system partition for Security Auditing logs

/celerra/ccc →Celerra Configuration Collector, also later 5.6 releases

/celerra/commoncache →Unisphere C3 Celerra Common Cache mechanism to improve GUI performance

/celerra/wbem →ECOM & SMI-S binaries & logs

**CELERRA 6.0 EXPRESS INSTALL [EI] STORY:**

→”Express Install” replaces the traditional Classic Install, and are designed for factory reset of Integrated systems, Control Station recovery, normal Gateway system install, and uses either the boot:install dialogue, or “kickstart” answer file. A Control Station “recover” is issued for a recovery or CS replacement.

→Reinstalls of systems require backend cleanup, similar to current procedures, using a new cleanup script on the Installation media [/media/cdrom/tools/nas\_systemcleanup] or the traditional nas\_raid –s cleanup script from /tftpboot

→Installs are done via CLI only, requiring serial connection to the Control Station, and initiated with either the “install” or “kickstart” options.

→Gateway products require EMC/Partner installation, and will use the EI methodology for either “install” or “kickstart”.

→Integrated products ship out as pre-installed systems from Manufacturing, and make use of an Install Guide and CSA.

→An integrated Celerra would only use the EI methodology if a system needed to be reset to factory (mfg) condition.

→Express Installs are not much different than a classic NAS install of a system.

→Systems requiring EI install (Gateways) are not customer installable.

→Express Installs are slightly different from from Classic Installs (pre-6.0), though the look and feel are pretty much the same. EI is a little faster overall—uses a ghost imaging process.

→Install media consists of either a 2-disc bootable CD-ROM set, or a single bootable DVD disc, approximately 960MB total

**Note:** Stage 1 would be to scribe Linux image on IDE drive & bring CS online. Stage 2 would be to scribe NAS software on backend and bring up the system.

#### **From the Express Install CD-ROM or DVD, these are the EI options:**

**boot: install** [Interactive install, Question and Answers throughout]

**boot: kickstart** [Interactive, but most Q's upfront—recommended]

**boot: recover** [Control Station recovery option only, not for fresh installs]

#### **DUAL COMPACT DISC INSTALL MEDIA:**

##### **Explorer view of contents on CD1:**

images

isolinux

tools

.cd1

→CD1 is bootable and leads to the “boot:” prompt

##### **Explorer view of contents on CD2:**

images

isolinux

tools

.cd2

#### **DVD INSTALL MEDIA:**

##### **Explorer view of contents on DVD:**

images

isolinux

tools

.dvd

→DVD is bootable and leads to the “boot:” prompt

#### **Benefits of Express Install:**

→Provides an ability to restart from interrupted installs

→Provides a method for setting a system back to factory configuration

→Provides for a simplified & quicker Control Station replacement process

→Overall reduces the time for installations

→Better media integrity. Media files are verified by checksums after they are copied to the installation partition on the Control Station from the CD or DVD media.

#### **REINSTALLS OF EXISTING SYSTEMS:**

→Gateways would require manual cleanup of the Celerra configuration for reinstall

→Integrateds use the /media/cdrom/tools/nas\_systemcleanup script on EI CD1

→Optionally, Integrateds can also use the traditional /tftpboot/bin/nas\_raid –s cleanup script

→If the Celerra was previously “joined” to the CLARiiON Storage domain, make sure it is “unjoined” as part of the cleanup steps  
Ultimately, you may need to manually deconfigure a Celerra from the backend in order to perform a fresh install ( remove Luns; RGs; SG; Initiators, etc)

→Remember to set the SPs back to the Celerra internal network IPs (128.221.252.200 & 128.221.253.201, SPA SPB, respectively)

#### **Generic Integrated cleanup Steps:**

1) Stop Proxy ARP service (resets the SPs back to Celerra internal IPs) using “clariion\_mgmt –stop”

2) Mount 1<sup>st</sup> CD-ROM media and execute cleanup script

# mount /media/cdrom

# /media/cdrom/tools/nas\_systemcleanup -all

NAS Control/Data LUN Removal Utility - Version 0.3

Fri Jul 16 16:54:42 2010

Enter Service Password [or type "ABORT" to exit]: [**TotalDestruction**]

You are about to prepare the system for cleanup operation. NAS service will be stopped and all File Systems will be umounted from Data Movers.

Do you want to proceed with the cleanup? [YES/NO] yes

**Note:** The traditional /tftpboot/bin/nas\_raid –s cleanup still works and is another option without requiring 6.0 Media

3) Do the reinstall without assigning the CS Hostname & external IP address

4) Use the CSA utility to complete the configuration of the system

### **Example of Successful System Cleanup:**

# **/media/cdrom/tools/nas\_systemcleanup -all**

NAS Control/Data LUN Removal Utility - Version 0.3

Wed Sep 1 07:35:47 2010

Enter Service Password [or type "ABORT" to exit]:

You are about to prepare the system for cleanup operation. NAS service will be stopped and all File Systems will be umounted from Data Movers.

Do you want to proceed with the cleanup? [YES/NO] yes

Checking for integrated Celerra.....

Stopping NAS service....

Initiating NAS service stop ... OK

Umount all FileSystems from Data Movers to prepare data deletion...

Confirming that file systems are unmounted on each Data Mover ...

Slot\_2 ... OK

Slot\_3 ... OK

Mount NAS partition...

Mounting system mountpoints ...

/nas ... OK

WARNING!! OPERATION NOT REVERSIBLE

You are about to delete all user and system luns from the storage system.

You will not be able to recover your data once this is done.

Do you want to proceed with the cleanup? [YES/NO] yes

WARNING!! OPERATION NOT REVERSIBLE

You are about to delete the content of this IDE. The Control Station will not be able to boot unless you install new system image on the system.

This operation could take some time to complete, do not power off or reset the Control Station at this time

Do you want to proceed with the cleanup? [YES/NO] yes

Operation Succeeded.

### **SYSTEM CLEANUP NOT SUPPORTED ON GATEWAY SYSTEMS (VG8):**

# **/media/cdrom/tools/nas\_systemcleanup -all**

NAS Control/Data LUN Removal Utility - Version 0.3

Fri Jul 16 16:54:42 2010

Enter Service Password [or type "ABORT" to exit]:

You are about to prepare the system for cleanup operation. NAS service will be stopped and all File Systems will be umounted from Data Movers.

Do you want to proceed with the cleanup? [YES/NO] yes

Checking for integrated Celerra.....

Error!! Cannot determine current system configuration.

This tool can only run against integrated systems.

Please investigate and correct the issue shown, and retry this task later.

Operation Failed.

→Run CSA to complete “Installation” of system

### **TYPICAL INSTALL CONSOLE OUTPUT MESSAGES:**

boot: install

Is this a Secondary Control Station(y/n/a)?

please swap in the second CD, and press ENTER when ready

System Reboot ...

Restarting system.

Starting EMC NAS Factory Installation

Setting up the internal network...

Setting up the Enclosure (this may take several minutes) ...:Done

Is this the expected number of movers in the cabinet? [yes or no]: yes

Checking for existing System RG/LUN:

Setting up SPA-SPB communication

Backend Security Setup Successfully.

Rebooting Data Movers...

EMC NAS PXE-BOOT Setup

## **CELERRA 6.0 UPGRADE STORY:**

→Upgrades are supported from NAS 5.6 to 6.0, or within the 6.0 family

→CFS, CNS, & NSxxx (CX series) Celerra platforms no longer supported

### **CUT TOOL:**

→Celerra is customer upgradeable using USM (Unisphere Service Mgr—CUT tool—Celerra Upgrade Tool)

→USM replaces the CLARiiON NST tool

→CUT does not support Dual CS systems (PUHC check will prevent)

→CUT does not support patch/nas.exe upgrades

→CUT will upgrade Gateway systems, but we prefer only EMC does this right now, not customers

### **Several Upgrade Methods:**

1) GUI CUT tool is the preferred method for upgrades for Customers/EMC/Partners

2) CLI CD-ROM or DVD media using install\_mgr –mode upgrade

3) CLI ISO image loop mounted on local hda10 partition for 6.0 to 6.0 upgrades

**Note:** Upgrade media is different than Install media

→Out-of-Family Recovery during upgrades

boot: serialrescue

/mnt/sysimage (locates existing Linux install and mounts under /mnt/sysimage)

sh-3.2# /recover

### **Message Seen During Upgrades:**

# cat /etc/motd.standby

EMC Celerra Control Station Linux Tue Jul 13 17:33:25 EDT 2010

Warning!!upgrade is in progress from 6.0.36-2 to 6.0.36-4

Warning!!Please log off IMMEDIATELY if you are not performing the operation on the Celerra

## **INSTALL MANAGER CHANGES & REFERENCE TO GUI:**

**./install\_mgr -m upgrade -list**

**Note:** Lists out the Tasks and estimated time for the upgrade

**./install\_mgr -m upgrade**

-----abridged-----

You can do this upgrade as an online upgrade. In online upgrades:

\* You MUST reboot the blades AFTER the upgrade to run the new software.

\* You will not be prompted during the upgrade about blade reboots.

\* File service disruption times shown above do not apply.

Do you wish to do an online upgrade? [ yes or no ]? > no

You can now perform upgrades with an easy-to-use GUI. The GUI can be run from

any PC that has access to this Celerra. To use the GUI:

1. Install Unisphere Service Manager (USM) on the PC from the Celerra

Apps and Tools CD.

2. Open USM and login into the system you wish to upgrade.

Do you wish to continue to use install\_mgr instead of USM [ yes or no ]?

> yes

## **SEVERAL UPGRADE METHODS:**

### **1) GUI--Unisphere Service Manager—Celerra Upgrade Tool**

Preferred upgrade method for qualified Integrateds is to use the Unisphere Service Manager CUT Wizards (Celerra Upgrade Tool).

But, we prefer that only EMC Providers perform Gateway upgrades using CUT, and not customers.

### **2) CD-ROM or DVD Media**

An alternate method for upgrade of Gateways, dual Control Station systems, etc., is to use either the 2-disk DCD (Dual Compact Disc) set, or a single DVD ISO image, and use the traditional install\_mgr –mode upgrade script

### **3) ISO Loop Upgrade within 6.0**

Another method for 6.0 to 6.0 upgrades is to load the DVD ISO image directly to the local partition HDA10 partition on the IDE drive, copy the ISO image to the partition, loop mount the image, and run the install\_mgr upgrade script from /celerra/upgrade/EMC/nas. See emc245885 for the procedure.

**CD-ROM UPGRADE MEDIA:**

**Explorer View Contents for CD1:**

CLARiiON

EMC

images

isolinux

repodata

/disc1

.discinfo

.treeinfo

.version1

autorun.inf

EMC.ico

**Note:** Disc 1 (CD1) has bootable linux code, and RPM packages, approximately 340MB

**Explorer View Contents for CD2:**

CLARiiON

EMC

repodata

/disc2

.discinfo

.treeinfo

.version2

autorun.inf

EMC.ico

**Note:** Disc 2 (CD2) has NAS code, approximately 470MB. Files are staged to CS harddrive and verified with checksums (install\_mgr -m upgrade)

**5.6 to 6.0 Upgrade Partition:**

/dev/hda9 14G 2.2G 11G 17% /partitionU

**6.0 DOS PARTITION RECOVERY:**

# /nas/sbin/install\_init -r

**NEW 6.0 LOCAL IDE PARTITIONS:**

# /sbin/fdisk -l

-----edited----- →Three new IDE partitions carved out of the local disk

/dev/hda8 26224 28312 16779861 da Non-FS data

/dev/hda9 28313 30139 14675346 da Non-FS data

/dev/hda10 30140 30401 2104483+ 83 Linux

**DETERMINING IF A CONTROL STATION HAS A DVD CAPABLE DRIVE:**

# cat /proc/sys/dev/cdrom/info

Example of System that does not have DVD reader:

# cat /proc/sys/dev/cdrom/info |grep "read DVD"

Can read DVD: 0

Example of System that can read DVD:

# cat /proc/sys/dev/cdrom/info |grep "read DVD"

Can read DVD: 1

Only the following Control Stations are DVD capable:

100-520-581

100-560-974

100-520-665

**6.0 UPGRADES VIA DUAL COMPACT DISCS (DCD) or single DVD:**

→DCD uses different software images than for Express Installs

→Need to provide two CD's for 6.0 upgrade media

Disc 1 has bootable linux code, and RPM packages, approximately 340MB

Disc 2 has NAS code, approximately 470MB

→Or, with systems that are DVD capable, a single DVD can be used

→Files are staged to CS harddrive and verified with checksums (install\_mgr -m upgrade)

**DUAL COMPACT DISC Upgrade:**

1) Insert CD #1 and # mount /media/cdrom

2) Change to CDROM directory and start install\_mgr script:

# cd /media/cdrom/EMC/nas

# ./install\_mgr –mode upgrade

*You can reboot blades during or after the upgrade.*

\* **DURING the upgrade :**

*Users will lose access to files served by each primary blade for 7 minutes during its reboot. The blades will not failover. The upgrade will pause and allow you to select the blades to be rebooted 46 minutes after you start the upgrade.*

\* **AFTER the upgrade :**

*Users will not lose file access during the upgrade. The blades will run the old software until you reboot them using Celerra Manager or the CLI server\_cpu command*

*When do you wish to reboot blades [ during or after ]? > during*

#### **Upgrade Annovance:**

Even after answering the above prompt to reboot blades during the NAS upgrade, the system will pause at the interactive message requesting the user to press the Enter key to reboot the Standby Server, then again for the Primary Servers.

*12:16 [ 45/77 ] Upgrade Standby Blades 7 minutes*

*Ready to reboot the Standby Data Mover (3). Press the ENTER key to begin...*

**3) After the Linux upgrade and reboot, run install\_mgr -m upgrade again, it runs a health check, and then creates the upgrade partitions, then instructs user to use the CD #2:**

*At this point you must swap discs to continue the NAS upgrade.*

*To swap discs, do the following:*

**1. Unmount and eject the current disc with the commands:**

```
cd  
umount /media/cdrom  
eject
```

**2. Remove the "Celerra Disc 1" media from the CD or DVD drive, and insert the media labeled "Celerra Disc 2" in its place.**

**3. Mount the CD-ROM with the command:**

```
mount -r /media/cdrom
```

**4. Resume the upgrade with the command:**

```
/media/cdrom/EMC/nas/install_mgr -m upgrade
```

*Result: Stopped*

**Note:** You must cd /, exit root, cd / again, then login as Root user, and issue # eject cdrom in order to get the CD ejected

**4) Mount CD #2 and start install\_mgr script:**

```
# mount /media/cdrom # cd /media/cdrom/EMC/nas # ./install_mgr -mode upgrade
```

**5) Shortly after, instructed to reboot again, and run the install\_mgr again before NAS began upgrading**

#### **NAS 6.0 to 6.0 DVD ISO LOOP MOUNT UPGRADE PROCEDURE:**

**Note:** For situations where the USM is not eligible or practical, or where onsite assistance is limited, the DVD ISO Loop mount method for upgrading within 6.0 is easy to perform

1. Create mountpoints and mount the local IDE partition /dev/hda10:

```
# mkdir /celerra/dvdiso  
# mkdir /celerra/upgrade  
# mount /dev/hda10 /celerra/dvdiso  
# cd /celerra/dvdiso
```

2. Upload the DVD.iso image to /celerra/dvdiso, loop mount the image to /celerra/upgrade, then proceed with the upgrade:

```
# mount -t iso9660 -r -o loop /celerra/dvdiso/6.0.36.2_image_DVD.iso /celerra/upgrade
```

```
# cd /celerra/upgrade/EMC/nas  
# ./install_mgr -mode upgrade
```

3. Reboot the Control Station at the following message:

*The Control Station must be rebooted now. This will take a few minutes.*

*To continue with the NAS upgrade, do the following:*

**1. When the Control Station finishes booting, login as "root".**

**2. Mount the ISO and make it your working directory:**

```
mount -r -o loop /celerra/dvdiso/6.0.36.2_image_DVD.iso /celerra/upgrade  
cd /celerra/upgrade/EMC/nas
```

**3. Continue the upgrade with the command: ./install\_mgr -m upgrade**

*Press Enter key to reboot:*

4. After approximately five minutes, log back into the Control Station. You may need to remount the /dev/hda10 partition to /celerra/dvdiso before loop remounting the iso image to /celerra/upgrade. Resume the the upgrade.

```
# mount /dev/hda10 /celerra/dvdiso  
# mount -t iso9660 -r -o loop /celerra/dvdiso/6.0.36.2_image_DVD.iso /celerra/upgrade
```

```
# cd /celerra/upgrade/EMC/nas
```

```
# ./install_mgr -m upgrade
```

## **UPGRADE TROUBLESHOOTING LOGS:**

**Note:** There are a variety of upgrade errors or issues that can occur during either the DVD/CD upgrade method, or USM method.  
→For CLI or GUI upgrades that are in progress, review the /var/tmp/upgrade.log to see what the last message details are.

=====SUMMARY=====

*Upgrade is still in progress. The Control Station is going to reboot now.*

*When the Control Station comes back up, rerun install\_mgr to resume the operation.*

*Status: Requested Reboot*

*Actual Time Spent: 9 minutes*

*Total Number of attempts: 2*

**Log File:** </var/tmp/upgrade.log>

→For PUHC health check logs, click on the GUI “Pre-Upgrade Log” link after the PUHC has run in order to see the detailed contents, or from CLI, go to /nas/log and view the contents of the check\_nas\_upgrade.xx.log file

## **UPGRADING SYSTEMS WITH DUAL CONTROL STATIONS:**

→Run the install\_mgr –mode upgrade script on CS0, as you would normally do

→At the end of the upgrade, the console screen directs you to use install\_mgr to upgrade CS1 (But see CPG for more verbose details)

=====SUMMARY=====

*Congratulations!! Upgrade for NAS software to release 6.0.36-4 succeeded.*

*To complete the upgrade, you must upgrade the standby Control Station.*

*Take the CD out of the primary control station, put it in the standby Control*

*Station, and start the upgrade on the standby.*

→CD2 contains the emcnassby code [/media/cdrom/EMC/nas/package/emcnassby\_6.0.36-4.i386.rpm]

→Use install\_mgr –mode upgrade to launch upgrade on CS1 (takes only about 10-15 minutes)

## **6.0 UPGRADES USING UNISPHERE SERVICE MANAGER (USM, formerly NST):**

→The CLARIION NST was renamed Unisphere Service Manager, and incorporates the Celerra Upgrade Tool (CUT) [Java-based]

→The Celerra Upgrade Tool (CUT) is a series of three wizards for upgrading qualified Celerra systems by Customers/Field/Partners

→The Download Software wizard determines the appropriate upgrade package and files from the dynamic Powerlink catalog (for 5.6 to 6.0, or 6.0 to 6.0 upgrades), and downloads to the Windows client’s EMC\Repository\Celerra\downloads\6.0.36.upg directory.

The .tar package is used for in and out-of-family upgrades, while ISO is also required for out-of-family upgrades: Release Notes; .tar package; .iso file

→“CUT” is now the preferred method for upgrading Celerra

→However, we are not officially endorsing that customers use CUT for Gateways, just Integrated systems, and, Systems with Dual Control Stations do not qualify for using CUT at all

→If you try to use the USM over an EMC network, the firewall will prevent the “Download Software” wizard from working (See emc250893). Basically, you need to download the necessary files (.iso & .tar) from Powerlink and prestage them on your laptop in a directory named “<nas\_version>.upg” in order for the USM CUT tool to run the ‘Pre-Upgrade Health Check’ and ‘Perform Software Update’ wizards

→Failed USM upgrades can be restarted from GUI, or via CLI install\_mgr—strongly recommended that Field folks keep a copy of the target upgrade media on CDs whenever performing upgrades

→USM can be launched as a stand-alone application, or from the Unisphere GUI (yet still requires that the client have the USM application installed)

→Must login as root user to use the CUT to upgrade from 5.6 to 6.0 (root is the default account and is greyed out and cannot be changed)

→Within 6.0, you can use root, nasadmin, or an imported array admin account, provided the Celerra is Joined and participating in the Storage Domain, and the imported accounts have been given the correct privileges [Group “fullnas(nasadmin)”, Client Access “Control Station shell allowed”]

→Celerra functionality is nested underneath the “Software” icon, with three Wizards that consist of the “Celerra Upgrade Tool”

### **Download Software wizard**

### **Pre-upgrade Health Check wizard**

### **Perform Software Update wizard**

→CUT content for Celerra is encapsulated in JAR files

→Supports NS20/40/80, NSX, NX4, NS-120/480/960, NS80G, NS-G2, NS-G8, VG2, VG8

→Localization for (8) languages (English; Spanish; Italian; German; Brazilian Portuguese; Chinese; Korean; Japanese)

→CUT cannot be used on dual Control Station upgrades

→CUT can only be used to upgrade from 5.6 to 6.0, or within the 6.0 family

→CUT cannot upgrade a system with Replicator V1 to 6.0

## **USM APPLICATION DOWNLOAD LOCATION ON POWERLINK:**

Support > Software Downloads and Licensing > Downloads T-Z > Unisphere Service Manager (USM) :

## Unisphere Service Manager (USM) Windows 1.0.0.1.0490

### USM USER ACCOUNTS, ROLES, and allowed ACTIONS:

| Local Celerra users  | Role                   | USM Actions  |
|--|------------------------|--|
| nasadmin*  | nasadmin               | Can login with Scope local and run all three CUT wizards           |
| root**   | root                   | Can login with Scope local and run all three CUT wizards           |
| Migrated Array users+  | imported_administrator | Can login with Scope global, but cannot run any of the CUT wizards |
| + Requires granting the user the Group Role of “fullnas(nasadmin)” and Client Access right of “Control Station shell allowed” in order to perform CUT upgrades, but only within the 6.0 family |                        |  |
| *The nasadmin account can only be used for upgrades within the 6.0 family, not from 5.6 to 6.0   |                        |  |
| **Root account is mandatory for CUT upgrades from 5.6 to 6.0   |                        |  |

\*The nasadmin account can only be used for upgrades within the 6.0 family, not from 5.6 to 6.0  
\*\*Root account is mandatory for CUT upgrades from 5.6 to 6.0

### USER ACCOUNT BEHAVIOR FOR USM & CLARIION DOMAIN MEMBERSHIP:

- For NAS 5.6 to 6.0 Upgrades, you must use the “root” user account and password (it is hard-coded for root user)
- For in-family 6.0 Upgrades, you can use either root or nasadmin “local” accounts
- Or, if you wish to use the migrated domain administrative accounts (provided the Celerra has properly ‘joined’ the CLARiiON Storage Domain), you must first grant the migrated user accounts the “fullnas(nasadmin)” Group role and “Control Station shell allowed” Client access rights in order to perform CUT upgrades, but only within the 6.0 family

**Note:** See emc245870

### Use LDAP Option:

→Option to use LDAP credential when logging into a system via USM

→Celerra needs to be configured with an LDAP directory server connection, as well as group mappings to the LDAP server

### USM UPGRADE METHODOLOGY FOR CELERRA SYSTEMS:

1. As a general rule, upgrade the Celerra NAS software first, after registering the Celerra system serial number on Powerlink
2. Login to the Celerra IP Address from USM, and run the wizards in the order that they appear on screen, to upgrade NAS
3. Login to the CLARiiON IP Address from USM, using an array admin account Scope Global, and run the wizards to upgrade FLARE or other software

### USM PUHC & UPGRADE LOGS:

→After the PUHC has run, there is a GUI link to “Pre-Upgrade Log” that displays the details of the PUHC checks

→The PUHC files are retained on the USM client and on the Control Station

### Control Station Logs during upgrades:

# ls -la /var/tmp/upgrade.log →Most useful log

/var/tmp/ →Many other temporary log files are kept here and may be of some value, depending on the issue

### Control Station Logs after upgrades:

/nas/var/log/check\_nas\_upgrade.100806-142946.log

/nas/log/upgrade.xxx.log

/var/tmp/.CUT/xxx

/var/tmp/cus.log

### USM Client Log location:

C:\EMC\repository\celerra\logs\HEALTH\_CHECK\_WIZARD\_10.241.168.30\_1281032963243\_log.txt

### USM CUT UPGRADE ISSUES:

#### Flare vs. NAS Compatibility:

→The USM does not prevent anyone from upgrading to Flare 30 first, before NAS is upgraded to a version that supports Flare 30  
→emc251289 is a solution for reinstalling or upgrading the nasStorageAPI version on a system, especially to address the issue where Flare 30 was applied prior to upgrading the NAS 5.6 system to a level that supports Flare 30. In any event, the action to take should be to escalate ALL such cases immediately to Support for resolution—the fix often requires EE assistance as well.

--NAS 5.6.50-2 provides nasStorageAPI-7.4-7, which supports Flare 30

--NAS 6.0.36-4 provides nasStorageAPI-8.2-12, which supports Flare 30

#### EMC FIREWALL ISSUE:

→EMC employees will encounter a firewall issue when using CUT and trying to automatically download the upgrade files from the Powerlink catalog

#### See emc250893 for more details, but the workaround is as follows:

1. Download the necessary .iso & .tar files to the c:\EMC\repository\celerra\downloads\6.0.36.upg directory
  - pkg\_6.0.36.4\_emcnas.tar
  - 6.0.36.4\_emcnas\_CD1.iso
2. Run Pre-upgrade Health Check and Perform Software Update wizards

#### Alternative Powerlink Access:

From external internet connection, connect to www.emc.com

Click link on upper righthand side of screen for “Customer/Partner Login”

Enter your NT username and FOB credentials

#### OTHER ISSUES:

Emc251622—Customer download issues—need to register Celerra system on Powerlink in order for Software Download wizard to work: [Support > Product and Diagnostic Tools > Celerra Tools > Register Your Celerra](#)

Emc251355—Patchwork primus with link to an Engineering paper on using the USM to upgrade Celerra systems, including Flare

Emc246820—New install FC system, CSA tries to Join Celerra to domain and fails

Emc252069—FC system upgrade to 6.0, upgrade screen says it joined Celerra to domain on completion page, but upgrade log shows that it failed

**Comment:** FC Systems are not designed to Join the Celerra to the Storage Domain for either Installs or Upgrades

Emc240345—Celerra will no longer be able to communicate or manage the array if the array admin password is changed—need to do the manual nas\_storage –modify –security step to sync new password to Celerra security files—currently no automatic mechanism in place to keep these sync’ed

Emc245870—CUT wizard errors related to User account privileges

## **6.0 UNISPHERE [Replaces Navisphere, NaviExpress, & Celerra Manager]:**

- The Unisphere management interface replaces Celerra Manager with NAS version 6.0, and Navisphere for Flare 30+ systems
- The recommended interface of choice for Unified Storage (Celerra and CLARiiON) is the Unisphere Client, a stand-alone application that runs on a Windows client (previously known as the Offarray UI), and offers the same interface as Unisphere
- Unlike the native Unisphere that launches via web browser, the Unisphere Client can be used to manage CLARiiON arrays running Flare 19-30, except AX4-5 systems where Navisphere Express is the licensed management software

**Note:** Upgrade NaviExpress to full Navisphere, then use the Unisphere Client to manage the AX4-5 system

→ The Unisphere Client can connect to pre-NAS 6.0 systems, but will only display system Alerts (Must still use Celerra Manager for 5.6 and below)

→ The advantages to using the Unisphere Client would be to provide a consistent version and interface for all systems that are members of the Storage Domain, as well as providing better performance than the Browser-based Unisphere interface

→ A major goal for Unisphere is to be able to provide a single common interface to manage NAS and Storage, as well as to lay the groundwork for unifying CLARiiON block and Celerra file platforms together as a single product

### **UNISPHERE Layout:**

→ Unisphere GUI provides a common framework. Both Navisphere and Celerra Manager components plug into the framework with essentially the same underlying capabilities as they had before.

→ The new GUI emphasis is for task-based navigation, with tables and task lists, vs. traditional object-oriented representations.

→ For Tables, you can easily export almost anything into .csv Excel files.

→ Users can customize the Dashboard display, sort & filter values in Tables, hide and unhide columns in the various screens, etc.

Unisphere Dashboard is a quadrant of screens that displays Systems by Severity, Alerts by Severity, CLARiiON capacity, and Celerra capacity.

→ Through the ‘single sign-on’ concept for Celerra, and the Domain Master role with Flare 30, a User can manage multiple arrays and Celerras via a single log-on session (once setup to do so).

→ Unisphere can scale to 100,000 objects and manage 50 systems

→ Navi plug-ins are (CIM/XML) & Celerra plug-ins (XML/HTML)

→ ECUE Compliant (EMC Common User Experience standard for management applications)

### **Top level Navigation Bar:**

→ Top level Navigation defaults to an “All Systems” view with Dashboard, System List, Domains, Alerts, Support

→ Celerra System presents a System, Storage, Sharing, Replicas, Monitoring, Settings, and Support view

→ Clariion System presents a Storage, Replicas, Monitoring, Hosts, Settings, Support view

### **Automatic Refresh:**

→ Occurs when an alert is added or removed

→ Occurs when a storage system is added or removed

→ Occurs when a user completes an operation in a dialogue box or wizard

### **UNISPHERE LICENSING & POWERLINK DOWNLOAD LOCATION:**

→ Older NS systems that are sold with NAS 6.0 will sell with either a file-only “Unisphere for File” license (NS-480), or the “Unisphere for Unified” license, which replaces the Native Block Option and Navisphere Manager licenses (e.g., NS-480FC)

→ An NX4 with Fibre Channel option can be managed with Unisphere on the NAS side and NaviExpress on the array side, or upgraded to a “Unisphere for Unified” license, which allows the customer to use Unisphere for both the Celerra and CLARiiON

### **UNISPHERE CLIENT:**

→ In the CLARiiON realm, formerly known as the Navisphere OffArray UI

→ This tool is the preferred management application for mixed Celerra/Clariion domains

→ Benefits of this application are; better performance; more current/consistent interface that can manage Flare 19 – 30 systems, as well as Celerra 6.0 systems. For example, you could not use a Browser to launch Unisphere for a Flare 29 system, but if using the Client, the management application is based on the Unisphere framework.

→ For FLARE 30 arrays, Unisphere will enforce two levels of certificate validation

Low: All certificates pass, essentially bypassing certificate validation

Medium: All certificates must be validated

### **Unisphere Client Powerlink Download:**

## **EMC Unisphere Client (Windows) 1.0.0.1.0492**

### **UNISPHHERE STORAGE DOMAIN CONCEPTS:**

- The new terminology today, and with future releases, will be Unified Management for Block (CLARiiON) and File (Celerra) systems
- Outside of the consolidation of the CLARiiON and Celerra GUIs into Unisphere, one of the more significant changes is that the Celerra will now be able to join and participate as a member system in the CLARiiON Storage domain, or ‘Unified Storage Domain’
- When discussing “domains” in the context of Celerra and CLARiiON, we are really talking about CLARiiON Storage Domains, where array global admin user accounts are shared among Celerra and CLARiiON systems, and used for the “single sign-on” concept in Unisphere whereby you can log into a single system, using a global array admin user, and then manage all the ‘joined’ systems from the same account as a “multi-domain” environment
- The concept of “joining” a CLARiiON domain is new with NAS 6.0
- After “joining” the CLARiiON domain, the domain admin accounts are copied to the Celerra with Group role membership in the “nasadmin(operator)” group, which is equivalent to Read-Only privileges on the Celerra, and Client Access privileges for “Unisphere allowed” and “API access allowed”
- In order for the migrated array admin accounts to be able to manage the Celerra, you must login to the Celerra as root scope local, and assign the Group membership for “fullnas(nasadmin)” and the Client Access privilege for “Control Station shell allowed”

### **Unisphere > Settings >User Management > Users**

**Note:** Shows the list of User accounts on the Celerra

#### **Single Sign-on Capability:**

- When logging in using default Global scope, Unisphere will attempt to log-in to all systems in the System and Domain list (works because Clarion domain users are copied to the Control Station on installs and upgrades)
- Celerra Only model would require the same username and password on all Celerras
- Applies to the Unisphere Service Manager (USM) as well, but in order to be able to use the USM CUT tool wizards with the migrated global array admin accounts, you would need to set the proper permissions for the account on the Celerra **fullnas(nasadmin)**

#### **Control Station shell allowed**

#### **Setting Privileges on Migrated Array accounts:**

- a) Log into the Celerra system as Root user, Scope local
- b) Go to Settings > User Management > Users, assign the desired privileges for the migrated domain accounts to allow for “single sign-on” management of both the Celerra and CLARiiON system(s).
- c) Assign the “fullnas(nasadmin)” privilege, and check the box for “Control Station shell allowed”

**Note:** Migrated accounts are granted the Operator privilege, and the access rights for “Unisphere allowed”, “API access allowed”  
→Domain membership can be seen in the “System List” or Domains > Local > Systems list

#### **What's a Unified Storage Domain?**

- A collection of systems (CLARiiON and Celerra) that are grouped together for ease of monitoring and management
- When properly configured, a single administrative global array user account can be used for “single sign-on” into the storage domain, for the purpose of administering all participating member systems
- You can have a single local domain with multiple systems, or multiple domains with multiple systems

#### **TYPES OF UNISPHERE DOMAINS:**

##### **Celerra Only List Unisphere Domain**

- Unisphere login Scope is Local (e.g., NX4 integrated where array is managed using NaviExpress
- Multiple Celerras can be added to the “list”. If the user account and password exists on all Celerra systems, when using Scope Global, then the credentials will be authenticated for every Celerra on the list, and all the Celerras can be managed from one session.
- For any Celerras on the list that cannot authenticate the user credentials, the system will appear in the System List with a “Not Logged In” status, and the user can rightclick and login at that time
- No CLARiiONS participate in the ‘Celerra Only List’

##### **CLARiiON Only Unisphere Domain**

- In order to use single sign-on for management of all joined systems, the domain master needs to be Flare 30
- Domain with only CLARiiON arrays as member systems
- Unisphere Client can be used to manage Flare 19-30 CX4 systems
- No Celerras
- Unisphere login Scope is Global

##### **Mixed Domains Unisphere Domain**

- Both Celerra 6.0 systems and CLARiiON R19-30 can be participants in the storage domain, as long as one of the arrays is running Flare 30 as Domain Master
- This is the optimum structure, where ‘single sign-on’ comes into play
- Unisphere login Scope is Global

#### **Local Domains vs. Multiple Domains**

--CLARiiONs can be initialized with a default ‘local’ domain, where other Arrays and Celerras can be added as participants of the local domain, with a single Domain Master

--You can also have a group of domains in a Multi-Domain environment, each with their own CLARiiON and Celerra systems, either with or without single sign-on user accounts (each domain can have its own separate admin accounts, or can share across the domains)

--Initially, you would Add a new domain to an existing Local Domain

## **CELERRA JOIN BEHAVIOR DURING INSTALLS/UPGRADES FOR 6.0:**

--Gateway systems will not auto Join the Storage domain during installs

--Gateway systems will not auto Join the Storage domain during upgrades

--Integrateds (i.e., non-shared array) will auto Join the Storage domain during installs (Using CSA)

--Integrateds (i.e., non-shared array) will auto Join the Storage domain during upgrades

--FC Integrateds (i.e., with shared array) will not auto Join the Storage domain during installs

--FC Integrateds (i.e., with shared array) will not auto Join the Storage domain during upgrades

**Note:** A future maintenance release may change the behavior of FC Integrateds to that during Installs and Upgrades they ‘Join’ the storage domain similarly to the Integrateds

## **CELERRA MEMBERSHIP IN STORAGE DOMAINS:**

→With NAS 6.0, Celerra can participate as a member system in the Storage Domain

**emc252609**

--NAS 6.0 Celerras can be joined to the host array storage domain as a member system if the array is running the latest Flare 26 patch, or a higher version of flare (at least testing seems to support this).

--NAS 6.0 Celerras cannot join the host storage domain as a member system for an array running less than Flare 26/031

--All NAS 6.0 Celerras can, however, be joined to any Flare 30 storage domain as an alternative, and ideally, this is preferred in order to run the single sign-on Unisphere management.

→This allows for enterprises to use single sign-on to administer multiple systems from a single logon session

→There are certain rules involved with the way the Celerra joins the domain

→When the Celerra Joins a domain, the array admin accounts are copied over to the Celerra with certain Group role membership and Access rights, which varies depending on the Celerra system

→Both Unisphere and Unisphere Service Manager use the array administrative accounts

## **ATTRIBUTES OF MIGRATED ACCOUNTS ON CELERRA:**

→By default, Gateway and FC systems will migrate the array accounts with the Group roles of “imported\_administrator” and “nasadmin(operator), and Client Access rights for API & Unisphere allowed, which equals Read Only access on the Celerra

→Integrated systems without a shared backend, and a “nasadmin” array account, will be copied to the Celerra with equivalent privileges and membership as for the native Celerra nasadmin user [Fullnas & Operator], except for the Client Access right of “Control Station access allowed”, which must be manually added

→To change migrated User privileges, login to the Celerra as Root, Scope Local, and assign the migrated account the Group privilege for “fullnas(nasadmin)”, and the Client Access privilege “Control Station shell allowed”

**Note:** Without the CS shell allowed privilege, the User cannot launch CLI fromUnisphere, or run any of the USM CUT wizards

## **MANUALLY JOINING CELERRA TO THE STORAGE DOMAIN:**

**CLI Join Method:** Not supported for NAS 6.0

# /nas/sbin/navicli -h 10.241.168.179 domain -add 10.241.168.80

WARNING: You are about to add following node(s) to the domain.

10.241.168.80

Proceed? (y/n) y

Domain add operation failed.

Error 10.241.168.80 is not reachable.

**GUI Join Method:**

1) Log into the Array using either Unisphere or the Unisphere Client (if the array is pre-Flare 30) and global admin account

2) From the top of the Unisphere screen: Domains > Add/Remove Systems > Add: Enter IP Address for Celerra Control Station, then root Username and Password, Scope Global

3) Verify:

- a) Click on the ‘Local’ object in the Domains section—the Celerra should appear as a registered system
- b) Use Navicli to verify:

# /nas/sbin/navicli -h 10.241.168.179 domain -list

Node: vg8

IP Address: 10.241.168.80 →Celerra Control Station

Name: vg8

Port: 80

Secure Port: 443

-----abridged-----

Node: APM00083201184

IP Address: 10.241.168.180  
Name: SPB  
Port: 80  
Secure Port: 443  
IP Address: 10.241.168.179 (Master)  
Name: SPA  
Port: 80  
Secure Port: 443

f) Close Unisphere and log into the Celerra as ‘root’ with ‘Scope’ ‘Local’

**Settings > User Management > Users:**

**Note:** Should be able to see the migrated CLARiiON domain accounts

g) Assign the desired privileges to the migrated accounts

→By default, all migrated accounts are assigned membership in the Group Role ‘Operator(nasadmin)’, with Client Access privileges for ‘Unisphere allowed’ and ‘API access allowed’ enabled, but without “Control Station shell allowed” enabled

**Auto Joining:**

→Part of the upgrade tasks are to check and join the CLARiiON Storage domain for qualified models

```
=====  
21:03 [ 79/81 ] Add celerra to domain           30 seconds  
Celerra was added to the domain.  
=====
```

**Assigning Rights equivalent to the native nasadmin local account on the Celerra:**

To be able to manage the Celerra, check the box for the “fullnas(nasadmin)” privilege and the access privilege “Control Station shell allowed” to grant privileges equivalent to the local Celerra nasadmin user.

**FILES CREATED WHEN CELERRA JOINS THE STORAGE DOMAIN:**

# ls -la /nas/http/domain

```
-rw-r--r-- 1 apache apache 69 Apr 22 15:13 domain_list  
-rw-r--r-- 1 apache apache 72 Apr 22 15:13 domain_master  
-rw-r--r-- 1 apache apache 65 Apr 22 15:13 domain_users
```

# cat domain\_list

```
DOMAIN_ADDRESS_LIST=<10.241.168.184>,<10.241.168.185!10.241.168.186>,
```

# cat domain\_master

```
MASTERIP=10.241.168.185
```

```
DOMAINID={87B90648-1BEE-41F5-8897-164BDDE71AC1}
```

```
PORt=443
```

# cat domain\_users

```
nasadmin:imported_administrator:580ABE52065C603C7BCBB4E3F98F8BCA
```

**REMOVING CELERRA FROM A STORAGE DOMAIN (Unjoin)—emc247813:**

→If you attempt to remove the Celerra from the Storage Domain while logged in as the domain admin user, but the user has not been granted the “root(root)” Group Membership role on the Celerra to be removed, the operation will fail with the following popup message:

**“User not privileged**

**X The current user does not have the privilege to perform domain operations on the Celerra.”**

→If the above situation occurs, you must perform the following steps to remove the Celerra from the domain:

**GUI Option:**

1. Using Unisphere, log into the Celerra with user “root” and Scope local
2. Settings > User Management > Users, select the domain user, properties, and assign the Global(Role)Membership “root(root)”
3. Exit Unisphere, reopen Unisphere, log into the SP with the modified domain user account, Scope Global
4. Remove the Celerra from the domain using Domains > Add/Remove Systems > vg8 > Remove, and accept the popup Warning message that says, “Warning: Removing a system from the domain will erase/invalidate all domain user accounts on the system...”

→Alternatively, you can use the CLI to remove the Celerra from the domain

**CLI Option:**

# /nas/sbin/navicli -h 10.241.168.179 domain -list

```
Node:          vg8  
IP Address:   10.241.168.80  
Name:          vg8  
Port:          80  
Secure Port:   443
```

# /nas/sbin/navicli -h 10.241.168.179 domain -remove 10.241.168.80

WARNING: You are about to remove following node from the domain: 10.241.168.80

Proceed? (y/n) y

#### Verify from CLI or GUI:

- 1) **# /nas/sbin/navicli -h 10.241.168.179 domain -list** → Celerra no longer listed as a member
- 2) All domain files have been removed from the /nas/http/domain directory  
→ From Unisphere (logged into Celerra scope local), all the formerly migrated domain array accounts show a ‘State’ of ‘Defunct’, with an ‘Account Type’ called ‘Defunct Storage Domain’

#### JOIN ISSUES:

- If the Celerra is already listed, the Join function will not work from the GUI
  - # navicli domain -list** → If the CS is already listed, make sure it is unjoined before attempting to rejoin to the Storage Domain
  - For CSA join failures, check startup\_wiz.log
- Note:** FC Enabled Celerras do not Join automatically, by design, though CSA and Installs do claim to try and fail
- Use the correct User account and Scope: Make sure you have logged into the Celerra using Root with Scope “Global” to perform the Join [Caution--Scope Local Join appears to work, but gives no error]

#### REJOINING CELERRA TO SAME STORAGE DOMAIN:

- Follow same Join steps as outlined above
- The domain user accounts are migrated to the Celerra, but do not override the previous accounts with the same name. Rather, the migrated accounts are given a ‘user1’, ‘user2’ local name, but maps to the original migrated name

#### Example:

secured1 → Mapped User Name “secured”

#### KNOWN ISSUES/LIMITATIONS:

- If the array user passwords are changed, the changes are not automatically propagated to the Celerra. Users will not be able to login and manage the Celerra from Unisphere, and the Celerra communication with the array will become broken. For example, new disks or storageAPI updates cannot be completed. The solution is to make sure that the following CLI command is run on the Celerra anytime that the Array user account passwords are changed:

#### **# nas\_storage -modify -security**

**Note:** Enter username and new password to update the Celerra storageAPI database

#### LOGGING INTO CONTROL STATION CLI WITH MIGRATED ACCOUNTS:

- If you want to log into the Celerra using CLI (using SSH, etc.), there is some trickiness involved, depending on whether the NAS system was ‘joined’ to the Storage Domain as an Integrated or as a Gateway.
- Basically, the first rule to know is that migrated accounts are never assigned the ‘Client Access’ privilege for “Control Station shell allowed”, so at a minimum, the Celerra admin must first log into the Celerra Unisphere as Root Scope Local, and grant the “Control Station shell allowed” privilege.
- Once the above step is completed, you would generally use the following syntax when logging in via Putty/CLI/SSH:

**login as: migrated\_username@storageDomain**

**migrated\_username@storageDomain@10.241.168.80's password:**

- The exception is that for any migrated username that already exists in the local Celerra database (e.g., nasadmin), the migrated name is given a new “Local Name”, such as “nasadmin1” in the case of the array nasadmin account migrated for a native Celerra Integrated system, and so you would need to use the “Mapped User Name” when logging in via CLI, not the “Local Name”

#### CLI LOGIN EXAMPLES:

##### For Celerra Integrateds where array admin name is “nasadmin”:

1. Log into the Celerra via Unisphere, using Root user, Scope Local
2. Click on the Celerra System, navigate to “Settings > User Management”, highlight the array account “nasadmin1”, select “Properties”, check the box under “Client Access” for “Control Station shell allowed”, then apply
3. Open an SSH session to the Control Station, logon with the following user account syntax and appropriate password:  
**login as: nasadmin@storageDomain**

**nasadmin@storageDomain@10.241.168.184's password:**

[nasadmin1@sleet-480 ~]\$

##### For all other Celerras (e.g., Gateway), where admin names are different:

1. Log into the Celerra via Unisphere, using the Root user , Scope Local
2. Click on the Celerra System, navigate to “Settings > User Management”, highlight the array account “secured”, select “Properties”, check the box under “Client Access” for “Control Station shell allowed”, then apply
3. Open an SSH session to the Control Station, logon with the following user account syntax and appropriate password:  
**login as: secured@storageDomain**

**secured@storageDomain@10.241.168.184's password:**

[secured@vg8~]\$

#### UNIFIED STORAGE DOMAIN ISSUES?

- Though we claim a Unified Storage convergence story, with Unisphere as the single management interface for Block (CLARiiON) and File (Celerra), there are many nuances involved with setting up Single Sign-on capabilities, Joining/Unjoining Celerras, etc.

→ If logging into Celerra via Unisphere with the local Root account, you login as Root Scope Local, but in order to “Join” a Celerra to the storage domain, you need to login as Root Scope Global during the join process

- Single sign-on Unisphere management of both CLARiiON and Celerra systems first requires that the Array user accounts are properly configured on the Celerra (after making sure that the Celerra is first ‘joined’ to the domain)
- Similarly, User accounts must also be properly privileged in order to run any of the Celerra Upgrade Tool wizards in the USM for NAS Upgrade activities

→Array password changes are not integrated with the Celerra. i.e., password changes to the domain admin accounts are not automatically propagated to the Celerra. You must actively log into the Celerra CLI and run # nas\_storage –modify –security –username –password, and use the new password to synchronize the passwords in the Celerra databases (/etc/.clar\_security)

## **6.0 CS & DART IPv6 SUPPORT:**

→NAS 6.0 provides support to all Celerra features that require IPv6 addressing that were not previously supported

→XMLAPI & MMC snap-ins support IPv6

→IPv6 allows for 128 bit addressing, more efficient routing, elimination of broadcasts, more security, better autoconfiguration

→Minimum MTU of 1280 bytes, with header size 40 bytes

→DART maintains default routes based on router advertisements

→Adds support for CAVA, CIFS, Usermapper, iSCSI, Kerberos, ReplicatorV2, NFSv4, NTP, XLT, LDAP-based Directory client configuration, & pNFS support

**Note:** GUI support not included in this release

→Adds support for SNMPv2 & SNMPv3

→Supports IPv6 name resolution only, for LDAP (not IPv6 addresses)

→Supports Local File name resolution using IPv6 addresses

→Supports DNS AAA address to name and name to address resolution & operation of IPv6 addresses

### **Forward Lookup Zones**

-pgace110.emc.com

**NS10-blade    IPv6 Host (AAAA)    2620:0000:0000:0000:0000:abcd:0059**

→Supports NIS name resolution using names or IP addresses using IPv6

→Supports Etherchannel, LACP, IP Reflect, FSN, and Jumbo frames

→Supports DNS/DDNS; NIS; LDAP; NFSv2, v3, v4; FTP; TFTP; iSCSI; SNMPv1, v2, v3; Ping6; CIFS; CDMS/DHSM; CAVA; Replication V2

### **IPv6 Limitations:**

→Cannot use Unisphere to configure or modify IPv6 addressing, only the CLI interface [Unisphere can read/display IPv6 values]

→Cannot use the CSA to Install or Configure using IPv6 networks

→IPRepV2 works with IPv6, but should be either all IPv6 or all IPv4

→Cannot use Host names in lieu of IPv6 address

→Cannot use WINS on IPv6 networks

→Cannot use External Usermapper on IPv6 networks

→Cannot use MPFS on IPv6 networks

→Does not support CLARiiON iSCSI or MirrorView

→Cannot use Link Local addresses on anything other than core IPv6 protocols (e.g., ping6, ftp)

→Control Station can operate in a dual-stacked IPv4 & IPv6 environment, but not a pure IPv6 environment

→DART can use IPv6 exclusively (except that CS to DM communications will still be IPv4 internally)

→Configure IPv6 addresses on Control Station using nas\_cs

→Configure IPv6 aliases using nas\_config

### **Configuring IPv6 on Control Station:**

**# /nas/bin/nas\_cs**

```
nas_cs
  -info [ -timezones ]
  | -set [ -hostname <host_name> ]
    [ -ip4address <ipv4_address> ]
    [ -ip4netmask <ipv4_netmask> ]
    [ -ip4gateway <ipv4_gateway> ]
    [ -ip6address <ipv6_address[/prefix_length]> ]
    [ -ip6gateway <ipv6_gateway> ]
    [ -dns_domain <dns_domain_name> ]
    [ -search_domains <domain_name>[,...] ]
    [ -dns_servers <ip_addr>[,...] ]
    [ -session_monitor_timeout <days> ]
    [ -session_idle_timeout <minutes> ]
    [ -time <yyyymmddhhmm[ss]> ]
    [ -timezone <time_zone_str> ]
    [ -ntp_servers <ip_addr>[,...] ]
  | -clear [ -ip4gateway ]
```

```
[ -ip6address ]
[ -ip6gateway ]
[ -dns ]
[ -search_domains ]
[ -session_monitor_timeout ]
[ -session_idle_timeout ]
[ -ntp_servers ]
```

| -reboot

**CREATING, CHECKING, DELETING IPv6 ADDRESS ON CONTROL STATION:**

```
# nas_cs -set -ip6address 2620::abcd:109
```

```
# nas_cs -info
```

IPv6 Address = 2620::abcd:109/64

```
# nas_cs -clear -ip6address
```

**CONFIGURING IPv6 NTP ADDRESS ON CONTROL STATION:**

```
# nas_cs -set -ntp_servers 2620::abcd:23
```

OK

**OUTPUTTING CS CONFIGURATION INFO:**

```
# nas_cs -info
```

```
Host Name = sleet-480
Version = 6.0.34-0
Location = system:NS-480:APM000738018380000|controlStation::0
Status = OK
Standby Location =
Standby Status =
IPv4 Address = 10.241.168.184
IPv4 Netmask = 255.255.255.0
IPv4 Gateway = 10.241.168.128
IPv6 Address = 2620::abcd:109/64
IPv6 Gateway =
DNS Domain =
DNS Domain search order = localdomain
DNS Servers =
Session Monitor Timeout = 0 Days
Session Idle Timeout = 0 Minutes
NTP Servers = 2620::abcd:23.
System Time = Wed Jul 07 14:41:15 EDT 2010
```

```
# nas_cs -reboot
```

Info 26575634438: Reboot request was successfully sent to Control Station.

**CONFIGURING IPv6 ON DATA MOVERS:**

```
# server_ifconfig
```

```
-all [ -ip4 | -ip6 ]
| -create -Device <device_name> -name <if_name>
-protocol { IP <ipv4_addr> <ipmask> <ipbroadcast>
| IP6 <ipv6_addr>[/PrefixLength] }
```

```
# server_ifconfig server_2 -create -name cge0_ip6 -Device cge0 -p IP6 2620::abcd:60 [Global Unicast address]
```

server\_2 : done

```
# server_ifconfig server_2 -a -ip6
```

server\_2 :

```
cge0_ip6 protocol=IP6 device=cge0      →Global Unicast address
inet=2620::abcd:60 prefix=64
```

UP, Ethernet, mtu=1500, vlan=0, macaddr=0:60:16:1d:22:c4

```
cge0_0000_ll protocol=IP6 device=cge0   →Link Local auto. created when Unicast addr. created [_ll and fe80]
inet=fe80::260:16ff:fe1d:22c4 prefix=64
```

UP, Ethernet, mtu=1500, vlan=0, macaddr=0:60:16:1d:22:c4

```
loop6 protocol=IP6 device=loop
inet:::1 prefix=128
```

UP, Loopback, mtu=32768, vlan=0, macaddr=0:0:0:0:0 netname=localhost

```
# server_ping6 server_2 2620::abcd:60
```

server\_2 : 2620::abcd:60 is alive, time= 0 ms

**NFS Export with both IPv4 & IPv6 addresses, netgroups, and hostnames:**

**\$ server\_export server\_2 -Protocol nfs -o access=128.221.15.35:[2080:0:0:0:8:800:200C:417A]h1:netgrp1 /fs1**

**Note:** Use : colon between successive IPv6 address entries when exporting. Link local addresses are not supported for Exports.

### **NFS EXPORT & MOUNTING USING IPv6:**

**# server\_export server\_2 -P nfs -o access=[2620::abcd:138],root=[2620::abcd:138] /fs1**

**# mount \[2620::abcd:59\]:/fs1 /fs1** →Remote mounting from Sun Solaris

### **Managing IPv6 Neighbor Discovery and Routing Tables:**

**# server\_ip server\_2 -route -list**

server\_2 :

| Destination | Gateway | Interface | Expires (secs) |
|-------------|---------|-----------|----------------|
| 2620::/64   |         | cge-1-1   | 0              |

→Use the –route option to List, Create, or Delete entries in the IPv6 route table, which are updated automatically by the Neighbor Discovery protocol

**# server\_ip server\_2 -neighbor -list**

server\_2 :

| Address       | Link Layer Address | Interface | Type | State |
|---------------|--------------------|-----------|------|-------|
| 2620::abcd:10 | 0:50:56:a4:60:6c   | cge-1-1   | HOST | STALE |

→Use the –neighbor option to List, Create, or Delete neighbor cache entries for troubleshooting

### **PORTS LISTENING & ESTABLISHED ON SERVER:**

**# server\_netstat server\_2 -A inet6 -a | -A inet -a (IPv4)**

### **6.0 CELERRA ADMIN ROLES FOR CLI USERS:**

→Administrative Roles (Role-based privileges) were implemented with NAS 5.6, for GUI Users only

→Roles define what a user can do with a Celerra object, and users are always associated with a primary group, and each group has a defined role

→Role privileges are defined as Read, Modify, or Full Control

→By default, all Roles are allowed to view objects, or to have Read privileges

→NAS 6.0 adds Admin Roles capability for CLI Users, using predefined or custom roles

→An Authentication Library is used for the CLI that will allow certain Role-based actions to occur, depending on a User's Group membership role, and the action being taken [Action + Object + Role=result] using nas\_cmd commands

→This is a passive feature; admin roles cannot be managed from the CLI. To test, you would need to setup Admin Role accounts from the GUI, then test via CLI to see what actions are allowed or denied. Use the /nas/tools/authorize\_client utility to check and test user privileges.

→Root user account UID=0 is not subject to the Auth Library check and is skipped when using the CLI, however, though root has all access and control, it does go through a authorization check if using Unisphere.

→An important concept for Roles is that a single Group can only be mapped to one role, but many groups can map to the same role

### **Database Files:**

**/nas/site/role\_user** →Admin Role users and roles

**/nas/site/group\_db** →Admin Role groups and roles

**/nas/site/role** →System defined Users (root & nasadmin) & Groups for GUI

### **Deciphering a User's Roles from the database file:**

**# cat /nas/site/role\_user**

```
:nasadmin:201:3,2,
:nasadmin1:500:3,2,9,
```

→Where field 1 is the username, field 2 = UID, & field 3 = role(s). So, “nasadmin1” is the name of the account, has a UID of 500, and group roles for 3 (operator), 2 (nasadmin), & 9 (imported\_administrator), respectively, as defined in the /nas/site/role file

**# cat /nas/site/role** (output abbreviated and edited)

```
2:nasadmin:system-defined:
```

```
3:operator:system-defined:
```

```
9:imported_administrator:storage-defined:
```

### **Creating and configuring Admin Roles:**

1. Create User with Network Admin role using GUI

Unisphere > Settings > User Management, with Account Type local, a password & expiration, and a Primary Group role, making sure to check the Client Access boxes for ‘Unisphere Manager allowed’ and ‘Control Station shell allowed’

2. Login to CLI as the new network admin User & test privileges

**\$ nas\_fs -name net2 -create size=1000M pool=clar\_r5\_performance -o slice=y**

Error 13422428165: The user is not authorized to perform the specified operation.

3. Or use authorize\_client utility to test access privileges for a given User

**\$ ./authorize\_client networker filesystem list**

**\$ echo \$? 1** --> Return code of 1 indicates that the action is allowed for the user

**\$ ./authorize\_client networker filesystem modify**

**\$ echo \$? 2** --> Return code of 2 indicates that the action is not allowed for the user

**Verifying existence of new User:**

# cat /etc/passwd | grep networker

networker:x:500:501::/home/networker:/bin/bash

**Example of user ‘networker’ with Network Admin Role:**

→User logs into Control Station using SSH

→User tries to create a file system, but because of Roles, is not authorized to do so and the operation fails

\$ nas\_fs -name net2 -create size=1000M pool=clar\_r5\_performance -o slice=

Error 13422428165: The user is not authorized to perform the specified operation.

**Using the authorize\_client script to Test & Troubleshoot CLI Roles:**

/nas/tools/authorize\_client

Usage: authorize\_client <user\_name> <object\_name> <action\_name>

**Note:** See emc236631 for a link to the complete authorization library table that shows the CLI command, Object name, Action allowed, and Privilege required

**Using Return Codes to test <user\_name> against <object\_name> based on <action\_name>:**

\$ ./authorize\_client networker filesystem list

\$ echo \$?

1 --> Return code of 1 indicates that the action is allowed for the user indicated

\$ ./authorize\_client networker filesystem modify

\$ echo \$?

2 --> Return code of 2 indicates that the action is not allowed for the user indicated

→Above examples show that user ‘networker’ can list file systems but not modify them

**Possible Return Codes using authorize\_client and the \$ echo \$? query:**

AD\_ALLOW = 1,

AD\_DISALLOW = 2,

AD\_USER\_NOT\_FOUND = 3,

AD\_ERROR\_CANNOT\_OPEN\_FILE = 4,

AD\_ERROR\_CANNOT\_ALLOCATE\_MEMORY = 5,

AD\_ACQUIRELOCK\_FAILED=6,

AD\_RELEASE\_FAILED=7,

**References:**

→Appendix A of the Celerra Security Configuration Guide lists the Commands, Object Actions, Category, and predefined roles for all the Objects where Admin CLI roles apply. There are many commands that do not fall under the role-based access umbrella (e.g., nas\_halt, server\_log, nas\_cel, server\_mpfs, etc.), and would require the traditional nasadmin or root user accounts. Similarly, there are a number of commands that all Roles have the right to execute (server\_ping, nas\_inventory, server\_uptime, etc)

→emc236631 contains a list of Commands, Objects, Actions, & privilege for testing User privileges using /nas/tools/authorize\_client

**6.0 CONTROL STATION SECURITY AUDITING:**

→New auditing feature added to Control Station with RHEL 5.0 kernel

→Based on Linux auditd daemon, records, events, and logs

→Basic purpose is to audit security-relevant events

→Auditing is enabled by default on new installations, keeping track of commands run, changes to system files, changes made to auditing, changes to user accounts/roles, and user authentication to the system

→Systems upgraded to 6.0, however, are not enabled by default

→NAS services are not required to run the audit daemon, hence new 6.0 /celerra/audit partition on the local Control Station IDE drive

→Auditing records are sync’ed to /nbsnas/var/auditing/cs0 or cs1 every 180 seconds based on nas\_mcd.cfg configuration

→For CS0 replacement, code will restore the audit files. CS1 replacement would require manual restore of audit files

/sbin/ausearch →Reading the audit trail

/sbin/aureport →Summary reports of audit logs

→One of the associated goals is to audit access to Data Mover root file systems over the internal NFS network using a Mount Monitor process

# ps -ef | grep mt\_mon

root 9656 9654 0 Aug06 ? 00:04:08 /nasmed/sbin/mt\_mon

**Note:** Audit Daemon monitors rules and passes records to Mount Monitor

→Can configure CS to shutdown if auditing is disabled

**New Local Partition:**

/celerra/audit

**Note:** Purposes of creating an internal IDE partition on the CS is to store the logs locally, not depend on NAS Services, and have ability to log on either CS0 or CS1

**Control Station Files:**

/etc/audit/auditd.conf →Auditd behavior, logs, log rotation rules, up to 7 logs

/etc/audit/audit.rules →Defines what auditd will audit

**/celerra/audit/audit.log, audit.log.1, audit.log.2, etc.** →Where audit logs stored

**/sbin/auditd** →Audit Daemon executable, startup based on auditd.conf

**/sbin/auditctl** →Audit subsystem control executable

#### **Audit Record Types:**

SYSCALL—system calls

PATH—file being accessed

CWD—current working directory of process

USER\_XXX—events associated with a user

FS\_WATCH—file system object access when explicit watch is enabled

#### **Configuring Auditing on Upgraded Systems:**

1. Edit auditd.conf or audit.rules if custom auditing desired
2. Configure the auditd daemon service to run on system startup

**# /sbin/chkconfig --levels 2345 auditd on | off**

**# /sbin/chkconfig --list auditd**

```
auditd      0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

3. Start the audit daemon service

**# /sbin/service auditd start**

```
Starting auditd: [ OK ]
```

#### **Difsync Backups from nas\_mcd.cfg:**

→backs up /etc/audit/auditd.conf & audit.rules, and /celerra/audit/audit.log to /nas/var/auditing/.backup, which is a link to /nas/var/auditing/cs0, every 180 seconds

#### **Backup location for audit.log and auditd.conf:**

#### **/nas/var/auditing**

```
lrwxrwxrwx 1 root root 21 Aug 3 20:34 .backup -> /nas/var/auditing/cs0  
drwxr-xr-x 2 root root 1024 Sep 9 00:20 cs0 →auditd.conf, audit.log, & audit.rules  
drwxr-xr-x 2 root root 1024 Aug 3 15:31 cs1
```

→During CS restore, auditing logs are restored to /nas/var/auditing/cs0

#### **Location of Audit Logs:**

**# ls -la /celerra/audit**

```
-rw----- 1 root root 7802979 Sep 8 20:00 audit.log  
-r----- 1 root root 15728749 Sep 8 18:30 audit.log.1 →Logs rotate after every 15MB of information recorded  
-r----- 1 root root 15728677 Sep 8 15:40 audit.log.2  
-r----- 1 root root 15728733 Sep 8 12:40 audit.log.3  
-r----- 1 root root 15728781 Sep 8 09:50 audit.log.4  
-r----- 1 root root 15728657 Sep 8 06:50 audit.log.5
```

#### **New Audit Directory on Control Station:**

#### **/etc/audit**

**/etc/audit/auditd.conf** →controls auditd behavior, log locations, log rotation, etc.

**Note:** This file defines auto log rotation rules and trimming—keeps up to 7 log files at 15MB each

**/etc/audit/audit.rules** →file telling auditd what to audit

**Note:** By default, logs commands run by users, list of sensitive files, changes to auditing, user accounts, roles, users authenticating to system

#### **ENABLING/DISABLING AUDITD:**

**/sbin/chkconfig --levels 2345 auditd on | off**

**# /sbin/chkconfig --list auditd**

```
auditd      0:off 1:off 2:on 3:on 4:on 5:on 6:off
```

**/sbin/ausearch** →reads audit trail, searches on many different keywords

**/sbin/aureport** →provides summary reports on logs

**# /sbin/aureport**

Summary Report

=====

Range of time in logs: 09/08/2010 09:50:03.666 - 09/09/2010 00:47:37.877

Selected time for report: 09/08/2010 09:50:03 - 09/09/2010 00:47:37.877

Number of changes in configuration: 0

Number of changes to accounts, groups, or roles: 0

Number of logins: 4

Number of failed logins: 9

Number of authentications: 8

Number of failed authentications: 4

Number of users: 2

Number of terminals: 10

Number of host names: 5

Number of executables: 28

Number of files: 27

Number of AVC's: 0

Number of MAC events: 0

Number of failed syscalls: 9

Number of anomaly events: 0

Number of responses to anomaly events: 0

Number of crypto events: 0

Number of process IDs: 2116

Number of events: 7911

/sbin/auditctl → kernel audit subsystem

/sbin/service auditd start | stop | status, etc.

### # /sbin/aureport --auth

Authentication Report

```

### # /sbin/service auditd start

Starting auditd: [ OK ]

### # /sbin/service auditd

Usage: /etc/init.d/auditd {start|stop|status|restart|condrestart|reload|rotate|resume}

/var/log/audit

### # ps -ef |grep audit

```
root 20750 1 0 Mar24 ? 00:02:12 auditd
root 21465 13074 0 Mar24 ? 00:00:02 /bin/sh /nas/sbin/dirsync /etc/audit /nas/var/auditing/.backup 180 auditd.conf audit.rules
root 21466 13074 0 Mar24 ? 00:00:02 /bin/sh /nas/sbin/dirsync /celerra/audit /nas/var/auditing/.backup 180 audit.log
```

### Mount Monitor Process Roots:

→Mount monitor process watches for automounting of the Server rootfs, detects and issues the file system watch for rootfs

### # ps -ef |grep mt\_mon

```
root 20752 20750 0 Mar24 ? 00:00:57 /nasmcd/sbin/mt_mon
```

**Note:** FS Watch capability and monitoring tool for rootfs

→Audit Daemon writes to log and passes record to Mount Monitor for action, as required

## **6.0 C3 CELERRA COMMON CACHE IMPROVEMENTS:**

→New Celerra Common Cache service (C3) for use by WEB-UI, JServer, XML-API, SMI-S, & CLI clients

### Logs:

### /celerra/commoncache/logs/c30.log.0

**Note:** Logs will show if client request was not met via the cache, indicated by “doPassThru”. Log will also show when an Indication is received that updates the cache: “Deleted Mount thru indication”. Indications are also logged in the /nas/log/cel\_api.log.

### Configuration Files:

/celerra/commoncache/bin/config/c3Configuration.xml (cache behavior, properties) | c3Logging.properties (logging)

→C3 uses Port 9824

→Cache is kept up-to-date via Indications mechanism

→Cache can also be updated manually via Refresh button and Invalidate Cache and Refresh section from Tools in Unisphere

## **NAS 6.0 HC MESSAGE FORMAT & IDs FOR PUHC/PAHC:**

HC\_BE\_14505017348

→New series of messages and descriptions that start with an “HC\_xxx” ID

- nas\_message –info cannot output the details of HC messages
- Primus solutions written for all Error and Warning PUHC messages, but many have incomplete content
- The PUHC healthcheck descriptions and IDs can be viewed in the following files:

#### /nas/tools/upgrade\_check\_tools/catalog/en

**cs\_msg.xml** →Control Station messages

**dm\_msg.xml** →Data Mover messages

**be\_msg.xml** →Backend messages

**sys\_msg.xml** →System messages

#### **PAHC/PUHC EXAMPLES:**

Error HC\_SYS\_14505213997: NAS services are not started on the Control Station.

Action : Run "service nas start" to restart the service...

Control Station: Check auto transfer status

Warning HC\_CS\_18800050417: The automatic transfer feature is disabled.

Action : EMC recommends the automatic transfer feature to be enabled...

Storage System : Check if Fibre Channel zone checker is set up

Information HC\_BE\_27389919354: You have not set up...this check...zoning cannot be checked.

#### **Some checks are used for multiple variables, as in the following examples:**

Blades : Check DNS connectivity and configuration

Warning HC\_DM\_18800115743:

\* server\_2: The DNS service is currently stopped and does not contact any DNS server.

Warning HC\_DM\_18800115743:

\* server\_2: The Network Time Protocol subsystem (NTP) has been stopped or is not connected to its server.

Warning HC\_DM\_18800115743:

\* server\_2: The NIS domain 'hosts.pvt.dns' is defined with only one NIS server.

Warning HC\_DM\_18800115743:

\* server\_2: The NIS server '192.1.4.210' is not accessible on the network (no answer from 192.1.4.210).

## **6.0 SERVER STATS & NAS STATS STATISTICS ENHANCEMENTS:**

→Additional Blade statistics reported, -summary switch replaced with –monitor, -table switch removed

→Statistics are reported in real-time and in time-series fashion

→Stats are housed in Tree format, and a statpath is the fully qualified path to a particular statistic, separated by periods (e.g., rep.v2.Session)

→statmonService enabled by default on Blades, using port 7777, and collects raw values for all the statistics

→Additional options added to server\_stats interface, all Blade stats now reported

→New Control Station nas\_stats interface to allow creation & management of statgroups, based on existing system-defined statgroups, as well as the use of thousands of possible statpaths

**Note:** A User would define a particular group of stats to gather, create a custom-defined statgroup, then invoke the statgroup name during a server\_stats –monitor <custom\_group> operation

→Default stat update sampling period “interval” is every 15 seconds, but can be modified between 1-300 seconds

→Stat Groups were added to help users run groups of stats without typing each individual statpath name, using system-defined groups, as well as allowing creation of custom user-defined groups

#### **Server\_stats still the main reporting interface:**

# **server\_stats server\_2 -service -status**

server\_2 : The statmonService has started.

interface=INTERNAL

port=7777

allow=128.221.252.100:128.221.252.101:128.221.253.100:128.221.253.101

The statmonService is listening for incoming network connections.

Max Connections: 32, Current: 0

→The –summary and –table switches for server\_stats have been deprecated

→Use \$ server\_stats –list and –info to obtain more information about statpath names for a Blade

# **server\_stats server\_2 –service –start –port 7777**

# **server\_stats server\_2 -service -status**

server\_2 : The statmonService has started.

interface=INTERNAL

port=7777

allow=128.221.252.100:128.221.252.101:128.221.253.100:128.221.253.101

The statmonService is listening for incoming network connections.

Max Connections: 32, Current: 0

# **server\_stats server\_2 -list |grep ntp**

Family ntp

```

Counter      ntp.firstHits
Counter      ntp.firstMisses
Counter      ntp.hits
Compound     ntp.lastDelta
Fact        ntp.lastDelta.usec
Fact        ntp.lastDelta.sec
Counter      ntp.misses
# server_stats server_2 -info ntp.hits
server_2 :
name       = ntp.hits
description = Number of successful contacts with the NTP server
type       = Counter
member_stats =
member_elements =
member_of   =
→New -monitor option replaces -summary for statpaths and statgroups
# server_stats server_2 -monitor basic-std (formerly -summary basic)
server_2 CPU Network Network dVol dVol
Timestamp Util In Out Read Write
% KiB/s KiB/s KiB/s KiB/s
13:06:59 0 14 1 0 12

```

**Note:** -monitor can be used to gather information on multiple stats by comma-separating each stat name, or, by using a single set of statpaths with sorting options

```

-monitor -action {status|enable|disable}
[ { -monitor {statpath_name|statgroup_name}[,...]
| -monitor {statpath_name|statgroup_name}
  [-sort <field_name>]
  [-order {asc|desc}]
  [-lines <lines_of_output>]
# server_stats server_2 -monitor net.device -sort device
server_2 device Network Network Network Network Network Network
Timestamp In In In Out Out Out
Pkts/s Errors/s KiB/s Pkts/s Errors/s KiB/s
13:15:24 mge0 23 0 29 14 0 2
mge1 0 0 0 0 0 0

```

#### Old Statistic Commands removed:

**server\_mpfs**  
**server\_cifssstat**  
**server\_nfssstat**

#### Example:

**# server\_nfssstat server\_2**

server\_2 :

Info 26306752351: server\_2 : This command has been deprecated and replaced with server\_stats command.

Error 2237: Execution failed: Segmentation fault: Operating system signal. [A\_ERROR\_SERVICE.last\_fatal\_error\_code]

#### Top Talkers -top switch from 5.6.47 replaced with the following:

##### CIFS Clients:

**# server\_stats server\_2 -i 1 -c 1 -te no -m cifs.client**

**Note:** Reports CIFS stats by Client IP addresses/Username for Reads/Writes, Suspicious operations, Averages for SMB1 & SMB2

##### NFS Clients:

**# server\_stats server\_2 -i 1 -c 3 -m nfs.client**

**Note:** Reports NFS stats by Client IP addresses for Read/Writes, Suspicious operations, Averages, for NFSv2, NFSv3, NFSv4

##### Quota Trees:

**# server\_stats server\_2 -i 1 -c 2 -te no -m fs.qtree**

**Note:** Reports file systems stats by quota tree Read/Write operations per second

#### **# server\_stats**

server\_stats <mountname>

-list

```

| -info [-all<statpath_name>[,...]]
| -service { -start [-port <port_number>]
  | -stop

```

```

| -delete
| -status }

|-monitor -action {status|enable|disable}
[{| -monitor {statpath_name|statgroup_name}|,...]
|-monitor {statpath_name|statgroup_name}
  [-sort <field_name>]
  [-order {asc|desc}]
  [-lines <lines_of_output>]

[-count <count>]
[-interval <seconds>]
[-terminationsummary {no|yes|only}]
[-format {text |titles {never|once|<repeat_frequency>}}|csv}]
[-type {rate|diff|accu}]
[-file <output_filepath> [-overwrite]]

```

**Note:** For printing stats, default format is text. If using .csv, use –file option to avoid seeing multiple title lines in output. For “–type”, it depends on whether the statistic is one that increases monotonically (network bytes), or one that displays a point-in-time value (CIFS connections). ‘Rate’ displays rate of change since previous sample. ‘Diff’ displays change in value since previous sample. ‘Accu’ displays change in value since initial sample. Default display ‘type’ is ‘rate’.

#### Server Stats Examples:

```
$ server_stats server_2 -monitor basic-std -interval 5 -count 5 -type rate | diff | accu
$ server_stats server_2 -monitor cifs-std -i 3 -c 5 (5 iterations of cifs-std statistics group at 3-sec. intervals)
$ server_stats server_2 -monitor cifsops-std -i 5 -c 3 (SMB dialect statistics outputs for CIFS)
$ server_stats server_2 -monitor netDevices-std -i 5 -c 3 (Network device summary every 5 secs, three times)
```

**Note:** Use “–terminationsummary no” option to not display the Min/Aver/Max summary for the devices (also, “te no”)

#### CONTROL STATION NAS STATS COMMAND:

→New command to help manage Statistic Groups

# nas\_stats

USAGE:

nas\_stats

```

-groups
{
  -list
  |-info [-all<statgroup_name>|,...]
  |-create <statgroup_name>
    [-description "<description_line>"]
    {<statpath_name>|<statgroup_name>}[,...]
  |-modify <statgroup_name>
    { [-rename <new_statgroup_name>]
      [-description "<description_line>"]
      [<statpath_name>|<statgroup_name>|,...] }
  |-add <statgroup_name>
    {<statpath_name>|<statgroup_name>}[,...]
  |-remove <statgroup_name>
    {<statpath_name>|<statgroup_name>}[,...]
  |-delete <statgroup_name> [-Force]
  |-database
    {-recover [-Force] →Tries to restore Statistic Groups db from latest NAS_DB backup; recreates default db if required
     |-verify }
```

#### Creating & using a custom StatGroup:

```
# nas_stats -groups -create nfsv4_group nfs-std,nfsOps-std,nfs.v4.op
'nfsv4_group' created successfully
```

# nas\_stats -groups -list

| Type   | Name            |
|--------|-----------------|
| System | basic-std       |
| System | caches-std      |
| System | cifs-std        |
| System | cifsOps-std     |
| System | diskVolumes-std |
| System | metaVolumes-std |
| System | netDevices-std  |
| System | nfs-std         |

System nfsOps-std  
User nfsv4\_group →Example of a custom-defined group name  
**Note:** Provides a list of system-defined Stat Groups, and user-defined Stat Groups, if created

```
# nas_stats -groups -info nfsv4_group
name      = nfsv4_group
description = nfsv4_group
type      = User-defined
member_stats = nfs-std,nfsOps-std,nfs.v4.op
member_elements =
member_of   =
```

```
# server_stats server_2 -monitor nfsv4_group
# nas_stats -groups -info basic-std
name      = basic-std
description = The basic system-defined group.
type      = System-defined
member_stats = kernel.cpu.utilization.cpuUtil,net.basic.bytesIn,net.basic.bytesOut,store.readBytes,store.writeBytes
member_elements =
member_of   =
# nas_stats -groups -create <statgroup_name> -description "description_here" <statpath_name(s)> [comma separated]
# nas_stats -groups -modify <stat_group> -rename | -description "new_descript" | -delete <statgroup_name> | -add | -remove
# nas_stats -groups -database -verify
```

Database is healthy.

#### **# nas\_stats -groups -database -recover**

Latest healthy database modified last on Fri Jul 23 13:50:45 EDT 2010.  
Any updates performed after the latest backup will be lost. Continue? [Y/N] y

nas\_stats: recovery completed successfully.

#### **# server\_stats server\_2 -service -status**

server\_2 : The statmonService has started.

interface=INTERNAL

port=7777

allow=128.221.252.100:128.221.252.101:128.221.253.100:128.221.253.101

The statmonService is listening for incoming network connections.

Max Connections: 32, Current: 0

#### **# server\_stats server\_2 -monitor -action status**

server\_2 : Statistics are enabled.

#### **New options under server stats:**

**-list** →lists all statpaths and statgroups

**-info** →detailed info on statpaths/statgroups

**-monitor** →specify a statpath or statgroup to collect stats on

**-service** →managing statmonService on the Data Mover

#### **Statistic Types:**

Family—corresponds to a major feature or sub-system in DART

Compound—stats that are grouped together

Set—collection of compound instances

Correlated Set—correlations across sub-systems

Element—an instance in a set or correlated set

Counter—an increasing value statistic

Fact—point in time information

Computed—create a statistic from 2 or more other stats

Statistic Group—collection of stats defined at the Control Station, an evolution of the Summary & Table collections

#### **Summary and Table collections replaced by statistic family groups:**

| System-defined statistics group name | server_stats collection name |
|--------------------------------------|------------------------------|
| basic-std                            | -summary basic               |
| caches-std                           | -summary caches              |
| cifs-std                             | -summary cifs                |
| nfs-std                              | -summary nfs                 |
| cifsOps-std                          | -table cifs                  |
| diskVolumes-std                      | -table dvol                  |
| metaVolumes-std                      | -table fsvol                 |
| netDevices-std                       | -table net                   |

nfsOps-std -table nfs

**CREATE & USE NEW STATGROUP FROM SYSTEM-DEFINED GROUPS & STATPATHS:****1. Create new statgroup**

# nas\_stats -groups -create newgroup basic-std,caches-std,ftp.auth.cifsFailures -description "New group"

'newgroup' created successfully

# nas\_stats -groups -info newgroup

```
name      = newgroup
description = New group
type      = User-defined
member_stats = basic-std,caches-std,ftp.auth.cifsFailures
member_elements =
member_of  =
```

**Note:** User nas\_stats -groups -add or -remove to add or remove statpaths to existing User-defined statgroups**2. Invoke collection of stats for the new statgroup**

# server\_stats server\_2 -monitor newgroup

| server_2  | CPU   | Network | Network | dVol  | dVol  | DNLC    | OF Cache | Buffer | Failed           |
|-----------|-------|---------|---------|-------|-------|---------|----------|--------|------------------|

**TROUBLESHOOTING SERVER STATS:**

# .server\_config server\_2 -m nfs.client -TRACE

**6.0 SMI-S PROVIDER—Web Based Enterprise Management (WBEM):**

→Features represents the Storage Management Initiative-Specification to provide an SMI-S compliant API for storage products (SMI-S 1.3)

→SMI-S is an infrastructure designed to manage storage devices

→CIM client, CIM server, &amp; Provider

→SMI-S is based on CIM, with clients able to manage Celerra via CIM

→Basically Web Based Enterprise Management (WBEM) using Common Information Model (CIM XML)

→Embeds the WBEM infrastructure on the CS in the form of a CIM Server (aka, ECOM, using CIMOM—CIM Object Manager) and a Provider

→ECOM &amp; SMI-S are embedded on the Control Station

→ECOM is the EMC Common Object Model CIM Server

**Starting ECOM Service:**

→vi edit /nas/sys/nas\_mcd.cfg and uncomment “cim conf”, “cim server”, and “SMIS” logs, stop &amp; restart NAS services daemon “cim server”

```
executable  "/celerra/wbem/bin/start_cim_server"
optional    no
autorestart yes
cmdline    "/celerra/wbem"
```

---

```
# daemon "SMISPlugin Log Trimmer"
#   executable  "/nas/sbin/log_trimmer"
#   optional    no
#   autorestart yes
#   ioaccess   no
#   cmdline    "-n /nas/log/smisi/SMISPlugin.log 1000 1 2 h t 4 y "
```

---

```
# daemon "SMIS cimomlog.txt Log Trimmer"
#   executable  "/nas/sbin/log_trimmer"
#   optional    no
#   autorestart yes
```

```
#    ioaccess    no
#    cmdline     "-n /nas/log/smis/cimomlog.txt 1000 1 2 h t 4 y"
# ps -ef |grep -i cim
root  25995 19683 0 10:19 ?      00:00:00 /bin/sh /celerra/wbem/bin/start_cim_server /celerra/wbem
root  26007 19683 0 10:19 ?      00:00:00 /nas/sbin/log_trimmer -n /nas/log/smis/cimomlog.txt 1000 1 2 h t 4 y
# ps -ef |grep -i ecom
root  28071 25995 3 10:20 ?      00:00:01 ECOM
```

#### Troubleshooting:

```
# ls -la /nas/log/smis
```

```
-rw-r--r-- 1 root  root  16738 Jul  2 18:34 cimomlog.txt
-rw-r--r-- 1 root  root    0 Jul  2 18:32 HTTP_trace.log
-rw-r--r-- 1 root  root  2458 Jul  2 18:34 securitylog.txt
-rw-r--r-- 1 root  root  22057 Jul  2 18:34 SMISPlugin.log
```

#### WBEM PORT:

```
# netstat -a |grep 5988
tcp    0      0 *:5988          *.*        LISTEN
```

## **6.0 MS IDENTITY MANAGEMENT FOR UNIX PHASE II (IDMU):**

→IDMU is a Microsoft solution that offers a centrally managed environment, under Active Directory, for both Windows and UNIX users

→Microsoft Active Directory, Identity Management for UNIX is comprised of a series of tools to help integrate a Windows environment with a UNIX environment, where the AD Domain Controller becomes the Master NIS Server and uses Password Synchronization to automatically synchronize passwords between Windows and UNIX users, for centralizing management of the Windows and UNIX environments

→IDMU is installed on an AD server, along with “Server for NIS”, “Administration Components”, “Password Synchronization”, and “Other Network File and Print Services: Microsoft Services for NFS”

→Celerra has supported IDMU since 5.6.39

→Kerberos authentication has been added to IDMU support for 6.0

→IDMU is found in Windows 2003 R2 and later

#### MS IDMU Active Directory Configuration:

--Server for NIS; Administration Components; Password Synchronization; Other Network File and Print Services: Microsoft Services for NFS  
--Create or configure an existing Group with UNIX GID and NIS Domain  
--Configure AD Users with UNIX username, etc.  
--Configure User Name Mapping,NIS for the NFS service, Simple Mappings, etc.

#### Celerra Configuration:

1. Make a copy of the default /etc/ldap.conf.idmu\_template\_v1 file and edit to reflect LDAP Base domain and AD Domain name

a) Edit the following fields to reflect your LDAP Base domain and AD domain name

```
# Replace "dc=mydomain,dc=com" by your base DN.
```

```
# If you have a dedicated container for netgroups, replace
```

```
# "cn=netgroup,cn=mydomain,cn=DefaultMigrationContainer30" by the right DN.
```

```
nss_base_passwd  cn=Users,dc=mydomain,dc=com?one
```

```
nss_base_group   cn=Users,dc=mydomain,dc=com?one
```

```
nss_base_hosts   cn=Computers,dc=mydomain,dc=com?one
```

```
nss_base_netgroup cn=netgroup,cn=mydomain,cn=DefaultMigrationContainer30,dc=mydomain,dc=com?one
```

2. Push file out to Data Mover as /etc/ldap.conf

3. Copy /nas/sys/nsswitch.conf.tmpl file and add “ldap” to each search order line, then push to DM as /etc/nsswitch.conf  
passwd: files ldap nis  
group: files ldap nis  
hosts: dns ldap nis files  
netgroup: files ldap nis

4. Configure and start LDAP client on Data Mover

**# server\_ldap server\_2 -set -basedn dc=idmu,dc=emc,dc=com -servers 192.1.8.158 -kerberos -kaccount compname\$**

Note: Where basedn is LDAP basedn; Servers = LDAP server; Compname = CIFS Name\$ (\$ sign required!)

5. Start NIS Service and set CIFS Resolver for NIS lookups:

a) **# server\_nis server\_2 hosts.pvt.dns 192.1.4.210**

server\_2 : done

b) **# server\_param server\_2 -facility cifs -modify resolver -value 1**

server\_2 : done

#### Testing/Troubleshooting:

```
# server_ldap server_2 -lookup -user <username>
```

# server\_ldap server\_2 -info

# server\_ldap server\_2 -i -v (Verifying LDAP configuration and connection to LDAP domain)

**Note:** Check Base DN, connection state, config files, etc.

### **BLACKBIRD:**

→Blackbird to become 64-bit to support DART, and will have libraries to support 32-bit Linux Control Station

→Runs on VMWare Workstation or Player host-based virtualization

### **6.0 SNMPv3 SUPPORT:**

→A new SNMPD daemon, supporting SNMPv1, SNMPv2, and SNMPv3, runs on the Data Mover

→SNMP consists of managed network devices, agents, and network management system applications

→SNMP is used to establish a baseline state for devices, and then uses network watchdog ‘agents’ to monitor, sending alerts or trap notifications to the management station when something changes/errors

→SNMPv3 uses a User Security Model (USM) to provide SNMP security on the network

→\$ server\_snmp is replaced with \$ server\_snmpd

# server\_snmpd server\_2

```
-info  
|-service {  
    -status  
    | -stop  
    | -start  
|-modify [ -location <sys_location> ]  
    [ -contact <sys_contact> ]  
    [ -community { -clear | <community> } ]  
|-user {  
    -list  
    | -create <name> -authpw -privpw  
    | -delete <name>  
    | -modify <name> -authpw -privpw
```

→SNMP collects and processes network information at fixed or random intervals, based on watchdog agents, which sends alerts via Traps

→MIBs databases are used to manage & monitor devices

→Managed devices collect & store NMI (Network Mgmt Information) and send to NMS (Network Mgmt System) using SNMP

→Main benefit of SNMPv3 are security and remote configuration enhancements (authentication, encryption, message integrity)

→Support for SNMPv1, v2c, and v3 for DART-only

→Current MIBs and IPv6 MIBs supported

→Will use MD5 for authentication and DES for privacy

### **CONFIGURING SNMPv3:**

#### **1. Create User & Authentication/Privacy passwords:**

# server\_snmpd server\_2 -user -create snmp\_user -authpw -privpw

Enter authentication password:

Confirm authentication password:

Enter privacy password:

Confirm privacy password:

server\_2 :

OK

#### **2. Set SNMP Location & Contact:**

# server\_snmpd server\_2 -modify -location "svt" -contact "me"

server\_2 :

OK

# server\_snmpd server\_2 -info

server\_2 :

enabled = Yes

location = svt

contact = me

community =

# server\_snmpd server\_2 -user -list

server\_2 :

snmp\_user

9bRL1SD73nrc9BbF5FdHYA82KeP1P36

# server\_snmpd server\_2 -service -status

server\_2 :

SNMP Running

### **USING SNMPGET ON CONTROL STATION:**

# snmpget -v3 -u snmp\_user -l authPriv -a MD5 -A nasadmin -x DES -X nasadmin 128.221.252.2 sysContact.0

SNMPv2-MIB::sysContact.0 = STRING: me

### **DISABLING SNMPv1 & v2:**

# server\_snmpd server\_2 -modify -community -clear

server\_2 :

OK

### **ENABLING SNMPv1/v2:**

# server\_snmpd server\_2 -modify -community private

### **CPW CHANGES:**

→Provides user with the option to skip provisioning of EFD disks as disk volumes, and instead reserve them for CLARiiON EFD Cache functionality

→If user wishes to use the CLARiiON EFD cache feature, they should proceed to Unisphere and configure EFD Cache on the array

### **Excerpt from CPW screen:**

“EFD Information

This system has unused EFD disks...By default, EFD disk provisioning is bypassed. To provision EFD disks, check the following box.

— Allow EFD disks provisioning for Celerra storage.”

### **CSA CHANGES:**

→CSA screen messages and popups will now conform to an Event Code that can be queried using nas\_message (aligns with CCMD messaging)

### **6.0 REPLICATION V1 NOT SUPPORTED:**

→IP Replication V1 is not supported on 6.0 and systems will not upgrade if any of the following conditions are seen by the PUHC

→Only resolution would be to remove all vestiges of RepV1 before upgrading

→See emc242421 for more details

### **V1 Replication Sessions running:**

Error HC\_CS\_14505083114: There are Celerra Replicator (V1) sessions or checkpoints on this Celerra. Replicator (V1) has been deprecated and is not supported in the NAS version to which you are upgrading.

### **V1 FS Copy Sessions running:**

Error HC\_CS\_14505083115: There are fs\_copy sessions on this Celerra. Replicator (V1) has been deprecated and is not supported in the NAS version to which you are upgrading.

### **V1 License still active:**

Error HC\_CS\_14505083116: There is a Celerra Replicator (V1) license on this Celerra. Replicator (V1) has been deprecated and is not supported in the NAS version to which you are upgrading.

### **6.0 CELERRA FAST REBOOT (aka Warm Reboot--Fixed times vs Variable times):**

→Main purpose to reduce the ‘fixed time’ for reboots (much of which involved BIOS/POST hardware checks) from 3 minutes to 30 seconds

→‘Variable times’ will still apply to overall system reboot/failover times, but are mitigated by improvements introduced with NAS 5.6.47 & later

→Still, the normal data mover warm reboot is extremely fast & a big improvement

→Warm reboot skips hard HW reset, BIOS, POST, & DOS loading steps

→Warm reboot is the default action for server\_cpu server\_2 –reboot now

→Must issue server\_cpu server\_2 –reboot –cold now to do cold reboot

→Certain conditions will not qualify for warm reboot, such as HW malfunction, Data Mover panics, t2reset issued, or for manual or automatic failover

→Purpose is to allow for faster reboots of the Data Mover by resetting the Operating System only, not the motherboard

→Warm reboot will skip the BIOS & POST steps, which are Fixed reboot times

**Note:** Still see a reference to the BIOS during Warm reboot, however

2010-05-06 10:24:50: ADMIN: 6: Warm reboot begins. Shutting down the server ...

2010-05-06 10:27:15: KERNEL: 6: System BIOS Rev Sledgehammer

→Fast/Warm reboot actually has Data Mover loading NAS image and config files first before Control Station tells Data Mover to then proceed with reboot

**Note:** Server failover & fallback does “Cold” reboot on the slot that fails over, and the slot that fails back

# server\_log server\_2.faulted.server\_3 -s -a |grep -i cold

2010-05-10 15:26:53: ADMIN: 6: Cold reboot begins. Shutting down the server ...

# server\_log server\_3 -a -s |grep -i cold

2010-05-10 15:31:49: ADMIN: 6: Cold reboot begins. Shutting down the server ...

→Warm Reboots are used during Installs and Upgrades

→NS20/40/80/NSX support this feature since they can flash firmware, unlike older platforms which flash from DOS, which is not supported by Warm Reboot

→Firmware updates may require two reboots, one Warm Reboot which flashes firmware, which then detects BIOS/POST change and requires Cold Reboot

→Default behavior for server\_cpu is to attempt a Warm Reboot, but if warm reboot does not qualify, will do a Cold Reboot

**Note:** Users need to know that the default server\_cpu syntax will warm reboot. Must stipulate server\_cpu –reboot –cold now.

#### **DEFAULT SERVER CPU IS WARM REBOOT:**

2010-05-07 09:15:51: KERNEL: 3: Warm Reboot: Trying CS ip address 128.221.252.100

2010-05-07 09:15:51: KERNEL: 6: Warm Reboot: boot.bat: gload -or c:\bin\nas.exe c:\slot\_3\boot.cfg

2010-05-07 09:15:59: ADMIN: 6: Warm reboot begins. Shutting down the server ...

#### **Outline of Traditional Boot Process**

→Controlled DART shutdown ~ 5 secs

#### **New Warm Boot Process**

DART shutdown ~ 5 secs

→Hardware reset ~ 10 secs

→BIOS ~ 50 secs

→Extended POST ~ 50 secs

→DOS load ~ 5 secs

→gload ~ 5 secs

Bootloader ~ 5 secs

→DART init ~ 55 secs

DART init ~ 20 secs

#### **Server Log for panic reboot:**

2010-05-07 09:30:25: ADMIN: 6: Command succeeded: param kernel autoreboot=600

**Note:** Log does not specify whether this is a Warm or Cold reboot

#### **Server Log for Warm Reboot:**

# **server\_cpu server\_2 -reboot -m now**

# **server\_log server\_2 -a -s |grep -i warm**

2010-04-05 15:13:27: ADMIN: 6: Warm reboot begins. Shutting down the server ...

#### **Cold Reboot:**

# **server\_cpu server\_2 -reboot cold -m now**

server\_2 : reboot in progress 0.0.0.0.0.0.0.0.1.1.1.3.3.4.done

#### **Server Log for Cold Reboot:**

# **server\_log server\_2 -a -s |grep -i Cold**

2010-04-05 15:05:24: ADMIN: 6: Cold reboot begins. Shutting down the server ...

# **nas\_logviewer /nas/log/sys\_log |grep -i cold**

Apr 5 15:07:36 2010:DART:CHAMII:INFO:103:Slot 2:::1270494490:Info: POST\_INFO: 04/05/10 19:07:05 : INFORMATION:  
Power Up Status (0x86): Coldfire Power Down caused reset;

#### **FILE SYSTEM & NFS PARAMETER CHANGES (all require rebooting blade):**

→Open NFS files, directory name lookup cache, vnode cache, and NFS threads are being replaced by regular DART parameters, as follows:

# **server\_param server\_2 -facility file -list**

| param_name  | facility | default | current | configured |
|-------------|----------|---------|---------|------------|
| dnlcNents   | file     | 384000  | 384000  |            |
| cachedNodes | file     | 256000  | 256000  |            |

→DNLC replaced by dnlcNents, provides mappings between filenames and files in all file systems on the server. Default size depends on physical memory of Blade: 4GB=484k; 8GB=768k; 24GB=2.304m

→Nodes replaced by cachedNodes, the vnode inode & block cache for files & directories globally for all server file systems.  
4GB=256k; 8GB=512k; 24GB=1.536m

# **server\_param server\_2 -facility nfs -list**

| param_name  | facility | default | current | configured |
|-------------|----------|---------|---------|------------|
| nthreads    | nfs      | 256     | 256     |            |
| ofCachesize | nfs      | 240000  | 240000  |            |

→Nfsd replaced by nthreads, the # threads dedicated to NFS requests. 4GB=256; >than 4GB=512

→Openfiles replaced by ofCachesize, the size of the NFS open files cache. 4GB=240k; 8GB=360k; 24GB=3080m

→All of the above parameters require System reboot before going into effect

#### **6.0 NDMPCOPY:**

→Open source program for copying/migrating file system data between Data Mover file systems in the same or different Celerra, or within same Data Mover

→Download the utility from [www.ndmp.org](http://www.ndmp.org) (or SUSE and Linux 1.2 version from Apps & Tools CD)

→Utility supported Red Hat 5.2, 5.3, HP-UX 11.3, Solaris 10, SuSE Linux 10 & 11

→Supports multi-protocol file systems, preserves CIFS & NFS permissions

→Supports data copy from 5.6 to 6.0 systems, 6.0 to 5.6, 6.0 to 6.0

→Requires use of username & password for NDMPCopy

**Note:** Create user and passwd for each blade using server\_user command

**LIMITATIONS/ISSUES:**

→Not recommended to run on the Control Station (may run over internal network)

→NDMPCopy uses clear text passwords

→Supports only NDMPv2 protocol

→Copy operation may hang if network communication not successful

→Copy operation may hang if Incremental Level 0 backup has no changes

→Does not support VBB or Tape Silvering

**NDMPCopy Example:**

# ./ndmpcopy -h

Usage: ndmpcopy src\_filer:/src/dir dest\_filer:/dest/dir

```
[ -sa none | user:password ] [ -da none | user:password ]
[ -sport ndmp_src_port ] [ -dport ndmp_dest_port ]
[ -dhost ndmp_dest_ip_addr ] [ -level ndmp_dump_level ]
[ -v ] [ -q ] [ -dpass ] [ -h ]
```

Defaults:

```
src_auth_type      = text
src_auth_user      = root
src_auth_password  =
dest_auth_type     = text
dest_auth_user     = root
dest_auth_password =
ndmp_src_port      = 0 (0 means NDMP default, usually 10000)
ndmp_dest_port      = 0 (0 means NDMP default, usually 10000)
ndmp_dump_level    = 0 (valid range: 0 - 9)
ndmp_dest_ip_addr  = (no default: user needs to override dest_filer value)
verbosity          = noisy
different_passwords = no
```

# **ndmpcopy <blade\_ip>:/fs1 <blade\_ip>:/fs20 -sa user1:passwd -da user2:passwd2**

**Note:** Specifying Username and Passwords for each Data Mover

**NDMPCOPY FROM ONE FS TO ANOTHER- DIFFERENT CELERRAS (From RHEL Host):**

# ./ndmpcopy 10.127.62.126:/fs2/bin 10.127.62.127:/fs3 -sa ndmp\_copy:nasadmin -da ndmp\_copy:nasadmin -sport 10000 -dport 10000 -v

2010-07-14 19:36:36: NDMP: 6: Thread nasa00 server\_archive: emctar vol 1, 47 files, 0 bytes read, 15028938 bytes written  
**# ndmpcopy <blade\_ip>:/fs1 <blade\_ip>:/fs20 -sa user1: -da user2: -dpass**

**Note:** Allows system to prompt to enter password for each Blade

#### **Troubleshooting NDMPCopy:**

```
$ server_log server_x -f  
$ server_pax server_2 -stats -reset  
$ server_pax server_2 -stats -verbose  
$ ndmpcopy -v -v -v -v →Debug information and port information
```

#### **6.0 INCREASED NDMP BACKUP STREAMS:**

→Support increased from 4 to 8 NDMP concurrent backup streams  
→But, can only have >than 4 streams if Blade memory 8GB or more  
→Default value left at 4 streams, any changes to param requires reboot

**# server\_param server\_2 -facility NDntDataStreams -value 8**

server\_2 :

Error 4418: server\_2 : 8 is not in range (1,4)

**Note:** Above error means that Data Mover does not have 8GB memory, so command fails

**# server\_param server\_2 -facility NDMP -info concurrentDataStreams**

```
server_2 :
name          = concurrentDataStreams
facility_name  = NDMP
default_value   = 4
current_value   = 4
configured_value =
user_action     = reboot DataMover
change_effective = reboot DataMover
range          = (1,8)
description     = Number of concurrent data streams
```

**Note:** The range 1,8 will only be reflected by systems running 8GB memory or greater. Systems under 8GB memory will only show a possible concurrent stream range of 1,4

#### **SETTING STREAMS TO 8 VIA CLI:**

**# server\_param server\_2 -facility NDMP -modify concurrentDataStreams -value 8**

server\_2 : done

Warning 17716815750: server\_2 : You must reboot server\_2 for concurrentDataStreams changes to take effect.

**# server\_param server\_2 -facility NDMP -info concurrentDataStreams**

server\_2 :

```
name          = concurrentDataStreams
facility_name  = NDMP
default_value   = 4
current_value   = 8
configured_value = 8
```

-----abridged-----

#### **SETTING STREAMS TO 8 VIA UNISPHERE:**

Click Celerra system > Settings > Data Mover Parameters > Select Server, NDMP Facility, ALL Parameters, highlight param to change, Properties, then set Value and follow instructions to reboot

#### **6.0 NDMP PORT RANGE FEATURE:**

→ Celerra has the ability to specify a range of ports for NDMP use

→ The default NDMP port ranges are 1024-65535, and are also min & max

→ The minimum number of ports allowed for a range is 32, though the best practice recommendation is to have at least a 100 ports in the range

→ Recommended ranges to use are 49152-65535

→ No server reboots required

**# server\_param server\_2 -facility NDMP -info portRange -v**

server\_2 :

```
name          = portRange
facility_name  = NDMP
default_value   = 1024-65535
current_value   = 1024-65535
configured_value =
user_action     = none
change_effective = immediate
range          = *
description     = Port range for NDMP data/mover listening
```

detailed\_description

Specifies the range of ports allowed for NDMP data/mover listening.

#### **Example:**

**# server\_param server\_2 -facility NDMP -modify portRange -value 62000-63000**

server\_2 : done

**# server\_param server\_2 -facility NDMP -info portRange**

server\_2 :

```
name          = portRange
facility_name  = NDMP
default_value   = 1024-65535
current_value   = 62000-63000
configured_value = 62000-63000
user_action     = none
change_effective = immediate
range          = *
```

description = Port range for NDMP data/mover listening

## **6.0 SAMBA 4 SUPPORT:**

- Samba4 runs on UNIX host as a 2003 AD server, complete with AD, LDAP, DNS, & Kerberos KDC server
- Purpose is to allow Unix and Linux systems ability to co-exist in a Windows AD environment
- Samba 4 supports AD logon & authentication (but does not support DFS)
- Requires Windows client running MS Client and Administration pack

### **Configuring Celerra Data Mover:**

**\$ server\_param server\_2 -facility ldap -modify SecurityLayer –value 0**

**Note:** Setting param to zero disables Signing & Encryption and sets the LDAP Bind security layer to 0

→Use regular CIFS create and Join commands

## **6.0 pNFS SUPPORT:** (Parallel Network File System, an extension of NFSv4.1)

- pNFS stands for Parallel Network File System, an extension of the NFSv4.1 standard, and an EMC implementation
- pNFS supports the NFSv4.1 standard included in Open Source Linux distributions, such as found in Fedora 11
- pNFS operates similarly to Celerra MPFS in that Hosts obtain direct block data access to the array (FC or iSCSI), via metadata mappings (pNFS) from Celerra file systems using NFS, for file to block-level addresses
- Support defined in RFC 5661 and NFSv4.1, but Celerra will only initially support Host block access to either CLARiiON or Symmetrix arrays using iSCSI or FC, not file or object access
- Storage Access protocols from Host Clients to array are FC or iSCSI for direct block access
- Control Protocol from Celerra to array is done using FC
- pNFS file mapping Protocol operates between Host Clients and Celerra
- Supported only for Celerra CLI
- Fedora 11 would represent a typical pNFS client
- Statistics for pNFS would be read from NFSv4 statistics
- No MPFS licensing required, only the regular NFS license
- Celerra pNFS is an EMC implementation of an Open Source standard using pNFS based on NFSv4.1, Block FC or iSCSI storage access protocols, and Fibre Channel control protocol, and has the FMP protocol built into the pNFS standard

### **Operational Overview:**

- LINUX clients using NFSv4.1, and pNFS RPMs, and either iSCSI or FC connectivity to the Array
- LINUX clients access data via NFS Exports from Celerra, or directly from array using FC & iSCSI
- Data Mover servers as metadata server to mapping data blocks for direct Host access to array
- iSCSI or FC network between the Hosts and the Array for direct data block access
- Celerra NFS and NFS protocols for file access permissions

**\$ server\_nfs server\_2 -pnfs -service -start | -stop**

### **pNFS CONFIGURATION:**

#### **I. Celerra Configuration Steps:**

1. Enable NFSv4.1 & pNFS on the Data Mover by adding “hivers=4” to “config” file line with nfs config:

**# vi /nas/server/slot\_2/config**

**nfs config hivers=4** →Add hivers=4 to the nfs config line

2. Reboot Data Mover and verify that NFSv4.1 and pNFS Services have started:

**# server\_nfs server\_2 -v4**

server\_2 :

----- nfsv4 server status -----

\* Service Started \*  
\* pNFS service Started \*

----- NFSv4 Clients -----

Confirmed Clients : 1  
UnConfirmed Clients : 0  
Domain Name : Not Defined

----- NFSv4 State -----

Opens : 0  
Locks : 0  
Delegations: 0  
Layouts : 0

3. Create Meta volume from a single dvol for each file system to be created:

Storage > Volumes > Create >Type: \*Meta

**Note:** Select an available dvvolume to create the ‘meta’ volume from for the pNFS file system

4. Create a file system from the Meta volume:

Storage > File Systems > Create > Create from: Meta Volume

5. Mount the file system for pNFS protocol:

**# server\_mount server\_2 -o pnfs pnfs /pnfs**

server\_2 : done

# **server\_mount server\_2**

pnfs on /pnfs uxf,perm,rw,pnfs

**6. Export the file system to Linux host for root access:**# **server\_export server\_2 -P nfs -o root=10.241.168.184 /pnfs**

server\_2 : done

**II. CLARiiON Configuration Steps:**

1. Configure SP iSCSI SLIC ports with IP addresses for Host access
2. Create Raid Group and two LUNs (for this example) for the Celerra file systems
3. Add LUNs to Celerra Storage Group
4. Rescan or run diskmark operation on Celerra to pull new storage volumes into the Celerra database
5. Register Linux Host iSCSI initiator records on the array  
--Obtain IQN from /etc/iscsi/initiatorname.iscsi file  
--Set 'Initiator Type' to CLARiiON Open with Failover Mode: failovermode 4  
--Add Host name & IP address in the "Host Agent Information" section
6. Create Fedora Linux Host Storage Group & add Celerra LUNs previously added to Celerra Storage Group  
--Assign the HLU values as 0 & 1 for the Fedora Host  
--From Hosts tab, move the Linux Host from 'Available Host' to 'Hosts to be Connected'

**III. Fedora Host Configuration Steps:****1. Load the iSCSI Initiator Utilities:**# **yum install iscsi-initiator-utils**

Loaded plugins: presto, refresh-packagekit

1/1

Installed:

iscsi-initiator-utils.x86\_64 0:6.2.0.870-10.fc12.1

Complete!

## **2. Modify and record iSCSI Initiator IQN name:**

# more /etc/iscsi/initiatorname.iscsi

**InitiatorName=iqn.1994-05.com.fedora:6eaf3214e054**

a) vi edit initiatorname.iscsi and add Hostname to last field, as follows:

# more /etc/iscsi/initiatorname.iscsi

InitiatorName=iqn.1994-05.com.fedora:**fedora-202**

**Note:** Save the IQN name for registration on the CLARiiON

## **3. Load and verify the NFS and Block layout drivers on the Host:**

# modprobe nfslayoutdriver

WARNING: Deprecated config file /etc/modprobe.conf, all config files belong into /etc/modprobe.d/.

# modprobe blocklayoutdriver

WARNING: Deprecated config file /etc/modprobe.conf, all config files belong into /etc/modprobe.d/.

# lsmod

Module           Size Used by

blocklayoutdriver 36800 0

nfslayoutdriver 18423 0

nfs 353047 2 blocklayoutdriver,nfslayoutdriver

## **4. Start iSCSI Service and perform iSCSI Target discovery:**

# iscsidadm -m discovery -t st -p **10.127.62.234**

Starting iscsid: [ OK ]

10.127.62.235:3260,2 iqn.1992-04.com.emc:cx.fnm00100900045.b4

10.127.62.234:3260,1 iqn.1992-04.com.emc:cx.fnm00100900045.a4

## **5. Remote mount Celerra pNFS file system and verify:**

# mkdir /pnfs

# mount -t nfs4 -o minorversion=1 **10.127.62.126:/pnfs1 /pnfs**

# cd /pnfs

## **6. Verify iSCSI Disk mounts on the Fedora Host:**

# fdisk -l

# grep LAYOUT /proc/self/mountstats

PNFS\_LAYOUTGET: 0 0 0 0 0 0 0 0

PNFS\_LAYOUTCOMMIT: 0 0 0 0 0 0 0 0

PNFS\_LAYOUTRETURN: 0 0 0 0 0 0 0 0

# mount

10.127.62.126:/pnfs1 on /pnfs type nfs4 (rw,minorversion=1,addr=10.127.62.126,clientaddr=10.127.62.202)

## **7. Copy data to the remote mount and observe on Celerra using server\_stats to verify operation**

# dd if=/dev/zero of=/pnfs/file\_75GB bs=1024 count=**75000000**

# server\_stats server\_x -monitor nfsOps-std

# server\_nfs server\_2 -v4

----- NFSv4 State -----

Opens : 1

Locks : 0

Delegations: 0

Layouts : 1

**Note:** If the Opens and Layouts values were 0, it would mean that the Data was transferred via the Data Mover and not NFSv4

## **CST SUPPORT:**

→RSA's CST 2.0 Common Security Toolkit support for LDAP authentication

**Note:** Replaces existing CSO libraries

→Purpose of CST for Celerra is for authenticating Remote LDAP users

## **Troubleshooting Remote Logins and LDAP:**

/nas/sbin/cst\_config utility and debugging of ldap communications by setting “–debug on” | -debug off

**Note:** Check /var/log/secure and /nas/http/logs/error\_log

/nas/site/cst

/nas/http/logs/error\_log

/nas/log/webui

/var/log/secure

/var/log/messages

Jul 2 13:57:04 sleet-480 sshd[13718]: Accepted password for nasadmin from 10.4.146.212 port 1230 ssh2

Jul 2 15:24:02 sleet-480 Unisphere: Authentication succeeded for user nasadmin1 from 10.4.146.212

## **CEPA SUPPORT FOR NFS AUDITING 4.6.6.2 (Celerra Event Enabler):**

- Celerra Event Enabler version 4.6.6.2
- Supports IPv6
- Implements auditing of NFS postevents
- Third party tool for auditing from DatAdvantage (Varonis)
- CEPA NFS events initiated via Celerra mount options  
--ceppnfs or nocepp

### **Events audited for NFS are:**

FileRead; FileWrite; CreateFile; CreateDir; DeleteFile; DeleteDir; RenameFile; RenameDir; SetSecFile; SetSecDir

- Server\_mount options for using CEPA for CIFS & NFS

# server\_mount |grep cepp

```
[ ceppcifs | ceppnfs | ceppcifs,ceppnfs | nocepp ]
```

## **6.0 MISCELLANEOUS FEATURES:**

- VSS 2.0 support iSCSI
- VDS 1.1 iSCSI support
- MPFS Client support Windows 2008 R2 SP2 64-bit; Windows 7; RHEL5; CentOS 5.4 (over iSCSI only); SLES 10 SP3 & 11
- MAC O/S 10.6 support for CIFS SMB1 clients (already support NFSv3)
- Celerra iSCSI LUN to CLARiiON iSCSI LUN migration procedures
- Prepare Celerra plug-ins, CSA, Registration Wizard, Install Manager, PAHC & PUHC for full Internationalization of multibyte character strings and XML or Java properties [Barossa maintenance release will then provide Language packs for various interfaces]
- Tolerance for 8Gb FC cards on V-Max, Enginuity 5874.207.168 and later

## **BAROSSA BMR1 6.0.40 MAINTENANCE RELEASE:** ETA Dec 2010

→ The main feature in this release is Celerra tolerance for Jupiter Flare 30.5, and FCoE I/O Modules on the SPs

→ Additionally, the release offers Japanese, Chinese, and Korean Unisphere Localization, and Unisphere Language packs

## **EMC CELERRA FAST (Fully Automated Storage Tiering) SOLUTION:**

### **What is it?**

→ Celerra FAST is a “solution” based on File Tiering (aka archiving) using the Rainfinity FMA (File Management Appliance) policy-based file utilization engine, Celerra FileMover API, and various Storage tiers as potential ‘resting places’ for inactive/unimportant data

→ Celerra FAST is based on file archiving (Marketing prefers the term ‘tiering’ vs. ‘archiving’), whereas CLARiiON FAST is block-based, using CLARiiON LUN migration technology

**Note:** There are potential DUDL scenarios here, since any LUN not using the Celerra/CLARiiON LUN naming convention (5.6.39+), risks being migrated under the CLARiiON FAST solution

→ Celerra FAST is not technically tied to the NAS 5.6.47 release, or even FMA 7.3, but for Marketing/Sales/Program Mgmt reasons, is being rolled out as a “solution” based on CMR10 & FMA 7.3 or FMA/VE ESXServer 3.5, via Direct/Channel Express

→ Celerra FAST is not customer-installable

→ Celerra FAST can be viewed as either ‘drive-based’ or ‘platform-based’ tiering

### **Why use it?**

→ Reduce costs--companies find it difficult to keep up with ever-expanding storage needs and costs, and see automatic storage tiering solutions as a way to ease the management costs and reduce capital expenditures

→ Create operational efficiencies--Tiering strives to optimize storage usage (hence costs) by keeping the most “active” data on the more expensive Primary Storage tier, while moving less active data to lower cost tiers. Tiering can reduce backup times and reduce administrative costs because it’s automated.

→ Improve service levels--Besides optimizing storage usage, Tiering can improve service levels & performance for important applications

### **How does it work?**

#### **Example:**

→ The Primary storage tier might be hosted by Celerra on EFD flash-drive luns. Using FMA File Archiving policies, along with file matching rules (access & modification times, size, filenames and/or extensions, etc.), filesystems are scanned, and files are moved first to a Secondary storage tier (FC drives), and then using Multi-tiering file & stub policies, with additional file matching and archive destination rules, files are moved again to a final Tertiary storage tier (SATA drives).

→ Consideration of various Celerra features needs to be taken into account, such as Deduplication (Secondary tiers only), File Retention for stub protection, Celerra PAX NDMP backup, Celerra Snapsure, & IP Replication.

→ The Celerra FAST solution is based on FMA 7.3, and involves the archiving (using FMA) of aging/inactive data from the high-cost Primary Tier to lower cost Secondary (FC Drives) and/or Tertiary (SATA drives) tiers, which could be Celerra, Centera, Windows, NetApps, or Atmos targets.

→ Celerra FAST is a linear solution going in one direction only (Highest to Lowest cost tiers). CLARiiON LUN-based FAST is also a one-way migration, but uses NaviAnalyzer tools to find “hot” lun candidates to migrate from FC to EFD drives, or “cold” luns from FC to SATA drives. Symmetrix FAST is bi-directional, and moves volumes back and forth from different drive tiers, as required.

### **File Retrieval Behaviors:**

→ With Celerra or Data Domain secondary or tertiary storage, file retrievals are ‘in-band’, meaning that the FileMover API handles the recall of files to Primary Celerra storage

→ With Centera or Atmos as secondary or tertiary storage, file retrievals are “out-of-band”, meaning that it requires the use of the FMA to retrieve the files

### **Celerra FAST Components:**

Celerra FileMover API (NAS 5.6.47)

Rainfinity FMA version 7.3 or FMA/VE version 7.3

Primary, Secondary, and optional Tertiary Storage tiers

**Note:** Tiers involve Primary Storage on Celerra, and archiving to other tiers [Celerra, Centera, Atmos, Windows, NetApps]

### **Planning Considerations for using FAST:**

Dataset should involve large files (stubs are 8kb, so >than 8kb for archiving)

Dataset should have a reasonable number of inactive files (if all files were active, solution would not work)

Be aware of FMA archive file limits (75 or 250 million)

Select a migration strategy & backup methodology

Determine single cabinet or multi-cabinet solution

NFS supports only single Tier archiving, CIFS supports multiple tiers

### **Migration Best Practices:**

--Single Tier Migration involves copying dataset to Primary Tier, then archiving in chunks to the Secondary Tier

--Multiple Tier Migration involves copying dataset to a temporary location, archiving from that location, then copying the remaining files and stubs to the Primary Tier using FVA, or some other stub-aware migration tool

### **Backup Best Practices:**

--Backup complete dataset using automatic passthrough reads so as not to “recall” files from Secondary tiers

--Backup Primary and Secondary Tiers separately using stub-aware backups

### **Replication Best Practices:**

--Replicate Primary and Secondary Tiers to separate destinations as independent sessions to better protect stubs and all the data

### **Overall Celerra FAST Best Practices:**

→Use NAS 5.6.47

→If using IP Replication in the environment, consider using ‘delayed stubbing’ policy with FMA in order to let Replication complete to the Destination before stubbing files on the Source

→If using IP Replication, consider replicating Primary Tier and Secondary Tier to separate locations to maintain stubs and content

→If stub protection is required, use File Retention and FMA Retention policy on file systems

→Consider using automatic file system extension in combination with Virtual Provisioning and Deduplication (the latter two on Secondary tiers only)

→Single Tier Migrations involve copying dataset to Primary tier, then archiving in chunks to Secondary tiers

→Multiple Tier Migrations copy dataset to a temporary site, archive from that site to a Secondary tier, then copies remaining files & stubs from temp site to the Primary tier using stub-aware migration tool

→Use Backups with auto passthrough reads so as not to “recall” files from Secondary tiers, or Backup Primary & Secondary tiers separately using stub-aware backup

#### **Other Information:**

→FMA accesses Celerra FileMover service using TCP port 5080

→Stub files reside on the Source Tier, and would be updated by the FMA engine as the file contents are moved from Tier to Tier

→When Retention Periods are used with files (WORM), stub protection is offered with NAS 5.6, preventing Stub files from being accidentally deleted or modified (FMA 7.3 only supports stub retention with NAS 5.6 Celerra to Centera archiving)

→Primary Storage Tier space requirements would need to support “active” files + 8kb Stub files used in the tiering process

→Celerra Deduplication is recommended for use with the FAST solution, but only for Secondary or Tertiary storage tiers, not on the Primary storage tier

→NFS files only support single Tiering, whereas CIFS supports Multi-tiered FAST

→With Rainfinity FMA version 7.3 (Q4 2009), Celerra FAST is a multi-tiered storage solution that consists of Celerra, Atmos, Centera, or Windows storage in a variety of Tier A, B, or C configurations

→While Centera or Atmos can be in Tiers B or C, further archiving cannot be done from them, only to them, so they are endpoints

**Note:** In otherwords, there is only a 3<sup>rd</sup> Tier if Celerra is used for Tier A and Tier B. If Centera or Atmos were in Tier B, there would be no Tier C. Celerra filermove is what pushes/pulls files from Tier to Tier.

→Solution leverages EFD, FC, and 2TB SATA drives, as well as NAS Deduplication feature

→Solution uses Rainfinity FMA and FMA/VE policy engines

#### **RAINFINITY FMA 7.3 & FMA/VE (ESXServer 3.5):**

##### **How does it work?**

→The FMA policy engine basically walks through the source file system to identify files to archive, and/or stub files to relocate. Files that match defined rules and policies will be archived to the desired location. Stub file offline locations are compared to a destination rule, and moved if the path differs from the rule. The offline path in the stub is then updated with new destination path, FMA database is updated, stub file is updated, and previous location of file data is deleted

→Rainfinity File Management uses a GUI to Configure storage platforms (Celerra, Netapps, Centera, Windows, Atmos), create Policies and file rules to perform archiving, and a Schedule function to setup tasks to execute policies at scheduled times, or on-demand, either as a Simulation or actual archiving. There is also an Archived Files function to view Simulated or archived files by list or by log activity

→Raininfinity also employs a CLI capability

→Stub files always reside on the Primary Tier. Stub files would be updated if the file contents were migrated from Secondary to Tertiary tiers, and then after a delay period, the previous file content’s location would be deleted

→FMA also allows the ability to migrate an entire archive set (Repository) from one tier to another

##### **Other Information:**

→FMA 7.3 supports a new policy called “multi-tier” archiving—file matching rules & archive destinations are used to relocate data across multiple tiers (e.g., Tier 1 Primary Storage, Tier 2 Secondary Storage, Tier 3 Tertiary Storage), scanning both files and stubs

→FMA 7.3 supports a new policy called “multi-tier stub policy”—this policy scans only stub files from already archived files (via the stub files located on the Source), and then migrates data from Secondary to Tertiary tiers

→FMA 7.3 uses a new “simulation” feature to evaluate the effects of a policy—essentially runs a real-time scan with reporting, without actually executing archiving [Previous feature was “preview” which only did this against snapshot metadata, not real-time]

→FMA 7.3 can migrate a NAS repository (Secondary archive tier) to another Tier NAS, Centera, or Atmos repository

→FMA 7.3 supports archiving using NAS 5.5 or 5.6

→FMA 7.3 now supports delayed stubbing when archiving from NAS to NAS—this would be used in situations where the archived tier was also being replicated to another Celerra location. Purpose of the delayed stubbing would be to not actually create the stub file on the Source system until Replication has completed. The idea here is that if the Archive Celerra were to become unavailable before Replication finished, the data itself would be orphaned.

→FMA 7.3 supports stub retention when archiving from Celerra running NAS 5.6, to Centera only

→FMA 7.3 supports Orphan and Stub delete policies that can be run Daily, Weekly, Monthly, or as Scheduled

**Note:** An orphan file is a file on Secondary storage without a stub file to reference it. Orphan files are identified via stub scanning. Orphans can be set to be automatically deleted, or in the case of Retention Files, deleted only when retention period has expired.

→FMA version 7.3 also allows the use of a single set of credentials for callback operations for all Celerras, rather than the previous requirement that each Celerra to have defined IP addresses (called IP Filtering)

→FMA archiving is based on file matching expression policies that are initiated by Request, Schedule, or Capacity triggers

→FMA 7.3 supports Atmos as an archive destination using Atmos API REST to write or recall data

**Note:** Atmos is EMC's cloud computing solution. Cloud computing is a model delivering convenient, on-demand network accessed to a shared pool of resources that are centrally managed but globally available.

#### **FMA 7.3 LIMITATIONS:**

→Windows 2003/2008 support is limited to only NTLM, no Kerberos, and no SMB Signing support

#### **How does a multi-tier archive policy work?**

1) FMA walks file system to identify files to archive, or stubs to relocate, based on defined policies

2) If a stub matches a rule, offline path is compared to archive destination in the rule. If it matches, nothing happens. If it does not match, then the archived file is copied to new destination. If a file matches a rule, it is archived to the destination specified, and the source is replaced with the stub file.

3) Offline path in the stub is updated with the new destination and in the FMA database

4) Location of archived file is deleted after specified delay period

#### **FMA 7.3 vs. FMA/VE 7.3:**

→FMA supports Celerra or NetApps at Primary Tier, FMA/VE only supports Celerra

→FMA supports Celerra, NetApps, Windows 2003/2008, Centera, or Atmos at the Secondary Tier, FMA/VE supports only Celerra/Centera

→FMA supports Celerra, NetApps, Windows 2003/2008, Centera, or Atmos at the Tertiary Tier, FMA/VE supports only Celerra/Centera

→FMA 7.3 increases file limit from 200 to 250 million, and FMA/VE 7.3 increases file limit from 50 to 75 million

#### **FMA SOURCES:**

Celerra and NetApp systems

#### **FMA TARGETS:**

Celerra, Centera, NetApp, Windows 2003/2008, Atmos

#### **FMA/VE SOURCES:**

Celerra

#### **FMA/VE TARGETS:**

Celerra and Centera

#### **FMA 7.25 vs. 7.3**

| <b>FMA Version 7.25</b>             | <b>FMA/VE Virtual Edition</b> | <b>FMA</b>                                |
|-------------------------------------|-------------------------------|---|
| Single Tier                         | VMWare ESX 3.5 + SW           | FMA 2U HW appliance + SW                  |
| Sources                             | Celerra                       | Celerra, Netapps                          |
| Targets                             | Celerra                       | Celerra, Netapps, Centera                 |
| File Limits                         | 50 million                    | 200 million                               |
| <b>FMA 7.3/VE (Virtual Edition)</b> |                               | <b>FMA 7.3</b>                            |
| Platform                            | VMWare ESX 3.5 +SW            | FMA 2U HW appliance + SW                  |
| File Limits                         | 75 million                    | 250 million                               |
| Sources                             | Celerra                       | Celerra, Netapps                          |
| Targets                             | Celerra, Centera              | Celerra, Netapps, Centera, Atmos, Windows |

**Notes:** Centera & Atmos are final tiers, data cannot be tiered from them. FMA 7.3 supports archiving from 5.5 or 5.6 Celerra. FMA 7.3 is a multi-tiering solution, whereas 7.25 is single tier only

#### **EMC File Management Appliance--FMA Version 7.3.1 'Denver':**

→One of the main purposes of this release is to bring FMA/VE into parity with capabilities of FMA

→The 'Rainfinity' name is officially dropped with this release

→Adds support for NetApp as an archive source FMA & FMA/VE

→Adds Data Domain, Windows, and NetApps as archive targets for FMA & FMA/VE

→Adds Data Domain as a NAS Repository

→Adds support for 250 million archived files for FMA/VE (from 75 million with 7.3)

→Adds support for (4) virtual CPUs (from 2 CPUs)

→Adds virtual support for 500GB HD (from 150GB)

→Support for NetApp OnTap 7.3 pass-through recall in FMA and FMA/VE editions (did full recall of files prior to 7.3)

→Data Domain is treated as a standard NFS archive, and NFS NAS Repository

→Data Domain supports stub management, orphan deletion, multi-tiering, and NAS migrations

→Adds support for NetApp as a (OnTap 7.3) source for Atmos destination archive, with full & pass-through recall support

→Provides upgrade path from FMA to FMA/VE

#### **TARGET SYSTEMS SUPPORTED BY 7.3.1:**

Celerra; Centera; Atmos on Premise; DataDomain; NetApp; Windows

#### **SOURCE SYSTEMS SUPPORTED BY 7.3.1:**

### **FMA Version 7.3.2 ‘Durango’:**

- Main enhancement will be the ability to convert DX/NAS stub files to FMA stub files without requiring recall
- DX NAS version 3.1 will use a Windows FileWalker executable to convert stubs one file system at a time
- DX NAS conversion does not support Deduplication or File Retention features
- Support for Atmos OnLine solution
- Supports Gen5, Gen6, & Gen7 hardware platforms

### **RAINFINITY FMA RULES:**

- Archiving based on Last Accessed Time, Last Modified Time, File Size, File Name/Extensions, High Watermarks
- Scheduling based on Now, Daily, Specific Day/Time of Week/Month, Once at future Day/Time, When capacity threshold reached
- Delete policy for orphaned files and when archived files retention period expires

### **RAINFINITY FMA/VE HIGH AVAILABILITY:**

- requires Virtual Center Server
- requires cluster of ESX servers
- requires NFS, iSCSI, or FC SAN Shared Datastore

**Note:** Virtual Center would monitor the ESX Servers and failover all VMs to another ESX Server if there was a problem, which requires that the datastore be shared among the ESX servers

### **Celerra FAST Best Practices:**

- Do not use deduplication on the primary tier
- Do not use the automatic file extension feature on the primary tier
- Disable Read recall policy on the primary tier and limit the age of snapshots
- Enable deduplication on Secondary tiers, with accessTime and modificationTime parameters disabled, set to 0
- Enable virtual provisioning on Secondary tiers, and allow space for disk growth
- Enable automatic file extension on Secondary tiers
- Delete orphan files from Secondary tier after 30 days
- Disable client access to Secondary tiers
- When possible, implement FAST solution first, then setup IP Replication between systems
- Celerra stub files can be read using /nas/tools/dhsm/get\_attributes

```
$ /nas/tools/dhsm/get_attributes -u rsadmin -p Stud3nt123 -w server_2 '/podE/LICENCE.TXT'|egrep
```

```
"WORM_STATE|RETENTION"  
    WORM_STATE="Worm"  
    RETENTION="1259176994"
```

### **IP Replication Recommendations for Celerra FAST:**

- If using IP Replication, the recommendation would be to have separate replication Sessions for Primary and Secondary tier file systems to protect the content on both Primary & Secondary tiers

### **Backup Recommendations for Celerra FAST:**

- The primary recommendation would be to backup the source file system using automatic passthrough Reads so that archived files from other Tiers are not recalled to the Primary tier (read\_pass\_through, which is the default anyways)

**Note:** Full restores, however, could be problematic as they would restore active and contents of the stub files to the Primary tier, which would likely exceed its capacity. Another disadvantage is that the backup window is larger since it must backup everything.

- If backup Windows are a big concern, could use a stub-aware backup solution to backup Primary & Secondary tiers separately, though this introduces special considerations when doing Restores to ensure that stub files retain proper links to the secondary tier.

### **Case of the orphaned file when using SnapSure:**

1. Create file\_1 on primary file system, then archive to secondary tier file system, which leaves source file\_1 as a stub file
2. Run a Snapshot of the primary file system, then delete the Stub file for file\_1
3. Create file\_2 on primary file system, then archive to secondary file system, which leaves stub file\_2 on source
4. Run FMA multi-stub policy to update stub files, and file\_1 will be listed as orphaned
5. Restore snapshot taken in step 2, run stub scanner update, and now file\_1 will show as archived, while file\_2 will be orphaned (since the snapshot restore overwrote the file\_2 stub)

**Note:** One of the points of this exercise is to show that file\_1's data does not get deleted just because the stub is deleted, hence it is accessible after the checkpoint restore

### **CLARiiON FAST LUN MIGRATOR (aka FASTLite, FAST I) Q4 2009:**

- FAST LUN Migrator is a feature which can identify and migrate LUNs that can benefit from Storage Tiering
- Migration scenarios are for moving Hot LUNs to EFD drives, or Cold LUNs to SATA drives
- CX4 platforms running FLARE 29 for LUN migration (though Flare 28 can do the lun analysis)
- Requires FAST LUN Migrator tool installation on a Windows platform, and a FAST LUN Migrator Enabler UPF install package on the array
- NaviAnalyzer and NAR archive files are used to generate the report of “Hot” and “Cold” luns for recommended migration. From the list of recommended LUNs, the CLARiiON FAST LUN Migrator tool will then automatically move luns to either a higher performance drive (EFD) for ‘Hot’ luns, or to archival drives (SATA) for ‘cold’ luns—outputs to XML and CSV

**Note:** Analysis Phase (Windows Host) & Migration Phase (CLI)

→LUN migration recommendation list must be edited to add destination RAID Group, and is used by the Migration Utility as an input file to actually perform the migration

**Note:** The User must kick off the actual migration

→CLI only for the migration piece

# fastlunmigrator lunanalyze <narfile> | fastlunmigrator –address <IP\_addr> lunassist –start –file <LUNID\_RGID\_list> -rate low | medium | high | asap | -cancel | -status

→CLARiiON FAST LUN Migrator tool will exclude LUNs with name “Celerra” from the report and .csv file. During migration, will also check and exclude any luns with name “Celerra” in the .csv input file

## **COMPARISON OF EMC FAST SOLUTIONS:**

### **CELERRA FAST:**

→Handles file-based migrations only, using Rainfinity GUI or CLI (create policy, defined rules, save policy)

→Demote across EFD, FC, or SATA drives on Celerra, Centera, or Atmos with Rainfinity FMA 7.3

→Archiving is one-way, from EFD to FC, FC to SATA, EFD to SATA

### **SYMMETRIX FAST:**

→2-way migrations allowed

→Handles Volumes for Mainframe CKD or FBA Open Host LUNs using SMC or CLI interface

→Can Promote or Demote luns (Bi-directional) across EFD, FC, or SATA drives

→Symm FAST supported with Celerra CMR11

### **CLARIION FAST:**

→1-way migration only

→Uni-directional LUN-based migration using CLI

→Not fully automatic, input file of lun candidates required to run the migration

→Migrates “Hot” luns from FC to EFD, and “Cold” luns from FC to SATA

→CLARiiON FAST will not recommend Celerra LUNs for migration if Celerra LUNs follow the 5.6.39 naming convention: e.g.,

[Celerra\\_sleet-120\\_17\\_d8](#)

### **CELERRA FAST:**

→1-way multi-directional tier-to-tier migration

→Uni-directional file-based migration, using Rainfinity FMA 7.3 GUI/CLI

→Demote files across Celerra, Centera, Windows, Netapps, or Atmos tiers

→Archiving is intended to be one-way

→A single Celerra cabinet solution might consist of EFD to FC, FC to SATA, or EFD to SATA archiving [marketing prefers the term ‘tiering’]

## **CELERRA and VMWARE**

→ESX Server is a physical platform that hosts the ESX Server and Virtual Machines (Guest Operating Systems)

→ESX Server can boot from a local drive or from iSCSI LUN or FC LUN on a storage array

**Note:** Requires installation of iSCSI or FC HBA on ESX

→VMWare Virtual Machines are instances of Operating Systems running in a virtualized environment on a single physical computer, usually one installed with an ESX Server. The physical machine is represented by software, with virtual RAM, CPU, NIC, Disks.

→The ESX Server abstracts processor, memory, storage, and networking resources for use with Virtual Machines (Virtualization)

→ESX Server installs a hypervisor layer as the virtualization layer which interacts directly with the underlying hardware on behalf of the subsequent Guest VMs or OSs that are installed later

→VMFS are high performance cluster file systems for ESX, defined by a set of encapsulated files, and stored on physical disks and partitions

→VMIInfrastructure Client used to connect to ESX Server, and also within the Virtual Center framework for multiple ESX Servers

→Virtualization allows one to install & run multiple O/S’s on a single hardware platform as VMs, and transfer the VM from one ESX Server platform to another

→An ESX Server sees each VM as a compilation of files (configuration file, virtual disk file, NVRAM Bios file, Log file)

→VMs do not directly access the underlying hardware

→Another method of using Virtualization is to use Host-based operating systems to install the VMWare Server or Workstation environment, which requires that the underlying ‘Console OS’ be installed first (Linux, Windows, etc)

→Datastores identify the specifics about the Storage that is being used by each VM machine

→Datastores can be created as NFS, iSCSI, or FC SAN Shared Datastores

## **OPTIMIZING VMWARE ESX SERVER WITH CELERRA**

→Celerra supports VMWare for CIFS, NFS, iSCSI, or FC protocols

→VMFS (Virtual Machine File Systems) are used to create the Datastore for the particular protocol to be supported

→Celerra recommends aligning VM storage partitions to 8kb tracks when using Block-based storage (iSCSI) for Windows VMs

**Note:** Partition Starting Offset would be set at 65,536 bytes—do not use 64kb alignment for NFS

→Use uncached option for Celerra file systems for NAS environment if IO is random and mixed workloads

**Note:** Server mount option “uncached”

→Consider disabling Celerra prefetch for NFS random and mixed workloads

**Note:** Server mount option “noprefetch”

→Use a hardware iSCSI HBA on the ESX Server for Celerra iSCSI if using sequential workloads (otherwise software iSCSI fine)

### **INSTALLING ESX SERVER ON CELERRA iSCSI LUN:**

1. Install the iSCSI HBA software (Qlogic)
2. Boot system and enter HBA BIOS to obtain HBA’s IQN name
3. Create Celerra file system; iSCSI Target; iSCSI LUN; iSCSI LUN Mask; Configure access to IQN name of HBA iSCSI Initiator and iSCSI LUN number; Configure CHAP; Enable iSCSI service on Data Mover
4. Configure iSCSI HBA in BIOS for IP address, mask, gateway; CHAP name and password; Target iSCSI Name, IP Address, and Boot LUN; set adapter boot mode to manual; reboot the system
5. Enter system BIOS and set iSCSI LUN to be the first Boot device
6. Install ESX Server onto the iSCSI LUN (iSCSI device driver is on the VMWare ESX install disc)

**Note:** MaxRequestHoldTime should be set to 600 seconds on Windows clients to tolerate Celerra reboots/failover

### **INSTALLING ESX SERVER ON CELERRA FC LUN:**

1. Install FC HBA software
2. Boot into QLogic BIOS and configure to boot from the FC LUN; set boot mode to manual; reboot system
3. Create RAID Group, Bind LUNs, assign to Storage Group; add ESX Hostname & Control Station IP to register
4. Reboot Host ESX system and enter HBA BIOS and select FC LUN as primary boot device, noting WWPN
5. Enter system BIOS and set iSCSI LUN to be the first Boot device
6. Install ESX Server onto the FC LUN

→The above ESX installation procedures are rough and untested, and are probably not completely in the correct order

### **VMWARE CELERRA PLUGINS:**

#### **ECM Celerra VMWare View Deployment Plug-in:**

→NAS 5.6.42, ESX 3.5, Virtual Desktop Manager 2.1 or VMWare View 3.0, plugin installed on Windows 2003 SP2 VDI Installation Server

#### **EMC Celerra VMWare vCenter SRM Failback Plug-in:**

→vCenter Server 2.5, VI Client, Site Recovery Manager Server with Site Recovery Manager 1.x & EMC Celerra Replicator Adapter 1.0

#### **EMC Celerra Plug-in for vCenter:**

→NAS 5.6.48 plug-in for provisioning NFS datastores, performing fast or full clones of VMDK files, compressing or uncompressing VMs in NFS datastores

→Install plug-in on a vSphere Client

**Note:** See 5.6.48.7 CMR11 section for more details

### **EMC ATMOS COS, Revision 1:**

→GA March 2010 using Dell R610 Server, Titan 40U or 44U (Dense) Racks, SAS ports, 1TB 7200rpm or 2TB 5400rpm drives

### **CSA CPW (CELERRA PROVISIONING WIZARD) (5.6.43.x CMR6):**

→Powerlink release is targeted for Feb 2009 as 5.6.43.84, Internal EMC and Partners only for first release

→CPW to be integrated into the NAS code branch for CMR9 release (July 2009)

→CSA\_CPW will support NX4, NX4FC, NS20, NS40, NS-120, NS-120FC, NS-120iS, NS-480, NS-480FC, & NS-480iS systems

→Designed as GUI wizard for Customer, Partner, EMC basic implementations

→Provides for CIFS Share & iSCSI Lun creation and attachment to Host, and NFS Export

→Adding storage provisioning capability to CSA tool in support of CIFS, NFS, iSCSI deployments

→Presents an “Install” and “Configure” button on CSA Welcome screen (Install button would be for new install configurations, while Configure button would represent the new CPW provisioning functionality)

→Includes ability to configure several different High Availability configurations for Network Interfaces (FSN, LACP, EtherTrunk)

→Provisioning tool is Host independent and can be initiated from any number of Hosts, multiple times

→Wizard will include context-sensitve Help and ToolTip hover messages

#### **Version Requisites:**

→Systems running NAS 5.6.40 or higher can use the provisioning functionality of the CSA

→Systems running NAS 5.6.39 can run the 5.6.43.84 CSA, but provisioning would not be available, only the Install function

#### **CLASSIC CSA 5.6.43 vs. CPW\_CSA 5.6.43.84**

##### **5.6.43.9 Classic CSA-Powerlink:**

Supports NX4, NS20, NS40, NS-120, NS-480, & NS-960 platforms

This version CSA will support NAS 5.6.40.3 -- 5.6.43.8 NAS Installations on the above platforms

##### **5.6.43.84 CPW CSA—Powerlink, EMC & Partners only:**

Supports NX4, NS20, NS40, NS-120, NS-480 platforms

Supports NAS 5.6.39.5 -- 5.6.43.8 NAS Installations, but only on the above platforms

Supports NAS 5.6.40.3 -- 5.6.43.8 for Provisioning, but only on the above platforms

#### **Other Questions:**

--Either version of CSA can be installed on Windows 2000, 2003, XP, & Vista clients

--Either version of CSA can be used on the branded Dell NX4

#### **CPW BACKGROUND:**

--The Celerra Startup Assistant has been in use now since the introduction of the NS20 in August 2007

--CPW came about for growing need to have tools available for customers & partners to implement Celerra outside of PS

--“Celerra Provisioning Wizard” (CPW) is the name of the enhanced functionality/wizards that have been incorporated into the CSA

--Not considered a complete implementation tool, but geared towards basic storage provisioning, NFS, CIFS, & iSCSI configurations

--The 5.6.43.84 version of CSA is posted on Powerlink, and will support NX4, NS-120, NS-480, NS20, & NS40 systems running NAS 5.6.40 to 5.6.43, limited initially to Internal EMC & Partners use

--The 5.6.45 release integrates the CSA with CPW capability into the regular NAS release cycle, and is qualified for use with NX4, NS-120, NS-480, NS20 & NS40. Original intent was to also support NS-960, but this has moved out to the 5.6.47 release.

--Unlike earlier CSA versions, provisioning capability can be run on any qualified Windows client, repeatedly, as the tool is re-entrant

--Provisioning capability to be formally integrated into the NAS 5.6.46 release [i.e., CMR9] for use by all on platforms that qualify

--Presents new “Install” and “Configure” buttons on CSA Welcome screen

--“Install” functionality the same as the original CSA, intended only for initial configuration & setup of factory pre-configured install

--“Configure” functionality is the new provisioning piece, 4-wizards available after logging into Celerra CS

#### **CSA CPW GUI Look and Feel:**

The application launches the same way as before, but now presents two options on the “Welcome to the CSA” screen: Install & Configure

**Install** →Select this to perform the traditional CSA discovery and basic configuration of a new Celerra system

#### **Basic flow for Install:**

Install flow is similar to current behavior, with Welcome and Initialization screens to discover and select the Control Station MAC address; to input Control Station hostname and IP; option to change system passwords; configuring various network settings and IP addresses for SPs; ConnectHome and Email User feature setup; license screen; Cable Check Healthcheck; Pre-Configuration apply for Proxy ARP and setting backend IPs, and committing configuration changes, including password changes; MPFS Initialization screens if the system is detected as an iSCSI model, where IPs are assigned to iSCSI ports on the SPs and the MPFS service is setup on Server\_2; Select a wizard screen and option to skip wizards and “Register the system”; followed by all the relevant steps to perform the Registration of the Celerra.

**Configure** →Select this option anytime after the initial “Install” and system “Registration” are completed to run Provisioning or implementation wizards. The purpose of this option is to perform system setup for production. The wizard can be run any number of times from any number of different Windows Hosts.

#### **Basic flow for Configure wizards:**

Select the Configure option on the Welcome to the CSA screen>Log in to the Celerra>Select a Configuration Wizard (Provision unused disks; NFS; iSCSI; CIFS; Celerra Manager).

#### **Provision unused disks:**

→Storage Provisioning screen basically presents information on the Celerra system and provides a choice between Express vs. Custom modes. The main difference between Express vs. Custom are the choices available for building R5, R6, or R1/0 system pools.

**Express Mode:** Defaults to provisioning all available disks in a “Capacity” clar\_r5\_economy system pool, though there is an option to select RAID 6 for additional Raid protection (clar\_r6).

**Custom Mode:** This mode allows a User to reserve disks for later configuration. It also allows a combination of two of the following three configuration types: Capacity (clar\_r5\_economy), Protection (clar\_r6), and Performance (clar\_r6). You can select either one or two of the configuration types at a time.

#### **Create NFS export:**

→Use this wizard to select a Blade, select a network device or create a new IP address or configure an HA interface configuration, designate a name for the export (becomes file system and mountpoint name), select the desired storage pool, file system export size, and whether the export is exported to RO, RW, or Root Hosts, etc.

#### **Create/Attach iSCSI LUN:**

→Use this wizard to select a network device, create a new IP or HA configuration, create and attach a new iSCSI LUN to an existing or remote Host, attache an existing iSCSI LUN to a Host, select Blade and target name (iSCSI LUN name), selected desired storage pool, lun size, etc.

**Note:** If getting iSCSI attach failure errors in the CSA, make sure the Client system is running the latest version of the MS iSCSI software initiator (version 2.08). See emc207977. Check startup\_wiz.log for more information on attach failure.

#### **Create/Attach CIFS share:**

→Use this wizard to select a network device (or create new IP/HA configuration), create CIFS share and attach to local Host, or attach an existing Share to a Host, enter Blade name, Storage pool, Share name (file system name) and size, local drive number to use, and whether to use an existing CIFS Server or to create a new CIFS server (which involves screen to enter Compname, Domain FQDN, DNS IP addresses, Domain Admin and password, whether to enable Local User support, and option to select a specific interface IP.

**Open Celerra Manager:**

→Strictly an applet to open up Celerra Manager

**Wizard Choices (Select a wizard screen):**

**Provision unused disks**

**Create NFS export (Unix/Linux)**

**Create/Attach iSCSI LUN**

**Create/Attach CIFS share (Windows)**

**Open Celerra Manager**

**GENERAL CSA/CPW LIMITATIONS:**

→Tool initially available only for EMC & Partners, not customers

→The tool only allows for a single CIFS Share or NFS Export per file system created

→The tool Exports or Shares the file system at the top level, which exposes the .etc and lost+found system directories, which is against best practices (emc208120/AR132379)

→No Summary Report page at the end of each logical operation, such as iSCSI Lun, CIFS Share, or NFS export (AR136153)

→No VDM CIFS support

→For CIFS Shares, you can only map drive letters and not UNC paths

→Cannot upgrade the CSA application (remove old, install new)

→Cannot resize the CSA window (difficult to use on laptops, etc.)

→Cancel button within wizards will close entire CSA application, not current operation. Only way to maneuver between wizards if not completing a wizard is to use ‘back’ button

→No Help menu available when using ‘Install’ CSA functionality

→Single iSCSI LUN per Target (cannot attach multiple iSCSI luns to one target—emc206712)

→NTP service configuration for server\_2 is provided as an option when running the ‘Install’ portion of CSA, but is not offered or enforced in the ‘Configure’ portion of CSA, and even if a CIFS Join were to be successful, without a proper NTP service configuration, the Data Mover time will drift and result in a future CIFS outage (emc206837)

→iSCSI wizard may fail due to incompatible MS Initiator version (latest version 2.08)

<http://www.microsoft.com/downloads/details.aspx?FamilyID=12cb3c1a-15d6-4585-befd1319f825&DisplayLang=en>

→Many iSCSI failure popup messages are not particularly helpful in leading the User to resolve the issue

**CPW Release Schedule for Powerlink Support:**

→Powerlink release scheduled for end of February 2009--UMPW will be later

**CSA/CPW FILES & LOGS OF INTEREST 5.6.43.84:**

**Logging on the Celerra Control Station:**

**/nas/log/cpw**

# ls -la

```
-rw-r--r-- 1 apache apache 778 Jan 29 11:05 CIFS_cifs_share_20090129111405.xml
-rw-r--r-- 1 apache apache 852 Jan 29 09:56 iSCSI_10.241.168.59_10.241.168.172_20090129100521.xml
-rw-r--r-- 1 apache apache 453 Jan 28 11:24 NFSEXPORT_dumble_20090128112059.xml
-rw-r--r-- 1 apache apache 837 Jan 28 15:02 PROVISIONING_123317265432404_168.159.16.45-20090128150142.xml
-rw-r--r-- 1 apache apache 2008145 Jan 29 10:43 startup_wiz.log_USCSMATTATL1C_168.159.16.45
```

**Note:** The above files are representative of logs created on the CSA Client when running the provisioning wizard. Specifically, whenever the CSA is opened, and the “Configure” option selected, all activity is logged in the startup\_wiz.log. Any of the CIFS, iSCSI, NFS, or PROVISIONING wizards will generate a separately named and dated file for the activity, which is then saved on the Client system and also transferred to the Control Station /nas/log/cpw directory using HTTP. Additionally, the startup\_wiz.log is renamed to include the CSA Client hostname and IP address.

**# tail /nas/log/provision.log**

```

### **CELERRA MANAGER CPW INTEGRATION (UMPW—Unified Manager Provisioning Wizard):**

- Functionality to be released with 5.6.45
- A separate qualification effort called UMPW (Unified Manager Provisioning Wizard) will bring CPW support into Celerra Manager
- Ability to de-provision LUNs, RAID groups, unused volumes, & spares via Celerra Manager for all platforms
- Ability to provision via Celerra Manager for NX4, NS20, NS40, NS-120, NS-480

### **CELERRA CLARIION ARRAY PRODUCTS:**

#### **CLARIION CLI's:**

Clariion uses a Java CLI (navicli.jar—discontinued Flare 26 release), a Classic CLI (navicli.exe—no longer installed by default beginning Flare 26), and Secure CLI (navisecccli.exe—Navi commands built on the latter as of Flare 22, introduced with Flare 19). Secure CLI replaces Java and Classic, outputs in XML, provides N+1 support, legacy Java & Classic support, security model, etc.

### **EMC CLARIION SOFTWARE RELEASES:**

#### **FLARE CODE VERSIONS:**

**Flare 7 →2.01** [first release to support CX200/400/600]

**Flare 11 → 2.04**

**Flare 12 → 2.05**

**Flare 13 → 2.06**

**Flare 13 → 2.06** [first release to support CX300, CX500, CX700]

**Flare 14 → 2.07**

**Flare**

→Patch 707 release Dec 2009, ECO for NAS NX4 is ECO70011; this version supports 4-port BOA FC IO module for CLARiiON, support for 2.5" SAS drives in same enclosure as 3.5" drives [2.5" SAS 10k rpm at 300GB & 146GB sizes], and support for 600GB SAS 15k rpm drives.

**Flare 24 → 3.24.x.5.x & 02.24.x** [Mars & Janus, CX3, CX300/500]. Mars supports CX [Fish CX300/500/700] and CX3 [Hammer] platforms, not AX, new 750Gb SATA II drives, ATA Drive map recovery, called Rebuild logging (NAS 5.5.26 Napa 5 release & 5.4.28.x). Flare 24 GA December 7, 2006. LUNS are now assigned to Global LUN pools until assigned to specific SPs—separate LUN folder in Navisphere; Support for iSCSI Jumbo Frames; Starting with Flare 24, SP access security can be managed by Navisphere Manager and an optional LDAP implementation through use of new LDAP/LDAPS login Scope, meaning that AD or LDAP can authenticate users. Classic NaviCLI Manager uses Global or Local Scope. Introduces Fast Bind of LUNs—luns are immediately available for use, though background zeroing occurs and may degrade performance til completed. Many TCE initiatives built into FLARE, such as simpler storage management, more wizard utilities, better pre-defined reports, capturing array configuration to XML file:

**# /nas/sbin/navisecli -h 192.168.1.200 arrayconfig –capture –output >/home/nasadmin/ex80\_template**

**SCOPE VALUES FOR SP LOGIN:**

Scope 0 Global

Scope 1 Local

Scope 2 LDAP

**# /nas/sbin/navisecli migrate –start –source 6 –dest 7 –rate low –user myname –scope 2 –password mypass**

**NAVISPHERE ROLES:**

Administrator; Manager; Monitor

**Note:** All 3<sup>rd</sup> Generation CX(3) platforms supported at this flare version

**Flare 26 →** Leo, GA Aug 31 2007, CX300/500/700 & CX3 arrays supported. CX200/400/600 not supported. Introduces RAID 6 to protect against dual drive failures in the same RG and media errors during rebuilds, etc.; implemented with even widths 4, 6, 8, 10, 12, 14, 16 only, with only one Proactive Spare allowed per Raid 6 LUN; Only navisecli supports creation of RAID 6 type; New Asymmetric Logical Unit Access (ALUA) failover mode without application involvement can allow access to LUN from all ports simultaneously; New security enhancements, Classic CLI filtering possible via Navi, but Secure CLI will become the default; Proactive sparing; NTPv4, etc. Supports IE 7.0, Netscape 7 & 8.0, FireFox 2.0; Minimum JRE 1.5; Introduces ability to add a “Security Administrator” role for administration in pure Flare 26 environments only—a Security Administrator can do everything except to see or bind luns, create mirrors, or install/update software; iSCSI Replication over MirrorView or SANCopy  
→Pisces patch release supports RAID 6 on AX4 array

**Note: Last flare version to support the 2<sup>nd</sup> Generation CX platforms, the CX300/500/700**

**Adding Security Administrator Role for User Secadmin with Global Scope:**

**# /nas/sbin/navisecli -user nat -password nat -scope 0 -address 10.241.168.149 security -adduser -user secadmin -password secadmin -scope global -role securityadministrator -o**

**# /nas/sbin/navisecli -user nat -password nat -scope 0 -address 10.241.168.149 security -list** (verifying entries)

**Disabling/Enabling ClassicCLI with Flare 26:**

**Note:** Flare 26 leaves ClassicCLI enabled by default, but provides the option to disable it

**NAVISPHERE:**

Navisphere>Arrayname>Rightclick and select “Enable/Disable Classic CLI” to enable or disable functionality on the fly

**USING CLI:**

**# /nas/sbin/navisecli -h 192.1.4.214 classiccli -disable**

Do you really want to disable Classic cli(y/n) y

ClassicCLI: Disabled Succesfully

**# /nas/sbin/navisecli -h 192.1.4.214 classiccli -status**

ClassicCLI ENABLED: No

**# /nas/sbin/navisecli -h 192.1.4.214 classiccli -enable**

Do you really want to enable Classic cli?(y/n) y

ClassicCLI: Enabled Succesfully

**# /nas/sbin/navisecli -h 192.1.4.214 classiccli -status**

ClassicCLI ENABLED: Yes

**# /nas/sbin/navisecli -h 192.1.4.214 classiccli -disable -o** [without prompt]

ClassicCLI: Disabled Succesfully

**Flare 28 →** Proteus 64-bit (mainly to address memory addressing limitations) Flare running on W2k3 to support new Fleet Clariion CX4 arrays, Nautilus, Ironclad, Trident, Dreadnought (New CX4-10 & replacements for CX3-20, CX3-40, & CX3-80, respectively), May 2008. Enhancements are Single SP Write Caching (GWCA—Greater Write Cache Availability—i.e., if an SP goes away, the other can still support Write Cache Enabled), Host I/O throttling to first five drives with queue depth ceilings, WWN port field bit allocation change, support for IPV6 with management module, Flexible I/O Ports—UltraFlex SLICs (FE or BE FC ports can be interchanged as needed—only fixed port will be port 0 on IO module 0, which is logical backend 0). NST will add a Flex IO Port

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Wizard. No Flare reversions possible, upgrades performed using Software Assistant. Management LAN ports now visible & configurable: networkadmin –get –all

**Celerra Support:**

Gateway models support Flare 28/Fleet beginning with NAS 5.6.39.5

NS-120 & NS-480 Integrated support introduced with NAS 5.6.41.2

NS-960 Integrated support introduced with NAS 5.6.43

**Flare 28 Mira Release—Flare 28.5:** GA December 8, 2008; 04.28.000.5.501 (factory)/.504 (download)

Patch release support for Virtual Provisioning (Thin Pools & Luns), Enterprise Flash Drives (EFD) 73GB for all Fleet arrays, and Data-In-Place Upgrades (DIP); 960-Drive Expansion Enabler for CX4-960; support for 400GB EFD (005048999)

Minimum NAS version 5.6.43

**Flare 28 Libra Release—Flare 28 ++ May 2009, 04.28.000.5.704 [ECO 67564 Flare 04.28.000.706]:**

Support for 4-port 8Gbps FC SLIC (Glacier card—303-092-100B) as a FRU

Minimum NAS version 5.6.45

**Note:** Arrays will now be able to support 1Gbps iSCSI, 2/4Gbps fibre channel on the backend DAE loops, and 2/4/8Gbps FC for Front-end hosts. SFPs between 4Gbps array ports & 8Gbps host front-end ports are different. Arrays still limited to 4Gbps internally.

**Flare 29 →Taurus release Aug 2009 (04.29.000.5.001); Update to CX4 series**

→New 2-port 10GB Poseidon iSCSI SLIC card support (requires optical SFPs, not RJ45 LAN ports as for 1Gbps iSCSI)

→Virtualization-aware Navisphere Manager

**Note:** Integrates with VMWare vCenter APIs to help manage virtual machines and storage resources. A free EMC Storage Viewer for CLARiiON download is available as a plug-in to vCenter to map logical and physical relationships between VMs and Storage

→Ability to change SP IP addresses without rebooting

→VLAN tagging for Management and iSCSI Clariion ports

→SPCollect improvements

→EMCRemote replaced with Remotely AnyWhere (RA)

**ESRS Issue:**

Per emc220481, ESRS DRM does not dynamically update its connection records, so Users must manually select the correct tool when connecting. In Oct 2009 the DRM will be able to dynamically update its connection records.

**RemotelyAnywhere Connection Options:**

- a) Connect to Navisphere /setup page and add IP address to RA filter list [Set RemotelyAnywhere Access Restrictions], then connect to SP IP address & Port 9519: [<sp\_ip:9519]. Use clariion1992 clariion1992 as username password. RA Dashboard page, select RA remote control feature to use. Use “clariion clariion!” as user and password to log into the SP’s Windows operating system.
- b) Use RA when connected to the SP’s LAN service ports [laptop set to 128.221.1.249/254 with mask 255.255.255.248]
- c) Use RA when connected to SP’s Serial port, IP address 192.168.1.2 [Start>Settings>Network Connections>New Connection Wizard>Set up an advanced connection>Connect directly to another computer>Guest>CIN1>Anyone’s use>Add a shortcut>Finish. Properties box, General tab>Configure>115200bps>close>Enter “clariion clariion!” for user and password>Connect. Use RA client.
- d) Connect to ESRS client, startup RCC client, enter storage serial number, search, highlight system, Connect, select SP, highlight RemotelyAnywhere, Request Session, Invoke Application or enter Target Connection IP of SP with Port 9519 specified. Enter clariion1992 clariion 1992 on RA authentication page, Login. RA Dashboard opens, select RA feature to use.

→NST/CUT Tool for Celerra

→SSD Phase 2 Support for SATA drives

→Virtual Server Integration for ESX support & VMWare ESX 4.0 support

→Virtual Provisioning Phase 2 (LUN shrink for W2k8 only) support for CLARiiON Replication applications using FC or iSCSI:

MirrorView/A; MirrorView/S; SANCopy (one time copies or ongoing replication between arrays)

→MView/A & S now support up to 64 members in a Consistency Group

→Thin LUNs supported Source or Target for MView, SAN Copy

→Policy-based Idle Raid Group SATA II drive spindown

→Adoption of ECOM Common Object Manager model for CIMOM & Web Services

→Integration of NST & Navisphere

→Support for Internet Explorer 8

→SLIC conversions

→Increased Initiator and LUN support

→Online drive upgrades

→Serviceability items

→RAID 6 rebuild logging

→New Navisphere roles for Local Replication Only, Replication, and Replication/Recovery

**Remotely AnyWhere (RA) Utility:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
RA replaces EMCRemote on CLARiiON systems, and is used to access the SPs. RA provides for IP Address Filtering, which means that all RA clients must be added to filtering table found on the /setup page in Navisphere. Default LAN Service IPs for RA-- 128.221.1.249; 128.221.1.254; and Serial RA IP address is 192.168.1.2.

## **LOGGING INTO THE SP USING REMOTELYANYWHERE (R29 +):**

- 1) Connect a LAN cable between a Windows client and SP A's Service LAN port.
- 2) Set the IP address and mask of the Windows client to 128.221.1.249 / 255.255.255.0.
- 3) Open a browser and access SP A's setup program: 128.221.1.250/setup.
- 4) Scroll down to the "Set RemotelyAnywhere Access Restrictions" button and add the Windows Client's IP address to the access list (e.g., 128.221.1.249), then "Apply Settings."
- 5) Close the browser, wait a minute, then reopen and try to connect to the RemotelyAnywhere service on SP B using "https": https://128.221.1.251:9519/
- 6) Enter the RemotelyAnywhere credentials:  
User Name: clariion1992  
Password: clariion1992
- 7) To the left of the screen, click on the "Remote Control" option and wait for the logon screen to appear.
- 8) Click on the "ctrl + alt + del" icon, then logon:  
Username: clariion  
Password: clariion!
- 9) Log off the SP using Start > Shutdown > Log off clariion
- 10) Log off the RA session by clicking the "End Remote Session" box, in red, at the top of the screen.

### **NST Changes:**

- Supports installation of 4 or 8GB FC SLICs, 1 or 10GB iSCSI SLICs
- DRU, Disk Firmware, and Disk Installation Utility now supports EFDs
- CLARiiON Software Assistant will automatically detect and notify users when Celerra system is attached when performing NDU
- New model designations with Poseidon 10Gb iSCSI modules: CX4-120C8X, CX4-240C8X, CX4-480C8X, CX4-960C8X

### **Flare 30 → Zeus will be a SW & HW release; last major SW release for CX4 arrays.**

- Introduction of low-end DPE (Zodiac) based on Magnum platform, supporting 6Gb SAS 2-port Coromandel SLIC card for communication & control with Viper DAE, supporting boot from SATA or SAS drives—hence BE support only; 3.5" Viper DAE with (15) 3G/6G SAS drives or SATA drives; 450GB 15K 3Gb SAS drives; 1.5TB/2TB SATA 3Gb drives; 300/450/600Gb 15k 6Gb SAS drives; 300/450/600 10k 6Gb SAS drives; 100/200GB SATA EFD drives with Chariot Paddle card to translate SATA to FC; ODFU—Online Disk Firmware Upgrade capability—basically, where drives have redundancy within a Raid Group, one drive will be upgraded at a time; SSPG support; Advanced SNAPS; Virtual Array; EFD Cache Phase I; TwinAx Passive cable support for 10Gb iSCSI as an alternate to Optical Fibre cables (SFF-8431 standard)

### **6Gb SAS IO Module Support:**

- Support for Coromandel 6Gb SAS 2-port SLIC for SP to DAE BE connectivity (SFP to mini-SAS connectors)

### **Viper DAE Support 15@3.5" Drives:**

- Supports SAS or SATA drives
- Requires (2) new 6Gb SAS LCC's per DAE

### **RAID 6 Parity Shredding:**

- When a RAID group is degraded, provides ability to write data to a parity position in the event of a dead drive. Data is copied back when drive restored from shed data position, and parity rebuilds

- Data integrity feature for RAID

### **LUN Auto-Tiering (FAST):**

- Allows for automatic migration of luns between EFD, FC, SATA drive types
- Based on hot vs. cold data on luns
- Tiers can be built on drive type, speed, capacity, and RAID type
- Requires installation of the auto-tiering enabler
- Auto-tiering works on lun analysis, review, and migration of luns  
navicli storagepool –autoTiering –list –tiers | -create –disks <disklist>  
navicli lun –list –l xx –tieringpolicy –initialtier –tiers  
autotiering –schedule –modify

### **Auto-Tiering LUN Framework:**

Zeus will provide an Enabler for Auto-tiering for LUNs within StoragePools, using a Default Schedule  
C:\>navisecccli –h <ip> autoTiering –modify | -info –state | -info –rate | on off (default) | -tierPreference bestFit

### **DLU Pool LUNs:**

- DLU pool Luns will replace typical Flare Lun in the RAID group as RAID 1/0 Pools
- DLU pool Luns can also be used as Clone Private LUNs, MView Write Intent Log Luns, & Reserved Luns
- Comprised of fully provisioned DLUs, presented as a pool of luns to customer
- Expand LUN capability for DLU & TLU's
- LUN Shrink capability for DLU & TLU's

**LUN Compression 1.6:**

- Uses Recoverpoint Algorithms
- Allows for compression of a LUN during migration to a Thin LUN target
- Use naviseccli compression -list | -on -l xx | migrate -list

**EFD Flash Cache:**

- New storage tier that will utilize EFD drives as write cache, resides between DRAM Memory & Disk Drives

**SATA EFD Support:**

- Based on solid state flash technology, 100 & 200GB sizes
- Formatted with native 520 byte block size
- Drive uses a Chariot paddle card to translate SATA II to FC protocol when used in FC DAEs

**Mixed DAE & RAID Group Drive Support:**

- Support for FC & SATA EFD drives in same DAE
- Support for FC & SATA EFD drives in same RG

**Navisphere Trusted Communications:**

- Current communication path uses SSL
- Revised communication path will use SSL to encrypt, but add Certificate Validation to ensure clients are Trusted

**Unisphere:**

- New GUI interface used for Clariion and Celerra system management, replaces Celerra Manager and Navisphere

**Unisphere Service Manager:**

- New name for NST
- Same look as Unisphere Service Manager
- Can launch USM from Unisphere
- Introduces Celerra CUT tool within the USM framework for upgrading NAS systems
- Intelligent Advisories (TAND)

**Online Drive Firmware Updates (ODFU)**

- Ability to upgrade drives one at a time within Raid Groups to minimize impact, hence “online”, though the upgraded drive itself is offline during the firmware update
- New wizard in USM

**VMware vStorage APIs for Array Integration (VAAI) Support:**

- Purpose is to offload work from the ESX Server Host to the Storage array by performing work directly on the array
- VMware Full Copy Acceleration enhancement for cloning of file blocks
- VMware ATS solution in clustered environments to alleviate multiple lock situations to single LU's
- Array Accelerated Zero; Array Accelerated Copy; Array Accelerated Locking
- EMC Storage Viewer application on vSphere Client has been renamed to Virtual Storage Integrator

**Backend Path Failure (BPF) Support:**

- Current behavior if drives are available from one SP, but not the other, is to have FLARE fault the drive
- New behavior is to allow drive paths to failover to other SP until the BPF situation is fixed

**EMC Secure Remote Support (ESRS 2.0) IP Client for CLARiiON:**

- Secure centralized 2-way connection from EMC to customer storage for remote management
- Consists of ESRS IP Client; ConnectEMC; Navicli; Unisphere Host Agent; EMCRemote
- Personnel connect via an EMC Service Link
- System with highest version of Flare serves as Portal system
- Other arrays in the domain will be auto-registered
- Auto-registration of devices with DRM (Device Relationship Manager)
- Automatic Capture and Upload (ACU) and Re-active SP Collects (RSC) will be enabled by default

**Misc. Enhancements:**

- Ability to support multiple logins between the iSCSI Initiator and Target (supports initiator's with multiple interfaces that use single IQN; booting from iSCSI Luns where BIOS retains connection to initiator; VMware MPIO support; Linux & Solaris login to all ports by default)

→Enhancement to SPCollect by grouping collection commands together for concurrency

**FLARE 30.5 →**Jupiter release. Provides SP support for 2-port FCoE module on CX4-120/240/480/960. Introduces FAST Cache Read/Write support for CX4-480.

**FLARE 31 →**SCORPION Release for new CX5 Fighters arrays

→Flare 04.31.000.5.xxx Hellcat lite, Hellcat, and Lightning arrays based on Sentry platform; 6Gb SAS backend; Viper 3.5" @ 15 drive SAS DAE; Derringer 2.5" @ 25 drive SAS DAE

**CX3 ARRAYS & FLARE SOFTWARE:**

Flare is installed on first (4) disks on backend loop 0

Disks 0\_0 & 0\_2 have mirrored copies of flare for SPA, Disks 0\_1 & 0\_3 have mirrored copies of flare for SPB

**CLARIION ARRAY PRIVATE SOFTWARE SPACE**

Clariion array uses the first (5) physical drives on the array for Private space, dedicated to a variety of databases, partitions, etc.  
 CX600 Fish family uses NT O/S for Flare, CX700 Fish family converts to XP O/S, Fleet will use W2k3 O/S 64-bit

**DECODING FLARE SOFTWARE BUILDS:**

**Example:** v02.04.0.60.5.005 [Flare Release 11]

Translation: v02 = 02 for 2GB Family; 04 = Minor Release Version, Release 4; 0 = SW Options, 0 = No Options 1 = AccessLogix; 60 = Hardware Identifier, 60 = CX600 (20=CX200; 40=CX400; 01=Chameleon2; 03=Longbow); 5 = SW Distr. Type, 5 = General Release; 005 = Build Iteration, 005 = SW Distr. Type >= 4

**CELLERRA/CLARIION FLARE vs NAS UPGRADE RULES:** (check eLab tables & emc203413)**GENERAL FLARE vs. NAS UPGRADE GUIDANCE:**

- See emc203413 for a Table that shows Flare vs. NAS compatibility for NAS 5.4, 5.5 and 5.6
- See CCA Guide for Flare Interoperability comments and guidance
- NX4, NS-120, NS-480, NS-960 systems use NST software assistant to perform FLARE NDU
- Older NS Integrateds (NS500, NS350, NS700, NX600, NS80, NS40, NX40G, NS20, NSX) should follow Celerra Procedure Generator guidance when upgrading FLARE with Celerra attached
- NST uses built-in FLARE Provider API for Rules Checking with Flare 23 and higher

**FLARE vs. NAS GUIDANCE IN NAS CCA GUIDE (Oct 2008):**

[http://3cgs.corp.emc.com/nascca/guide/nas\\_cca\\_guide.htm](http://3cgs.corp.emc.com/nascca/guide/nas_cca_guide.htm)

“The **number one rule** of FLARE / NAS Code interoperability is that **the FLARE can never be upgraded to a version that the NAS Code version doesn't support**. There are currently **NO** circumstances where this rule can be broken.”

**Example where one would upgrade FLARE prior to upgrading NAS, which does not break the above rule:**

“emc186425 - Do not upgrade or install NAS code 5.6 on a Celerra attached to a CLARiiON running Flare code version 24 Due to an issue specific to FLARE R24, the CLARiiON must be upgraded to R26 prior to upgrading the NAS Code to 5.6.”

**LEGACY UPGRADE RULES:**

1. General rule, upgrade NAS code first, then FLARE

**Note:** However, with Napa 5.5.26.4 Release, NAS code for CX Fish arrays will only support Flare 19 and higher, and for CX3 Hammer arrays, NAS 5 will only support Flare 22 and higher.

2. Previous CCA rules required (emc108354) that Celerra be offline before upgrading FLARE Code

**Note:** March 3, 2006 Clariion Online Update procedure released to allow NDU Upgrades with attached Celerra for NS & NSX systems only, with minimum Flare version 16, and NAS versions 5.3.23 ro 5.4.20 and above.

3. Likewise, always shutdown Celerra if adding ATA DAE or upgrading Flare with ATA drives involved
4. Upgrading from Flare 7/8 requires Utility Partition first, upgrade to Flare 11, then latest Flare
5. Prior to upgrades, verify that LUNs are not trespassed or in transition
6. Verify that there are no faults on the array, obtain resume information, run SPCollects and analyze, etc.
7. Install CAP2 program on laptop prior to upgrading array to Release 16

**Caution:** In Clariion world, NDU means that Array itself has valid failover software for SP's, meaning that upgrade occurs on one SP at a time, so whole system does not need to be down. Utility Partition is added to first four Fibre Channel Boot Drives [Vault Drives] and is meant to be used as a Recovery Image to recover from a corrupted boot image. As a general note, Clariion Procedure Generators are NOT specific-enough and do not unequivocally state that Celerra Servers should be offline during Flare Upgrades, though it does state that ATA chassis require all I/O to be halted. See Primus emc90820.

### **ATA DRIVES AND FLARE UPGRADES:**

- Stop I/O to array during NDU when ATA drives are involved
- Manually disable and zero write cache until update is complete

--Clariion rules state that ATA Chassis should have all LUNs assigned to one SP or the other, and not both

**Note:** FLARE upgrades include new firmware [FRUMON code] for LCCs on attached DAE and ATA chassis. The firmware upgrade on LCCs can cause loss of access to Array for Celerra Servers and is the ultimate reason for never performing an OnLine Flare Upgrade with Celerra. Primus emc93310.

### **ATA DRIVE ISSUES:**

- Clariion Flare upgrades should have Hosts offline if it involves ATA drives
- Clariion uses ATA in RAID 3 configurations only (Not Celerra)
- Drives have single port to backend via LCC card, as opposed to fibre channel, which has two ports to backend
- Flare 19 fixes major ATA drive issue with unrecoverable or invalid sectors being logged for bitflip problem

### **TRY NDU UPGRADE USING SKIPRULES SWITCH:**

**Note:** If you still encounter a failure, you may need to run the NDU Upgrade from the Off-Array SIW

**# /nas/sbin/navicli -h 10.241.168.57 ndu -install /home/nasadmin/flare19/FLARE-Operating-Environment-02.19.600.5.027.lst -skiprules -delay 360**

Item number: 0  
Name of the software package: FLARE-Operating-Environment  
Revision of the software package: 02.19.600.5.027  
Already Installed Revision 02.16.600.5.019  
Installable YES  
Disruptive upgrade: NO  
Ndu Delay: 360 secs

The requested package(s) will be installed. Do you wish to proceed? : (y/n)? y

### **MONITOR THE FLARE UPGRADE:**

**# /nas/sbin/navicli -h 10.241.168.57 ndu -status**

Is Completed: NO  
Status: **Disabling the cache**  
Operation: Install  
#/nas/sbin/navicli -h 10.241.168.53 ndu -status  
Is Completed: NO  
Status: **Running check scripts**  
Operation: Install  
#/nas/sbin/navicli -h 10.241.168.57 ndu -status  
Is Completed: NO  
Status: **Installing software on secondary SP**  
Operation: Install  
#/nas/sbin/navicli -h 10.241.168.57 ndu -status  
Is Completed: NO  
Status: **Activating software on secondary SP**  
Operation: Install  
#/nas/sbin/navicli -h 10.241.168.57 ndu -status

Operation: Install  
#/nas/sbin/navicli -h 10.241.168.57 ndu -status  
Is Completed: NO  
Status: **Waiting due to DMP delay**  
Operation: Install  
#/nas/sbin/navicli -h 10.241.168.57 ndu -status  
Is Completed: NO

Status: **Installing software on primary SP**

Operation: Install

# /nas/sbin/navicli -h 10.241.168.58 ndu -status

Is Completed: NO

Status: **Rebooting primary SP**

Operation: Install

# /nas/sbin/navicli -h 10.241.168.58 ndu -status

Is Completed: YES

Status: **Operation completed successfully**

Operation: Install

## **UPGRADING FLARE 19 PATCH 027 to 034 USING OffArray SIW & LAYERED APPLICATIONS:**

### **OffArray SIW Upgrade from Laptop:**

1. Download FLARE bundle: <http://www.cs.isus.emc.com/csweb2/dgweb/software/index.asp>

**CX600-Bundle-02.19.600.5.034.pbu**

2. Download the "**Navisphere OffArray UI's (Windows) 6.19.2.6.5**" from Windows Management Station section of website

3. Doubleclick and install the SIW executable: **Windows\_UIs\_6.19.2.6.5.exe**

4. Connect to Array using Start.html file, located at:

Program Files>EMC>ManagementUI>6.19.2.6.5>WebContent>**start.html**

5. Enter IP address at the Navisphere Connection window & log into the array using valid User and Password:

10.241.168.52>connect

Navisphere Login →User \*\*\*\*\*

6. Enter Eng. Mode: ctrl + shift + f12 & enter messner for password

7. Rightclick array>Software Operations>Software Installation Wizard>next>NDU Upgrade Delay (360)

Browse to .pbu file, doubleclick—unpacks and transfers files to Clariion SP

A list of available software appears>Click Next to start software installation

8. After upgrade begins>click Finish to modify software progress, or use ndu -status from Celerra

Installs sw on Secondary SP first

Reboots Secondary SP

Repeats same steps for Primary SP

9. After verifying software upgrade success, go back into Navisphere Manager>rightclick array>properties>Software>highlight Flare-Operating-Environment for 02.19.600.5.034 Active (Commit required) and commit the software

**# /nas/sbin/navicli -h 10.241.168.57 ndu -commit FLARE-Operating-Environment**

10. Verify using ndu -list:

**# /nas/sbin/navicli -h 10.241.168.57 ndu -list**

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 02.19.600.5.034

Commit Required: NO

Revert Possible: NO

Active State: YES

Is installation completed: YES

11. After commit is completed, failback any trespassed Celerra LUNs as a result of the SP reboots during upgrade

**# /nas/sbin/navicli -h 10.241.168.57 getlun -trespass**

LOGICAL UNIT NUMBER 91

Default Owner: SP A

Current owner: SP B

LOGICAL UNIT NUMBER 0

Default Owner: SP A

Current owner: SP B -----output abridged-----

**# /nas/sbin/navicli -h 10.241.168.57 trespass lun 0**

**Note:** For MirrorView luns, may need to trespass luns from other side if following message seen

**# /nas/sbin/navicli -h 10.241.168.58 trespass lun 113**

Error: trespass command failed

Error returned from Agent

You are not allowed to transfer the LUN to the other SP (0x4000805a)

**Note:** In the above case, the mirrored lun was lun 28, which was successfully trespassed back from the other side

## **CELLERRA FLARE NDU UPGRADE ISSUES:** Flare 24 & 26

DIMS 180689

ETA emc173153 for Flare 24 and emc1877241 for Flare 26

### **Causes:**

A problem exists in all versions of Flare 24 prior to patch 016. When the ndu -install command is initiated, the NDU process must

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
first run a series of rules that ensures that the system is not faulted and is safe to proceed with an upgrade. In this particular instance, the runrules process can produce events that are greater than 255 characters, and causes a corrupt event log, and a resulting timeout and failure of the ndu command. For Flare 26, exact cause is unknown, but likely related to ssl\_socket communication timeouts.

**SYMPTOM:**

# /nas/sbin/navicli -h 192.1.4.214 ndu -install /home/nasadmin/CX3-40-Bundle-03.26.040.5.005.pbu -delay 360

Error returned from the target: 192.1.4.214

Please specify valid IP address of the storage system and try again.

**WORKAROUND:**

1. Make sure that Naviseccli security is updated with a valid Global CLARIION Administrator account and password:

# /nas/sbin/navisecccli -h 192.168.1.200 -AddUserSecurity -scope 0 -user nasadmin

Enter password:

2. Use the skiprules switch to force the FLARE Upgrade

Caution: Do not use -skiprules without a thorough array healthcheck first! If in doubt, do not continue this procedure.

# /nas/sbin/navicli -h 192.1.4.214 ndu -messner -install /home/nasadmin/CX3-40-Bundle-

**03.26.040.5.005.pbu -skiprules -delay 360**

Item number: 0

Name of the software package: FLARE-Operating-Environment

Revision of the software package: 03.26.040.5.005

Already Installed Revision 03.24.040.5.006

Installable YES

Disruptive upgrade: NO

Ndu Delay: 360 secs

The requested package(s) will be installed. Do you wish to proceed? : (y/n)? y

3. Use the -status switch to monitor the FLARE upgrade progress:

# /nas/sbin/navicli -h 192.1.4.214 ndu -status

Is Completed: NO

Status: Waiting due to NDU delay

Operation: Install

# /nas/sbin/navicli -h 192.1.4.214 ndu -status

Is Completed: YES

Status: Operation completed successfully

Operation: Install

4. Do the following post-upgrade steps:

Re-enable statistics logging on each SP.

Verify that Write cache has been enabled and array is healthy.

Fail back any Celerra LUNs to Owner SP.

Commit the FLARE version.

Restart NAS Services if applicable (single blade systems only)

**Note:** The use of –skiprules is similarly required in some situations involving Clariion Layered Applications

**FLARE 24 NDU MAY REQUIRE USE OF NAVISECCLI (emc235884):**

# /nas/sbin/navicli -h 192.168.1.200 ndu -install CX3-40-Bundle-03.24.040.5.022.pbu -delay 360

Unable to access jarfile /opt/Navisphere/bin/SIWMain.jar

Pre installation rules have been run to ensure the success of this software upgrade. The above conditions have been detected that need to be corrected before running this command again. If this condition persists please contact your EMC Service representative.

# /nas/sbin/navisecccli -h 192.168.1.200 -user nasadmin -password nasadmin -scope 0 ndu -install CX3-40-Bundle-03.24.040.5.022.pbu -delay 360

Running install rules...(edited for brevity)

Pre installation rules have been run to ensure the success of this

software upgrade. One or more rules has a warning. The installation can continue with warnings.

The requested package(s) will be installed. Do you wish to proceed? : (y/n)?

**LISTING RULES FOR A FLARE PACKAGE:**

# /nas/sbin/navicli -h 192.168.100.200 ndu -runrules CX3-40-Bundle-03.26.040.5.005.pbu -listrules | -

**verbose** (verbose list of rules)

Your configuration will run the following rules

=====

Special Conditions

Redundant SPs  
All Packages Committed  
No Trespassed LUNs  
Statistics Logging Disabled  
No Transitions  
Acceptable Processor Utilization  
No Active Hot Spares  
Version Compatibility  
No Un-owned LUNs  
No Active Replication I/O  
No System Faults  
Host Connectivity  
SP Event Log Verification

### **RUNNING NDU RULES FROM NAVICLI:**

**# /nas/sbin/navicli -h 10.241.168.150 ndu -runrules \***

Version Compatibility : Rule passed.  
Redundant SPs : Rule passed.  
Acceptable Processor Utilization : Rule passed.  
No Trespassed LUNs : Rule passed.  
No Transitions : Rule passed.  
No System Faults : Rule passed.  
All Packages Committed : Rule passed.  
Special Conditions : Rule has warning.  
Statistics Logging Disabled : Rule failed.  
Host Connectivity : Rule passed.  
SP Event Log Verification : Rule passed.  
No Un-owned LUNs : Rule passed.  
No Active Replication I/O : Rule passed.  
No Virtual Provisioning Transitions : Rule passed.

1 rule(s) have warnings.

1 rule(s) failed.

Detailed rule results:

=====

RULE NAME: Special Conditions

RULE REVISION: 6.28.20.1.40.1

RULE STATUS: Rule has warning.

---output abridged-----

### **BACKEND ENABLER:**

Backend Enabler software is used for “captive” Celerra/Clarion configurations that use NAS personality modules to “enable” the AUX ports when connecting DM’s to Backend ports. Certain “Integrated” models (NS600/700) require the Backend Enabler, but the **NS350, NS500, NS704, NS40, NS80** Celerras do not use AUX ports, therefore have no ‘personality’ module or Backend Enabler software to install. Use the normal Flare bundle from Clariion website for all Integrateds except the original NS600/NS700’s.

**Caution: Do not use the Backend Enabler on SAN systems or the ports will be disabled!**

### **FLARE 24 to 26 UPGRADE:**

Flare NDU on NS Integrated models running Napa 8 or higher requires use of Control Station CLI. Beginning with NX4 product, the NST will be used to perform Flare NDU on Integrated systems. Basically, if you use NST and get the following popup, then use of GUI is not supported: “This feature is not supported”

**# /nas/sbin/navicli -h 192.168.100.200 ndu -install /home/nasadmin/flare26/CX3-40-Bundle-03.26.040.5.005.pbu -skiprules -delay 360**

Exception : A network error occurred while trying to connect: '192.168.100.200'.Message : Error occurred because connection refused. Management Server is not running.

**Note:** Found that the only way to do the upgrade is to use the –skiprules syntax—the above network error was benign and the upgrade proceeded. Root cause of the problem is with a Flare 24 bug, where RunRules can generate Events that are >than 255 characters, which corrupts the Event Log, and causes NDU command to timeout, and fail. See ETA emc173153 for more detail.

### **CELERRA NS40/NS80:**

--NS systems designed to support new CX3 arrays, as well as traditional CX and DMX platforms

--Uses Dewars Control Station

## **NS40 & NS40G:**

- GA NAPA II release based on new Clariion CX3 arrays, replacement for NS500 Platform
- Based on Sledgehammer hardware, DM blades are dual Intel 2.8Ghz processors with 4GB memory & 800MHz fsb
- SAN Gateway versions can connect to most array backends, while Integrated model connects only to Sledgehammer (CX3-40)
- Projected replacement for NS500 & NS700 based on Clariion CX3-40 platform
- 1U Enclosures, 1 or 2 blades only (Data Movers), single Chivas Control Station (2GB memory), (4) Power Supplies, Internal Management Switch, (2) serial ports for DART console—COM1 & COM2
- NS40 Blade with NAS personality will have dual 2.8GHz Nocona P4 processors, (2) serial console ports on lower left side, (2) RJ45 connectors to Internal Management switch, (4) Broadcom 5704 Gigabit Ethernet Optical ports [cge0-cge3] [or (2) Copper fge ports & (2) Optical cge ports], (2) Agilent 1/2/4Gb Aux Fibre Ports, and (2) Agilent 1/2/4Gb BE Fibre Ports
- SAN blades for SP's can have either (2) or (4) Fibre ports each, while NAS blades have only (2) Fibre ports
- Internal Management switch built into Motherboard, as opposed to NSX, where Management Switches are FRU's, with (2) RJ45 ports for access
- SPs run in SAN AUX mode using copper Fibre Channel HSDCC2 cables between SPs and DMs for Integrated, and SAN mode for Gateway using Fibre Optic cables
- NS40 can have 16TB per DM blade using FC drives, or 32TB using mixture FC/ATA drives, and supports up to 240 drives

## **NS80 & NS80G:** Supported NAS 5.5.24.2 Napa 4

Gateway & Integrated models. Replacement to NS702 & 704G. Offers 40u cabinet, non-UPS, between (2) and (4) Xblade 60/65 Servers, 1 CS upgradeable to two; Support for 10GbE Ethernet IO module on X-blade 65 and 4Gb FC IO module; NS80G GA NAPA 4 release Oct 9, 2006; NS80 Integrated GA Nov 17, 2006.

### **NS80FC [Model name NS80-AUX-FC]:**

AUX TLA NUMBER: 100-520-828

AUX Model Number: NS80-AUX-FC

**Note:** Also requires Navisphere & Port-Enabler license (NS80-FCOPT-L)

#### **Minimum Configuration:**

| Model          | Description                  | Qty             |
|----------------|------------------------------|-----------------|
| NS80-FCOPT-L * | NS80 FC enablement License   | 1               |
| RACK-40U-60    | 40U EMC Rack                 | 1               |
| NS80CDME6x     | 2 x NS80 Blades + enclosure  | 1 [Xblade60/65] |
| NS80-AUX-FC    | NS80-AUX B/E with 4 FC ports | 1               |
| NS-4PDAE-80    | First Disk Shelf             | 1               |
| NS80-CS        | First Control Station        | 1               |

→Will be released May 2008, no upgrading to or from an NS80FC (new installation of NS80FC only)

→RPQ-only product, ships with 5.6.37.x or higher

→Single or Dual blades only (X-Blade 60 or X-Blade 65), no 2<sup>nd</sup> enclosure, Single or Dual CS's possible [DME60 or DME65]

→Non-CSA setup by CS using Installation procedure distributed with RPQ approval

→See Celerra Procedure Generator. The NS80FC is actually installed as a direct-connect NS80G gateway, and will report itself as such.

→Two AUX ports are available per SP for Open Hosts as direct-connect Gateway style system (4 total FC ports)

→There are no simple commands to tell whether a system is an NS80FC

**Note:** System will report as NS80G and CallHome as an NSX

/nas/sbin/model

NS80G

### **TS PROCEDURE FOR INSTALLATION OF NS80FC:**

#### **The basic steps required are as follows:**

- Enable Access Logix and Navisphere Manager on the array and assign customer LAN IP addresses to the SPs.
- Remove the Celerra control LUNs already on the array and destroy RG0.
- Insert floppy and installation CD into the Control Station and reboot it.
- Begin a destructive "serialinstall" with the customer-provided IP information for the CS.
- Installs as Gateway model and prompts for entering SPA & SPB IP Addresses, and array security account & password
- Select Direct-Attached when prompted by installation script.
- Complete the NAS installation.
- Put Additional 4 FC ports on CLARiiON, unused by NAS, into SAN for SAN host attachment.

### **CELLERRA LUNS:**

LUNs 0-5 are created on Raid Group 0, located on the first 5 disks of the array

LUN 00 →contains the DOS partition (NAS image & DM Config files), /nbsnas/dos & /nas/dos, located on /dev/ndal on the backend—Server Logs, Dumpfiles, and DOS partition are located here. LUN 00 size now 11263

LUN 01 →ufslog partition, LUN size 11263

LUN 02 →Linux CS0 partition, all systems except NS Series, size 2047

LUN 03 → Linux CS1 partition, all systems except NS Series, size 2047

LUN 04 →contains /nbsnas partition (NASDB CS config files), located on /dev/nde1, size 2047

LUN 05 →contains /nbsnas/var partition (NASDB backups, dumps, log files), located on /dev/ndf1, size 2047

## **CELERRA AUTO-ASSIGN & AUTO-TRESPASS GUIDANCE:** emc95145

### **For all Celerra systems attached to Clariion backends, the following applies:**

→Beginning with NAS 5.2.16.x and NAS 5.3.10.4 GA release, full NAS Package upgrades will change the default behavior of both Auto-Assign and Clariion Trespass Option for all Celerra systems with Clariion backends. Please note that DART patch would only change the Clariion\_no.trespass value, not the Auto-Assign value.

→Be aware that with NAS 5.4 release, the Auto-Assign feature will be Disabled because the Celerra Host will be able to negotiate its own Trespass capability, as do other Clariion-attached hosts.

### **NAS 5.5.30.4 Defaults:**

Auto-assign

# /nas/sbin/navicli -h 192.168.1.200 getlun 0 -aa |grep assign

Auto-assign: DISABLED

# /nas/sbin/navicli -h 192.168.1.200 getlun 0 -at |grep trespass

Auto-trespass: DISABLED

# /nas/sbin/navicli -h 192.168.1.200 arraycommpath

Current arraycommpath setting is: 0 [0=Disabled]

# /nas/sbin/navicli -h 192.168.1.200 failovermode

Current failovermode setting is: 0

### **VALUES FOR ALL CELERRA SYSTEMS WITH CLARIION BACK ENDS:**

clariion no\_tresspass=0 (Disabled) →Param default is 0 for NAS 5.2.16.x and higher

# .server\_config server\_2 -v "param clariion no\_tresspass" [Syntax for NAS 5.5]

clariion.no\_tresspass INT 0x010c3f00 0 0 (0,4294967295) FALSE REBOOT 'NA'

**Auto-trespass:** Disabled (this is the Navi value that we are talking about with the no\_tresspass param above)

**Auto-assign: Enabled or Disabled** →Disabled by default NAS 5.4/5.5 +

**arraycommpath=0** →Disabled by default NAS 5.5 (Value seen as 0 for Disabled & 1 for Enabled in Navisphere)

**failovermode=0**

### **DEFINITION AND PURPOSE OF CELERRA/CLARIION PARAMETERS:**

clariion no\_tresspass=0

**Auto-trespass: Disabled:** Default Clariion setting is 0 to disable this feature, and Celerra LUNs should also be disabled. If the feature were enabled, if an IO were sent by a Host to an SP for a LUN that it does not currently own, then the trespass command would fail the lun over to the SP and the IO would succeed. Normally, if a Data Mover cannot drive I/O down a certain path, it will send a trespass command to the alternate SP to take over--note that Hosts must also initiate the trespass back to the original SP after a trespass occurs. Setting value to 0 enables the Host to control trespassing for IO requests.

**Note:** In certain situations, setting the value to 1 is done to help trespass Celerra LUNs to their owner SP, but only as a temp measure

**Auto-assign: Disabled:** Disabled by default on Clariion. For Clariion, if an IO request comes to an SP that does not OWN the LUN, the SP will honor the IO request and failover the LUN if the peer SP is not present. If the peer SP is present, the IO request will be denied to the non-owner SP the ownership of a LUN when an SP fails. The trespassed LUN does not get automatically transferred back to its Owner unless specifically told to do so, or unless the system reboots. This feature does not affect Ownership of the LUN. Auto-assign is a mechanism devised in those configurations where failover software was not employed.

**Note:** Auto-Assign must be enabled to ensure that any “un-owned” LUNs are trespassed, works in conjunction with Clariion no\_tresspass parameter.

**arraycommpath: Disabled, 0:** Arraycommpath is a Clariion feature used by PowerPath to set the communication path to the Array for LUNZ support—Celerra does not use or recognize this feature, therefore HLUs and Storage Groups that are created for Celerra Systems should not have it enabled. ATF applications require that the setting be 0, not 1.

**failovermode: Disabled, 0:** Failover Mode works in conjunction with PowerPath and ATF applications. Celerra requires that this setting be set to 0 so that if IO fails to one SP, and DART then tries to send to an alternate path and SP, the non-owning SP will reject the command with a Check Condition 04/04/00 illegal request error. DART will recognize this scsi sense code and realize that it must initiate a trespass command to the alternate SP, thus failing over the LUN to the alternate SP, and re-driving IO down this path.

### **DETERMINING DATA MOVER IO FAILOVER PATHS NS704G:**

\$ .server\_config server\_2 -v "fcip bind show"

\*\*\* Persistent Binding Table \*\*\*

Chain 0000: WWN 500601603060090b HBA 0 SP-a0 Bound →I/O failover would be Chain 48 HBA1 SPA port 1

Chain 0016: WWN 500601683060090b HBA 0 SP-b0 Bound →I/O failover would be Chain 32 HBA1 SPB port 1

Chain 0032: WWN 500601693060090b HBA 1 SP-b1 Bound

Chain 0048: WWN 500601613060090b HBA 1 SP-a1 Bound

Chain 0064: WWN 500104f0008a3496 HBA 2 N\_PORT Bound

Chain 0080: WWN 5006048000000000 HBA 3 N\_PORT Bind Pending

**Note:** I/O failure down a specific HBA chain will cause failover to alternate HBA and different SP port on same SP. I/O failure down both chains for SPA will cause LUN trespass to SPB

## **VERIFYING VALUES:**

### **clarion no\_tresspass**

**\$ .server\_config server\_2 -v "param clarion" or "param clarion no\_tresspass"**

clarion.no\_tresspass 0x011cf874 0x00000000 0x00000000 -->Example output shows that value is set to 0, which is correct

**# .server\_config server\_2 -v "param fulldescription clarion no\_tresspass"**

clarion.no\_tresspass 0x010488dc 0x00000000 0x00000000

**Note:** Required syntax change for NAS 5.5

### **auto-assign**

1.) **#/nas/sbin/navicli -h spa storagegroup -list** (SAN-attached Systems only—run to obtain list of HLU/ALU luns)

2.) **#/nas/sbin/navicli -h 10.14.32.90 getlun -aa** (Use for both Integrated & Gateway systems)

**Note:** The storagegroup -list is shown to illustrate that the Celerra LUNs for Gateway systems will have an HLU number associated with them, and the above output in "step 1" shows the HLU-to-ALU association, which would be needed if values required changing

## **CHANGING ARRAYCOMMPATH/FAILOVER USING NAVISPHERE or CLI:**

ArrayCommpath & Failover Modes are assigned to the SP's WWNs on an initiator basis, but associated to a particular Data Mover Hostname for the HBA port—the values can be changed individually on SPA or SPB Ports 0 & 1.

### **UPDATING WWN HOST INITIATOR RECORDS FROM NAVISPHERE:**

1. If values need to be changed on all data movers, make the change on the Standby Server's Host Records for the appropriate SP and ports using the following methodology:

a.) Navisphere>APM Array>log into Eng. Mode using ctrl + Shift + F12, and password ‘messner’

b.) APM Array>Connectivity Status>highlight the Initiator Name/Server Name>Click on “Info” to see what the current Array Commpath and Failover Mode settings are [Correct values are Disabled and 0, respectively]

c.) APM>Connectivity Status>Highlight Initiator Name record>Group Edit>Select the correct WWN Initiator record from the “Available” WWN list and move to the “Selected” WWN list [Update only one record at a time]

d.) Select “Array Commpath: Disabled” [Disabled=0], “Failover Mode: 0”, and “Existing Host” [Make sure the change is applied to the intended Hostname associated with the WWN record being updated]

e.) Click o.k. to apply, click Yes on popup warning box to acknowledge the activity>Success ‘o.k.’

f.) Repeat the process for each WWN Initiator record that needs updating

| SERVER NAME (DM HOST NAME) | INITIATOR NAME (SP WWN)                         | PARTITION ID |
|----------------------------|---|--------------|
| laip2_dm3_p0               | 50:06:01:60:90:60:25:c4:50:06:01:68:10:60:25:c4 | A-1          |
| laip2_dm3_p1               | 50:06:01:60:90:60:25:c4:50:06:01:69:10:60:25:c4 | B-0          |
| laip2_dm2_p0               | 50:06:01:60:90:60:25:c4:50:06:01:60:10:60:25:c4 | A-0          |
| laip2_dm2_p1               | 50:06:01:60:90:60:25:c4:50:06:01:61:10:60:25:c4 | B-1          |

### **CLI:**

**# /nas/sbin/navicli -h 10.241.168.57 storagegroup -list |grep Name**

Storage Group Name: Celerra\_hammer1

Storage Group Name: Celerra\_nyip1

**# /nas/sbin/navicli -h 10.241.168.57 port -list -gname Celerra\_nyip1**

2. Failover production server to Standby slot, then change arraycommpath & failovermode values on the ‘faulted’ server slot, i.e., the slot not in production!

3. Fallback data mover and repeat as needed

### **UPDATING WWN HOST INITIATOR RECORDS FROM CLI:**

1. Make sure you correctly identify the Data Mover Host Initiator names that are associated with each SP port and run command against Standby Server Host records first:

**#/nas/sbin/navicli -h spa storagegroup -sethost -host laip2\_dm3\_p0 -arraycommpath 0 -failovermode 0**

**#/nas/sbin/navicli -h spa storagegroup -sethost -host laip2\_dm3\_p1 -arraycommpath 0 -failovermode 0**

WARNING: Changing configuration options may cause the array to stop functioning

correctly. Do you wish to continue (y/n)? y

2. Failover production server to Standby slot, then change arraycommpath & failovermode values on the ‘faulted’ server slot, i.e., the slot not in production! In otherwords, if Server\_2 were failed over to Standby Server\_3, the Host Initiator Records for “laip2\_dm2\_p0” and “laip2\_dm2\_p1”, which are tied to physical slot\_2 and not in production, would be used to change the values.

```
#/nas/sbin/navicli -h spa storagegroup -sethost -host laip2_dm2_p0 -arraycommpath 0 -failovermode 0  
#/nas/sbin/navicli -h spa storagegroup -sethost -host laip2_dm2_p1 -arraycommpath 0 -failovermode 0
```

3. Fallback data mover and repeat as needed for multiple Data Mover systems

#### arraycommpath

```
#/nas/sbin/navicli -h spa arraycommpath (Integrated systems only)
```

```
#/nas/sbin/navicli -h spa port -list -all (SAN-attached Systems only)
```

#### failovermode

```
#/nas/sbin/navicli -h spa failovermode (Integrated systems only)
```

```
#/nas/sbin/navicli -h spa port -list -all (SAN-attached Systems only)
```

Server Name: ns600g\_dm30

ArrayCommPath: 1

Failover mode: 1

**Note:** Both the arraycommpath & failovermode output can be misleading, as the array itself could have the values set to 1, while the individual Celerra Host Name records may be set to 0. Use Navisphere GUI to verify arraycommpath/failovermode values for the specific Host Name/Initiator Records in question. Navisphere should correctly show Celerra Host Name records with Array CommPath ‘Disabled’ and Failover Mode ‘0’.

#### NAS 5.5.31.6 CHANGES:

Upgrades will check to see if Array CommPath & Failover Mode are disabled/set to 0, and apply the default settings to each Host Initiator record one a time so as not to disrupt HA paths.

#### DATA MOVER, NAVISPHERE, & REGISTRATION PROCESS:

Windows Hosts automatically register their WWNs and IP address to the Array, and run as a Navi Server with two-way communication between the array. The Celerra Data Movers, on the otherhand, do not function as a Navi Server and register their WWNs via Hostnames, with only a one-way communication for the registration process. Because of this limitation (See AR99780), when trying to use the Storage Wizards in Flare 24 or higher, to create or allocate additional backend storage for the Celerra, this will fail because the Data Movers are not registered as Servers that run the real Navi agent, and the Data Movers simply do not show up in the Wizard lists. The proposed fix to this issue would use the Control Station Hostname & IP Address as the basis to provide a Navi-Server functionality so Wizards would work, and Data Mover WWNs would become registered via IP address and not just Hostname.

To make matters more confusing, whenever trying to manually Register Data Mover WWNs, the IP address field requires that a unique IP address be entered [though it isn’t used and can be any bogus IP address], along with the Hostname for the Initiator record. However, the factory installation of the new NS20/40 Integrateds bypassing the IP address problem and uses only the Hostname, meaning that an IP address will not be seen in the properties of the Host Initiator record.

#### Agent tab under Host Initiator Record Properties:

<hostname> is not a Managed Host, unable to retrieve Remote Agent Configuration.

### SETTING CORRECT SYSTEM VALUES FOR CELERRA/CLARIION SYSTEMS:

#### SETTING NO\_TRESPASS=0:

- 1.) `param clariion no_trespass=0` (set in /nas/site/slot\_param)
- 2.) `$.server_config server_2 -v "param clariion no_trespass=0"`
- 3.) Reboot Server

**Note:** Default value 0 for NAS 5.2.16.x --disables the Clariion LUN trespass mechanism, allowing Celerra Hosts to control LUN failover

#### SETTING AUTO-ASSIGN:

```
#/nas/sbin/navicli -h spa chglun -l 00 -a 1 [ALU lun number—run command to change each Celerra LUN]
```

#### SETTING AUTO-ASSIGN FOR CAPTIVE & NON-CAPTIVE BACKENDS:

- 1.) Run following While True Loop Script for Captive Systems

```
#for i in <Celerra LUN numbers>
```

```
>do
```

```
>/nas/sbin/navicli -h spa chglun -l $i -a 1
```

```
>done
```

- 2.) Run Storagegroup List command for non-captive backend and use ALU column for LUN numbers and repeat Step 1 script

```
#/nas/sbin/navicli -h spa storagegroup -list
```

**Note:** Non-Captive systems use AccessLogix & Storage Groups to control Host access to luns.

#### SETTING ARRAYCOMMPATH & FAILOVERMODE ON CAPTIVE & NON-CAPTIVE BACKENDS:

```
#/nas/sbin/navicli -h spa arraycommpath=0 (Captive Systems)
```

#**/nas/sbin/navicli -h spa failovermode=0** (Captive Systems)

#**/nas/sbin/navicli -h spa storagegroup -sethost -host ns600g\_dm30\_p0 -arraycommpath 0 -failovermode 0**

**0** (See new procedure outlined above for conducting with Celerra online but Production Server failed over)

**Caution:** With care, ArrayCommPath settings can be changed while the Celerra is online. However, the correct method for changing Array Commpath values with Servers online would be to change the values first on the Standby Server, then failover each production server and change the values on the Host Name Records of the "faulted" Server slot. In otherwords, the records should only be changed if the physical Server slot is not in production! If the changes are made to a Server while in a production status, there is a potential that IO could be mishandled, resulting in file system corruption, Data Mover panics, etc. If there is any question about this cautionary note, please contact your local EMC Support person.

**Note:** Storagegroups with Celerra Hosts must have arraycommpath & failovermode set to disabled. Repeat for each Celerra Host listed from “port –list –all” on Non-Captive backends [NS600G/NS700G, etc]

## **CHANGE DEFAULT LUN OWNERSHIP:**

#**/nas/sbin/navicli -h 192.168.59.71 chglun -l 0 -d 0** [0=SPA, 1=SPB]

# **/nasmcd/sbin/navicli -h 10.241.168.57 chglun -l 100 -d 1**

Error: chglun command failed

Error returned from Agent

The attribute(s) cannot be set for private lun(s)

**Note:** Cannot change default ownership from navicli for Private Write Intent Log LUNs

## **CELERRA LUN TRESPASS MECHANISM**

### **HOW CELERRA PERFORMS LUN TRESPASS WITH CLARIION:**

→DART uses scsi mode sense commands to trespass LUNs on SPs, not navicli. If an SP is failing, DM should receive sense key information of the failure, and after a number of retries, should drive IO down an alternate path & trespass the LUN. If Data Mover gets SK/ASC 05/04/00 scsi sense command, it will know that the LUN needs to be trespassed and will issue the trespass command to SP and re-issue the IO. Essentially, with setting failovermode=0 for DART LUNs, we are allowing the non-owning SP to reject any media access commands with a Check Condition 05/04/00 sense code error, meaning that DART will then know that it has to initiate the trespass to the SP in order to be able to drive the IO down the alternate path, in this case, to the other SP.

→Issue can occur with hardware failures, such as LCC card, in which sense key information is returned from both SP's that the lun is no longer owned, and lun could be trespassed from one SP to the original owner SP.

## **CELERRA INTEGRATED(Captive) vs. GATEWAY(SAN/Switch) CLARIION ARRAYS:**

### **CELERRA INTEGRATED CLARIION ARRAYS:**

#### **CAPTIVE = INTEGRATED = DIRECT-ATTACHED = DEDICATED STORAGE = NS600/NS700**

**Note:** All of this terminology is being supplanted by the use of “Unified Storage” to indicate the Celerra Integrated platform that can support all protocols (FC, iSCSI, NAS IP, MPFS)

# **nas\_storage -query:\*** -fields:IsCaptive -format: %s\n

False [returns false if not an Integrated, though reports False even for FC models]

--An integrated Celerra/Clariion solution means that the Storage Array system is dedicated to Celerra Servers only—No other Hosts are connected to the Array

**Note:** This definition has changed now that FC-enabled models are allowed [NS20FC/NS40FC], where certain Integrateds are allowed to “share” the backend array with other Hosts

--Uses CX600 or CX700 Arrays, with (2) SP's, (2) SPS's, and (1) or more DAE2 Shelves

--An Integrated Array does not use Optical SAN ports

**Note:** NS80's, NS20's, & NS40's now all use Fibre Optic SFPs to connect directly to the SPs.

--An Integrated system delivers NaviEventMonitor backend events to the Celerra as configured by the /nas/sys/nas\_mcd.cfg file using navilog\_mon, but only a few events will generate a CallHome—Events are posted in the sys\_log

--Data Movers are direct-connected to the Array using copper FC Arbitrated loop cabling [except all new models use Fibre Optic SFPs]

--Never Uses Access Logix

**Note:** Again, this is no longer true. Storagegroups and AccessLogix are used for NS80, NS40, & NS20 systems.

--Uses AUX modules

--Connects from DM's BE0 ports to SPA, while BE1 ports connect to SPB, using FC AL Copper cabling

**DM2-BE0 – AUX 0 SPA-2**

**DM2-BE1 – AUX 0 SPB-2**

**DM3-BE0 – AUX 1 SPA-3**

**DM3-BE1 – AUX 1 SPB-3**

--Connects to AUX0 for Backups using MIA and optical cabling from DM  
 --Integrated Arrays can be upgraded to SAN Gateway Arrays via SW and HW changes

--Change Internal IP address scheme per procedure found in Integrated Array Setup Guide

**Note:** Integrated NS Series systems are connected only to Clariion Storage Systems [NS700/NS500]

**IDENTIFYING LEGACY INTEGRATED SYSTEMS:****#cat /etc/hosts |grep -i APM**

```
192.168.1.200 A_APM00040601637 SPA # CLARiiON SP [Usually a captive backend will retain default IP structure for SP's]
192.168.1.201 B_APM00040601637 SPB # CLARiiON SP
```

**# nas\_storage -i APM00040601637** [Serial number of array from /etc/hosts]

```
id          = 1
arrayname   = APM00040601637
name        = APM00040601637
model_type  = RACKMOUNT
model_num    = 600 [Array Model Number: CX600]
```

**num\_storage\_grps = 0** [Lack of Storagegroups indicates a captive backend—no shared SAN]

**captive\_storage = True** [Captive = True for dedicated array for single host]

**# /nas/sbin/navicli -h 192.168.1.200 storagegroup -list**

Error: storagegroup command failed

This version of Core Software does not support Access Logix

**Note:** Also a key indicator as only SAN-attached uses Storagegroups & Access Logix

**# cat /nas/sys/nas\_mcd.cfg** (Gateway models do not use navilog\_mon for NaviEventMonitor)

daemon "Navi Event Monitor"

```
executable  "/nas/sbin/navilog_mon"
optional    no
autorestart yes
```

**IDENTIFYING FILE SYSTEMS ASSOCIATED WITH SPECIFIC LUN ON CAPTIVE SYSTEMS:****CELERRA FILE SYSTEM LUNS/DETERMINING FILE SYSTEM LUNS, etc:****Determining Which File Systems are built on Lun 27(hex=001B)?****# nas\_disk -l**

```
id  inuse sizeMB storageID-devID type name      servers
1   y     4095  APM00040601637-0000 CLSTD root_disk  1,2
2   y     4095  APM00040601637-0001 CLSTD root_ldisk 1,2
3   y     2047  APM00040601637-0002 CLSTD d3       1,2
-----output abridge-----
17  y     912405 APM00040601637-001B CLATA d17      2,1
18  y     912405 APM00040601637-001D CLATA d18      2,1
```

**Note:** Since this is a captive system without Storage Groups, the concept of HLU/ALU does not apply and the nas\_disk -list will give you the true LUN number in HEX for every dvolume on the Celerra. Convert the HEX number to DECIMAL. Device ID 001B is HEX for decimal 27, or LUN 27 on the Clarion array, using dvolume “d17”. So, any filesystem with “d17” is built in part from LUN 27.

**# nas\_fs -i ata**

```
id      = 24
name    = ata
symm_devs = APM00040601637-001D,APM00040601637-001B
disks   = d18,d17
```

**# server\_devconfig server\_2 -p -s -a**

```
chain= 0, scsi-0
tid/lun= 1/11 type= disk sz= 0 val= -5 info= DGC RAID 5 02061B0000DBCACL
chain= 16, scsi-16
tid/lun= 1/11 type= disk sz= 912405 val= 17 info= DGC RAID 5 02061B0000DBCACL
```

**Note:** Devconfig output will show Controller, Target, and Lun that “d17”, LUN 27, is mapped to from Celerra perspective—in this example SPB owns the LUN on Chain16.

**CELERRA GATEWAYS:****SAN = GATEWAY = FABRIC-CONNECTED = NS600G/NS700G/NS700G 4-Way**

--Gateway configurations allow other Hosts, outside of Celerra, to share the Clariion Array via a SAN network

**Note:** Only a SAN-attached system will contain Storage Groups, with HLU and ALU pairs for LUNs. To find LUNs on Integrated, use nas\_disk -list and take the device number (hex) and convert to decimal value, which then equals ALU/HLU LUN number.

### # /nas/sbin/navicli -h 10.241.169.35 getagent

Revision: 2.04.1.60.5.007 → Flare code shows value of 1 in third field, indicating use of Access Logix to manage Storage Groups for SAN-attached arrays

### # /nas/sbin/navicli -h 10.241.169.35 storagegroup -status

Data Access control: ENABLED → Means that Access Logix is installed

**Note:** Max. of 256 luns can be assigned to a storagegroup

### # /nas/sbin/setup\_backend/setup\_clariion2 list config APM00034202048 [Shows overall status of Backend]

fcTach.linx\_speed\_be0 0x0005f4a788 0x00008000 0x00008000  
fcTach.linx\_speed\_be1 0x0005f4a78c 0x00008000 0x00008000

## NS700 (integrated) & NS700G (gateway) PRODUCTS:

GA 9 February 2004. Midrange storage solution running DART 5.2 on Clariion CX700 or Symmetrix backends.

--SP speeds increased to 3.0Ghz and 533 Bus speed & NS700-AUX memory is 8GB.

--NS700, NS701-FD, NS702, NS702-FD consists of a “captive NS700 NAS head” [Data Mover], an AUX module, a Control Station, and Disk Array Enclosures

--NS700 SPs have 4 FC ports, two for Backend loops and two for Data Movers

**NS704G 4-Way:** GA Aug 4, 2004 → Compatible with NAS 5.3, 4-Data Mover and Dual-CS model

--NS704 connects to backend where SPs can support 4 backend loops and 4 Blades (8 FC ports/SP)

**NS700G PHASE I:** NS700 that can share some ports on array with a SAN. Data Movers in this model are direct-connected to CX700, but CX700 contains extra fibre ports connected to a switch to allow for other external hosts to access storage. Uses ‘Access Logix’ and StorageGroups to restrict access to LUNS to specific Hosts.

**NS700G PHASE II:** All hosts, including data mover, connect to fibre switch to access the CX700

**NS700:** Contains new ‘Ajaguar’ (9) network port NAS personality module with (7) copper GB ports and (2) optical GB ports

**WWN:** Each data mover has unique WorldWideName seed stored in PROM. Prefixed numbers for WWN will be different if plugged into a different chassis.

### **STORAGE GROUPS:**

Storage Groups contain WWNs and LUNs and Host fibre port HBA Initiators. NS700G requires use of Storage Groups. Storage Groups provide for LUN masking for specific Hosts. The LUN numbers presented to one Host in one Storagegroup could be reused for a different Host in a different StorageGroup. Use storagegroup –list

### **RESERVED CELERRA LUNS:**

LUNs 0-15 are reserved on the Celerra. Data LUNs should always be created on LUNs 16 and higher. NAS 5.3 prevents the illegal configuration of data LUNs on Celerra Reserved Luns.

### **CLARIION RESERVED LUNS:**

**\$ /nas/sbin/navicli -h 10.241.168.52 reserved -lunpool-list -freeluns**

Name of the SP: SP A

Unallocated LUNs: None

### **CELERRA NBS SERVICES:**

**Note:** NBS (Network Block Storage) is an EMC proprietary iSCSI technology that enables NBS network clients (such as the Control Station) to access block storage devices connected to NBS network servers (Data Movers). NBS transactions are more efficient than other protocols because it uses block data transfers. NBS is implemented in a Client-Server model, where pseudo disk instances of each storage object are exported to the Client by the Block Server--presenting remote storage devices as local disk devices. Client block device driver receives requests from applications and pass to Block Server using TCP. Block Server processes Client requests and replies. NBS version 2.0 with NAS 5.3. NBS runs over TCP. CS NBS Client is used to connect to backend “nas” & “dos” partitions using Data Mover as NBS Server.

### **COMPONENTS:**

Client & Server NBS processes

Internal Celerra network

Storage volumes exported by Data Mover

### **CONTROL STATION BOOT OPERATION & ARRAY COMMS WITH CLARIION SYSTEMS:**

The Celerra Control Station boots directly from the Storage System drives with the CFS-14 and CNS14 families. With the NS-family, however, such as the NS600 & NS700, the Control Station boots from an internal IDE drive and not from the Storage Array drives [though it does store a copy of its configuration data on the array]. The NS-family Control Station does not directly copy data to the Backend Array and does not have a Fibre Channel host bus (HBA), but uses Network Block Service (NBS) to access LUNs on the Array. The implications here are that the CS is dependent on NBS (a network service that runs on the Data Mover) to read and write to its database configuration on the Array, and also to conduct a NAS software install.

The Control Station sends NBS data over the Private LAN to the Data Mover, the latter which then forwards the information to the Array over Fibre Channel. NBS runs as a Client on the CS and as a Service on the DM. NBS is used only for block data.

### **VERIFYING NBS SERVICES:**

**# ps -ef |grep nd-clnt**

```
root 1062 1 0 Oct13 ? 00:00:02 [nd-clnt 0 1]
root 1067 1 0 Oct13 ? 00:00:06 [nd-clnt 4 5]
root 1073 1 0 Oct13 ? 00:00:00 [nd-clnt 5 6]
```

### **VERIFYING CS CONNECTIVITY TO NBS DEVICES:**

**# /sbin/fdisk -l /dev/ndf1**

```
Disk /dev/ndf1: 255 heads, 63 sectors, 229 cylinders
Units = cylinders of 16065 * 512 bytes
```

### **NBS SERVICES ON NS702G:**

**# ps -ef |grep nd-**

```
root 1210 1 0 Oct18 ? 00:00:55 [nd-clnt 0 1] → Process that retrieves NBS data from DM/backend
root 1211 1 0 Oct18 ? 00:44:29 [nd-clnt 4 5]
root 1212 1 0 Oct18 ? 00:01:16 [nd-clnt 5 6]
root 1213 1 0 Oct18 ? 00:01:49 [nd-sndd 0 1] → Process that sends NBS data to DM/backend
root 1214 1 0 Oct18 ? 00:03:19 [nd-sndd 5 6]
root 1215 1 0 Oct18 ? 02:08:43 [nd-sndd 4 5]
```

**# /nas/sbin/t2tty -C 2 "nbs info" (also use .server\_config -v to output same thing)**

nbs start
```

**STOPPING & RESTARTING NBS SERVICES:**

**#/sbin/service nbs stop | start**

**Note:** Above is one way to stop and restart NBS.

Another method might be less intrusive and doesn't require PXE booting of servers to restore access to the backend:

### # server\_cpu ALL -q now

**Note:** This command seems to stop NBS access to the backend from the Servers [Data Movers], but does not actually stop the NBS client processes on the Control Station [ps -ef |grep nd- still shows client services running], meaning that to recover NBS fully does not require PXE booting, just a simple reboot of any of the Data Movers.

### VERIFYING NBS VOLUMES:

#### # /sbin/service nbs status

Configured NBS devices:

```
254: 0  NbsId: 1
Disk_Name: nda

Chain 0048: WWN 0000000000000000 HBA 3 ID 3 Inx 03:81 Pid 0048 S\_ID 000000 Non

**Note:** NBS must be configured on Chains 0 and 16 on direct-connect captive systems or else NBS may not function correctly. With Fabric-connected systems, NBS can be on Chains 0, 16, 32 & 48.

#### **CONTROL SYSTEM LUNS FOR CELERRA (Celerra Control LUNs):**

**Note:** LUNS define logical disks on the array presented to Hosts, and usually spans a group of physical disks known as a “RAID GROUP”. Several LUNS can comprise a Raid Group.

→NS500/NS700 LUNS 0-5 are always RAID GROUP 0 Raid5 4+1 & are located on first (5) disks on first shelf in array, and should be only LUNs in this Raid Group.

#### **LUN 0: /nas/dos or /nbsnas/dos**

/nas/dos partition on array from which Data Movers boot—actually a symbolic link to /nbsnas/dos for /dev/nda1

Data Movers use this partition to boot and load DART and also to obtain individual configuration files

#### **NAS PARTITION:**

/nas is actually mounted on the Control Station’s IDE drive on /dev/hda5, but many of the configuration database files/folders are symbolic links to the NBS partition on the array known as the “NASDB”, or NAS configuration database. So, if the Control Station is not able to talk to an NBS Server to actually get to the backend partition via the symbolic links, then the locally mounted /nas directory will contain only some configuration directories and files. Note that during normal operation, a “dirsync” process runs on the Control Station which copies any changes from /nas to /nbsnas.

#### **LUN 1: Used by data movers**

#### **LUNS 2 & 3: Reserved**

#### **LUN 4: /nbsnas**

/nbsnas is the mountpoint for the NBS partition /dev/nde1 on the array and contain mountpoints for “dos” & “var” partitions

/nbsnas contains NAS configuration database and is known as the home for the “NASDB” [/nbsnas/server, etc.]

#### **LUN 5: /nas/var symbolic link to /nbsnas/var**

/nbsnas/var is the mountpoint for the NBS partition /dev/ndf1, which contains the NASDB backups, dumps, log files, & other files

**Note:** To find correct array LUN for the Control Luns, run storagegroup -list and MAP HLU LUNs 0-5 to the ALU number on array

#### **DIRSYNC PROCESS TO KEEP NAS & NBSNAS PARTITIONS SYNCHRONIZED:**

**\$ ps ax |grep dirsync**

1701 ? S 1:16 /bin/sh /nas/sbin/dirsync /nas /nbsnas 180

1702 ? S 1:23 /bin/sh /nas/sbin/dirsync -c /nas/sys /nasmcd/CHomeFi

**Note:** There can be many different reasons for /nas or /nbsnas, or both, to become full--dumpfiles extracted to /nas, logfiles that have grown disproportionately large, or JServer database files have grown too large. To complicate matters, the NS Series Celerra, which runs NBS Services for Control Station access to the backend, runs a Dirsync process on the Control Station to keep the /nbsnas

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
partition in sync with the /nas partition. One of the quirks of this file syncing process is that you cannot properly delete files from either partition to reduce the file system capacity without stopping NAS Services first to stop the dirsync process, as files will be rewritten to the partition(s) from cache, even if you have manually deleted them and df -h shows healthy partition space.  
→Running pstree against NAS MCD process shows hierarchy of processes. “Dirsync” is a process designed to sync any file changes on the local /nas partition with the backend /nbsnas partition, every 3 minutes. It also syncs any changes from /nbsnas/sys to the local /nasmcd/CHomeFiles directory, every 5 minutes.

**# pstree -pau 25137 | grep dirs**

```
dirs,30078 /nas/sbin/dirs /nas /nbsnas 180
dirs,30118 /nas/sbin/dirs -c /nas/sys /nasmcd/CHomeFiles 300
```

## **CLEANING UP SPACE ON /NAS & /NBSNAS FOR NS CELERRAS:**

1. Run #df -h before any changes

**# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/nde1  | 1.7G | 1.8G | 0     | 100% | /nbsnas    |
| /dev/hda5  | 2.0G | 2.0G | 0     | 100% | /nas       |

2. Stop NAS Services as Root

**Caution:** For dual-control station NS systems, you must first stop NAS Services on the Standby Control Station (CS1), then stop NAS on CS0/.

**# /sbin/service nas stop**

/nbsnas is in use by the following processes(uid)

```
/nbsnas: 25444 26044 26052 26053 26056
```

NAS:/etc/init.d/nas: ERROR: Failed to stop NAS services

**Note:** Please be aware that if you or another User are sitting in the /nas or /nbsnas partition, NAS may give an error saying it could not be properly stopped. In all cases, you must verify that both Box Monitor and NAS Services are stopped before continuing. The most likely situation is that Box Monitor will be stopped, but NAS will remain running--if you find this to be the case, you will need to kill the NAS processes manually:

**# ps -ef |grep boxm**

```
root 27221 24916 0 11:01 ttyS0 00:00:00 grep boxm
```

**# ps -ef |grep -i nas\_mc**

```
root 1189 1 0 Nov13 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root 1363 1189 0 Nov13 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root 1364 1363 0 Nov13 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
```

**# pkill nas\_mcd**

pkill: 1484 - No such process

# ps -ef |grep nas\_mc

```
root 1189 1 0 Nov13 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root 1363 1189 0 Nov13 ? 00:00:00 [nas_mcd <defunct>]
```

**# kill -9 1189**

**# ps -ef |grep nas\_mc**

3. Manually remount partitions on Control Station:

**#mount /nbsnas #mount /nas #mount /nas/dos #mount /nas/var**

4. Delete necessary files from /nas, then the same files from /nbsnas--one way to determine what directories in /nas or /nbsnas are contributing to the full condition is to run the following from within the /nas or /nbsnas directory:

**# du -sh /\***

**Note:** In some cases you will find that JServer logs are contributing to most of the space being used on /nas & /nbsnas. In this situation, you will need to obtain customer approval before running #js\_cleandb. Also be aware that in older NAS Versions, #js\_cleandb only deleted files from the /nas partition--you must still manually delete the odb and sdb directories from /nbsnas/jserver. Finally, in many situations, log files have grown disproportionately large and can be zeroed out by running the following, but please do not run this against log files if you do not know the impact:

**# ls -la**

total 39048

```
-rw-r--r-- 1 root root 22827157 Nov 9 09:25 access_log.5
```

**# cp -i /dev/null access\_log.5**

cp: overwrite `access\_log.5'? y

**# ls -la**

```
-rw-rw-rw- 1 root root 0 Apr 11 2002 access_log.5
```

5. When partition cleanup with completed, run df -h to verify:

**# df -h**

| Filesystem | Size | Used | Avail | Use% | Mounted on |
|------------|------|------|-------|------|------------|
| /dev/nde1  | 1.7G | 857M | 828M  | 51%  | /nbsnas    |
| /dev/hda5  | 2.0G | 778M | 1.1G  | 41%  | /nas       |

**Note:** Keep in mind that just because the dirsync process is designed to keep /nbsnas in sync with any changes on /nas, the two partitions are not necessarily identical in size

6. Restart NAS services & verify that Box Monitor, NAS, and dirsync are running:

**# /sbin/service nas start****# ps -ef |grep nas\_m**

```
root 372 1 0 11:40 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root 483 372 0 11:40 ? 00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
-----output abridged-----
```

**# ps -ef |grep boxm**

```
root 938 372 0 11:41 ? 00:00:00 /nas/sbin/nas_boxmonitor /nas -i
root 998 938 0 11:41 ? 00:00:00 /nas/sbin/nas_boxmonitor /nas -i
root 999 998 0 11:41 ? 00:00:00 /nas/sbin/nas_boxmonitor /nas -i
-----output abridged-----
```

**# ps -ef |grep dirsync**

```
root 25439 25312 0 10:58 ? 00:00:00 /bin/sh /nas/sbin/dirsync -skipj
```

**CONTROL STATION NETWORK INTERFACES:****NS600 CONTROL STATIONS:**

→eth0 as lower network port connected to local network switch  
→eth1 as upper network port connected to public network

**NS700 FALCON CONTROL STATIONS:**

→eth0 2<sup>nd</sup> port from left, connecting to primary local network switch  
→eth1 1<sup>st</sup> port from left, connects to cross-over to eth1 on CS1  
→eth2 3<sup>rd</sup> port from left, connects to secondary local network switch  
→eth3 4<sup>th</sup> port from left, connects to public network

**CONTROL STATION SERIAL PORTS:**

**Note:** Serial port devices are accessed and read via /dev/ttySx

/dev/ttyS0 Located on back of CS for serial modem access, COM1

/dev/ttyS1 Located on front of CS for serial console access, COM2

**Note:** Change console redirection from COM1 to COM2 by accessing BIOS

/dev/ttyS4 Located on 4-port serial cable and connects to data mover in slot\_2

/dev/ttyS5 Located on 4-port serial cable and connects to data mover in slot\_3

/dev/ttyS6 Located on 4-port serial cable and connects to data mover in slot\_4

/dev/ttyS7 Located on 4-port serial cable and connects to data mover in slot\_5

**Note:** Use following command to check if processes are using Serial ports—only Box Monitor should be using the ports  
#fuser /dev/ttyS4

**ADDING SECOND CONTROL STATION TO NS700 SYSTEMS TO SETUP CS IPMI NETWORK:**

**Note:** Refer to CNS Hardware Upgrade Procedures Guide, ‘Adding a Control Station to an NS700G 4-Way’ system

1. Connect all cables from CS-1 to DMs and new secondary switch
2. Setup secondary CS network on CS, on DM’s, & reconfigures NBS using:

**#/nasmcd/sbin/upgrade\_to\_dual\_intnet**

**Note:** Above script upgrades from eth0 primary internal network and eth0:0 secondary internal network, to the new CS\_IPMI network (192.168.3.0) that allows for communications between Control Stations, eth0:0 is deleted. All data movers must be up and NAS Services must be stopped or script will fail.

**CS IPMI NETWORK CONFIG:** Control Stations are networked between eth1 on CS0 to eth1 on CS1 for IPMI

**# cat ifcfg-eth1**

```
DEVICE=eth1
IPADDR=10.0.3.100
NETMASK=255.255.255.0
NETWORK=10.0.3.0
BROADCAST=10.0.3.255
ONBOOT=yes
```

**Troubleshooting:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Upgrade logs are put in /tmp directory; Files upgraded are /etc/hosts; /etc/nas\_device.map; /etc/modules.conf; /etc/sysconfig/network-scripts/ifcfg-eth1 & ifcfg-eth2; /nas/site/nas\_param; /nas/server/slot\_x/ifconfig; and /etc/sysconfig/network-scripts/ifcfg-eth0:0 file is deleted. There is a problem noted in ETA emc149610 that the upgrade script can remove all VLAN tag ID's and MAC addresses from the CS & DM interfaces.

3. Power-up CS1 and answer prompts, if no mismatch, setup will complete [Control Station comes with software installed]

## **CLARIION TROUBLESHOOTING/NS TROUBLESHOOTING COMMANDS & TOOLS:**

### **BASIC TROUBLESHOOTING:**

# /nas/sbin/getreason

# /nas/sbin/getboxmask -r

# /nas/sbin/t2reset reboot -s 2

→NASDB\_BACKUP and RESTORE options

→Stop and Restart NAS [#/sbin/service nas stop | start]

### **VERIFY CS & NBS PROCESSES:**

#ps -ef |grep nd- [Should be (3) processes, one for each of the (3) NBS devices that are mounted]

**nd-clnt 0 1 →device /dev/nda [/nas/dos]**

**nd-clnt 4 5 →device /dev/nde [/nbsnas]**

**nd-clnt 5 6 →device /dev/ndf [/nas/var]**

# ps -ef |grep -i nas\_box [Should be minimum of (6) Box Monitor processes]

# /sbin/fdisk -l /dev/nda | /dev/nde | /dev/ndf [To verify access to the partitions]

→Ping data mover

→Stop and start NBS services if necessary & manually mount /nas /nas/dos /nas/var

**# /sbin/service nbs stop | start**

**# /sbin/service nbs status**

Configured NBS devices:

254: 0 NbsId: 1

Disk\_Name: nda

Capacity: 11534272 KB

Crnt\_Server: 0X202a8c0

Server\_List: 0X302a8c0 0X202a8c0 0X301a8c0 0X201a8c0

num\_io: 48095 time 89843750 ms num\_sect 1481313 que 0

Avg\_blk: 15 K throughput 8 K/s resp\_tm: 9 ms, ops/sec 0 (output abridged)

### **USING T2TTY FACILITY TO CHECK NBS:**

**/nas/sbin/t2tty -C 2 “logsys add output console” “camshowconfig” “nbsid list” “nbs info” “fcp bind show” “export” “share” “volume info NBS1” “nbsstat list”**

BlkSrvConfigID: : nbsid:1, idtype: 1, name:S1 . . .

BlkSrvConfigID: : nbsid:5, idtype: 1, name:S5 . . .

BlkSrvConfigID: : nbsid:6, idtype: 1, name:S6 . . .

**# /nasmd/sbin/t2tty -C 2 “logsys set output disk=root\_log\_2”** [slot id of DM—turns off output to console]

**# /nasmd/sbin/t2tty -C 2 “logsys add output console”**

**# /nasmd/sbin/t2tty -C 2 “logsys delete output console”**

### **Data Mover NBS Configuration File:**

**/nas/server/server\_1/nbs.cs**

**/nas/server/server\_2/nbs.cs**

**nbs.cs -> /nas/server/slot\_2/nbs.cs.ro**

### **CS NBS Config File:**

**# cat /etc/nbs.conf**

#

# Simple configuration file for nbs service

#

# Format: devIndex:NbsId:Host1,host2,...:

0:1:server\_2,server\_3b,server\_2b,server\_3:

4:5:server\_2,server\_3b,server\_2b,server\_3:

5:6:server\_2,server\_3b,server\_2b,server\_3:

### **T2TTY COMMANDS:**

→Use t2tty commands to send commands to DART serial console, force PXE boot, etc. [Stop NAS Services first]

→Can also use t2tty facility to send commands to DART via RPC [ t2tty –C 2 “ifconfig”]

#/nasmcd/sbin/t2tty -c 2 “logsys add output console” “ifconfig” “fcp bind show” etc.

#/nasmcd/sbin/t2tty -p 2 [Forces DM to PXE boot from DART kernel stored on CS]

**Note:** Disable Data Mover output to console when completed using “logsys set output disk=root\_log\_x” [x=slot]

#### **REBOOTING DATAMOVER USING PEER POWERCONTROL:**

**# /nas/tools/.server\_peer\_powerctrl -reboot 3** [Use only if other DM is not hung]

#### **MINICOM:**

→Use CS Minicom terminal program to observe data mover boot [Stop NAS Services before using]

**Note:** Setup data mover profile using minicom –s & then run “minicom dm2” to access data mover. Use esc + O + Q keys to access BIOS on bootup. This program is useful with NS Series, since it has a serial connection between CS & DM.

#### **T2PXE BOOTING DATA MOVERS:**

**Note:** CS acts as PXE Boot Server for Data Movers

→Stop NAS Services, Start PXE services on CS [/nasmcd/sbin/t2pxe –s –R 4]

#### **Conduct automatic PXE boot using following:**

#/nasmcd/t2tty –p 2 [NAS 5.2.7 and higher—see t2pxe boot section for more recent PXE Boot procedure]

#### **MANUAL PXE BOOT PROCEDURE TO ENTER POST:**

1. Stop NAS Services and manually remount /nbsnas, /nas, /nas/dos, /nas/var

2. Verify dhcp daemon running on CS: #ps –ef |grep dhcp

3. Reset data mover using t2reset reboot –s 2

4. Startup minicom session to the Data Mover

5. At beginning of the Extended POST, the following key sequence is seen on the screen:

*ABCab << Stopping after POST >> DEabcdeFGHabcdIJK*

a) Anytime during the above sequence, press “ctrl + c”, which will allow POST to complete, and then offers the “Storage System Failure...” message, at which point a password can be entered.

**Note:** “ctrl + c” replaces the previous method of using the “esc” key to interrupt POST. Use the “esc” key if ctrl + c does not work.

6. Enter POST configuration password: SHIP\_it or DB\_key (later versions, DB\_key puts you into FCCBOOT menu)

7. Select 40) ICA Sub-Menu and then 2) PXE Boot

8. Observe bootup and perform commands as necessary to troubleshoot

9. Exit minicom when finished (ctrl + A, then type ‘exit’) and disable PXE booting: #/nasmcd/sbin/t2pxe –e

#### **USING SETUP SLOT:**

**Note:** Use setup\_slot only if access to backend through NBS is available. Can help resolve Reason Code 14 issues.

1. Stop NAS Services

2. Mount /nas /nbsnas /nas/dos /nas/var

3. #/nasmcd/sbin/setup\_slot –init 2 [Will regenerate boot.bat & boot.cfg files & bootup data mover with configuration]

#### **CLARIION CACHE DIRTY CONDITION (aka, UNOWNED LUNS):**

#### **ACCESSING ARRAY VIA XP REMOTE DESKTOP TO CLEAR DIRTY CACHE:**

1. Startup XP Remote Desktop

2. Login using clarion clarion!

3. c:>admin tool

4. Select option 2: Recovery Menu →Clear Cache Dirty LU

Password: 29814

Enter LUN Number

5. FSCK file systems as appropriate

**Note:** If getlun does not show an owner, LUN is unowned. All LUNs that have had cache dirty condition should be FSCK’ed before being mounted back on the Celerra Server.

#### **CLEARING CLARIION DIRTY CACHE WITH FLARE 19+:**

Dirty Cache occurs when an SP cannot properly flush its dirty pages or modified data to disk, due to some unusual event

Dirty Cache means data lost

Flare 19 and higher, Dirty Cache can be fixed by right-clicking Unowned LUN in Navisphere>Bring LUN Online

#### **CLARIION UNOWNED LUNS:**

→All Hot Spares are Unowned LUNs held in a special Raid Group

→Orphaned LUNs are Unowned

→CRU signature error results in Unowned LUN, say a disk is physically removed before unbound

→Dirty Cache can also result in Unowned LUN

#### **CLARIION HOT SPARES:**

→Only invoked for User LUNs

→Drive type of HS must be the same as failed disk, except for Blizzard & Northstar drives, which can Hot swap for each other

→Size of LUNs cannot exceed size of Hot Spare

→Recommendation is to use (1) HS per 20 or 30 drives

→A disk rebuild reconstructs private data in flare db, and reconstructs RAID data on logical unit partitions

### **CHECKING FOR DIRTY CACHE FROM NAVICLI:**

# /nas/sbin/navicli -h 10.241.168.52 luncache -list

LOGICAL UNIT NUMBER 0

LUN Offline (Cache Dirty Condition): NO

### **CLEARING DIRTY CACHE FROM NAVICLI:**

# /nas/sbin/navicli -h 10.241.168.52 luncache 0 -clear

### **NAS 5.4 CLARIION STORAGE API CHECKS & HEALTHCHECK TOOL:**

# nas\_storage -list

# nas\_storage -sync -all | id=1 (nas\_storage -sync -all did not work)

**Note:** Synchronizes the Control Station's view of the backend Storage array with any changes that may have happened on backend

# nas\_storage -check -all | id=1

Discovering storage (may take several minutes)

Error 5010: Storage API code=3593: SYMAPI\_C\_CLARIION\_LOAD\_ERROR:

**Note:** Used as a healthcheck command for backend to check if High Availability is configured and available.

### **DETERMING DRIVE FIRMWARE LEVEL:**

# /nas/sbin/navicli -h 128.221.252.200 getdisk -capacity -product -rev -type -vendor -drivetype

Bus 0 Enclosure 0 Disk 0

Capacity: 68238

Product Id: ST373453 CLAR72

**Product Revision: 8A0C**

Type: 0: RAID5 1: RAID5 2: RAID5 3: RAID5 4: RAID5 5: RAID5 16: RAID5 17: RAID5

Vendor Id: SEAGATE

Drive Type: Fibre Channel

### **PEFORMING DRIVE FIRMWARE UPGRADE ON CELERRA INTEGRATED SYSTEMS:**

→As of this entry, several procedures are being written to address the different Integrated platforms [e.g., CX class, CX3 class, etc.]

→Drive firmware upgrades requires that all Hosts be offline, so Celerra Data Movers are halted for all the procedures

→All procedures involve the use of the NST tool and built-in Disk Firmware Upgrade wizard to perform the drive upgrade

→Basic flow is to identify the IP addresses used on the SPs, halt the data movers but leave the Control Station online, connect to either the Internal Celerra network to access the SPs, or connect directly to the array LAN ports using a mini-switch, along with a service laptop on the same network as the SPs, connect to SPA using the NST tool, perform the DFU activity using the wizard after logging into Eng. Mode (ctrl + shift + f12 SIR), then restore Celerra to operation after the Clariion firmware work is done

### **PERFORMING FIRMWARE UPGRADE ON NS350/500/600/700:**

**Note:** The following steps are an outline only, and may differ from the actual published procedure that will be released

1. Connect to Serial port on Control Station from laptop and open hyper-terminal session

2. Connect to Control Station over IP using SSH

3. Do healthcheck & identify SP IP addresses

/nas/sbin/getreason

/nas/bin/nas\_checkup

tail /etc/hosts

/nas/sbin/model

nas\_version

navicli -h getcrus | getagent | getcache (record Read and Write cache values) | getdisk -product -rev -type -vendor

4. Halt each Data Mover using server\_cpu –halt now, disconnect from SSH session, then remove Data Movers physically from backplane (or unplug the power to the Data Movers)

5. Configure laptop with IP address on Celerra Internal network (usually 192.168.1 or 128.221.252)

6. Plug laptop LAN port into 8-Port Allied Telesyn switch located behind the Control Station

7. Ping IPs of SPA and SPB to ensure connectivity (SPA IP 128.221.252.200; SPB IP 128.221.252.201)

8. Launch NST tool, connect to SPA, log into system, then proceed to Eng. Mode using ctrl + shift + f12 and password: SIR

9. Click on Engineering>Upgrade Disk Firmware: Disk Firmware Upgrade wizard Welcome screen

10. Follow prompts and browse to .fdf firmware upgrade package and proceed with upgrade

11. If Vault drives are involved in the upgrade, the DFU wizard will have to be run a 2<sup>nd</sup> time, as the code will only allow 2 vault drives to be upgraded during each pass. With vault drives involved, the DFU wizard will show a Red Error for the “Verifying second

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
pass disks upgraded” message, at which point the NST should be completely closed. Relaunch the NST, login, then run the DFU wizard to complete the remaining drive firmware upgrades.

**Note:** The firmware itself is flashed in seconds, with the majority of the time taken to allow both SPs to reboot a couple of times during the DFU process

12. Once NST says the firmware upgrade is completed, confirm array status by opening Navisphere, check for any faults, rightclick arrayname>Disk Summary to visually check firmware version, then open the SP Event Log and look for 778 event, which should have a message: “LCC Firmware complete on all.”

13. Reboot Control Station

14. Reinsert Data Movers

15. Wait about 5 minutes, then log into Control Station using SSH, and healthcheck the Celerra system

/nas/sbin/getreason

/nas/bin/nas\_checkup

server\_mount ALL

navicli -h getcache | getcrus | getlun -trespass

## **CLARIION STORAGE ARRAY PRODUCTS:**

→Clariion AX100i, CX300i, and CX500i Native iSCSI Storage Arrays, Feb 2005 [iSCSI support--NAS, NetWin, Symm, Connectrix] CX300, CX500, & CX700 GA 9 February, 2004, running embedded Windows XP O/S on SPs

→Each data block on array contains 8 bytes error checking data (LRC, Shedstamp, Writestamp, Timestamp), and SNiiFER runs in backup continuously checking block data integrity

→All fibre disks are dual-ported

→LCC A is located on right of system and B on the left, when viewed from rear

→Backend loop for CX arrays consists of a single FC\_AL loop from Primary port on DAE2 and through all 15 disks of the enclosure, then out to the next DAE via the Expansion port to the next LCC card, and all disks, eventually returning via the alternate LCC path and drives to the SP

→Backend loop consists of SP Port, Cables, Cable Ports on LCC/BCC, and Disk Drives

## **SP AMBER LIGHTS CX/CX3/CX4:**

¼ Hz indicates system doing BIOS

1 Hz indicates system doing POST

4 Hz indicates O/S is booting, but FLARE/NDUMON are not yet started

Solid Amber indicates a fault condition

Lights off indicates normal operation

## **CLARiiON CX3 ULTRASCALE SERIES:**

### **CX3-10 ULTRASCALE TACKHAMMER PLATFORM:**

GA Feb 14, 2007; Flare 24 patch 008 minimum; 60TB capacity

→CX3-10C offers both iSCSI and FC connectivity for Hosts, 64 Hosts maximum, 60 drives max., 128 Host initiators, 512 LUNs

→No hardware upgrades to CX3-10c until a future timeframe

→Clariion is marketing only the CX3-10c model, which will support either all FC drives, FC vault drives and ATA, or all ATA vault drives & ATA drives; Single 1.8GHz processor per SP; 1GB memory per SP; (2) 1Gb/s FC/iSCSI ports per SP, (2)4Gb/s FC front-end ports per SP, & (1) 4Gb/s FC BE port for DAE per SP; Single SPS with 2<sup>nd</sup> SPS optional; (2) LAN management ports; (2) Serial ports

→Base system comes with SPE3 enclosure & single 1000watt DC SPS, 4-power supplies/cooling fans, two SPs, single DAE with minimum 6 drives

#### **CX3-10C Front-End Connectivity:**

(2) 4Gb FC optical ports/SP

(2) 1Gb copper Ethernet ports for iSCSI/SP (iSCSI targets via GbE LAN, direct-connect to NIC, or connect to Host Initiator HBA)

#### **CX3-10C Back-End Connectivity:**

(1) 4Gb FC arbitrated loop port/SP

#### **CX3-10DC-FD ULTRASCALE SERIES:**

Model GA July 2007, NEBS certified with 2U chassis for DC power, FC ports only, Aries Flare code, no SPS units, no PowerPath 2GB memory per array; 64 Hosts per array; (4) FC-only ports per array & (2) BE ports; Max. 60 drives, 30TB, 512 LUNs; FC Drives

#### **CELLERRA CX3-10 VARIANTS:**

**Note:** CX3-10 is stripped down version of CX3-20—no Combo card and SP's have only 1GB memory

#### **CX3-10 for NS2-AUX (Celerra NS20):**

(2) FE FC Ports

(1) BE FC Port

#### **CX3-10F for NS2-AUXF (Celerra NS20 where SPs have additional Headhunter Quad IO Module):**

(6) FE FC Ports  
(1) BE FC Port

### **CX3-20/CX3-40 PLATFORMS:**

- Replacement to CX300/500 family
- Both CX3-20 & CX3-40 family supports 2 or 4GB UltraPoint disk array speeds (DAE3P) & 4GB FC port speeds
- First offering for Tiered Services (NS20 only) and for CRU (Customer Replaceable Units)
- Flare 22 patch 034, support increased to allow for upgrades from CX2/3/4/5/6/7 models to the CX3 platform, and for new 500GB SATA II disk drives
- Some configurations will allow both iSCSI and FC clients, though access to both protocols from the same Host is not allowed

### **CX3-20 ULTRASCALE JACKHAMMER PLATFORM:**

Flare 24 minimum, 55-59TB capacity, Single 2.8GHz processor per SP, 4GB total memory per array, max. Write Cache 1053MB; 120 drives max; 128 max Hosts; 1024 LUNs; CX3-20 arrays will be Customer-installable, and will use Navisphere Service Taskbar (NST) tool for limited hardware maintenance and software upgrades

#### **CX3-20 Front-End FC Connectivity:**

(2) FE FC ports to FC Switches or Servers/SP

#### **CX3-20 Back-End FC Connectivity:**

(1) BE FC port to DAE's/SP arbitrated loop

#### **CX3-20c ULTRASCALE SERIES:**

Same hardware as CX3-20 except for addition of iSCSI IO module; Flare 22 patch 506; max 120 drives, 128 Hosts, 256 initiators per array, 1024 LUNs

#### **CX3-20C Front-End FC Connectivity:**

(1) FE FC ports to FC Switches or Servers/SP

(4) FE 1GbE iSCSI ports (targets) to GbE LAN, Host NIC, or Host HBA Initiator/SP

#### **CX3-20C Back-End FC Connectivity:**

(1) BE FC port to DAE's/SP arbitrated loop

#### **CX3-20F ULTRASCALE SERIES:**

Max 120 drives, 128 Hosts, 256 initiators; 1024 LUNs per array; No iSCSI; Requires Flare 24, patch 007 minimum

**Note:** Ports labeled 0 Fibre – 5 Fibre, & BE0

#### **CX3-20F Front-End FC Connectivity:**

(6) FE FC ports to FC Switches or Servers/SP

#### **CX3-20F Back-End FC Connectivity:**

(1) BE FC port to DAE's/SP arbitrated loop

#### **CX3-20FDC or FD ULTRASCALE SERIES:**

Same hardware as CX3-20F except the FDC supports DC power for NEBs certification: Flare 24 patch 008 minimum--Flare 03.24.040.5.008; 4GB memory, 64 Hosts, (12) FC ports, (2) BE ports, 120 drives, 59TB, 1024 Luns per array; (6) optical Front-end ports & (1) Back-end copper port per SP

### **CX3-40 ULTRASCALE SLEDGEHAMMER PLATFORM:**

Flare 24 minimum, 114-119TB capacity

(2) 2.8GHz processors per SP, 8GB memory per array with max 2500MB Write cache; 240 drives max; 128 Hosts and 2048 LUNs;

#### **Front Chassis View, I-to-r, SPA, SPB:**

Power Supply Fan & Supply module, I-to-r, PS A0, PS A1, PS B0, PS B1 [green LEDS, steady or flashing amber with faults]

#### **Back Chassis View, I-to-r, SPB, SPA:**

IO modules, Fibre optical, Fibre copper, Ethernet, and Serial connections

Power LED green for normal; Fault LED 1/4Hz for BIOS checking; 1Hz for POST; 4Hz for Booting OS; 2Hz for NMI Button pressed

#### **CX3-40 Front-End FC Connectivity:**

(2) FE FC ports to FC Switches or Servers/SP

#### **CX3-40 Back-End FC Connectivity:**

(2) BE FC ports to DAE's/SP arbitrated loop

#### **CX3-40C ULTRASCALE SERIES:**

Flare 22 patch 506; Same hardware as CX3-40 except for new Combo iSCSI IO module; max 240 drives, 128 Hosts, 256 initiators per array; 2048 LUNs

#### **CX3-40C Front-End FC Connectivity:**

(2) FE FC ports to FC Switches or Servers/SP

(4) FE 1GbE iSCSI ports (targets) to GbE LAN, Host NIC, or Host HBA Initiator/SP

#### **CX3-40C Back-End FC Connectivity:**

(2) BE FC ports to DAE's/SP arbitrated loop

#### **CX3-40F ULTRASCALE SERIES:**

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Max 240 drives, 128 Hosts, 256 initiators per array; 2048 LUNs per Storage system; No iSCSI ports this model; Flare 24, patch 007 minimum

**Note:** Ports will be labeled 0-3 Fibre for Front-end, and BE0-BE3 for Back-end

#### **CX3-40F Front-End FC Connectivity:**

(4) FE FC ports to FC Switches or Servers/SP

#### **CX3-40F Back-End FC Connectivity:**

(4) BE FC ports to DAE's/SP arbitrated loop

**Note:** Celerra will use the CX3-40F for the NS40F Model

#### **CX3-40FDC MODEL:**

Same hardware & IO ports as CX3-40F except the FDC supports DC power for NEBs certification—Flare 24 patch 008 minimum

### **CX3-80 ULTRASCALE HAMMERHEAD PLATFORM:**

Flare 24 minimum, 234-239TB capacity, Highend SAN/NAS storage, replacement for CX700, 4U Enclosure, Dual 3.6GHz Processors, 16GB memory per array; max. 480 drives, 256 Hosts, 2048 LUNs, 512 max. initiators per array; No iSCSI ports for this model; SAN Management Module allows communication between SPs; LCCs provide point-to-point comms between SPs and DAE3Ps; FC Copper SFP to HSSDC2 cable from SPs to DAE3Ps; HSSDC2 to HSSDC2 FC Copper cables between DAE3P enclosures; LC to LC FC optical cables between SAN Hosts and SPs; (8) port GbE module for NAS support (6 cu and 2 optical);

#### **Front-End Connectivity:**

(4) port fibre optical 4GB FC Module for FE SAN/NAS per SP

#### **Back-End Connectivity:**

(4) port arbitrated loop 4Gb/s FC BE ports per SP

### **ULTRASCALE DISK DRIVES:**

73GB or 146GB 2Gb/s FC 10k RPM drives; 73GB or 146GB 4Gb/s FC 15k RPM drives

300GB 2Gb/s FC 10k RPM drives

500GB 2Gb/s FC 7200rpm drives

500GB 4Gb/s SATA II 7200rpm drives

### **RAID TYPES FOR ULTRASCALE ARRAYS:**

RAID 0 3-16 drives; no data protection

RAID 1 2 drives; mirrored pairs

RAID 1/0 2-16 drives; mirrored and striped [Not supported until Wormwood platform]

RAID 3 4+1 or 8+1 parity

RAID 5 3-16 drives; parity striped across drives

#### **BE PORT TYPES:**

HSSDC2 copper arbitrated loop FC connectors

### **CLARiiON CX4 FLEET SERIES:** GA August 4, 2008, Flare 28 04.28.000.5.008 bundle used on all CX4 platforms

**Models:** CX4-120C, etc. “C” denotes that arrays are sold with combination Fibre Channel & iSCSI IO ports on SPs

Nautilus (CX4-120), Ironclad (CX4-240), Trident (CX4-480), and Dreadnought (CX4-960—4U chassis) to replace the CX3 UltraScale Series CX3-20, CX3-40, & CX3-80, respectively.

64-bit Flare 28 “Proteus” Windows 2003 kernel for SPs (CX3 ran XP)

Mix & match support for FC, iSCSI, SAS, GbE, 10Gb IO modules

Based on Black Widow system design for next generation of Clarion and NAS products

Single SP Write Caching (GWCA—Greater Write Cache Availability)

IO Throttling on vault drives

5-6 different IO modules available, billed as “self-installable”, though requires array reboot—SLIC IO modules will be customer installable, but EMC maintained

Increase in drive count and performance

Support for SAS/SATA IO modules and enclosures

ICA Image to be on a Flash card (image of boot partition for an SP)

IPV6 support

In Place Upgrades from CX or CX3

Replacement SPs will not ship with DIMMs or CPU board—replace components from existing SP

Write cache is not disabled during NDU operations, single SP failure, single SP removed or rebooted, etc.

#### **Jupiter Program—Flare 30.50x GA Q4 2010:**

→Rollout of the 2-port 10Gb FCoE SLIC for CX4 class arrays, as a direct connection from the array to an FCoE switch

→Allowing use of Active Twinax cabling for 10Gb iSCSI modules

→Modification of the CLARiiON CLI Test Event for Heartbeat

**navicli -h <sp\_ip> eventmonitor -heartbeat -insert**

- First release will not support layered application functionality
- Automatic checking for SnapShot Rollback status prior to doing a Clone Sync or Reverse Sync operation
- Support limited to Windows 2003/2008, VMware, and Linux hosts (Post GA support for SUN, AIX, HP-UX)

### **BLACK WIDOW SPO CPU:**

- Black Widow 2U SPE CPU module, with either a single 2.2GHz or Dual-core 1.6GHz processor system, up to 8GB memory, 64-bit architecture, for both Trident and Ironclad platforms, respectively
- (5) IO modules max. for both Blades & SPs, with max. of 20 ports per Blade & SP
- Akula SAN Mgmt module [with integrated Broadcom BCM5397 switch used to connect the Service & Mgmt LAN ports to either CPU, with a crosslink connection between ports for peer Mgmt]
- Nimitz NAS Mgmt module, with (2) LAN mgmt ports & (1) Uplink port (1 GbE), (1) micro DB-9 serial port, (1) USB port for external connections, and an NMI button, to be used with Trident & Ironclad Clariions
- Tomahawk 4-port Fibre Channel I/O module [1-4Gbps capable]. Any of the I/O ports could be configured for direct FE Host connectivity, Switched fabric connectivity, or BE DAE connectivity, and can also be Optical or Copper SFPs.
- Harpoon 2-port iSCSI I/O module
- Enclosure ID will be stored in midplane resume PROM

**Note:** Resume PROM is stored in non-volatile memory on the backplane. Software is used over serial buses to determine unique enclosure addresses for system components and then store them.

### **DREADNOUGHT (CX4-960):**

- CLARiiON Fleet CX4-960 Flare 28 Proteus 64-bit O/S, replacement for CX3-80, max 960 drives & 32GB system memory
- 4U SPE enclosure, Wildcat-S Quad-core Clovertown 2.33GHz processor; 16GB memory per SP, 512 initiators per array (256 Hosts per SP), 2-port iSCSI Harpoon IO modules, 4-port FC Tomahawk IO modules,
- Uses the Wildcat-S 3.0GHz dual socket CPU running at 1.33GHz FSB
- Supports Clariion, Symmetrix (first HW platform to support Symm—‘Eagle’ low-end & ‘Tigon’ high-end), and Clariion families
- Typhoon or Earthquake NAS Management modules/switch for the Dreadnought & Tigon Arrays (Q3-2008)
- Earthquake NAS module will have ability to redirect serial console to Mgmt LAN network, and implements heartbeat discovery algorithm over mgmt network to assign IDs to each enclosure
- Will support (8) Data Mover blades in DMEs
- Supports (6) IO modules per SP, with max of (16) FC ports, (8) iSCSI ports, & 15 Flex Ports per SP
- 960 FC and/or SATA II drives, up to 64 DAEs, 120 drives per loop, and 8 loops per array
- Supports 512 Initiators per SP, 1024 per Array, with 512 HA hosts
- Supports 4096 LUNs, 256 LUNs per RG, 256 LUNs per SG, 1024 SGs, RAID 0, 1, 3, 5, 1/0, 6

### **DREADNOUGHT EFD DRIVES (Enterprise Flash Drives, flash-based solid state drives):**

- GA date Oct 2008, for Dreadnought platforms only
  - 73GB STEC Zeus drives @52,000 read IOPS/18,000 write IOPS, compared to conventional drives of 250 read/125 write IOPS
  - Flare 28 base, Proteus and Mira
  - Minimum bus speed 2GB
  - Not supported for Vault drives
- Note:** Initially not allowed on Bus 0 [only bus 1 enclosure 0, called the “Enzo” enclosure]
- FC FSSD allowed in multiple enclosures, with no mixing of other drives within same enclosure
  - RAID 5 4+1 or 8+1 configurations
  - Drive type reported as Fibre Channel Solid State Drive
  - Drive format is 512 byte, meaning that Clariion has to use an SFD [Sata Filter Drive] to convert to 520 byte
  - Mira Flare program plans to support a 2GB FC 512byte STEC drive type, and a 4GB FC 520byte STEC drive type

### **TRIDENT (CX4-480) PSN 900-566-002:**

- CLARiiON Fleet CX4-480 Flare 28 Proteus, replacement for CX3-20, max 480 drives
- 2U SPE enclosure, Blackwidow Dual-core Single CPU Xeon 2.2Ghz processor, up to 8GB memory per SP, 256 Hosts per array (128 per SP), 2-port iSCSI Harpoon IO modules, 4-port FC Tomahawk IO modules
- Default Read Cache 512MB
- 1200 Watt 1U SPS per SP, for supporting SPA or SPB & first DAE LCCA or LCCB (Enclosure 0, Bus 0)
- (2) 400 Watt 2U Power Supplies per SP
- Supports (5) IO modules per SP, with max of (12) FC ports, (8) iSCSI ports, and 11 Flex ports per SP
- 5-480 FC and/or SATA II drives, (32) DAEs, 120 drives per loop, 4 loops per array
- Supports 256 Initiators per SP, 512 per array, with 256 HA Hosts
- Supports 4096 LUNs, 256/RG, 512 SGs, RAID 0, 1, 3, 5, 1/0, 6

### **IRONCLAD (CX4-240) PSN 900-566-001:**

CLARiiON Fleet CX4-240 Flare 28 Proteus, replacement for CX3-20, max 240 drives

2U SPE enclosure, Blackwidow dual-core Woodcrest Intel Xeon 1.60GHz processor, 4GB memory per SP, 256 Hosts per array (128 per SP), 2-port iSCSI Harpoon IO modules, 4-port FC Tomahawk IO modules

→Supports (5) IO modules per SP, with max of (8) FC ports & (8) iSCSI ports per SP, & 7 Flex Ports per SP

→5-240 FC and/or SATA II drives using (16) total DAEs (FC, SATA, SAS later on)

→Supports 256 Initiators per SP, 512 per array, and 256 HA Hosts

→Supports 1024 LUNs, 256 LUNs per RG, 256 SGs, RAID 0, 1, 3, 5, 1/0, 6

### **NAUTILUS (CX4-120) PSN 900-566-004:**

→CX4-120 array Q3 2008, replacement for CX3-10 array, 5-120 FC or SATA II drives

→Diskless SPE; max 120 drives; min 5 disks; Dual-core Single 1.2GHz CPU for SPs; 3GB memory per SP; FC, SATA, or SAS; new 1.2KW SPS

**Note:** If you look at the SP system itself, the CPU reports itself as 1.60GHz, which is what the native CPU horsepower is. For Nautilus, FLARE throttles down the CPU to 1.2GHz

→(2) 400 Watt 2U Power Supplies per SP

→Support for up to (5) I/O modules per SP, 2 BE FC ports per array, total of 8 FC ports per SP, 4 iSCSI ports per SP (No FLEX ports)

→Supports 128 Initiators per SP, 256 per array, 128 HA Hosts per array

→Supports 1024 LUNs, 256 LUNs per RG, >2TB LUN size, 16 drives per RG, 128 Storage Groups, RAID 0, 1, 3, 5, 1/0, 6

→Support for RAID 0, 1, 3, 5, 6, 1/0

→Data-in-place conversions from CX or CX3 arrays

→Self installation, upgradeable, replaceable components, Fibre Channel and iSCSI support

→SPs are Hot-Swappable

### **FLEET LED/CX4 LED INFORMATION:**

#### **SPS LEDs:**

##### **Active LED**

Top LED solid green means SPS is On-Line, Fully Charged, and Ready—i.e., operating normally; Blinking green means SPS battery is recharging, On-Line, Charging, Not Ready. Green LED is out if any Amber LEDs are lit.

##### **On Battery LED**

2<sup>nd</sup> LED from top; Amber LED lit = On-Battery mode, AC Power interrupted & SPS supplying battery power to SP/DAE; also illuminated during battery testing

##### **Replace Battery X LED**

3<sup>rd</sup> LED from top; Amber LED lit battery lifetime exceeded or self-test failure occurs, SPS not charged & not able to perform cache destaging function, resulting in write cache disabled

##### **Internal Check/Triangle Fault LED**

SPS has an internal fault, Amber LED lit, write cache disabled

### **SP TRIANGLE LED, AMBER LIGHT:**

¼ Hz indicates system executing BIOS

1 Hz indicates system executing POST

4 Hz indicates O/S is booting, but FLARE/NDUMON are not yet started

→Solid Amber LED indicates a fault condition

→Blinking Amber 1-3-3-1 sequence on bootup indicates Memory problem

→LED off indicates normal operation (or power is off to SP)

→NMI button will reflect 2Hz flashing Amber LED while dump is in progress, remaining until SP reboots

### **SP TRIANGLE LED, BLUE LIGHT:**

¼ Hz indicates Windows OS has booted

1 Hz indicates Flare driver starting

4 Hz indicates Flare drive started

→Solid blue LED indicates SP running in Degraded Mode

→Blue LED off indicates FLARE ready for IO and NDUMon started

### **SP HAND ICON LED, WHITE LIGHT:**

→This is a special LED represented by a “hand” and if illuminated with White light, means that the SP cannot be safely removed

White LED off indicates SP can be serviced normally

White LED on indicates SP cannot be safely removed (Peer could be panicking or rebooting without its Cache configuration; SP could be doing BIOS/POST or Resume prom update; SP could be dumping cache to vault)

### **SPE ENCLOSURE LEDs CX4-120 to 480:**

→Located front middle section of SPE between the 2<sup>nd</sup> & 3<sup>rd</sup> Power Supplies

→Top round LED solid Amber light indicates enclosure is faulted (normal operation is LED off)

→Bottom round LED solid Blue light means SPE is powered up

### **SP MANAGEMENT MODULE:**

Upper left LED off, no power

Upper left LED Amber, faulted

Upper left LED Green, operating normally

RJ45 ports, LED Green off, no link; Amber LED off, no activity; Green LED on, Link; Amber LED flickering, activity

### **SP POWER SUPPLY MODULES—4 modules located on Front of array:**

Solid green LED indicates powered on and normal operation

Solid amber LED indicates faulted module

Blinking amber LED indicates fault external to module (missing AC cord, SP removed, etc)

### **TOMAHAWK FC IO MODULE (SLIC):**

Upper LED off, no power; Upper LED Amber on, faulted; Upper LED Green on, normal powered on

#### **Fibre Port LEDs Green or Blue:**

--LEDs off, no link or SFP;

--Blinking 1Hz green, 1G/2G link speed port marked

--Solid green normal, 1G/2G link speed

--Solid blue normal, 4G link speed

--Blinking 1Hz blue, 4G link speed port marked

--alternating 1Hz blinking blue and green, SFP faulted or not supported type

### **HARPOON iSCSI IO MODULE (SLIC):**

Upper LED off, no power; Upper LED Amber on, faulted; Upper LED Green on, normal powered on

#### **iSCSI Port LEDs Yellow or Green:**

--Power LED, Green indicates good link and should be on

--Link/Act off could be connected or unconnected

--Link/Act blinking Amber 1Hz indicates transmit or receive activity

--Both Link/Act and Power LEDs blinking indicates port marking

### **DISK DRIVE LEDs:**

LED off means not powered on

Solid green LED indicates normal operation

Blinking green LED indicates drive access activity

Solid amber LED indicates drive faulted

Blinking amber LED indicates diplex flash command from navi

### **FLEET LEDs UNDER HW CONTROL:**

→Power supply fault LED

→Air mover module fault LED

→I/O module power fault power good LED

→Tornado power good LED

→System enclosure power on LED

→Diplex LCC fault

### **FLEET LEDs UNDER SW CONTROL:**

→Enclosure fault

→Management module Fault

→IO port RX Loss fibre channel

→IO port connector link and activity LEDs

→IO module power fault LED amber

→CPU module removed

→SP fault [Blue/Amber LED; 1/4Hz amber=BIOS; 1Hz amber=POST; 4Hz amber=Starting OS; 1/4Hz blue=OS booted; 1Hz blue=Flare drive init; 4Hz blue=Flare drivers completed; Off=Flare ready for IO; Steady amber=SP faulted]

→Tornado fault

→Disk drives

### **FLEET DISK DRIVE SUPPORT:** FC, SATA II, SSD

146GB 15k RPM 2Gb or 4Gb FC interfaces

400GB 10k RPM 2GB or 4Gb FC interfaces

300GB 15k RPM “ “

1TB 7200RPM SATA

1TB 5400RPM SATA

73GB SSD (STEC FC Solid State Drives) 2Gb FC Controller, 512-520BPS Emulation, 3.5" form factor

## **MISCELLANEOUS FLEET CLARiiON PROCEDURES/FRU INFORMATION:**

### **Changing SP IP Addresses for Customers:**

- 1) CLARiiON recommends “Destroy Security and Domain Information” using /setup program, then Restart Management Server, and do on both SPs
- 2) Change IPs on SPs and Restart Management Server for each SP
- 3) Connect to SP using Navisphere and select Yes to initialize security
- 4) Once connected to Navisphere, go to File>Set Up Domain>Select Master and highlight SPA

## **DIRECT CONNECTING TO CX4 SERVICE LAN & USING NST or NAVISPHERE:**

### **I. NST**

- 1) Configure laptop with an IP address on CLARiiON default system network:

**128.221.1.249**

**255.255.255.248**

- 2) Open NST, select Options>Network Address Translation (NAT) Connection, and enter default system IP addresses for each SP

**128.221.1.250 SPA**

**128.221.1.251 SPB**

- 3) Log in and use the NST

**Note:** The NAT limitation does not exist for normal public connection to the SP over the Management LAN port

### **II. NAVISPHERE**

- 1) Open web browser and enter public or hard-coded IP address for SPs (e.g., 128.221.1.250)

### **CX4 SERVICE LAN PORTS:**

→Unlike the CX3 arrays, where you physically connected to the Service Port on SPB in order to connect to SPA, the CX4 array Service LAN ports are cross-connected on the midplane between the SPs, meaning that you can physically connect to either SPA or SPB and then connect via Navisphere to either SP. For NST use, use NAT when connecting to the array.

**Note:** See emc199379 for more details.

→Service LAN port is the lefthand port indicated by the “wrench” symbol

→Management LAN port is the righthand port and is typically used by Celerra for the Internal management network configuration

→VLANs are used to separate the Service LAN ports from the Management LAN ports

→Crossover or straight Ethernet cables will work because the built-in BCM Broadcom switch is auto-MDIX enabled, and uses auto-sensing for Tx/Rx transmissions

**Note:** Important point here is that Support folks should NOT use a Hub or Switch between Laptop and SPA and SPB ports, as typically done on CX3 arrays—this may cause packet storm problems that are only resolved by reseating the Management Switch

### **SP MANAGEMENT SWITCHES:**

→Switches are hot swappable, meaning they can be safely removed and re-inserted on a live SP

### **Connecting to Fleet SPs Using Serial Port:**

- 1) Connect mini-db 9 serial cable to SP’s serial maintenance port (wrench symbol)
- 2) Open HyperTerminal and configure as 9600/8/N/1/Hardware Flow Control
- 3) Reboot SP from CLI or Navisphere GUI
- 4) Press esc key during “ABabCabcdefg.....” Output
- 5) Enter password: DB\_key to access Diagnostic Menu

### **Diagnostic Menu**

- 1) Reset Controller
- 2) Display Warning/Errors
- 3) DMI Log Sub-Menu
- 4) DDBS Service Sub-Menu
- 5) FCC Boot Sub-Menu

### **To access the CLARiiON Utility Toolkit Menu:**

→Select 4) DDBS Service Sub-Menu

- 1) Drive Slot ID Check
- 2) Utility Partition Boot
- 3) Force Degraded Mode

→Select 2) Utility Partition Boot

### **CLARiiON Utility Toolkit Main Menu**

- 1) About the Utility Toolkit
- 2) About this Array
- 3) Reset Storage Processor
- 4) Image Repository Sub-Menu
- 5) Plugin Sub-Menu

- 6) NVRAM Sub-Menu
- 7) Enable LAN Service Port
- 8) Enable Engineering Mode (Special password required)
- 9) Install Images to Recover OS
- 10) Save Logs

→Select 9) Install Images to Recover OS if you need to perform a Flare reinstall of the CLARiiON System (contingent on the vault drives having intact utility partitions and the base flare to reload)

#### **Engineering Mode for Toolkit Menu**

- 10) Install Images to Restore Factory Configuration
- 11) Invalidate Data Directory

### **REINSTALLING FLARE OS ON CLARiiON (ICA):**

- a. Ensure both SPs are plugged into the midplane
- b. Connect to Serial Maintenance port on SPA and open HyperTerminal session
- c. Reboot SPA and access ‘Diagnostic Menu’ during POST “ABabCabcdefg...” using esc key, then password DB\_key
- d. Select DDBS Service Sub-Menu>Utility Partition Boot
- e. Enter Engineering mode: 8) Engineering Mode  
password: wombat
- f. If restoring OS from existing partitions, invalidate data directory first: 11) Invalidate Data Directory
- g. Then select 9) Install Images to Recover OS

#### **Select Images to Install →1)**

- 1) ICA\_FLARE\_PARTITION\_REGION 04.28.000.5.003 (Selected this Image for FLARE)
- 2) ICA.Utility\_PARTITION\_REGION 04.28.000.5.001

Are you sure you want to install these images? y

#### **Select Storage Processors to install images for... →3)**

- 1) This SP (SPA)
- 2) Peer SP (SPB)
- 3) Both SP’s

--Select 3) “Both SP’s”

WARNING!! Continue with image installation? y

h. At this point, the ICA takes place in about 30 minutes

i. Reset Storage Processor at the end

**Note:** SPA will reboot several times to complete its FLARE installation—this will take awhile

j. Reboot or reset SPB

**Note:** When reapplying FLARE to system, found I had to also run the above procedure while connected to SPB, with SPA removed from its slot, but did not do the Invalidate Data Directory step—then everything worked.

#### **Other Menus of interest**

#### **CLARiiON Utility Toolkit Image Repository Menu**

- 1) Back to the Main Menu
- 2) List Image Repository Contents
- 3) Delete Files from the Image Repository
- 4) Copy Files from the RAM Disk to the Image Repository
- 5) Copy Files from the Image Repository to the RAM Disk

#### **Image Repository Contents**

- ICA Flare Partitions 0-8
- ICA Utility Partitions 0-5
- Persistent Events.db
- Parameters.cfg
- NonParameters.cfg
- ktrace-20081024\_000638-A.zip
- NonParameters.cfg.old

### **CLARiiON CX5 FIGHTERS SERIES:**

→Next generation CLARiiON arrays

→Using 6Gb SAS backends only (DPE & SPE-based)

**Note:** Future release will support SAS front-end ports

→Flare 31 ‘Scorpion’

→Samsung Flash drive support

→Maximum of (10) DAE’s allowed for a single back-end bus

→Mezzanine card on the SP’s is considered “onboard” or built-in I/O module, therefore will not be a FRU. Also contains SAS & FC controllers.

### **VCX5-75 (CX5-75 Hellcat Lite array):**

- New low-end platform
- Codenamed “Hellcat-Lite”
- Flare 31
- Uses a 3U Sentry Lite DPE consisting of 15-drives, (2) SP’s, single SPS, Power Supplies, Nehalem dual core 1.86GHz CPU Modules, I/O Modules, 4GB memory DIMMs, and (3) internal Fan packs that are not FRUs (loss of 2 fans will shutdown SP)
- Note:** DPE type with “getagent –cabinet” will display DPE7
- SAS, SATA & EFD drives, max. of 75 drives allowed
- Single 6Gb SAS backend bus using only Port 0, of the two SAS ports

### **VCX5-125 (CX5-125 Hellcat array):**

- Replacement for CX4-120
- Codenamed “Hellcat”
- Flare 31
- SAS, SATA & EFD drives, max. of 125 drives
- Uses 3U Sentry DPE consisting of 15 drives, (2) SP’s, single SPS, Power Supplies, dual core Nehalem 2.0GHz CPU Modules, I/O Modules, 8 Gb memory DIMMs, and (3) internal Fan packs that are not FRUs (loss of 2 fans will shutdown SP)
- Note:** DPE type with “getagent –cabinet” will display DPE7
- Two 6Gb SAS backend buses using SAS ports

### **VCX5-250 (CX5-250 Lightning array):**

- Replacement for CX4-240
- Codenamed “Lightning”
- Flare 31
- SAS, SATA & EFD drives, max. of 250 drives
- Uses a 3U Sentry DPE with 15 drives, and (2) SP’s, (2) SPS’s, Power Supplies, quad core 2.13GHz Nehalem CPU Modules, I/O Modules, 12GB memory DIMMs, and (3) internal Fan packs that are not FRUs (loss of 2 fans will shutdown SP)
- Will have more memory, faster CPU, and will use both SAS Ports for (2) back-end buses
- Dual 6Gb SAS backend buses

### **VCX5-500 (CX5-500):**

- Codenamed “Spitfire”, Scorpion Flare, SAS/SATA drives, XPE
- 2U SPE, 2.4GHz Westmere CPU’s for SPs, with 18Gb memory
- Supports SAS, SATA & EFD drives, 500 drives max. using 6Gb SAS ports for (4) backend buses

### **VCX5-1000 (CX5-1000):**

- Codenamed “Mustang”, Scorpion Flare, SAS/SATA drives, XPE
- Uses 2U SPE, 2.80GHz Westmere CPU for SPs, with 24Gb memory
- Supports SAS, SATA & EFD drives, 1000 drives max. using 6Gb SAS ports for (4/8) backend buses

#### **Available DAE’s:**

- VIPER—3U 15@3.5” SAS/SATA drives
- DERRINGER—2U 25@2.5” SAS drives
- VOYAGER—4U 60@3.5” SAS/SATA drives

#### **Available I/O Modules:**

Supercell—1Gbps 4-port FE iSCSI module, for Host or switch connectivity via copper GbE ports. All CX5 arrays except for Hellcat Lite. FRU/CRU.

Hypernova-V—1.5, 3, or 6Gbps SAS 2.0 4-port BE to DAE connectivity to SAS or SATA drives (Viper, Derringer, Voyager)

Cold Front—1.5, 3, or 6Gbps SAS 4-port FE module

Eruption-V—10GbaseT 2-port copper iSCSI module for host-attached (CAT 6/6a/7 cabling), and as 10GbE module for Data Movers  
Cat 6: 55 meters max distance for 10Gbps

Cat 6a/7: 100 meters max distance 10Gbps

Cat 5e: 1Gbps only

Poseidon II—10Gbps 2-port iSCSI module with upgraded chipset

#### **Growler Mezzanine Card:**

- This is an onboard I/O module that contains (2) Backend SAS ports and (4) Frontend FC ports [NOT a FRU]

#### **Heatwave**

- 10GbE 2-port FCoE FE module, to be used with CX4 & CX5 arrays
- Direct-attached Hosts are not supported--FCoE Hosts will connect via an FCoE switch port to which the array will connect to
- Connection interfaces will use 10G optical SFP+ connectors or TwinAx active connectors (1, 3, or 5M lengths)
- CX4-120, 480, & 960 support will be added with Jupiter FLARE Q3 2010
- CX5 support will be added in the Culham release timeframe
- VG2/VG8 will support FCoE Initiator mode connections to FCoE switches with Heatwave IO Module in slot\_0

#### **FCoE:**

Fibre Channel over Ethernet uses lossless full duplex Ethernet, with a dual-port FE IO Module on the SPs for sending FC frames natively over 10GbE Ethernet. FCoE represents a merging of SAN FC over IP Networks. FC0 & FC1 layers in the FC stack are replaced with Ethernet, which runs above TCP & IP layers, therefore FCoE is not routable (limited to a single subnet). Normal Ethernet does not have a flow control mechanism. Enhancements to the Ethernet standard were made to introduce flow control, making it “lossless” Ethernet, or Converged Enhanced Ethernet. Sold with two connector types, an optical SFP+ with optical cables and Active Twinax and 1/3/5M cables (supporting fibre channel frames over 10GbE). Only Jumbo frames of 2240 bytes are supported. Requires use of an FCoE switch and FCoE SLIC on the SPs. Direct connections between Host and Array using FCoE is not supported.

**FCoE Standard:** FC-BB-5

Suitable Ethernet extensions for FC-BB\_E usage are the PAUSE mechanism defined in IEEE 802.3-2008 and the Priority-based Flow Control mechanism defined in IEEE 802.1Qbb (these are the two extensions used to obtain lossless full duplex Ethernet networks).

**Supported Hosts:**

--Linux, Windows 2k3/2k8, VMware

**Ethernet Enhancements for FCoE:**

--Encapsulation of FC frames into Ethernet frames

--FIP, FCoE Initialization Protocol

--Extension to Ethernet standard for lossless Ethernet with Priority Flow Control (PFC)

**NAVICLI Shutdown Behavior changes:**

Both the **shutdownsp** & **shutdownpeersp** commands will shutdown and hold the SP in reset, and also powers down half the drives in the enclosure. To recover, you would need to use rebootpeerSP command from active SP.

The **iportconfig –replace & –upgrade** commands will also shutdown the SP and hold it in reset.

**Backend Bus:**

# **/nas/sbin/navicli -h 10.241.168.188 backendbus -get -all**

Bus 0

Current Speed: 2Gbps.

Available Speeds:

3Gbps.

6Gbps.

**Backend Port connectors:**

**backendbus -get -connstate**

→Will show connector state when mini-SAS HD connectors are inserted into BE SAS ports

**backendbus -get -prominfo**

→Information about Front-End SFP+ ports and mini-SAS HD connectors

**IO Port Info:**

iportconfig –list –iomodule –sp a

**CLARIION AX SERIES—2008:**

**AX4-5/AX4-5F8—MAMBA:**

→Uses Boomslang CPU Module [Sossaman 1.66GHz processor], 32-bit architecture, 2U Disk Processor Enclosure, 4Gb FC backend DAEs, 128 initiator limit per SP (64 HA hosts), max 512 LUNs, 256 LUNs per initiator, 3U DAE with 15 drives; 2U DAE with 12 drives, Release 23 Flare for this platform

→Supports 4-60 drives

→AX4-5F8(100-562-104) array variant for NX4 uses 02.23.050.5.703 Flare

**TYPES OF CLARIION BACKEND LOOPS:**

→Katana Backend loop requires all traffic to pass through each disk’s receiver and transmitter—if one disk R/T is bad, all traffic could be corrupted.

→Klondike ATA Backend loop uses a BCC for the loop

→Stiletto DAE2P & DAE3P Backend loop uses disks that switch into and out of the loop, meaning that only traffic to a bad disk is corrupted—soft SCSI errors isolated to single disk. Still, single bad cable or LCC port can corrupt all traffic and give soft SCSI errors across all disks in the loop

→All CX, CX3, & CX4 arrays use UltraPoint Disk Array Enclosures (DAE2P & DAE3P, respectively), which allow for direct connection to each drive via a switch mechanism within the LCC

**CLARIION DISK ENCLOSURE TYPES:**

→DAE2 Katana 2Gb Disk Drive Enclosure

→DAE2-ATA Klondike SATA I 2GB Disk Drive Enclosure

→DAE2P Stiletto 2GB Disk Drive Enclosure

→DAE3P Stiletto SATA-II Northstar 4GB Disk Drive Enclosure

→DPE2 CX2/3/4/500

→SPE CX700

→SPE3 Jackhammer, Sledgehammer (CX3-20/CX3-40)

→SPE2 HammerHead (CX3-80)

### **TOTAL OF 5 SYSTEM DRIVES FOR CLARIION USING RAID3:**

**SPA Boot Drives 0 & 2**

**SPB Boot Drives 1 & 3**

**Note:** FLARE Configuration & PSM located on first 3 drives

### **CLARIION AX100 STORAGE ARRAY (Piranha):**

Supported with NetWin 200 Version 2.0 & NetWin 110

Entry-level array with (12) Serial ATA (SATA) drives in 2U 3.5" rack-mounted enclosure, max. of 2TB

Supports Windows, Linux, NetWare Servers

AX100SC = Single Controller model/AX100 = Dual processor Controller model with mirrored cache

### **SPS BATTERIES:**

Tested once/week, default is that both are tested at once, which disables write cache, but in actuality, Flare code will allow only one SPS to test itself at a time. Whole purpose of SPS's are to destage data from write cache to vault disks in event of power failure, 2 minutes of backup time. At least one SPS must be fully charged for Write-Cache to be enabled.

### **CLARIION CX700 BARRACUDA STORAGE ARRAY:**

58.4TB capacity with (4) 3GHz processors and (8) back-end fibre ports, support for up to 256 HA Hosts

SPE enclosure houses SPs, Pwr Supplies, Fan modules, SPS units

Vault drive private space uses about 6.4GB per first five drives [SPA Boot on Disks 0 & 2; SPB Boot on Disks 1 & 3; PSM on disks 0-2; Vault area 2.1GB on each disk for all disks 0-4; Flare DB on disks 0-2; NAS core on disk 4; Image repository on disk 4

Mix ATA and Fibre Drives (max. 240 drives, either 4-loop configuration, 60 drives per BE port, or 2-loop configuration with 120 disks per BE port), dual 3.2GHz SPs, 200K IOPS

(4) @2GB Optical FC LC Front-end ports per SP for Host connectivity

(4) @2GB HSSDC-style copper Back-end FC ports per SP—two HSSDC connectors for BE0, BE1, and two HSSDC connectors for BE2/AUX0 & BE3/AUX1 as additional backend loops

(2) 2GB FC CMI [Communications Messaging Interface] channels between each SPs on 64-bit 100MHz PCI-X bus

High-end midrange array with dual 3-GHz processors per SP; Each SPE contains 4GB Cache per SP (3072MB Write, 144MB Read) and 2GB DAE2 disk array enclosure; ranging from 5-240 disks, either Fibre and ATA drives

Max. of 256 Hosts per array at 8/port, 240 drives, 2048 LUNs

**Fibre Channel Drives (DAE2 Katana LCC Cards):** 36GB & 73GB 10k/15k; 146GB 10k;

**ATA Drives (Klondike DAE2 BCC Cards):** 250GB 5400k ATA

### **Fibre Channel Drives (DAE2P Stiletto Enclosure):**

Drives are on a FC loop but only one disk is switched onto the loop at a time—switching technology

**Note:** Enclosures are daisy-chained together, but all traffic must pass through entire backend loop

Requires Flare 13, and has four backend fibre channel ports per SP, uses Windows XP embedded O/S

Max. 256 Hosts per array, max 16 drives per RAID Group, max 128 LUNs per RAID group, 2048 LUNs per array, max. 512 Storage Groups per array; Max 256 LUNs per Storage Group (Initiator)

Min. config is a 4U SPE, a 1U SPS, and a 3U DAE2 = 8U

Max. config is a 4U SPE, a 1U SPS, and (16) 3U DAE2's = 53U

Main difference in ATA enclosures vs. FC are the disks and a modified LCC called a BCC (Bridge Controller Card) that converts FC signals to Serial ATA and vice versa

Upgrade from CX300/CX500

### **CX700 xPB Module:** L-to-R

10/100 LAN port | Grn & Yel LEDs, pwr & fault + Bios, Post, Boot, respectively | SPS async comm. port | IOIOI async console port | Aux0 & Aux1 Fibre Ports | BE0 & BE1 for BackEnd fibre channel ports

### **CX700 NAS Personality Module:** L-to-R

GbE Ports 11, 12, 13 on one PCI-X Bus | GbE Ports 14, 15, 16 on other PCI-X Bus with Green Link light & Yellow activity LED

### **CX700 SAN Personality Module:** L-to-R

2Ghz Fibre Ports 0, 1, 2, 3 FrontEnd Host connections with Green Link LED

### **LAYERED CLARIION APPLICATIONS:**

#### **Clones (BCVs):**

Consistent clones in Flare 19

#### **SnapView Snapshots V2.19:**

Application that can create instantaneous point-in-time virtual copies of LUNs with copy-on-first-write capability, or full Clone point-in-time copies of LUNs; 8 per source LUN, 300 total per array, 100 Snapshot sessions per storage system ((2) types of Snapshots--copy on first write, and BCV clone copies). A Snap rollback to source LUN can be done instantly from any session. BCV's can be

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
incrementally updated from source; Snapshots & BCV's can be mounted RW on Hosts; Fracture a BCV before Host can access;  
Consistent snaps in release 19. Snaps are useful for backing up LUNs, cloning LUNs, etc.

#### **MirrorView/S:**

Full copy synchronous remote mirroring of LUNs between (2) or more arrays (FC4700/CX400/500/600/700).  
LUN of equal-size on a separate storage system that receives host writes simultaneously  
WIL (Write Intent Log) keeps track of in-flight writes to primary side, allowing SP to rebuild fracture log if SP is rebooted  
Consistency Groups keep all LUNs in a set mirrored (16 luns per consistency group, max of 16 consistency groups per CX600/700)  
Requires LUN Masking

#### **MirrorView/A:**

Full copy asynchronous remote mirroring of LUNs between (2) or more arrays, using delta sets  
Snapshots of both Source and Target LUNs can be made, but BCVs of Source/Target not supported  
Rules are similar to MirrorView/S

#### **SANCopy:**

--LUN copy across SAN between arrays or within the same array, both Full and Incremental, of LUNs, metaLUNs, BCV's (eliminates need for Hosts to move the data)  
--Useful for one-time copies of data, or for ongoing Replication between sites  
--Requires installation of the SANCopyEnabler-01.01.5.002-xpfree.ena on the array

### **OTHER APPLICATIONS:**

#### **PowerPath 4.4:**

Host-based path load-balancing and failover, with (8) different policies available [Basic load balancing disabled; Clariion Optimized; Least Blocks Load Balancing; Least I/O Load Balancing; No redirect; Request—uses O/S default; Round Robin; Symmetrix Optimized].

Supports I/O prioritization, FC and iSCSI arrays, automatic path failover, up to 16 HBA's per Host (Hosts that use PowerPath can allow trespassed luns to be restored automatically, whereas Celerra does not)

PowerPath 5.2 supports Windows 2008 hosts

#### **CLARAlert 6.2:**

Remote support for Clariion arrays with Windows management station and modem; notifications sent via emails or dial-up

### **CLARIION CX500 TARPON STORAGE ARRAY:**

NAS 5.3.11-4 and higher

Mid-size array with support for up to 128 HA Hosts, 3U Assembly, DPE2 houses both SPs, 15 disks, two pwr supplies, & cooling fans  
Fibre & ATA Drives mixed in same array, up to 120 drives total with max. of 120,000 iops; Dual SPs; Up to (7) added DAE2's;  
2GB disk array ranging from 5 -120 disks, Fibre or ATA [36GB 10/15k; 73GB 10/15k; 146GB 10k; 250GB 5400rpm ATA]

Requires Flare 13 and supports up to (2) GB Cache per SP [4GB total cache]

DPE2 contains dual 1.6GHz Intel P4 Xeon processors (SP's) with 533MHz FSB, and first (15) drives

DPE2 contains both CX500 SPs and up to (15) drives in the enclosure, while DAE2 contains (2) LCC cards and up to (15) drives  
Two SPS units--from back, RH SPS power-out & sense cables connect to pwr supply A and SPA, LH SPS to pwr supply B and SPB  
Flare resides on first (5) drives, user data resides on 6.4GB and higher portion of each drive

Max. 512 MetaLuns per Storage Array, max. lun size 2TB, and max. number of volumes to build lun is (16), max. storage groups 256  
(4) front-end FC ports and (4) back-end FC ports

(2)@2GB Fibre Channel CMI between SP's (Communications Messaging Interface), Fibre channel running on 100MHz bus

(2)@2GB Optical SFF LC (Lucent Connector) FE ports per SP—Port 0 used only for Host connection; Port 1 can be used for Host connection, unused, or for Remote Mirror connection & (2)@2GB HSSDC Copper BE fibre loops ports for each SP (BE0 & BE1)

**Note:** ATA implementations use BCC (Bridge Controller Cards) that are used to convert FC signals to serial ATA signals on the drives, and vice versa. CX300/CX500 use DAE2 with SP integrated into the LCC

Max. of 128 hosts/array, 4/port, 120 drives, 1024 LUNs

### **CLARIION CX500i/CX300i iSCSI ARRAYS:**

120/60 disks, respectively; 1.6GHz/800MHz SPs, respectively; (2)@1Gb copper ethernet iSCSI FE ports per SP; (2)@2GB BE ports per SP for CX500, (1)@2GB BE port per SP for CX300; 4GB & 2GB Cache per SP, respectively; PowerPath V4.3.1 supports iSCSI arrays; MirrorView and SAN Copy are not supported; Gbe Jumbo frames not supported; Only (1) login per iSCSI name per SP port; MS iSCSI HBA initiator uses same name for all NICs and allows only (1) login per Server to each SP array port; QLogic iSCSI HBA initiator can allow (1) login per HBA name to each array SP port.

### **CLARIION CX300 SNAPPER STORAGE ARRAY:**

Small-size array with large capacity—13TB

Fibre & ATA Drives, up to 60 drives [DPE2 module with 15 drives, which also houses SPs, PwrSupplies, Cooling fans, & up to (3) DAE2 enclosures of 15 drives each]; Upgrades from CX200 not supported; 1GB memory per SP; SP's run 800MHz PIII Tualatin-LP processor with 512KB Level 2 cache; Single or two SPS units

(2)@2GB FE fiber optical ports per SP; (1)@2GB BE HSSDC port per SP; (2) serial ports; Single LAN port

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Disk array, ranging from 5 – 60 disk drives [36GB 15k; 73GB 10/15k; 146GB 10k; 250GB ATA]; Requires Flare 13, supports (2) GB Cache per SP, uses embedded Windows XP O/S

**Note:** The CX500/CX300 arrays are essentially the DAE2 model with the SP integrated into the LCC  
Max. 64 Hosts/array, 4/port, 60 drives, 512 Luns

### **MAX CAPACITY FOR FIBRE CHANNEL DRIVES:**

| Disk  | CX700  | CX500  | CX300 |
|-------|--------|--------|-------|
| 36GB  | 8.6TB  | 4.2TB  | 2.1TB |
| 73GB  | 17.5TB | 8.6TB  | 4.4TB |
| 146GB | 35TB   | 17.4TB | 8.6TB |
| 300GB | 72TB   | 36TB   | 18TB  |

**Note:** Max number of FC drives per RAID Group is 16

### **MAX CAPACITY FOR ATA DRIVES/ATA STORAGE:**

| Disk  | CX700 | CX500  | CX300  |
|-------|-------|--------|--------|
| 250GB | 56TB  | 26.2TB | 11.2TB |
| 320GB | 72TB  | 33.6TB | 14.4TB |

**Note:** Max number ATA drivers per RAID Group is 16, first DAE is FC with min. of (5) drives. 250GB drives are 7200RPM SATA; 320GB drives are 5400RPM PATA. Outside of first DAE, others can be mixed ATA or FC.

**Note:** PATA stands for Parallel ATA drives, with parallel buses from controller to disk using ribbon-type cable, running on 133Mbps buss. Serial ATA using serial communication between controller and disk and runs at 150mbps bus speeds.

### **CLARIION ATA DRIVES/STORAGE:**

Large drives faster than tape but cheaper than fibre-channel. Initial Celerra release consisted of single AVM profile for archiving purposes. Current RAID 5 6+1 Groups with ATA-DAE2 consist of (15) 250GB drives, for a total storage of 2.7TB per Shelf (max. of 4TB allowed per DM for Fibre Channel drives, while 16TB total allowed for ATA drives per DM). Non-integrated storage is storage allocated to Celerra using Access Logix storage groups included in SAN/NAS configurations. Default clarata\_archive profile will attempt to find two LUNs from different RAID groups to create a file system, or from a single unallocated LUN if that fails.

SATA—Serial ATA Drives, first type used

PATA—new 250GB & 350GB PATA Drives used with CX600/CX700.

### **FLARE 19 PATCH 21 ATA DRIVE ISSUES:**

250GB PATA drives have potential issue with systems that are not running Flare 19 Patch 21:

→Disk drive may report successful completion of Write that later results in error on Read: Flare 19 Patch 21 fix is to verify each write

→Disk drive may intermittently timeout during error handling, resulting in faulted drive: Flare 19 Patch 21 fix is to adjust the timeout issues to prevent

→Regular ATA drive rebuild operations will be enhanced by a factor of (3) after drive failures

→Background sniffer operations are 4x faster than previously (Detects and corrects many ‘Soft Media Error’ event 820)

### **SOFT MEDIA ERROR FROM SPCOLLECT:**

```
02/13/2007 15:08:54 Bus 3 Enclosure 0 Disk 11(6a0) Disk soft media error [0x00] 0      22
02/13/2007 18:46:44 Bus 3 Enclosure 0 Disk 11(820) Soft Media Error    [0x00] 0      5
02/13/2007 18:46:46 Bus 3 Enclosure 0 Disk 11(689) Sector Reconstructed [0x00] 267a748 28003000
02/15/2007 05:08:32 Bus 3 Enclosure 0 Disk 11(684) Parity Sector Reconstructed [0x00] abc4c8 28003000
```

### **WINDOWS O/S FOR ARRAY MODELS:**

→CX700/500/300 arrays run embedded XP  
→CX600/400/200 & FC4700 run embedded NT

### **NS700 PLATFORMS:**

#### **BACKENDS:**

CX700→Barracuda      CX400→Tarpon      CX200→Snapper

#### **NS-BARRACUDA: Integrated & Gateway Models**

**Specs:** BARRACUDA SPE 4U Assembly--(2) @3GHz P4 Xeon processors per SP; 533 MHz FSB 4GB 266MHz DDR Memory

**Front-End:** NAS personality card with (6) copper Broadcom 10/100/1000 ports & (2) optical GB ports

**Back-End:** Support for Symm 5.0 & 6.0 DMX only; CX600, CX400, CX200; FC-AL for NAS-only and direct-attached SAN/NAS; FC-SW for fabric-attached SAN/NAS with Access Logix required; Support for FLARE 13; Supports baseline 8GB memory per SP. Supports 15k 36GB FC, 10k 73GB FC, 15k 72GB FC, 10k 146GB FC, 250GB ATA, 320GB ATA. O/S runs on XP. CX700 has four buses to backend, so AUX-0 and AUX-1 can be used for BackEnd or Tape Drives [BE-2 & BE-3, respectively]

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
Raid 5 (4+1, 8+1); Raid 5 (4+1); Raid 1; Raid 5 (6+1) ATA drives; (3) Fan Modules; 2-minute SPS for Write Cache destaging as backend for SPE and first DAE2; Max. 240 drives per array; same DAE2 style as the CX600

- (4) 2GB front-end fibre LC ports per SP
- (4) 2GB back-end copper HSSDC fibre channel loops (BE0-BE3)

#### **Requirements:**

NAS 5.2 & Flare 13 that supports both non-Access Logix & Access Logix

Supports Timefinder/FS & RDF

#### **NS4B BARRACUDA:**

- Gateway NAS version with (4) Data Movers [3 Primary and 1 Standby]  
Enclosure 0 = Server\_2 & 3 Enclosure 1 = Server\_4 & 5
- Dual Control Station support [Falcon 1U SPO Storage Platform Operations]
- CS reset using IPMI v1.5 Intelligent Platform Management Interface [CS will use IPMI to reboot and detect presence of standby]—CS communicates with hardware via BIOS. IPMI consists of a physical link between Control Stations and can be verified with the following command if logging “IPMI Connection Failure” events. Cannot reboot the other CS if this link is down, though CS failover would still occur.

#### **#/nasmcd/sbin/t2tty -m emcnasotherIPMICS\_i3**

- Com1 & Com2 will be used to communicate to CS0 and CS1
- Broadcom Ajaguar NAS personality card optional [8 Ethernet and 1 Management ports]
- CS boots from Linux OS from onboard IDE driver and accesses NASDB & DOS via NBS protocol
- DMs PXE boot from CS ide drive if they cannot find DOS boot partition on backend storage—if no Enclosure ID is found, or DM MAC addresses mismatched, DM boots to minimal config from slot\_99 with reason code 14
- New Linux boot loader replaces LILO [GRUB]

#### **NS INTEGRATED SYSTEMS:**

- setup\_clariion script is run on CS, via Celerra Manager or CLI, to configure backend
- Availability of System\_defined Templates, as well as use of User\_defined Templates

#### **CX Standard Raid 5 Template:**

- 4+1 RAID 5, HS, 8+1 RAID5 for 1<sup>st</sup> Shelf
- (3) 4+1 RAID 5 for next shelf, following by alternating 4+1 RAID5 8+1 RAID5, and (3) 4+1 RAID5

#### **CX All 4plus1 Raid 5 Template:**

- 4+1 R5, HS, 4+1 R5, HS, HS, HS, HS 1<sup>st</sup> shelf
- All other shelves use (3) 4+1 R5

#### **CX Standard Raid 1 Template:**

- 4+1 R5, HS, 8+1 R5 on 1<sup>st</sup> shelf
- All other shelves have (7) RAID1 groups

#### **User Defined Templates:**

- greater flexibility in mixing shelves of diff. RAID types, each shelf must be defined by User, RAID3 can be used and mixed with RAID 5 shelves
- RAID3 Introduced in NAS 5.4 for ATA B2D solutions
- Configure RAID1 for logs and RAID5 for tablespace for Oracle solutions

**Note:** Arrays with ATA storage must be setup using User\_defined Templates, using CLI

#### **CHECKING SP IP ADDRESS CONFIGURATION:**

#### **# /nasmcd/sbin/navicli -h 10.241.168.52 networkadmin -get**

Storage Processor: SP A  
Storage Processor Network Name: nyip2spa  
Storage Processor IP Address: 10.241.168.52  
Storage Processor Subnet Mask: 255.255.255.0  
Storage Processor Gateway Address: 10.241.168.128

#### **CHANGING IP ADDRESSES OF SP's:**

#### **C:>navicli -h 192.168.1.201 networkadmin -set -address 192.168.1.200 –subnetmask 255.255.255.0 –gateway 192.168.1.100**

**Note:** SP's reboot when changing IPs, until Flare 29

#### **CHANGING CLARiiON SP IP ADDRESSES WITH GATEWAY CELERRA:**

#### **Prerequisites:**

NAS 5.6.40 or higher

See emc200831 for the published procedure. Please note that the following procedure contradicts the official CLARiiON procedure in that SP's should be removed from the Security Domain and all security destroyed before changing SP IP Addresses. The following

Celerra TechGuide EMC CONFIDENTIAL--INTERNAL USE ONLY—NOT A FORMAL EMC PUBLICATION!!!  
procedure to update the symapi with the changed IP addresses will not work if the Security Domain is removed. It's possible, yet untested, that the Clariion steps could be performed to change IP addresses, re-establish Domain Security, and then the Celerra symapi updated.

1. Change the IP address for SPA using Navisphere or CLI
2. After waiting for SPA to reboot and stabilize, repeat Step 1 for SPB

**Note:** Wait until array settles back to normal operation before continuing

3. Use either of the following commands to update the symapidb with the new IP addresses:

**# nas\_storage -modify id=3 -network -spa 10.241.168.40 -spb 10.241.168.41**

Changing IP address for APM00030600863

**# nas\_storage -check -all**

Discovering storage (may take several minutes)

Done

4. Update CLARiiON Security cache files on the Control Station:

**# nas\_storage -modify id=3 -security -username nasadmin -password nasadmin**

Setting security information for APM00030600863

Done

5. Verify security file updates:

```
# ls -la
-rw-rw-r-- 1 nasadmin nasadmin 276 Oct 21 15:49 .clar_security
-rw-rw-r-- 1 nasadmin nasadmin 0 Oct 21 15:49 .clar_security.lck
# ls -la /etc/.clar*
-rw-rw-r-- 1 nasadmin nasadmin 276 Oct 21 15:49 /etc/.clar_security
-rw-rw-r-- 1 nasadmin nasadmin 0 Oct 21 15:49 /etc/.clar_security.lck
# pwd
/nas/symapi/config
# ls -la
-rw-rw-r-- 1 nasadmin nasadmin 229 Oct 21 15:49 emcpwddb.dat
```

6. Vi update the /etc/hosts and /nas/site/sp\_info files with new IP addresses

7. Reboot Control Station, then verify IP communication & Navicli authentication with the array

**# /nas/sbin/navicli -h 10.241.168.40 security -list**

Username: nasadmin

Role: administrator

Scope: global

8. Trespass LUNs to Owner SP if required, using Celerra Manger or CLI ‘trespass lun x’

9. Run setup\_clariion -check\_and\_update -all

**# /nas/sbin/setup\_clariion -check\_and\_update APM00030600863**

CLARIION(s) APM00030600863 will be setup.

Setup CLARiiON APM00030600863 storage device...

System 10.241.168.40 is up

System 10.241.168.41 is up

Clariion Array: APM00030600863 Model: CX600 Memory: 4022

Validating APM00030600863 storage group 'Hammer1'

Setup of CLARiiON APM00030600863 storage device complete.

Discovering storage (may take several minutes)

Done

## **CELLERRA NSX SERIES:** (aka Celerra Hammerhead)

--Titan 40U-60 cabinet consists (single or dual 24 AMP service) of Enclosures, Control Stations, ATS Boards, UPS's, and Modems

--First released with NAS 5.4.14.3, Champagne code—Gateway solution only

--NSX System totals up to (4) Data Mover enclosures, (2) Control Stations, (2) UPS, and (2) Modems

--Units ship with minimum 4-Blades and up to 8-Blades maximum, and minimum of 2-Control Stations

--High-end NAS Gateway using up to (8) data movers [aka Blades, XBlade 60 used in this first generation model] (4-enclosures daisy-chained with Ethernet) and 1-2 Chivas Control Stations

--Designed to replace the CNS cabinets [upgrade from CNS or NS-Barracuda-4]

--Supports Clariion and/or Symmetrix

--No serial communication between CS and DM, only RPC via internal network

--Shipped with Titan cabinet of (4) DM enclosures pre-wired

**Note:** Chivas CS will only be used with NSX series

## **NSX CABINET Bottom-to-Top:**

### **NSX HAMMERHEAD FEATURES:**

- NS & NSX Gateway Models will have ability via ksnas.cfg file to automatically configure Zoning, WWN's, LUNs, RAID GROUPS, and STORAGE Groups during installation for CONTROL LUNS only, as well as Ethernet for CS & DM's
- boot: serialkickstart ksnas.cfg** → Installs are invoked with this command after booting from install floppy
- faster NAS installs as there are multiple PXE boots of servers [User LUNs created after install]
- New utilities to add, remove FRU's & enclosures, as well as to verify cabling: setup\_enclosure; enclosure\_status
- Updated t2tty facility for NSX that uses internal network to pass commands from CS to DM (no serial from CS to DM with NSX)
- New getreason -e facility and codes to troubleshoot cabling and hardware issues

### **XBLADE 65 H2G2 2<sup>nd</sup> GENERATION NSX:**

- New Xblade65 data mover supported with NAPA II NAS 5.5.22.2, GA Aug 11, 2006
- 3.6GHz P4 processor 4GB memory 800MHz fsb with (3) I/O Modules & Wildfire-4 motherboard:  
One ‘twister’ blade module with four 4GB FC ports [BE0, BE1, FE0, FE1] for tape and storage connections, one ‘blizzard’ blade module with two Optical 1GB Ethernet ports [fge0, fge1] and six Copper 10/100/1000 BaseT Ethernet ports [cge0, cge2, cge3, cge5], and a third ‘tempest’ module with a single Neterion Xframe Optical 10GbE port [fxg0]
- NSX supports 2-4 blades, 2 Control Stations, 2 ATS, 2 UPS, 2 Modems, contains Broadcom 5325M 5-port Management switch—3 ports [Port 0 Uplink eth0, Port 3 Downlink to Port 0 next enclosure, Port 4 to CS1 or UPS management port in Enclosure 2] are accessed from front of the switch and the other two are wired into the backplane and accessed from RS232 Serial Ports—A port is for Blade0, B port is for Blade1, requiring special USB-to-Serial cable Part # 038-003-157

### **NSX BLADE ENCLOSURES:**

NSX can have up to (4) Blade Enclosures, called Blade Enclosure 0 – 3, each with (2) Data Mover “Blades” per Enclosure  
Each Enclosure consists of (2) DM's, (2) Management switches, & (2) Power Supplies

Data Mover module contains Fibre IO module on left side and Ethernet IO module on right side, memory in middle, CPUs in back

### **ENCLOSURE MONITORING:**

4 fans; 2 pwr supplies; 2 Management Switches; 2 DM blades; 2 I/O Modules per DM blade;

Cabinet UPS Monitoring & new FRU faults; (1) I/O annex per DM blade

**Note:** NSX/NS80 IO Annex sits underneath the Blades, with left-half of the Annex for Server\_3 and right-half of Annex for Server\_2. IO Annex supports 10GbE Ethernet IO card. See 100-561-787 for IO Annex Assembly.

### **REPLACING ENCLOSURES:**

→ Stop NAS, Replace Enclosure, run following commands:

```
# /nas/sbin/setup_enclosure -removeEnclosure <encl id>
# /nas/sbin/setup_enclosure -checkSystem
# /nas/sbin/setup_enclosure -addEnclosure <encl id>
# /nas/sbin/setup_enclosure -checkCable
# /nas/sbin/setup_enclosure -changeSubnet 0 | 1 <new subnet>
# /nas/sbin/setup_enclosure -checkSystem autoRepair
```

→ Configure new WWNs and Storage Group configurations, restart NAS

```
# /nas/sbin/enclosure_status -e 0 -v
```

**Note:** Output below is for Enclosure 0—adjust syntax when troubleshooting other Enclosures. Checks for Alarms, Status, and FRU failures

## **RESUME CSUM ERRORS & AMBER LEDs ON ENCLOSURE EXAMPLE:**

Enclosure\_status command was returning following error

**# /nas/sbin/enclosure\_status -e 0 -v**

-----RESUME CSUM ERRORS-----

```
Failed    Typhoon x Csum Error Failed
```

```
Pass     PS x Csum Error Pass
```

```
Pass     CB x Csum Error Pass
```

```
Pass     Midplane Csum Error Pass
```

**Corrective Action:** Reset the Management Switches by rebooting the switches

**# /nas/sbin/setup\_enclosure -resetMgmtswitches**

Run the appropriate reset checksum command to the affected switch:

**# /nas/sbin/t2net\_test -SetResumeCksum 4 20**

**Note:** The first number “4” is slotID [between 2-9] & second number is the operand--“20” is Hex for decimal value 32, which is Management Switch A. You may want to check with EE before using this command—see emc153229

**# /nas/sbin/t2net\_test -SetResumeCksum 4 34**

Resume cksum for this device has been updated. New Cksum = 0x6a8f57d9

t2net\_test: Command succeed

**Note:** Another syntax example, not sure which one is the correct one

### **operand values:**

1(Blade A Smbus Slave Port)

2(Blade B Smbus Slave Port)

3(Blade A Fault Expander)

4(Blade B Fault Expander)

5(Power Supply A)

6(Power Supply B)

7(LM93 A)

8(LM93 B)

**Following Decimal values work on all NAS 5.4 and 5.5.28.0+ code (AR80391)—convert to Hex for earlier versions of 5.5:**

32(Mgmtswitch A) →Hex = 20, etc.  
33(Mgmtswitch B)  
34(Blade A)  
35(Blade B)  
36(I/O Annex A)  
37(I/O Annex B)  
38(Blade A I/O A)  
39(Blade A I/O B)  
40(Blade B I/O A)  
41(Blade B I/O B)  
42(Power Supply A)  
43(Power Supply B)  
44(Midplane)  
45(Blade A - I/O Blade 0 SFP0)  
46(Blade A - I/O Blade 0 SFP1)  
47(Blade A - I/O Blade 0 SFP2)  
48(Blade A - I/O Blade 0 SFP3)  
49(Blade A - I/O Blade 1 SFP0)  
50(Blade A - I/O Blade 1 SFP1)  
53(Blade B - I/O Blade 0 SFP0)  
54(Blade B - I/O Blade 0 SFP1)  
55(Blade B - I/O Blade 0 SFP2)  
56(Blade B - I/O Blade 0 SFP3)  
57(Blade B - I/O Blade 1 SFP0)  
58(Blade B - I/O Blade 1 SFP1)

**Example of getreason -e codes and comparison to Getsyscode output for Slot\_2:**

# /nas/sbin/getreason -e

5 - slot\_2 contacted (Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c)

**Note:** Post Code is operand value 3; Mid Code is operand 8; Blade Code or fault is operand 6

# /nas/sbin/t2net\_test -Getsyscode 2 3

The returned system value is 0x61

# /nas/sbin/t2net\_test -Getsyscode 2 8

The returned system value is 0x80

# /nas/sbin/t2net\_test -Getsyscode 2 6

The returned system value is 0x2C

**Getsyscode Operand Values are different from SetResumeCksum:**

# /nas/sbin/t2net\_test -Getsyscode

**operand values:**

0(Blade ID),  
1(Enclosure ID),  
2(Backplane ID),  
3(POST code),  
4(Reason code),  
6(Blade Status or Fault Code),  
8(Middle Byte of 24-bit POST Code),  
9(I2C PS0 Device Error Mask),  
10(I2C PS1 Device Error Mask),  
11(I2C Device Error Mask)

**ENCLOSURE RESUME PROM CHECKSUM ISSUES:** TMobile & Nationwide & Amber LED issues on Enclosures

**TMOBILE FIX:**

**Force flashing Coldfire Mgmt Switch & Resetting Cksums on Typhoon Enclosure Resume Prom:**

# cat /etc/hosts |egrep MGMT

```
192.168.1.50 mgmt_2_3      #ENCLOSURE-0_MGMT_A
192.168.1.51 mgmt_4_5      #ENCLOSURE-1_MGMT_A
192.168.1.52 mgmt_6_7      #ENCLOSURE-2_MGMT_A
192.168.1.53 mgmt_8_9      #ENCLOSURE-3_MGMT_A
192.168.2.50 mgmt_2_3b     #ENCLOSURE-0_MGMT_B
192.168.2.51 mgmt_4_5b     #ENCLOSURE-1_MGMT_B
```

```
192.168.2.52 mgmt_6_7b      #ENCLOSURE-2_MGMT_B  
192.168.2.53 mgmt_8_9b      #ENCLOSURE-3_MGMT_B  
# /nasmcd/sbin/setup_enclosure -flashFirmware force 192.168.1.50
```

```
# /nas/sbin/enclosure_status -v -e 1
```

-----RESUME CSUM ERRORS-----

Failed Typhoon x Csum Error Failed

```
# /nas/sbin/t2net_test -SetResumeCksum 4 34 Resume cksum for this device has been updated. New Cksum = 0x6a8f57d9
```

#### **NATIONWIDE FIX:**

```
# /nas/sbin/setup_enclosure -initSystem force
```

Run setup\_slot on blades in the Enclosure that was replaced or faulted

#### **AERA ENERGY FIX—NS80 INSTALL:**

**Amber LEDs on Both Enclosures on NS80, along with Cksum Error on enclosure status -v -e output—fixed with following:**

```
# /nas/sbin/t2net_test -SetResumeCksum 4 20
```

**Note:** The 20 value is in hex because of NAS 5.5.25 code

#### **ADDING ENCLOSURE:**

→Add to next available slot and connect to Ethernet networks

→Run setup\_enclosure –addEnclosure, -checkSystem, and –checkCable to verify installation

#### **ENCLOSURE COMMAND OUTPUT:**

```
# /nas/sbin/setup_enclosure
```

Usage:

```
/nas/sbin/setup_enclosure [-q]
```

```
| -checkCable  
| -checkSystem  
| -probeSystem  
| -readConfig
```

```
# /nas/sbin/setup_enclosure -checkCable
```

Executing -checkCable option

## **NSX X-BLADE 60 DATA MOVER:**

- Consists of CPU Board, a Fibre I/O Module, & GbE I/O Module
  - Data Mover ‘Blades’ are 64-bit capable, with 16GB memory, but code won’t be available to utilize this until end of FY06
  - Only 4GB memory currently supported
  - 3.4/3.8GHz P4 processor with HT (Hyper-Threading) Technology, 800MHz FSB
- Data Mover comes with (2) I/O Modules, one for BackEnd [4-FC ports] and one for FrontEnd [2-Fibre GbE & 6-Copper GbE ports]  
(4) – (8) Data Movers with 2-DM blades for each enclosure, 2-Mgement switches, 2-Pwr Supplies, & 2-Fans each  
Each DM blade will be able to support up to 16TB of storage, for total of 112TB per Cabinet (typo? 128TB?)

**Note:** No Serial connection presently built-into the data mover, but access to DM Console can be done via USB Serial port & cable from respective blade Management Module—requires special USB-to-Serial Cable #038-003-157. NSX will support 4-8 Blades (DM's). Connect to upper middle USB port with USB-to-Serial cable.

**DATA MOVER BLADES USE SFP (Small Form Pluggable) FIBRE CONNECTIONS→NO MIAs**

**NSX BLADE ENCLOSURE COMPONENTS: (2) Blades, (2) Mgmt Switches, (2) Pwr Supplies, (4) Fans, (2) I/O Modules per Blade**

LH side Management Switch B & Power Supply B, (2) Fibre I/O Modules with 4-ports per DM, DM A & B Modules located behind Ethernet/Fibre Boards, (2) Ethernet Modules with 2-Fibre GigE ports and 6-Copper GigE ports per DM, RH side Management Switch A & Power Supply A

**DM Fibre I/O Module {Tsunami}: →Tape Devices and/or Storage**

Left-to-Right, BE0, BE1, AUX0, AUX1

Top Module, with (4) @GB Fibre ports that require connection to FC Switch

Aux ports connect to tape devices

BE0 ports connect to Clariion and/or Symmetrix Storage

**DM GbE I/O Module {Blizzard}: →Customer Networks**

Bottom Module with (2) Fibre 2GB GbE ports, left-to-right, fge0 & fge1--  
and (6) Copper 10/100/1000 Ports top l-to-r cge0, cge1, cge2; btm l-to-r cge3, cge4, cge5

**Note:** Troubleshoot the fge interfaces using “bcm” in .server\_config commands

**DM BLADE REPLACEMENT:**

→Remove I/O Modules, Remove & replace Blade, Re-install I/O Modules, run setup\_slot -i 2 [Blade ID]

**ADDING DM BLADE:**

→Install blade, cable to Ethernet & Fibre

→Run setup\_slot and follow script

→Add WWN's into Storage Groups

→Configure Zoning to match other Blades

→Complete setup\_slot instructions

**NSX CHIVAS CONTROL STATION (100-560-688):**

--No quad Serial port between CS and DMs [Management & monitoring now conducted via Management Switch modules]

--No attached (8) port Ethernet Switch--now built into CS

--2GB RAM for CS

--Dual CS configurations standard, with crossover IPMI cable connecting CS0 to CS1

**CS Ports:**

eth3 = External network; eth0 = Internal network to Management Switch A Enclosure 0;

Gb1 = IPMI interface to eth1 of alternate CS;

Gb2 = Internal Network to Management Switch B Enclosure 0;

Com1 = (1) Serial Modem for CallHome

Video Port connection

Green power LED and Yellow Fault LED & Blue enclosure LEDs

**ATS (Automatic Transfer Switch) UNITS:**

Each CS has its own ATS backup power supply to deal with short-term power loss, and each ATS has a power path to both UPS units

**CONTROL STATION REPLACEMENT:**

→Replace failed CS and load same NAS code using CS recovery option [restores CS from backend backup]

→Run rebuild script to integrate to Mgt Network

**#nas/sbin/setup\_enclosure -rebuildConfig**

**Note:** Follow CS recovery procedures from Avatar

**NSX MANAGEMENT SWITCHES {Typhoon}:**

(1) Switches per Enclosure, Switch A is primary and on the right, Switch B is secondary and on the left

→Each Switch contains (3)Broadcom 5325M Ethernet ports, Motorola Micro-Controller, Firmware, I2C Bus connections,

Interconnection to peer module through backplane on Enclosure, LED Indicators for Enclosure ID, (2) USB Serial ports for Blade console connection and debugging

**Note:** Each Enclosure contains two data movers, as well as two management switches. Observe Data Mover bootup from special DB9-to-USB serial cable (is actually a Serial port) called Serial Port 1, inside usb-style port on switch, with right-hand switch A for data mover 2 and left-hand switch for data mover 3, etc. Upper leftmost USB port is used for connection.

**RS232 Ports 1 & 2:**

Port 1, or upper left USB-style RS-232 serial port is used to connect to Laptop to observe and troubleshoot Data Mover—the other Port is not used—only manufacturing.

**Note:** Laptop connection to Data Mover requires special db9-pin-to-USB converter. Hyperterm session uses 9600 8 N 1 None.

### **LED INDICATORS:**

Amber LED for Fault

Green LED for Power

LED's 0-3 are Blue to indicate Enclosure ID

### **RIGHT SIDE MANAGEMENT SWITCH A CABLING ENCL 0:**

Switch consists of (3) ports on top, (2) ports on bottom, amber Fault, green Power and blue Enclosure ID LEDs

→Top left Port 0 Ethernet—Connects from Switch A to Enclosure 1's Port 3 on Switch A

→Top right are two USB-style RS-232 Serial ports—only the leftmost USB port is used, for connecting Laptop to Data Mover to observe bootup process

→Lower left Port 3 Ethernet—Connects from Switch A (Enclosure 0) to 10/100 Port on CS0

→Lower right Port 4 Ethernet—Connects to 10/100 Port on CS1

### **LEFT SIDE MANAGEMENT SWITCH B CABLING ENCL 0:**

→Top left Port 0 Ethernet—Connects from Switch B to Enclosure 1's Port 3 on Switch B

→Top right are two USB-style RS-232 Serial ports—only the leftmost USB port is used, for connecting Laptop to Data Mover to observe bootup process

→Lower left Port 3 Ethernet—Connects from Switch B to Gb#2 Port on CS0

→Lower right Port 4 Ethernet—Connects from Switch B to Gb#2 Port on CS1

### **ENCLOSURE 1 SWITCH A:**

→Port 4 connects to Ethernet Port on UPS 0

→Port 3 already mentioned above, connects to Port 0 on Encl 0 Switch A

### **ENCLOSURE 1 SWITCH B:**

→Port 4 connects to Ethernet Port on UPS 1

→Port 3 already mentioned above, connects to Port 0 on Encl 0 Switch B

### **CROSSOVER IPMI CABLE BETWEEN CONTROL STATIONS:**

Gb#1 on CS0 connects to Gb#1 on CS1

### **DEFAULT INTERNAL MANAGEMENT NETWORK NSX:**

|                          | Primary Network | Secondary Network                  |
|--------------------------|-----------------|------------------------------------|
| Enclosure 0 Mgmt Switch: | 192.168.1.50    | 192.168.2.50                       |
| Enclosure 1 Mgmt Switch: | 192.168.1.51    | 192.168.2.51                       |
| Enclosure 2 Mgmt Switch: | 192.168.1.52    | 192.168.2.52                       |
| Enclosure 3 Mgmt Switch: | 192.168.1.53    | 192.168.2.53                       |
| CS0                      | 192.168.1.100   | 192.168.2.100                      |
| CS1                      | 192.168.1.101   | 192.168.2.101                      |
| Blade 2                  | 192.168.1.2     | 192.168.2.2                        |
| Blade 3                  | 192.168.1.3     | 192.168.2.3 [etc., for Blades 4-9] |
| UPS0 Right Side          | 192.168.1.90    | 192.168.2.90                       |
| UPS1 Left Side           | 192.168.1.91    | 192.168.2.91                       |

### **CELLERRA NSX MANAGEMENT SWITCHES:**

Control Network IP's are preconfigured at install from DHCP Server running on CS0

Management Switches are required to detect, query, and reboot DMs

### **INTERNAL MANAGEMENT IP ADDRESSES:**

Enclosure 0 Management Switch A 192.168.1.50 mgmt\_2\_3

Enclosure 0 Management Switch B 192.168.2.50 mgmt\_2\_3b

Enclosure 1 Management Switch A 192.168.1.51 mgmt\_4\_5

Enclosure 1 Management Switch B 192.168.2.51 mgmt\_4\_5b

Enclosure 2 Management Switch A 192.168.1.52 mgmt\_6\_7

Enclosure 2 Management Switch B 192.168.2.52 mgmt\_6\_7b

Enclosure 3 Management Switch A 192.168.1.53 mgmt\_8\_9

Enclosure 3 Management Switch B 192.168.2.53 mgmt\_8\_9b

### **TROUBLESHOOTING MANAGEMENT SWITCH ISSUES:**

#### **# /nas/sbin/t2net\_test**

## **USING T2NET TEST TO POWER UP A BLADE:**

**# /nas/sbin/t2net\_test -Bladecontrol**

Usage: t2net\_test -Bladecontrol {slotID operand}

where:- slotID = 2 to 9

operand = 0(RST),  
1(Hold in RST),  
2(Release from RST),  
3(RST+Hold in POST),  
4(RST+Hold in POST+PXEBoot),  
8(Power Off),  
9(Power On),  
11(Power On+Hold in POST),  
12(Power On+Hold in POST+PXEBoot)

**# /nas/sbin/t2net\_test -Bladecontrol 2 9**

**Note:** Similar to t2reset pwron -s 2

## **EXAMPLE OF MANAGEMENT SWITCH ISSUE:** Problem was cabling

1. cannot ping data movers or CS
2. cannot see contents of /nbsnas or /nas
3. # ./setup\_enclosure -checkCable

Executing -checkCable option

System discovery on both subnets .....

Discover 0 Mgmtswitches in Primary subnet A, 0 Mgmtswitches in Secondary subnet B

Cannot find any Mgmtswitch in this system

ZERO Mgmtswitch detection may due to one or more of the following cases:

- Miswired cabling on Mgmtswitches that causes switch looping
- Loose/bad cable between Enclosure ID# 0 and CS
- Bad Ethernet port on CS
- Bad Mgmtswitch

Error: checkCable FAIL (EDISCOVER)

Error: CABLECHECK\_CMD retval = -4 (EDISCOVER)

4. Getreason -e returns error code 25:

**# /nas/sbin/getreason -e**

- 10 - slot\_0 primary control station
- 25 - slot\_2 management switch error
- 25 - slot\_3 management switch error
- 25 - slot\_4 management switch error
- 25 - slot\_5 management switch error

**Note:** Came across this in the lab for 5.6.46 CS replacement exercise--needed to run -initSystem force to get internal switches back

#### **Management Switch Failure/Replacement:**

1. Identify Failing Module:

**# /nas/sbin/setup\_enclosure -checkSystem**

2. After replacing new Switch, reconfigure:

**# /nas/sbin/setup\_enclosure -replaceMgmtswitch enclosure-id**

3. Check Hardware:

**# /nas/sbin/setup\_enclosure -checkSystem**

1. Verify Cabling:

**# /nas/sbin/setup\_enclosure**

### **CELERRA PLATFORM MANAGEMENT SWITCH TYPES:**

#### **Scorpion Switch:**

→Used in Sledgehammer systems (NS20 & NS40), mgmtfirmware\_sc.s19; bootblock\_sc.s19 (aka sh.s19)

#### **Typhoon Switch:**

→Used in Hammerhead systems (NS80, NSX), mgmtfirmware\_ty.s19; bootblock\_ty.s19 (aka hh.s19)

#### **Earthquake Switch:**

→Used in Foxglove systems (NS960, NS-G8), mgmtfirmware\_eq.s19; bootblock\_eq.s19 (aka fg.s19)

#### **Nimitz Switch:**

→Used in Argonaut systems (VG2/VG8), mgmtfirmware\_nm.s19; bootblock\_nm.s19 (aka ag.s19)

### **NSX APC UPS POWER SUPPLIES:** located at bottom of Titan cabinet

UPS0 connected to Management Switch B and Power Supply B on all DM enclosures, as well as to each CS

UPS1 connected to Management Switch A & Power Supply A on all enclosures, as well as to each CS

Both UPS's connect to Management Switches on Enclosure 1 via 10/100 Ethernet

Serial connection for direct connect to workstation, and initial setup

**Note:** ACTS (AC Transfer Switch) provides AC pwr from both UPS devices to CS in the event of a power failure. Lower ATS0 is for CS0, and ATS1 is for CS1. UPS's maintain power directly to Data Movers (BEs).

→Connect to UPS's via special UPS serial cable to laptop or via Telnet after initial setup to IP 192.168.1.90 for UPS 0 and 192.168.2.90 for UPS 1

### **PROBLEM WITH POWER LOSS TO UPS UNITS emc154409:**

1. Power loss to one of the two UPS legs:

#### **sys\_log:**

UPSMonitor 12 The UPS has been switched off by a management station →CallHome is immediate

UPSMonitor:4:13 emcnasUPS\_i1: UPS: Entered sleep mode.

**BoxMonitor:2:519** enclosure 1 power supply B fault →BoxMonitor is the Facility, Severity 2 indicates Critical, 519 is the EventID  
CallHome:6:200 Successful error file transfer via email

**# nas\_event -I -a callhome**

UPSMonitor 3 The UPS has failed its internal self-test

UPSMonitor 12 The UPS has been switched off by a management station

UPSMonitor 17 The UPS batteries require immediate replacement

UPSMonitor 18 An Environment contact closure has faulted

UPSMonitor 20 The UPS is on bypass due to an internal fault

UPSMonitor 24 The base module bypass power supply needs repair

```
UPSMonitor 25 The base module fan needs repair
UPSMonitor 51 The battery charger has failed
UPSMonitor 53 The battery temperature threshold has been violated
UPSMonitor 77 An abnormal condition has been detected
# nas_event -l -f -i |grep UPS
id facility
140 UPSMonitor
# nas_event -l -f UPSMonitor
id description
12 The UPS has been switched off by a management station
# cat /nas/site/cron.d/nas_sys|grep apc
0-59/5 * * * * nasadmin /nas/sbin/get_apc_ups_status /nas/log/ups_status.xml >/dev/null 2>&1
1 0-23/2 * * * nasadmin /nas/sbin/get_apc_ups_status -resume /nas/log/ups_resume.xml >/dev/null 2>&1
# cat /nas/sys/nas_eventlog.cfg
UPS MOnitor
#
facilitypolicy 140, 7
    disposition range=0-1000, logfile "/nas/log/sys_log"
    disposition range=3-3 severity=1-2, callhome immediate
    disposition range=12-12 severity=1-2, callhome immediate
    disposition range=17-18 severity=1-2, callhome immediate
    disposition range=20-20 severity=1-2, callhome immediate
    disposition range=24-25 severity=1-2, callhome immediate
    disposition range=51-51 severity=1-2, callhome immediate
    disposition range=53-53 severity=1-2, callhome immediate
    disposition range=77-77 severity=1-2, callhome immediate
    disposition range=0-1000 severity=1-4, trap "/nas/site/trap.cfg 2"
```

2. Trap sent by UPS unit to Control Station creates .acloss0 or .acloss1 (UPS 0 and UPS 1, respectively) in /nas/log directory:

```
# cat /nas/log.acloss1
```

100

3. Current problem is that a restore to the UPS power leg fails to remove the .acloss\* file due to missing trap action on CS

**Note:** During proper operation, when A/C power is lost to either power leg for the UPS units (there are two UPS Battery Backup supplies for an NSX system), an SNMP trap is sent from the UPS unit to the Celerra. The Celerra will log an event in the sys\_log, generate a CallHome, and write a temporary .acloss0 or .acloss1 file to the /nas/log directory. Later, when power is restored, an SNMP trap is generated and sent to the Control Station, which is then supposed to remove the /nas/log/.acloss0 (or .acloss1 for UPS leg 1) file as part of its recovery and cleanup from the event. With NAS 5.4/5.5, this recovery does not happen and the .acloss file is not removed, meaning that if the other UPS leg subsequently lost A/C power for any reason, the Celerra would think that both UPS units were faulted and power down the Celerra.

4. Workaround:

a. Using a vi editor, add the following entry to the /nas/sys/snmptrapd.conf file:

```
traphandle .iso.3.6.1.4.1.318.0.8 /nas/sbin/apc_ups_trap ACRESTORE
```

The new /nas/sys/snmptrapd.conf file will look like this:

```
# cat /nas/sys/snmptrapd.conf
```

```
traphandle .iso.3.6.1.4.1.318.0.6 /nas/sbin/apc_ups_trap WARNING
```

```
traphandle .iso.3.6.1.4.1.318.0.8 /nas/sbin/apc_ups_trap ACRESTORE
```

```
traphandle .iso.3.6.1.4.1.318.0.12 /nas/sbin/apc_ups_trap SEVERE
```

b. Force the snmptrapd process to re-read the newly edited snmptrapd.conf file using HUP:

```
# ps -ef |grep snmp
```

```
root 17201 1 0 Mar06 ? 00:00:00 /usr/sbin/snmptrapd -c /nas/sys/
```

```
# kill -HUP 17201
```

**Note:** Issue the HUP against the process ID for the snmptrapd daemon—notice that the PID does not change since the process is not actually killed—the HUP forces the snmptrapd.conf file to be re-read with the new configuration

c. Check for and remove any .acloss0 or .acloss1 files from the /nas/log & /nbsnas/log directories

```
# ls -la /nas/log/.acloss*
```

```
-rw-r--r-- 1 root root 0 Mar 12 07:40 /nas/log/.acloss0
```

```
# rm -f /nas/log/.acloss*
```

## **UPS APC FILES, COMMANDS:**

**apc\_ups\_cfg (to config.snmp & traps); apc\_ups\_cfg.exp (config.snmp mib & traps to CS); apc\_ups\_cron\_setup (cron jobs); apc\_ups\_trap (handles traps received from UPS unit and logs toCS eventlog)**

DM 4 MAIN FAST YES YES

DM 5 MAIN FAST YES YES

DM 6 Not detected by SMB

**# ./t2tty →NSX sends communications between DM and CS using RPC over the internal net**

Celerra\IP DM Command Utility....

Usage:

Force Data Mover in slot # to PXE boot

t2tty -p 2

Check IPMI connection to other CS

t2tty -m hostNameOrIP

Send dart command "cmd" to data mover in slot # over RPC Interface

t2tty -c # "cmd" or t2tty -C # "cmd"

for example: t2tty -c 2 "ifconfig"

**# ./t2tty -c 4 "ifconfig"**

Devices:

mge0 dmtu=9000, dmac=0:60:16:5:36:e9

# /nas/sbin/t2tty → send console commands to DART over internal network using RPC vs. serial communications [T2net Library]

Note: Regular NS product sends the commands over the serial connection between CS and DM, which we do not have for NSX

### # /nas/sbin/t2tty -t

ttyS4 on → Means serial port is up and connected between Server and Control Station

ttyS5 on

ttyS6 on

ttyS7 on

Note: ttyS0 is used for Modem access; ttyS1 is used for Serial access

## GETREASON CODES NAS 5.4 NSX SYSTEMS:

# /nas/sbin/getreason | -e → new reason codes (getreason -e)

Note: Run getreason -e to obtain the complete error codes for the Reason Code failure

15 Blade flashing firmware, BIOS or POST, cannot be reset

16 Blade PXE booted

17 Blade Hardware fault detected

18 Memory test failure, BIOS detects memory error

19 POST test failure, general POST error (hardware issue)

20 POST NVRAM test failure, invalid NVRAM content error

21 POST invalid peer Blade type

22 POST invalid Blade part number

23 POST FC test failure, error in controller, fibre discovery, etc.

24 POST network test failure, error in Ethernet controller

25 NSX DM T2NET error, unable to get reason code due to management switch problems

## MISCELLANEOUS SECTION:

### # /nas/sbin/t2cab

3 - CELERRA IP CABINET

The Cabinet child is : 11 - a CELERRA HAMMERHEAD

# /nas/sbin/getboxmask -e [Enclosure IDs and error codes]

### # /nas/sbin/getreason -e

10 - slot\_0 primary control station

5 - slot\_2 contacted (Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c)

5 - slot\_3 contacted (Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c)

5 - slot\_4 contacted (Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c)

5 - slot\_5 contacted (Post Code = 0x61 ; Mid Code = 0x80 ; Blade Code = 0x2c)

## REASON CODES:

15 DM flashing firmware, BIOS, or POST, cannot be reset

16 DM PXE booted from CS  
17 DM hardware fault  
18 Memory test failure, BIOS detected memory error  
19 Post test failure  
20 Post NVRAM failure  
21 Post invalid peer DM type  
22 Post invalid DM part number  
23 Post fibre channel test failure, error in blade fibre channel connection  
24 Post network test failure, error in Ethernet controller  
25 T2NET error, unable to get reason code due to management switch problems

**Note:** If DM stuck at reason code 17-24, use getreason -e to obtain specific POST error code using getreason -e. Lookup the 2<sup>nd</sup> hex number in the Post Code to determine error—appendix C NSX Recovery Procedures.

# **/nas/sbin/t2reset** [Use to power-off, power-on, reset any blade]

# **/nas/sbin/t2led** [Use to control enclosure LEDs]

### **PXE BOOTING NSX:**

# **./t2pxe**

Usage:

To stop pxe services: t2pxe -e

To start pxe services: t2pxe -s {-I|-R} cnt# [x.y.z] [a.b.c]

cnt#: number of data movers in the cabinet

-I : used for starting PXE interactively and/or when slot IDs are not set

-R : used for starting PXE when slot IDs are present

x.y.z and a.b.c are the primary and backup internal subnet addresses.

Subnet definitions will be extracted from /etc/nas\_device.map if not provided

To start tftp service alone: t2pxe -tftp [-setroot dir] start

To stop tftp service alone: t2pxe -tftp stop

**Note:** -tftp start also starts PXE services, and you may want to stop # t2pxe -e

### **CANNOT PXE BOOT DM WITH BOX MONITOR RUNNING:**

# **./t2tty -p 5**

Attempting to force data mover PXE boot:

Error, Can't PXE boot when BoxMointor is running.

Please retry after stopping the BoxMonitor (service nas stop)

Slot-5 Forced PXE Boot Failed.

### **PXE BOOTING CONFIGURED DATA MOVER WILL BRING TO RC 14 HARDWARE MISCONFIGURED STATE:**

# **./t2tty -p 5** -->Forcing PXE boot of configured DM brings it to RC 14 slot\_5 hardware misconfigured—boots from CS

Attempting to force data mover PXE boot:

Resetting Slot-5 with t2reset...

Waiting for DM network connectivity after PXE booting

### **PXE BOOTING DATA MOVER ON NSX:**

1. Stop NAS Services and manually remount /nbsnas /nas /nas/dos /nas/var

2. Start PXE boot services on Control Station: # **/nas/sbin/t2pxe -s -R 8** [2 4 8 dm's]

3. Force blade to PXE boot from CS: # **/nas/sbin/t2tty -p 2** [where 2 is slot number]

**Note:** Data Mover will boot to RC14 if already configured—just reboot and it will come up normally

4. Stop PXE Boot Services on CS: # **/nas/sbin/t2pxe -e**

**Note:** NSX series requires onsite DB9-to-USB connection via laptop to the Data Mover in order to watch PXE boot. Requires use of special serial cable with USB-type connector to connect from COM1 port on Laptop to middle USB connection on Management Switch A, or B (Data Mover 2 is A, DM 3 is B)

### **HYPERTERMINAL CONFIGURATIONS FOR NSX SYSTEMS:**

I. CONTROL STATION →COM1 or 2 19,200 8 N 1 Hardware Flow Control

II. DATA MOVER-----→” “ 9,600 8 N 1 None

III. UPS A & B-----→” “ 2,400 8 N 1 Hardware

### **NORMAL BOOT SEQUENCE FOR HAMMERHEAD/POST & FCCBOOT MENUS:**

### **CALLHOME EVENTS:**

Fan Fault; Power Supply Fault; Management Switch Fault; Blade HW Fault; IO Module HW Fault; DM Boot Fault; DM RC Fault

### **NSX TROUBLESHOOTING:**

```
# /nasmcd/sbin/setup_enclosure -showAll | -v | -checkCable | -checkSystem (Checks connectivity to Mgmt Switches) | -rebuildConfig | -resetMgmtswitches | -flashFirmware | -dhcp stop start addDynamicIPRange | -addEnclosure | -removeEnclosure | -replaceEnclosure | -replaceMgmtswitch | t2net_test [Main script used to troubleshoot management switch issues]
```

**Note:** T2net Library is a UDP-based network relay between Management modules and Tier 2 for control and info commands

### **REPLACING FAILED MANAGEMENT SWITCH MODULE:**

```
# /nasmcd/sbin/setup_enclosure -v -checkSystem [Use this to verify system before replacing management switch]
```

```
# /nasmcd/sbin/setup_enclosure -v -replaceMgmtswitch enclosure-id [Use this to setup new replacement switch]
```

1. Identify failing module for replacement:

```
# /nas/sbin/setup_enclosure -checkSystem
```

2. Physically replace module

3. Configure new switch module:

```
# /nas/sbin/seup_enclosure -replaceMgmtswitch enclosure-id
```

4. Verify:

```
# /nas/sbin/setup_enclosure -checkSystem
```

```
# /nas/sbin/setup_enclosure -checkCable
```

### **REPLACING SINGLE BLADE NS20/NS40 SYSTEM:**

1. Log into system as nasadmin and su to root, then cd to /

2. Stop nas services

```
# /sbin/service nas stop
```

3. Manually remount NAS partitions

```
# mount /nbsnas
```

```
# mount /nas
```

```
# mount /nas/dos
```

4. Halt the Data Mover

```
# server_cpu -halt now
```

**Note:** This hangs the console session, User will need to Putty into CS again, where /nasmcd/sbin/getreason shows slot\_2 powered off

5. Physically swapped out slot\_2 with a new blade

6. Powered on the slot

```
# /nasmcd/sbin/t2reset pwron -s 2
```

7. Ran switch replacement commands for the replacement blade:

```
# /nasmcd/sbin/setup_enclosure -replaceMgmtswitch 0 [no errors, completed]
```

```
# /nasmcd/sbin/setup_enclosure -checkSystem
```

8. PXE boot the system in order to be able to successfully run the setup\_slot on the replacement blade:

```
a.) /tftpboot/bin/t2pxe -s -R 2 128.221.252 128.221.253
```

```
b.) /tftpboot/bin/t2tty -p 2
```

```
c.) /tftpboot/bin/t2pxe -e
```

```
d.) /nas/sbin/setup_slot -i 2
```

e.) Rebooted server\_2 to verify that all was still well

f.) Rebooted Control Station to verify NBS connectivity and let NAS services start normally

9. /nas/bin/nas\_checkup

### **ADDING NEW BLADE:**

1. Install and cable new blade

2. Conduct setup\_slot -i 3

**Note:** Direct connected FC Enabled models should just use -g syntax for setup\_slot to add WWNs to StorageGroup, etc.

3. Add new WWN to Storage Group

4. Configure Zoning
5. Complete setup\_slot

### **ADDING NEW ENCLOSURE:**

1. Install new enclosure and connect cabling
2. Add enclosure and verify:  
# /nas/sbin/setup\_enclosure –addEnclosure enclosure-id  
# /nas/sbin/setup\_enclosure -checkSystem  
# /nas/sbin/setup\_enclosure -checkCable

### **REPLACING NSX ENCLOSURE:**

**# /nasmcd/sbin/setup\_enclosure –v –replaceEnclosure enclosure-id** [Use to replace an Enclosure after stopping NAS services first, then update storage backend configuration with WWN values for new enclosure blades]

1. Stop NAS services
2. Remove old enclosure and replace with new hardware

**Note:** Please be aware that a special procedure may need to be run to convert the base SAN personality Enclosure to NAS personality

3. Run following to remove old ID and then generate new ID for replacement:

```
# /nas/sbin/setup_enclosure –removeEnclosure enclosure-id  
# /nas/sbin/setup_enclosure -checkSystem  
# /nas/sbin/setup_enclosure –addEnclosure enclosure-id  
# /nas/sbin/setup_enclosure -checkCable
```

4. Configure new WWNs for blades into Zoning and Storage Groups
5. Restart NAS

### **REPLACE ENCLOSURE & DM:**

1. **# /nasmcd/sbin/setup\_enclosure –v –addEnclosure**
2. Use getboxmask –e to verify that new enclosure can be seen
3. Power up DM and run setup\_slot
4. Update storage backend configuration for new DM

### **REPLACING CS:**

1. Remove old CS and insert new hardware
2. Load same NAS code version
3. During install, will ask if this is replacement CS—answer Yes and let rebuild continue
4. Rebuild management switch configuration

**# /nas/sbin/setup\_enclosure –v –rebuildConfig**

5. Verify management switch configuration

**# /nas/sbin/setup\_enclosure –v -checkSystem**

**# /nas/sbin/t2net\_test -Discover | -Getreason | -Getstatusflags | -Getsyscode | -GetmgmtswitchMAC | -Readfwversion | -ReadallenclosureByIP <internal ip addr> | -Readallenclosure | -StatusCodeList**

**# ps -wef |grep dhcp** [verify that dhcp daemon is running]

getreason code of 25 indicates management switch problem

### **COLLECTING LOGS FOR NSX HARDWARE ISSUES:**

1. General HW issues, Pwr Supply, Management Station issues, collect all sys\_logs & following outputs:  
\$tar -chf ~/sys\_logs.tar sys\_log\*; \$/nasmcd/sbin/getreason –e > ~/getreason.out; enclosure\_status –e <x> -v  
>~/enclosure\_status\_x.out; t2net\_test -ReadallenclosureByIP 192.168.1.5x > ~/t2net\_test\_1.5x.out; t2net\_test -ReadallenclosureByIP 192.168.2.5x > ~/t2net\_test\_2.5x.out; server\_log server\_x -a -s > ~/slogx.out
2. Voltage issues, Fan faults, Temp alarms—collect following info & sys\_logs:  
\$/nas/sbin/nsx\_cs\_sensors > ~/nsx\_cs\_sensors.out  
\$Scp /nas/log/local\_hw\_status\_slot\_0.xml
3. UPS Issues:  
--Collect all /nas/log/sys\_logs and /var/log/messages files  
--Test that UPS subsystem is accessible:  
\$ping emcnasUPS\_i0; \$ping emcnasUPS\_i1  
--Check /etc/hosts file if ping fails  
--Telnet to UPS subsystem:  
\$telnet emcnasUPS\_i0; login using “apc” and password “apc” → Show see UPS management console  
--Run snmpwalk against each UPS Hostname:  
\$snmpwalk -c public -m /nas/sys/powernet361.mib emcnasUPS\_i0 upsBasicOutputStatus > /emcnasUPS\_i0\_snmpwalkBasicStat.out  
--Additional snmpwalk output commands:  
\$snmpwalk -c public -m /nas/sys/powernet361.mib emcnasUPS\_i0 upsBasicStateOutputState >  
/emcnasUPS\_i0\_snmpwalkBasicStateoutputState.out

```
$snmpwalk -c public -m /nas/sys/powernet361.mib emcnasUPS_i0 upsAdvStateAbnormalConditions >
```

```
/emcnasUPS_i0_snmpwalkAdvStateAbnormalConditions.out
```

## **SAMPLE NSX CONFIGURATION FILES:**

Setup of CLARiON APM00023801040 storage device complete.

Discovering storage (may take several minutes)

### ***NS500 INTEGRATED & GATEWAY CELEERRA (Exterminator):*** [mid NAS 5.3 product]

→GA Sep 10, 2004, as low cost NS600 replacement with Gateway (SAN) & Integrated (Captive) versions

→Captive NS500 backend is Tarpon-Aux [DAE2 enclosure replacing LCC cards] modified CX500 array

→Clarion Tarpon technology [1.6Ghz processors on DMs; 533 FSBus; 2GB RAM; (4) Ethernet 10/100/1000 ports per DM]

→3U DME Front End, 3U Backend, 1U Falcon Control Station, 1U SPS [Optional DAE2's]

→Supports CX300/CX400/CX500/CX600/CX700/Symm 5.x/Symm DMX

→Tarpon Front End "Aspen" NAS personality card using Katana DAE2 enclosures

→Gateway DMs will ship with optical GBIC in port BE1 and MIA in port BE0

→Requires FLARE 14 or higher

→Supports 501/501G, 502/502G, limited to two Data Movers only!

#### **CAPTIVE CABLING:**

BE0 on both DMs use copper HSSDC to copper SFP cable to SPA

BE1 on both DMs use copper SFP to SFP cable to SPB

MIA and optical cable can be plugged into AUX0 for backups

#### **SAN GATEWAY CABLING:**

BE0 on both DMs use MIA with optical fibre cable to connect to primary switch

BE1 on both DMs use SFP GBIC for optical SFP cabling to secondary fibre switch

MIA optical cable on AUX0 for backups

**Note:** emc139623 documents an issue with POST versions less than 02.25 when replacing Data Movers, especially with RoHS compliant part numbers that are not recognized by the old POST version, causing Data Mover not to boot properly.

### **NS704G 4-WAY:**

--New 4-way high performance mid-tier system that includes (4) NS700 3.1Ghz DMs and (2) Falcon Control Stations (Optional)

--Model is always a fabric-connected Gateway system cabled to FC Switch using fiber optic cables and MIA's

--Crossover cable and subnet between Control Stations called IPMI (Intelligent Platform Management Interface)—192.168.3.x

--Dual CS configurations should use IP Aliasing to provide consistent IP address for access to Primary CS

**Note:** Torrey Pines Intel motherboard and Transcend memory problems on bus

--NAS 5.3 minimum

--I/O card with (6) Copper ports and (2) GigE optical ports

**Note:** The six copper Ethernet network ports on the Data Movers are labeled **cge0 - cge5**. The port labeled **cge6/mgmt** is reserved for the private LAN connection to CS1, when installed. All ports are 10/100/1000 & use standard RJ-45 connectors.

#### **SWITCH CONFIGURATIONS:**

→Use two switches for High Availability, with all BE0 ports to one switch, BE1 ports to the other switch

→Can have (4) fibre channel connections from each Data Mover if desired

→Set switch port speeds to highest setting (1Gb or 2Gb) but NOT autonegotiate

→Set DM Fibre Channel ports to autonegotiate, default setting

#### **TYPICAL NS704G vs. NS700 BIND TABLES:**

**\$ .server\_config server\_2 -v "fcp bind show"**

## **CELERRA RESERVED LUNS/CELERRA LUN PROTECTION/CELERRA ILLEGAL HLUs:**

HLU lun decimal numbers 6-15 are considered “reserved luns” for special use. As such, Data LUNs should never be assigned an HLU value that falls in this range. NAS code changes have eliminated this problem, as outlined below:

### **HLU values 6-15 for CLARiiON Systems:**

Beginning with NAS 5.5.27 & 5.6.36, NAS code will not diskmark illegal HLU luns on CLARiiON backends—operation will fail. Beginning with NAS 5.6.38, NAS code will allow diskmark operation to complete, but will auto reassign a valid HLU number.

## **ILLEGAL USE OF CELERRA RESERVED LUNS:**

### **DETERMINING HLU/ALU LUN ASSIGNMENTS & CORRECTING:**

**Caution:** The following procedure is meant to address only NSxxG SAN-attached systems. Captive NS platforms will require a different procedure involving data migration to new luns, or data backup, then unbind and rebind of luns with correct HLU assignments, since captive systems do not have Storage Groups or use Access Logix. Typically, the setup\_clariion script will build the backend config with the correct luns bound during the install.

#### **1. First step is to find WWN numbers for all Celerra HBA's:**

**\$ server\_log server\_3 |grep -i wwn |grep -v ONLINE →NS600G**

2004-11-08 10:48:19: CAM: 4: FCP ONLINE HBA 0: ALPA 000001 WWN: **50060168006007b9**

2004-11-08 10:48:23: CAM: 4: FCP ONLINE HBA 1: ALPA 000001 WWN: 50060169006007b9

**\$ server\_log server\_2 |grep -i WWN |grep -v ONLINE →NS700G**

2004-10-01 08:48:34: FCP: 4: ONLINE HBA 0: S\_ID 6a1113 WWN: **50060160106025c4**

2004-10-01 08:48:39: FCP: 4: ONLINE HBA 1: S\_ID 6a1013 WWN: 50060161106025c4

**Note:** Repeat for DM\_3

#### **2. Locate Matching WWN in Storagegroup List output to obtain HLU/ALU List:**

**\$ /nas/sbin/navicli -h 10.64.25.148 storagegroup -list** (AccessLogix is in use)

Storage Group Name: **NS600G**

Storage Group UID: 80:84:D6:A0:64:6D:D8:11:80:2C:AA:9C:3F:37:5E:FC

HBA/SP Pairs:

| HBA UID | SP Name | SPPort |
|---------|---------|--------|
| -----   | -----   | -----  |

1 y 11263 APM00030600872-0015 CLSTD root_disk 1,2
2 y 11263 APM00030600872-0016 CLSTD root_ldisk 1,2
15 y 48332 APM00030600872-001D CLSTD d15 2,1 →001D is ALU in Hex, decimal=29 on “d15”
16 n 48332 APM00030600872-001E CLSTD d16 2,1 →001E is ALU in Hex, decimal=30 on “d16”
```

**Note:** d15 and d16 will need to be deleted, but determine what file systems are in use, if any, via following commands:**\$ nas\_volume -i d15****\$ nas\_volume -i slice2****\$ nas\_volume -i ext2**

id = 120

name = ext2

acl = 0

in\_use = True

type = meta

volume\_set = slice2

disks = d8

**clnt\_volume = fs02**

5. Unmount File Systems and ensure that they are no longer in use.
6. Remove HLU LUNs 6 & 7 from StorageGroup using Navisphere
7. Add original ALUs 29 & 30 back to StorageGroup, but assign an HLU above 15 decimal
8. Reboot Data Mover
9. Run diskmark utility:

**#/nas/bin/nas\_diskmark -m -a**

11. Remount file systems if applicable and verify access

## **CORRECTING WRONG HLU LUNS ON PRODUCTION FILE SYSTEMS (SHORT VERSION):**

1. Identify all file systems built on the incorrect HLU numbers 0-15

**Note:** HLU's 0-15 are reserved only for Control Volume usage, when applicable

2. Permanently unmount all affected File Systems
3. Reassign HLU numbers using Navisphere and the following steps:
  - Connect to SPA/SPB using NAVISPHERE Manager>SPA>Storage Groups>rightclick and 'Select LUNs'
  - Select the incorrectly assigned LUNs and click on arrow to remove from Storage Group, then click apply
  - Select same LUNs from left pane and readd to Storage Group using arrow
  - Click on Host column (blank), rightclick, select any of the valid HLU numbers displayed that are > than or = LUN 16
  - Click apply to commit the change for the new HLUs
4. Reboot the affected Data Movers
5. Re-diskmark volumes:  
# nas\_diskmark -m -a
6. Remount all production file systems & verify access

## **MULTIPLE LUN 0 ISSUES:**

When adding LUNs to an existing system, it's possible to configure multiple HLU LUN 0's—this can cause boot problems for the data mover, but usually only after a binding table clear and rediscover. Quick way to check for LUN 0's on a system:

**\$ nas\_disk -query:"\*"-fields:Name,SymmId,ServerTable -format:"%s %s %q\n" -query:"\*"-fields:address -format:"%s " |grep t0l0**

root\_disk APM00023800390 c2t0l0 c18t0l0 c0t0l0 c16t0l0 c2t0l0 c18t0l0 c0t0l0 c16t0l0

→See emc109343 for more discussion and examples of the LUN 0 problem

## **CORRECTING BIND TABLE PROBLEM WITH CHAIN 0/2 LUN 0 CONFIGURED TO SEE SPB:**

1. Various arraycomm path settings were different among the SP ports—these were corrected in accordance with Primus emc95145 by issuing commands:

**# /nas/sbin/navicli -h 10.1.10.140 storagegroup -sethost -host nswebmgr2\_dm2\_0 -arraycomm path 0**

WARNING: Changing configuration options may cause the array to stop functioning correctly. Do you wish to continue (y/n)? y

**# /nas/sbin/navicli -h 10.1.10.141 storagegroup -sethost -host nswebmgr2\_dm2\_1 -arraycomm path 0**

2. Data mover needed to have Chain 16 restored. Fibre cables and zoning were checked, customer took action to shutdown Celerra and then reboot NS500 array, after which all LUNs were on the correct SP and devices were visible down Chain 16 on the Data Mover. In most cases, connectivity can be restored via less drastic measures!

3. Binding Table cleared

4. Setup\_slot conducted and bind table rebuilt with Chain 0 HBA0 seeing SPA and Chain 16 HBA1 seeing SPB

5. Do devconfig probe and “fcp bind show” to verify

### **Comments:**

LUNs 0-5 are used for Control Volumes. User ‘data’ LUNs begin at HLU 16.

**ALU—Array Luns are identified using \$ nas\_disk -l and are stated in Hex—convert to decimal for LUN number**

**HLU—Luns are identified using \$server\_devconfig -p -s -a and display in Decimal**

**Note: StorageGroup HLU data LUNs for Celerra cannot be less than 16. Verify HLU's from Navisphere, Server\_Devconfig, or Navicli StorageGroup list**

Create RAID Groups for Hot Spares as needed

**Caution:** In situations where Clariion Devices are added to StorageGroups and the HLU's are not manually assigned, the system will assign HLUs using LUNs 06 -15, which are reserved and not allowed for Data volumes. See Primus emc86551 to see if this issue can be resolved. Procedure entails unmounting any file systems that might be built on these luns, removing LUNs from storagegroup, adding back with correct HLU assignments, rebooting Servers, running nas\_diskmark -m -a and remounting all file systems.

**Note: NAS 5.3 no longer allows the assignment of HLU's 6-15 (decimal)(0x6—0xF hex) on the Celerra when creating Data Volumes—see primus emc94879.**

## # nas\_volume -n test2 -c d16

Error 3147: volume d16 resides on a reserved disk

## LOCATION OF BIOS & POST VERSIONS FOR NS PLATFORMS :

/nas/dosfs

NS600 → C2\_BIOS.rom

C2\_POST.bin

NS500 → TARPBIOS.rom

TARPPPOST.bin

## NAS 5.5 BIOS AND POST LEVELS:

# cat bios

```
<DataMoverBIOSInfo Host="server_3">
<VERSION_INFORMATION BIOS_VERSION="3.42" POST_VERSION="Rev. 03.37" />
```

# server\_sysconfig server\_2 -P

server\_2 :

Processor = Intel Pentium 4

Processor speed (MHz) = 2000

Total main memory (MB) = 4024

Mother board = Chameleon II XP

Bus speed (MHz) = 400

Bios Version = 3.42

Post Version = Rev. 03.37

## VERIFYING DATA MOVER SERIAL NUMBERS:

Note: NAS 5.3 introduces a new serial number validation entry in the /nas/server/slot\_x/start file for NS systems, but the entry is not used nor populated in the start file for single DM systems:

uniqueid validate=LKE00024100134

# nas/sbin/get\_data\_mover\_status -resume server\_2 5080 /tmp/dm2.resume

# grep EMC\_SERIAL\_NUMBER /tmp/dmx.resume

Comment: Data Mover will boot to State 14 to indicate a misconfigured hardware state if this entry is incorrect or if a Data Mover has been changed without a setup\_slot, etc.

## USING EXPECT TO VERIFY DM SERIAL NUMBER:

# expect -f encl\_mon.exp resume server\_3 5080 |grep RESUME\_INFORMATION\_MIDPLANE

IDS exp7 1 RESUME\_INFORMATION\_MIDPLANE

```
<RESUME_INFORMATION_MIDPLANE EMC_PART_NUMBER="005047766" EMC_ARTWORK_REVISION=""  
EMC_ASSEMBLY_REVISION="A14" EMC_SERIAL_NUMBER="APM00025002080" VENDOR_NAME="" L

## **DATA MOVER HARDWARE INFORMATON/PART NUMBERS:**

### **1. Obtain Part number info from file:**

```
# cat /nas/log/data_mover_resume.server_3.xml|head
```

```
<?xml version="1.0"?>
<DataMoverResume Host="server_3">
<RESUME_INFORMATION_BLADE
  EMC_PART_NUMBER="100-562-150"
```

### **2. Run get\_data\_mover\_status to collect information on particular server:**

```
# /nas/sbin/get_data_mover_status -resume server_3 5082 /home/nasadmin/server_3Resume.xml
>/dev/null 2>&1
```

```
# cat /home/nasadmin/server_3Resume.xml|head
<?xml version="1.0"?>
<DataMoverResume Host="server_3">
<RESUME_INFORMATION_BLADE
  EMC_PART_NUMBER="100-562-150"
```

**Note:** Port number 5082 is the new port used with NAS 5.6—no longer using port 5080

## **CURRENT HARDWARE STATUS:**

```
$ cat /nas/log/data_mover_status.server_2.xml
```

```
<?xml version="1.0"?>
<DataMoverStatus Host="server_2">
<ENCLOSURE_INFO PSA_INS_N="1" PSB_INS_N="1" PSA_FLT="0" PSB_FLT="1" PSA_SHTDN="0
" PSB_SHTDN="1" PSA_AC_FAIL="0" PSB_AC_FAIL="1" PSA_AMB_OT="0" PSB_AMB_OT="0" FA
N_FLT_M1="0" FAN_FLT_M2="0" FAN_FLT_M3="0" MULT_FAN_FLT="0" ENCL_LED_ON="1" SFP1
_STATE="0" SFP2_STATE="0" />
```

## **CELLERRA MANAGER ALERTS:**

Hardware Status alerts are queried by the APL Manager, which performs an inventory query, and logged to /nas/log/webui/alert\_log  
System Status alerts are generated by processes or components and also logged to alert\_log and sys\_log

**Note:** Deleting or Accepting ‘Alerts’ to cleanup the display is problematic. You can highlight all entries using ctrl + a, but if any of the underlying alerts are exact duplicates, the dupes may not be removed. So, you may need to do this a few times to cleanup all of the alerts. AR119686.

## **BIOS/POST UPGRADE PROCEDURE FOR NAS 5.5:**

1. Connect to the Primary Control Station (either via SSH or serial console)
  2. Rename /nas/sbin/recover\_slot to /nas/sbin/recover\_slot.orig to prevent data mover from getting rebooted during this process.
  3. Start PXE services by running the command “/nas/sbin/t2pxe -s -R <Number of data movers>”
  4. Copy the 5.5.30.5 Dart image onto the Control Station /tftpboot/nas.exe (overwrite existing file)
  5. Connect to the Data Mover’s serial console (details: 9600 baud, 8-N-1)
  6. Reboot the Data Mover using “server\_cpu server\_X –r now” where X is the slot id of the data mover.
  7. On the serial console of the data mover, press Esc key twice when the characters “ABabcdefgCDE...” start appearing, to break into the Extended POST
  8. Type the password “SHIP\_it” without the quotes to get into the Extended POST menu
  9. Enter the ICA submenu (option 24) and use option 2 to PXE boot the blade
- Note:** The blade will now boot from the new Dart image in min config mode (none of the filesystems will be mounted). As part of this process, it will also update the POST from 2.42 to 2.57 (and BIOS from 5.10 to 5.14). This process can take 2-5 minutes. After flashing the new firmware, the data mover will reboot. The Data Mover will now load the Dart image from the backend (5.5.28.1)
10. Wait for the reason code of the data mover to change to 5
  11. Stop PXE services by running the command “/nas/sbin/t2pxe –e”
  12. Remove /tftpboot directory
  13. Rename /nas/sbin/recover\_slot.orig to /nas/sbin/recover\_slot to allow failover to function properly.
  14. Repeat steps 5 through 12 on all data movers that need the new BIOS/POST.

## **CHANGING FIBRE CHANNEL CARD SPEED ON DM USING FCCBOOT OPTION:**

1. Connect null modem cable from service laptop to DM port
2. Reboot DM and press esc during Aabcde... string
3. Enter “FCCBOOT” and enter
4. Enter 2) FCC Boot Sub-Menu
5. Enter 3) BEO FCC Boot
6. Enter 4) Set Port Speed
7. Enter 0=1Gb
8. Repeat options for second port
9. Enter 1) Reset Controller

## **USING MINICOM TO CHANGE FCCBOOT SPEEDS ON NAS 5.3 SYSTEMS:**

1. Run minicom program on Control Station to setup profiles on ttyS4 and ttyS5 for DM2 and DM3, respectively [A, E, E, F, Save profile using a name such as dm2]: #minicom -s
2. Turn off NAS Services prior to resetting Server
3. Use t2reset to boot data mover  
#/nas/sbin/t2reset reboot –s 2
4. Initiate minicom serial session to DM2 from the Control Station:  
#minicom dm2
5. At following sequence, press the “esc” key [Aabcdef.....]
6. Type ‘FCCBOOT’ (Bios Menu for SP’s on Backend) and scan for targets or set port speed

**Note:** Password = SHIP\_it

FCC Boot Sub-menu

BEO FCC Boot

1.) Scan for target

2.) Set port speed

## **FCCBOOT SCREENS:**

**AabcdefBCDEabFabcdGHabIab** [Type the “ctrl + c” keys and let POST finish]

## CELERRA IP & CELERRA CX600 PRODUCTS:

First Disk Enclosure Units are all configured with (1) 4+1 RAID 5 Disk Group, (1) 8+1 RAID 5 Disk Group, & (1) Hot Spare  
Celerion II consists of public SAN Storage CX600 using AccessLogix on BackEnd [Setup methodology much different than C1]  
CX600 is being marketed as EMC Celerra Clustered Network Server (CNS) and CLARiiON Storage. CX600 CLARiiON Storage  
consists of (4) front-end Fibre Channel Ports per SP, (4) Back-End Fibre channel ports per SP, 4/8GB Cache Memory per SP, & an  
Ethernet management port. CX600 supports Synchronous Remote Mirroring using MirrorView, Snapshot Point-in-time Copies, Non-  
Disruptive Upgrades, Access Logix.

### UNBINDING CONTROL LUNs:

# /nas/sbin/navicli –h 192.168.1.200 unbind 0 –o [Repeat for LUNs 0 – 5]

### BINDING CONTROL LUNs:

#/nas/sbin/navicli –h 192.168.1.200 bind r5 0 –rg 0 –rc 1 –wc 1 –aa 1 –sp a –sq gb –cap 4

```
#/nas/sbin/navicli -h 192.168.1.200 bind r5 0 -rg 1 -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 4  
#/nas/sbin/navicli -h 192.168.1.200 bind r5 0 -rg 2 -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 2  
#/nas/sbin/navicli -h 192.168.1.200 bind r5 0 -rg 3 -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 2  
#/nas/sbin/navicli -h 192.168.1.200 bind r5 0 -rg 4 -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 2  
#/nas/sbin/navicli -h 192.168.1.200 bind r5 0 -rg 5 -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 2
```

### **VERIFYING BIND STATUS & OUTPUT:**

```
# /nas/sbin/navicli -h 192.168.1.200 getlun 39 -owner  
# /nas/sbin/navicli -h 192.168.1.200 getlun 39 -state -bind
```

State: Binding  
Prct Bound: 3

### **TROUBLESHOOTING HYPER TERMINAL & COM PORTS ON CONTROL STATION:**

#### **Verify use of null modem cable and settings:**

COM Port: Bits per second: 19200 Data bits: 8 Parity: none Stop bits: 1 Flow control: hardware

#### **Verifying Console Redirection:**

1. Connect null modem cable to CS laptop and reboot
2. BIOS screen press F2 to enter setup
3. In Boot menu, verify that “Serial Console Redirection” is enabled and that “COM2 2FB IRQ3” is selected for “Serial Port”
4. Remove null modem and reconnect using Hyper Terminal

### **WHAT IS PXE BOOT?**

PXE stands for "Preboot Execution Environment" and is an open industry standard that allows PCs to boot over the network from a "boot image file" using a PXE-enabled Network Interface Device. PXE uses the Dynamic Host Configuration Protocol (DHCP) to assign the Client PC a temporary IP Address to work in conjunction with the Network Interface Card (NIC). Data Movers must use the PXE Boot method for installation and for troubleshooting when they cannot boot-up from the Array—in this situation, Data Movers boot from a NAS image on the CS over a private LAN connection using PXE & DHCP services, and a boot.cfg file.

### **PXEBOOT PROCESS (Revised PXE Boot steps):**

#### **Data Mover Blade Boot Rules:**

- Blade will try to boot from backend via BE0
- If Blade cannot boot from backend BE0, will try to PXE boot
- If PXE boot fails, the Blade will then try to boot from backend via BE1
- Additionally, the Control Luns need to be available on Chains 0 or 16 in order to boot

#### **1. Use /tftpboot/bin commands for PXE process:**

**Note:** If tftpboot directory does not exist, extract from /nas/tools. There is a command that creates the tftpboot directory, which also turns on tftp services, but also turns on the PXE services, which you may not want to do without specifying the subnets as shown below: # /nas/sbin/t2pxe -tftp start

```
# gzip -d /nas/tools/tftpboot.tar.gz  
# cd /  
# tar -xvf /nas/tools/tftpboot.tar
```

#### **2. Stop NAS Services and then mount the /nas partition:**

```
# /sbin/service nas stop  
# mount /nas
```

#### **3. Start PXE Services**

```
# /tftpboot/bin/t2pxe -s -R 2 128.221.252 128.221.253 [where -R x could be 2, 4, 6, or 8 depending on number of even blades in the cabinet]
```

```
=====  
EMC NAS PXE-BOOT Setup  
=====
```

```
Using Local Subnet 128.221.252.x for primary network  
Using Local Subnet 128.221.253.x for backup network
```

Starting PXE Services...

Done.

#### **4. Verify slot 2 & 3 config files that are created by PXE services:**

```
# cat /tftpboot/slot_2.cfg  
-serial swapserial  
flashupg post=upgrade bios=upgrade  
param config cs_ip=128.221.252.100:128.221.253.100
```

```
bufcache
device pci pci-0

```

## **5. PXE Boot the desired Blade by slot:**

```
# /ftpboot/bin/t2tty -p 2 [slot_2 in this example]
```

Attempting to force data mover PXE boot:

Resetting Slot-2 with t2reset...

Waiting for DM network connectivity after PXE booting..

Data mover has PXE booted successfully.

You can now stop pxe services on CS by running t2pxe -e

Slot-2 Forced PXE Boot Succeeded.

## **6. Stop PXE Services**

```
# /ftpboot/bin/t2pxe -e
```

```
=====
EMC NAS PXE-BOOT Setup
=====
```

```
=====
Stopping PXE Services...
```

## **7. Verify that NBS client access has been restored to Backend:**

```
# /sbin/fdisk -l
```

```
-----output abridged-----
Device Boot Start End Blocks Id System
/dev/ndal * 1 17 136521 6 FAT16
/dev/ndal3 654 1435 6281415 8e Linux LVM
```

## **8. Restart NAS Services & run healthcheck:**

```
# /sbin/service nas start
```

**Note:** NAS services may take 5 minutes or more to completely start. Use ps -ef |grep nas\_m and ps -ef |grep boxm to verify that NAS Services & Box Monitor processes are running before running the healthcheck.

```
# nas_checkup
```

## **NAS 5.2/5.3/5.4/5.5 PXEBOOT RECOVERY ON NS SYSTEMS:**

**Note:** If Data Movers are not running, or are failing, and Control Station cannot see backend Control Luns using NBS protocol, then the only choice is to PXE Boot the data movers so that they boot from an image on the local IDE drive on CS0 using dhcp & TFTP protocol.

### **CONFIGURING MINICOM & USING PXEBOOT TO RECOVER NBS SERVICES: NAS 5.2 – 5.5**

**Note:** Minicom only works with NS600/500/700 Series Celerras—there is no serial connection between CS & DM Blades for NSX

1. Connect to Control Station via normal modem dialup, webex session, telnet, ssh, or serial port using hyper-terminal client

2. Login as User nasadmin, then root

3. Stop NAS Services

```
# /sbin/service nas stop
```

**Note:** If the /nas partition is in use by the system or a user, NAS Services may not stop cleanly. Always verify that all nas\_mcd processes have been stopped before continuing, and kill any remaining nas\_mcd processes. As a last resort, reboot Control Station and try stopping NAS Services again.

**Example:**

**# /sbin/service nas stop**

```
NAS:/etc/init.d/nas: ERROR: Failed to stop NAS services
/nas is in use by the following processes(uid)
/nas:      15477e 15478e 18172e 18177e 23209e 23210e
/nbsnas is mounted
# ps -ef |grep nas_m
root   1198  1 0 Sep26 ?    00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root   1453 1198 0 Sep26 ?    00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
root   1656 1453 0 Sep26 ?    00:00:00 /nasmcd/nas_mcd -h /nasmcd /nas/
# pkill nas_mcd (stops all nas_mcd processes except parent ID 1198)
# kill -9 1198
```

4. If this procedure is being used to configure a Minicom profile and then access the Data Mover's POST or BIOS Systems (NBS Services are running normally and the backend partitions are available to the CS), simply remount the partitions:

```
# mount /nbsnas # mount /nas # mount /nas/dos # mount /nas/var
```

5. Setup Minicom profiles for each Data Mover (as required):

**#minicom -s**

Select 'Serial port setup'

Select "A" & manually change /dev/ttyS1 to /dev/ttyS4 for DM2, /dev/ttyS5 for DM3, /dev/ttyS6 for DM4, /dev/ttyS7 for DM5, then press the "enter" key

Select "E" twice to configure Speed/Parity for 9600 8N1 & press "enter"

Select "F" key to change Hardware Flow Control to No & press "enter"

'Save setup as...' and give a name to the profile, such as "dm2" & repeat for other Data Movers if required

Exit from Minicom

6. After minicom profiles have been configured, proceed with PXE Boot Recovery, stopping any existing PXE Boot Services:

**#/nas/sbin/t2pxe -e**

```
=====
          EMC NAS PXE-BOOT Setup
=====
Stopping PXE Services...
```

7. Restart PXE services in one-install mode:

**#/nas/sbin/t2pxe -s -R 2** [-R 2 for (2) Data Mover systems or -R 4 for (4) DM systems]

```
=====
          EMC NAS PXE-BOOT Setup
=====
```

Starting PXE Services...

Done.

8. Verify that the DHCP Daemon is running on the Control Station:

```
# ps -ef |grep -i dhcp
root   31302  1 0 13:36 ?    00:00:00 /usr/sbin/dhcpd -cf /tftpboot/dh
```

9. Force the Data Mover to PXE boot using t2tty -p command:

**#/nas/sbin/t2tty -p <slot\_x> &**

Attempting to force data mover PXE boot:

Resetting Slot-2 with t2reset...

Slot-2 Reset Successfully.

Waiting for DM To Come Up To PXE Boot Option....

Selecting DM PXE boot option...

Data Mover Is PXE Booting.

Waiting for DART to start after PXE boot...

Data mover has PXE booted successfully.

You can now stop pxe services on CS by running t2pxe -e

Slot-0 (ttyS2) Forced PXE Boot Succeeded.

**Note 1:** Forces the DM to boot from a nas.exe image located locally on the CS in the /nas/tools/tftpboot.tar.gz file. If this file is corrupt, upload a new file based on the same NAS version. There may be instances where PXE fails because of a problem with HBA0. If this happens, either unplug HBA0's fibre channel connection, or reboot Data Mover to access POST Menu & force PXE Boot.

```
# tar tzvf /nas/tools/tftpboot.tar.gz |head  
drwxr-xr-x 4294967294/4294967294 0 2006-08-30 18:35:03 tftpboot/  
-rwxr-xr-x 4294967294/4294967294 25208729 2006-08-30 18:34:55 tftpboot/nas.exe  
10. Alternatively, to watch the bootup process, ctrl + z the PXE Boot process and open a Minicom session
```

**# minicom dm2** (“dm2” represents minicom profile created in earlier step for Data Mover 2)

**Note:** Use “ctrl + A”, then enter “x” to exit minicom session. Be aware that the ctapty logs record each Data Mover boot and can be easily verified by going to the appropriate log for each Server:

/var/log/ctaptyS4.log (ctapty log for Server\_2)

11. If the Data Mover successfully boots, NBS Services should allow the Control Station to see its Backend Volumes—try remounting the volumes manually & continue troubleshooting your specific issue:

**# mount /nbsnas # mount /nas # mount /nas/dos # mount /nas/var**

12. Stop PXE Services:

**# t2pxe -e**

13. Reboot Data Mover using server\_cpu

**# server\_cpu server\_2 -r now**

14. Restart NAS Services

**# /sbin/service nas start**

### **TROUBLESHOOTING PXE BOOT DIFFICULTIES:**

→May need to reboot CS0 & retry PXE boot if it is failing

**# reboot -n -f**

→Have DM physically reseated and try again

→Check CTAP Logs for errors, etc: **/var/log/ctaptyS4.log**

→Verify Internal IP Address scheme in /etc/hosts file

→Access BIOS program & move PXE boot order to top of list (remember to set back to original position later)

→Verify status of Allied Telesyn 8-Port Internal 10/100 Ethernet Switch in back of Celerra Unit (power off, power on, cables, etc)

→Use FCCBOOT program to verify BE0, BE1 port speed settings, Scan for Backend Targets, Reset the HBA Controllers

**# /nasmcd/sbin/t2reset -s 2**

# minicom dm2 (or Hyper Term sessions via direct serial connection)

At following BIOS screen, “Aabcde...” type “esc” to exit bootup: Type “FCCBOOT” to enter FCCBoot Program

Select 1) to Reset Controller, Select 2) for FCC Boot Sub-menu and then 2) to Display Port Settings or 3) to enter BE0 FCC Boot menu, 1) Scan for target

### **FORCING PXE BOOT BY BYPASSING NORMAL BIOS BE0, PXEBOOT, BE1 BOOT ORDER:**

1. Stop NAS Services
2. Setup minicom profile for data mover from control station
3. Stop PXE Services and then restart in one-install mode
4. Reboot data mover using t2reset command
5. Initiate minicom session to DM from CS
6. At following message, press “esc” key [Aabc.....]
7. Enter password: SHIP\_it
8. Locate appropriate ICA Sub-Menu
9. Select 2) PXE Boot from the ICA Sub-Menu to force immediate PXE Boot that bypasses the normal BE0, PXE, BE1 Boot Order
10. Troubleshoot issue at hand
11. Stop PXE Services
12. Reboot Data Mover
13. Restart NAS Services

**Note:** There are references to older procedures that recommend changing the Boot Order by accessing the BIOS program upon Data Mover bootup using F2, then moving the PXE-2.0 boot order up above BE0 temporarily so as to be able force a PXE Boot. The above procedure is much simpler and does not muck with any permanent BIOS settings.

### **ACCESSING BIOS AND CHANGING BOOT ORDER WITH NAS 5.5:**

1. Stop NAS Services
2. Configure minicom profile
3. Reboot Data Mover
4. At following screen, press F2 repeatedly until BIOS menu appears:

Phoenix ServerBIOS 3 Release 6.0.

EMC BIOS Release 3.42

CPU = 4 Intel(R) Xeon(TM) CPU 2.00GHz

637K System RAM Passed

4031M Extended RAM Passed

512K Cache SRAM Passed

System BIOS shadowed

ERROR

0211: Keyboard error

Press <F1> to resume, <F2> to Setup

5. Press arrow key twice to scroll over to the “Boot” menu (→)

6. Highlight PXE-2.0 using down arrow key

7. Move Boot Order up or down using <shift +> or - key, respectively

8. After changes are made, arrow over to Exit Menu and select appropriate item:

Exit Saving Changes

Exit Discarding Changes

**Note:** Data Mover will reboot. Exit minicom using <ctrl + a >, then <x>

## **USING MINICOM TO TROUBLESHOOT & INITIATE PXE BOOT RECOVERY:**

**Purpose:** Minicom is a terminal program that runs on the CS and uses serial ports to connect to the Data Mover console, but only applies to old-style NS products: NS500, 600, 700, etc. Program is useful to observe Data Mover boot process. Also, this program is a necessary ‘backdoor’ to the CX600 backend if both data movers are down and /nbsnas is not mounted. You would use minicom to change the boot order if you needed to PXE Boot the data movers, which means that the data movers would boot a nas image directly from the Control Station’s internal IDE drive using the iscsi & PXE protocols.

The Linux Control Station for NS Series Celerra uses an internal serial modem program called 'Minicom' by which a user can connect to the Data Mover 'Console' from the Linux command shell or via a HyperTerminal session, to observe reboots, PXE boots, to access BIOS, POST, or FCCBoot menus, or to initiate commands directly to a Data Mover using the t2tty facility.

In order to use the Minicom Modem facility, a 'profile' must first be setup on the Data Mover, and given a name that is later used to invoke the actual 'Minicom' session between Control Station and Server. The following procedure explains how to setup a profile and how to initiate a Minicom session, and then exit the application.

### **I. Setup the Minicom profile for a Data Mover:**

a. Stop NAS Services and manually remount /nbsnas, /nas, /nas/dos, & /nas/var

# /sbin/service nas stop # mount /nbsnas /nas /nas/dos /nas/var

b. Start Minicom and setup profile:

**# minicom -s**

**Select ‘Serial port setup’**

**Select “A” & change /dev/ttyS1 to /dev/ttyS4 for DM2,/dev/ttyS5 for DM3, /dev/ttyS6 for DM4, /dev/ttyS7 for DM5, enter**

**Select “E” twice to configure Speed/Parity to 9600 8N1 & press enter**

**Select “F” key to change Hardware Flow Control to No & press enter**

**Save setup as... and give a name to the profile, such as “dm2”, enter [repeat to create other profiles: e.g., “dm3”, etc.]**

**Exit from Minicom** [to quit the profile session]

### **II. Establish Minicom session for Server\_2:**

a. Reboot or PXEBoot Data Mover

b. During system reboot, start Minicom Session by typing "minicom dm2" [just type to screen, even if Linux prompt is not visible]

c. Observe Data Mover reboot, enter Data Mover commands at CONSOLE> once system is up, etc.

**Note:** Alternatively, check the appropriate Server Log to observe bootup entries: /var/log/ctapptyS4.log (Server\_2)

d. To shutdown the Minicom Session, use “ctrl + a” then “x” to exit

e. If NAS Services were previously stopped, start NAS

#/sbin/service nas start

## **PXE BOOTING WITH NAS 5.2 & 5.3:**

**# /nas/sbin/t2pxe -e (Stops PXE boot services)**

**# /nas/sbin/t2pxe -s (Starts PXE boot services)**

**Note:** t2pxe is a shell script designed to assist data movers in creating a PXE boot configuration file (slot\_x.cfg) and in starting DHCP and TFTP services

**# /nas/sbin/t2pxe -s -R 2 [slot\_# 1, 2, or 4, etc]**

**# /nas/sbin/t2pxe -p <slot>** (forces PXE boot)

## **COMMAND SYNTAX FOR T2TTY :**

**# /nas/sbin/t2tty**

Celerra\IP Serial Connection Tester....

Usage:

Count active serial connections on ttyS4 thru ttyS9

t2tty -n

Check serial connection signal on ttyS4 thru ttyS9

t2tty -t

Check serial connection signal to a given slot (2-5)

t2tty -s 2

Force Data Mover in slot (2-5) to PXE boot

t2tty -p 2

Send dart command "cmd" to data mover in slot (2-5)

t2tty -c # "cmd" [e.g., t2tty -c 2 "ifconfig"]

## **NORMAL BIOS BOOT ORDER FOR NS DATA MOVERS :**

BE0

PXE

BE1

## **PXE BOOT RECOVERY PROCEDURE FOR CELERRA NS600:**

**Note:** # /nas/sbin/t2pxe -s 192.168.1.2 → New NAS 5.2 to setup PXE Booting, requires /nas/tools/tftpboot.tar.gz file—use IP address after -s if Internal IP address has changed.

1. Connect Serial cable from PC to CS0 and setup Hyper Terminal session

2. Establish serial port minicom session to DM2: #minicom dm2

### **CONSOLE>**

**Note:** Stop NAS Services prior to using Minicom [/sbin/service/nas stop]. Manually remount /nas, /nbsnas, /nas/dos, & /nas/var, if applicable.

3. Reboot data mover locally, or reseat server. With minicom session open, observe boot up process and access DM bios to change the Boot Order.

4. Press the following key combinations in order to access the Bios Setup Menu—run the key combinations during System RAM and at end of Extended RAM Checks:

Phoenix Server BIOS 3 Release 6.0

CPU=4 Intel ® XEON ™ CPU 2.00GHZ

637K System RAM Passed

4031M Extended RAM Passed

512I Cache...

**esc shift + O shift + Q**

**Note:** On some keyboards, this can be achieved using F2

5. Press right arrow key twice to move over to “Boot” Menu options. Change Boot Order of PXE in the “Boot” Menu by highlighting “Intel UNDI, PXE-2.0 (build 079)”. Use the – or + key to move entry up or down. Place ‘PXE-2.0’ entry just below the “Extended POST” line and above the “Fibre Port BE0” line:

PXE BOOT:

```
PhoenixBIOS Setup Utility
Main Advanced Boot Exit
                                Item Specific Help
· Intel UNDI, PXE-2.0 (build 079)
· Removable Devices
· Extended POST          . Keys used to view or
· Fibre Port BE0           . configure devices:
· Fibre Port BE1           . <Enter> expands or
· +Hard Drive              . collapses devices with
· Removable Devices        . a + or -
```

6. Save changes to Boot Menu by pressing “esc”, “esc” and then “enter” when “Exit Saving Changes” is highlighted. Press enter again until program exits.

7. Start the PXE Service [See step 2 of above minicom procedure for tftpboot file info]: #/etc/rc3.d/s95nas -p

=====

EMC NAS PXE-BOOT Setup

=====

[Nov 17, 17:22:13]

Detecting movers in cabinet: 2

Starting PXE Services...

/etc/rc3.d/s95nas: chkconfig: command not found

Done.

8. Verify PXE Services: # ps -ef |grep dhcp

root 5544 1 0 15:10 ? 00:00:00 /usr/sbin/dhcpd -cf /tftpboot/dh

9. Reboot Server using /nas/sbin/t2reset reboot -s 2 in order to initiate PXE boot.

10. Open minicom session [#minicom dm2] to observe boot process or use cat to check data mover boot state: #cat </dev/ttys4  
Use ctrl + c to exit the cat session. Alternatively, use #/nas/tools/.server\_tty -s 2 to check on DM state.
11. Exit minicom using “Ctrl+A”, then “x”
12. Conduct recovery tasks. When completed, restore correct Boot order in Bios Setup Menu.
13. Disable PXE Boot Service by running following commands:

```
# killall dhcpcd  
# rm -rf /tftpboot
```

14. Restart NAS Services

#### **Using Minicom to Observe Backend Storage Processors:**

1. Use serial cables S3 or S4 on laptop to connect to backend storage processors using null modem cable
2. Use setup procedure referenced above and use “ttys6 or ttys7” for S3 or S4 ports, respectively
3. Save setup and exit Minicom, then perform setup as in Step 2. above, but use new connection just created to access SP.

#### **AVM—AUTOMATIC VOLUME MANAGEMENT:**

Profiles must be selected before implementation in order to use Web UI

#### **CLARIION STORAGE PROFILES:**

clar\_r5\_economy: CLARiiON RAID 5 disk vols from 8+1 RAID group, aggregated by a stripe over an SP-balanced pair  
clar\_r5\_performance: CLARiiON RAID 5 disk vols from 4+1 RAID group, aggregated by a stripe over an SP-balanced pair  
clar\_r1: CLARiiON RAID 1 disk vols, aggregated by a stripe over an SP-balanced pair [2 Mirrored drives]  
clarata\_archive: CLARiiON ATA disks built on a Raid 5 raid group--New profile with 5.1.18 + code

#### **AVM RULES:**

- Clarion always requires an 8k stripe, whereas Symmetrix should stripe 32k for NFS, 8k for CIFS, and 256k for Highroad
- Try to allocate most important file systems first
- Do not use AVM with Timefinder environments
- Take one volume from each RAID group & alternate SP ownership
- Stripe volumes together in groups of (4) luns
- Do not spread file systems across more than one profile
- Web UI can only manage fs using profiles [i.e., fs created from CLI cannot be managed from Web UI]

#### **DETERMINING DISK POOLS FOR NAS 5.2:**

```
# /nas/bin/nas_cmd @nas_pool -l
```

| id | inuse | acl | name                |
|----|-------|-----|---------------------|
| 1  | n     | 0   | symm_std            |
| 2  | n     | 0   | clar_r1             |
| 3  | n     | 0   | clar_r5_performance |
| 4  | n     | 0   | clar_r5_economy     |
| 5  | n     | 0   | symm_bcv            |
| 6  | n     | 0   | symm_std_rdf_tgt    |
| 7  | n     | 0   | symm_bcv_rdf_tgt    |

| 12+2 RAID6(CX3)    | ATA                    | clarata_r6             | 4                |
| 4+2 RAID6          | LCFC                   | clarata_r6             | 2                |
| 6+2 RAID6          | LCFC                   | clarata_r6             | 2                |
| 12+2 RAID6         | LCFC                   | clarata_r6             | 4                |

**Note:** Clariion rules say that all ATA LUNs in a RG must be owned by a single SP. You would balance SP ownership across RG's or Shelves. Fibre Channel drives can be R5, R1, or R6 for Celerra configurations. ATA drives can be R5 or R3 for CX arrays, and also R6 for CX3 arrays.

**TEMPLATE DISK GROUP REQUIREMENTS:**

- First enclosure on any system is always RAID 5
- All other enclosures can be either all RAID 5 or all RAID 1, but not both
- All disk groups must have (2) disk volumes bound for user data
- CX600/CX700 & NS600/NS700 have up to (15) disk devices per DAE
- FC4700 uses (10) disk devices per shelf
- First (6) disks NS600/NS700 are configured as a RAID5 (4+1) Disk Group with (5) control disks and (1) Hot Spare
- CNS CX600/CX700/FC4700-2 systems are configured at system install time using one of the templates
- All other Clariion systems can have remaining disk devices configured per the templates
- ATA drives cannot be configured for Bus 0 Enclosure 0

**STANDARD CELERRA TEMPLATES:** CX-Standard\_Raid\_5; CX\_All\_4plus1\_Raid\_5; CX\_Standard\_Raid\_1

**CX STANDARD RAID5 TEMPLATE**

|                   |           |           |           |

## **UPDATING CACHE CONFIGURATIONS ON CLARIION AFTER CODE UPGRADES:**

### **#/nas/sbin/setup\_backend/nas\_raid cache configure**

**Note:** NAS 5.1M and higher recommends use of Read Cache to improve performance [32MB to 256MB max]

## **MONITORING DMs AS THEY BOOT:**

#cat /dev/ttyS4 [DM2; ttyS5=DM3] >server2 |tail -f

## **NAVICLI COMMANDS:**

**#/nas/sbin/navicli -h 192.168.1.200 getagent | getcrus |getdisk | getrg | getlun | getcache | getlog**

## **CABLING BETWEEN SPE & SPS:**

Wrong cabling may disable cache & make DMs appear to be reset or not booted from CS

**#/nas/sbin/navicli -h 192.168.1.200 getcrus** [Checks cabling status, SPS status, Disk status, SPA status, and shows faults]  
If DM LED is green, probably in contacted state

## **VERIFYING FLARE CODE:**

**#/nas/sbin/navicli -h 192.168.1.200 ndu -list | getagent**

**# /nas/sbin/navicli -h 10.241.168.57 getall –sg** (same output as storagegroup –list)**# /nas/sbin/navicli -h 10.241.168.57 -np getdisk**

**Note:** Use -np option to retrieve object info from cache and not directly query each object on array—faster

**-NP PERL SCRIPT FOR NAVICLI (From AR106276, emc175499):**

**Note:** Following script can be used to replace the symbolic links /nas/sbin/navicli and /nas/opt/Navisphere/bin/navicli, which point to nas\_navi, with a file named “navicli”—just copy the contents to notepad and then into a new file called navicli and copy to the two locations after removing the symbolic links. Script enforces the use of -np switch on array commands, retrieving objects from cache whenever possible as opposed to querying every object, making navi commands work faster.

#!/usr/bin/perl -w

```
#
# This is a hack supplied by EMC development to make sure the
# -np option is applied to every navicli command
#
# This perl script should replace the symlink navicli -> nas_navi
# in the /nas/sbin and /nas/opt/Navisphere/bin directories
#
$navi = "/nasmcd/sbin/classic_navicli";
$cmd = join(" ", @ARGV);
if( $cmd =~ m/-np/ ) {
  @out = `$navi $cmd`;
}
```

```

else {
    @out = `$navi -np $cmd`;
}

$status=$? >> 8;

print join("", @out);

exit $status;

## **DETERMINING HOT SPARE STATUS:**

**# /nas/sbin/navicli -h 10.241.169.35 getlun -default -owner**

LOGICAL UNIT NUMBER 6

Default Owner: SP B

Current owner:

**# /nas/sbin/navicli -h 10.241.169.35 getlun 6**

Name LUN 6

RAID Type: Hot Spare

## **PLACING DISK DRIVE IN FAULTED STATUS FOR TESTING:**

# /nas/sbin/navicli -h 192.168.1.200 getdisk 0\_0\_12 |grep Bus |grep -v Ticks

Bus 0 Enclosure 0 Disk 12

# /nas/sbin/navicli -h 192.168.1.200 getcrus (No faults noted)

# /nas/sbin/navicli -h 192.168.1.200 cru\_on\_off -messner 0\_0\_12 0 (this places disk 12 down)

# /nas/sbin/navicli -h 192.168.1.200 getcrus

DAE3P Bus 0 Enclosure 0 \*FAULT\*

(Bus 0 Enclosure 0 : Faulted; Bus 0 Enclosure 0 Disk 12 : Removed)

# /nas/sbin/navicli -h 192.168.1.200 cru\_on\_off -messner 0\_0\_12 1 [places drive back up]

### DETERMINING FRUMON VERSION ATA LCC's:

# /nas/sbin/navicli -h 192.1.4.220 getcrus -lcreva -lcrevb

SPE3 Enclosure SPE

DAE3P Bus 0 Enclosure 0

Bus 0 Enclosure 0 LCC A Revision: 7.71

Bus 0 Enclosure 0 LCC B Revision: 7.71

### VERIFYING SP PORTS FOR SAN-CONNECTED DM's:

\$ /nas/sbin/navicli -h 10.64.25.148 port -list

Information about each HBA:

HBA UID: 50:06:01:60:80:60:07:B9:50:06:01:68:00:60:07:B9

Server Name: ns600g\_dm30

Server IP Address: 192.168.1.3

HBA Model Description: ns600g

HBA Vendor Description: celerra

HBA Device Driver Name: N/A

Information about each port of this HBA:

SP Name: SP A

SP Port ID: 1

HBA Devicename: N/A

Trusted: NO

**Logged In:** YES

Source ID: 1

Defined: YES

Initiator Type: 3

StorageGroup Name: NS600G

### VERIFYING SP SPEED SETTINGS:

# /nas/sbin/navicli -h spa ssportspeed -get

Storage Processor : SP A

Port ID : 1

Speed Value : 2

Storage Processor : SP A

Port ID : 0

Speed Value : 2

Storage Processor : SP A

Port ID : 3

Speed Value : 2

Storage Processor : SP A

Port ID : 2

Speed Value : 2

### CHANGING SP FC PORT SPEED:

# /nas/sbin/navicli -h spa ssportspeed -set -sp a -portid 0 2 [Sets port 0 on SPA to 2GB]

### RUNNING SPCOLLECT TO GATHER CLARIION LOGS:

1. C:>Program Files\EMC\Navisphere CLI>navicli -h 192.168.1.200 spcollect -messner [password=messner]

**Note:** Script collects a variety of files and zips them.

2. Monitor spcollect using: >navicli -h 192.168.1.200 managefiles -list | -delete | -retrieve

3. Retrieve SPCollects:

C:>navicli -h 192.168.1.200 -retrieve -file SPA\_WRE00021500537\_90a1f\_07-24-2003\_14-25-05\_data.zip

### TRANSFERRING SPCOLLECT FROM SP TO HOST:

**C:>Program Files\EMC\Navisphere CLI>navicli -h 192.168.1.200 managefiles –retrieve <path> –file**

**SPA\_WRE00021500537\_90a1f\_07-24-2003\_14-25-05\_data.zip**

**Note:** SPCollects are the basic starting point files for any Clariion escalation and can be sent to following email address, along with Case #, Customer Name, and brief description of issue: GCSC@emc.com. Starting with FLARE 19, SPCOLLECTS can be setup to run automatically, so that there is always an SPCollect available. However, only a single collect is maintained and only records a finite amount of information—so if there is a lot of activity, the logs may have wrapped.

### **CONTROL STATION SCRIPT AUTOMATES SP COLLECT:**

**# /nas/tools/.get\_spcollect**

Generating spcollect zip file for Clariion(s)

Creating spcollect zip file for the Service Processor A\_APM00023801040. Please wait...

spcollect started to pull out log files(it will take several minutes)....

Wait until new \_data.zip file size becomes final(it will take several minutes)

Retrieving new \_data.zip file...

spcollect zip file APM00023801040\_SPA\_2006-04-10\_20-02-39\_a5c1b\_data.zip for the Service Processor A\_APM00023801040 was created

Creating spcollect zip file for the Service Processor B\_APM00023801040. Please wait... -----output abridged-----

Zipping all spcollect zip files in one SPCOLLECT.zip file and putting it in the

**/nas/var/log** directory...

adding: APM00023801040\_SPA\_2006-04-10\_20-02-39\_a5c1b\_data.zip (stored 0%)

adding: APM00023801040\_SPB\_2006-04-10\_20-06-50\_a34fc\_data.zip (stored 0%)

**-rw-r--r-- 1 root root 6073082 Apr 10 16:09 SPCOLLECT.zip**

### **RUNNING BACKGROUND VERIFY ON LUNS:** LRC checks

**# /nas/sbin/navicli -h 192.168.1.200 setsniffer 4 1 -bv -bvtimer asap**

**Note:** Above command runs a background verify against LUN 4 (/nas /dev/sde1), best method to check actual condition of LUNs

### **VERIFYING STATE OF LUNS ON BACKEND:**

**# /nas/sbin/navicli -h 10.241.168.57 getlun -trespass -status**

**\$ /nas/sbin/navicli -h 10.241.169.35 getlun -state -owner -default**

LOGICAL UNIT NUMBER 228

State: Bound

Current owner:

Default Owner: SP B

LOGICAL UNIT NUMBER 17

State: Bound

Current owner: SP B

Default Owner: SP B

-----abridged-----

### **VERIFYING STORAGEGROUPS ON ARRAY:** [Works only with Access Logix]

**\$ /nas/sbin/navicli -h 10.241.169.35 storagegroup -list**

Storage Group Name: NS600G

Storage Group UID: BC:C5:B1:A2:B7:42:D8:11:80:0A:91:05:4E:AD:DB:DC

#### **HBA/SP Pairs:**

| HBA UID   | SP Name | SPPort |
|---|---------|--------|
| 02:00:00:00:01:00:00:00:02:00:00:00:01:00:00:00 | SP A    | 1      |
| 50:06:01:60:90:60:15:50:50:06:01:68:10:60:15:50 | SP A    | 1      |
| 02:00:00:00:01:00:00:00:02:00:00:00:01:00:00:00 | SP A    | 0      |
| 50:06:01:60:90:60:15:50:50:06:01:60:10:60:15:50 | SP A    | 0      |
| 02:00:00:00:01:00:00:00:02:00:00:00:01:00:00:00 | SP B    | 1      |
| 50:06:01:60:90:60:15:50:50:06:01:69:10:60:15:50 | SP B    | 1      |
| 02:00:00:00:01:00:00:00:02:00:00:00:01:00:00:00 | SP B    | 0      |
| 50:06:01:60:90:60:15:50:50:06:01:61:10:60:15:50 | SP B    | 0      |

#### **HLU/ALU Pairs:**

| HLU Number | ALU Number |
|------------|------------|
| 0          | 0          |
| 1          | 1          |
| 2          | 2          |

3 3  
4 4  
5 5  
16 16  
17 17

Shareable: YES

## **COLLECTING CONFIGURATION INFO AFTER INSTALL:**

**# /nas/sbin/log\_config -outfile**

Usage: log\_config  
[ -outfile <filename> ] [ -default ] [ -nozip ] [ -callhome ]  
| -start  
| -stop  
| -version  
| -help

**#/nas/sbin/log\_config -outfile /home/nasadmin/config.log**

**# /nas/sbin/model**

**Note:** The model command runs /nas/bin/nas\_xml and looks at 2<sup>nd</sup> entry in PRODUCT\_NAME field to determine system Model

**# nas\_xml -info:ALL**

**# nas\_xml -info:server -level:3**

**Note:** Extremely useful command to obtain overall Celerra, CS, and Data Mover hardware and software information, as well as NIC status.

```
<CELERRA SRC='controlstation'>  
<CELERRA_MANAGEMENT_UNIT NAME='APM000421031830000' TYPE='Celerra IP'

-----abridged-----
```

## **VIEWING SP LOG:**

**#/nas/sbin/navicli -h 192.168.1.200 getlog >/tmp/cx600.log**

## **CREATING PPP [VPN—Virtual Private Network] CONNECTION TO CX600:**

1. Start>Settings>Network and Dial-up Connections>Make New Connection>Next>\*Guest>Connect directly to another computer
2. Select a Device: COM1>\*For all Users>Configure COM1: Max speed 115200; Enable hardware flow control
3. Finish>Enter Clariion clarion! >Connect
4. Once connected open Internet Explorer and enter IP Address to Service PC: http://192.168.1.1/setup
5. Enter IP Address, Hostname, Mask, Gateway, Peer IP Address, Management Ports
6. Next task would be to install the Navisphere CLI on the Service PC
7. Open cmd prompt to execute navicli commands to backend  
c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 ndu -list [Checks for software revision on SPs]

## **VERIFYING ACCESSLOGIX IS ENABLED ON CX600:**

**1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -status**

“Data Access Control Enabled” [Means AccessLogix is enabled]

2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -enable -o [Run this to enable AccessLogix]

## **CONFIGURING CX600:**

### **SETTING FIBRE PORT SPEEDS ON CX600 SPs:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 spportspeed -set -sp a -portid 0 1 [Sets to 1GB/sec]

### **CREATING & SHARING STORAGE GROUPS ON CX600 WITH DMs & CS:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -create -name nas\_san

2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -shareable -name nas\_san yes

## **ADDING WWNS TO CX600:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -setpath -o -name nas\_san -hbauid <CS0  
WWN> -sp a -spport 0
2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -setpath -o -name nas\_san -hbauid <DM1  
WWN> -sp b -spport 0
3. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -setpath -o -name nas\_san -hbauid <DM2  
WWN> -sp a -spport 0

## **SETTING CX600 CACHE:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 setcache -wc 0 -rca 0 -rcb 0
2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 setcache -wsza 0 -wszb 0 -rsza 0 -rszb 0
3. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 setcache -wsza 1497 -wszb 1497 -p 8 -I 70 -h 90
4. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 setcache -wc 1

## **CREATING RAID GROUPS:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 createrg 0 0\_0\_0 0\_0\_1 0\_0\_2 0\_0\_3 0\_0\_4

**Note:** Creates Raid 5 RG on System LUNS for disks 0-4

2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 createrg 200 0\_0\_14 [Creating Raid Group on disk 14]
3. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 bind hs 200 -rg 200 -sp a [Binding LUN on new RG]
4. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 bind r5 0 -rg - -rc 1 -wc 1 -aa 1 -sp a -sq gb -cap 4 -elsz 128 [Creates a 4 GB LUN]

## **MOVING CONTROL SYSTEM LUNS INTO STORAGE GROUPS:**

1. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -addhlu -name nas\_san -hlu 0 -alu 0
2. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -addhlu -name nas\_san -hlu 1 -alu 1
3. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -addhlu -name nas\_san -hlu 2 -alu 2
4. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -addhlu -name nas\_san -hlu 3 -alu 3
5. c:\Program Files\EMC\Navisphere CLI>navicli -h 192.168.25.114 storagegroup -addhlu -name nas\_san -hlu 4 -alu 4

## **CREATING USER LUNS:**

1. Create on any 4+1 Raid 5, 8+1 Raid 5, or Raid 1 raid groups [Must spread evenly across SPA & SPB]
2. Move new LUNs into Celerra Storage per previous procedure
3. Run server\_devconfig –create to update Celerra database

## **TROUBLESHOOTING CELERRA CLARIION/NS600 BACKEND ISSUES:**

### **NAS 5.3.14.2 NAVICLI COMMANDS:**

# /nas/sbin/navicli -h

### **OBTAIN IP ADDRESS OF SPA/SPB:**

Control Station: #cat /etc/hosts

Clariion → 172.24.11.110 A\_F20013800379 [SPA, etc—FC4700]

NS600 → 192.168.1.200 A\_WRE00022100964 [SPA, etc]

**NS600:** #cat /etc/hosts

|               |                       |              |
|---------------|-----------------------|--------------|
| 127.0.0.1     | localhost.localdomain | localhost    |
| 192.168.1.200 | A_APM00023700169      | SPA [Node A] |
| 192.168.1.201 | B_APM00023700169      | SPB [Node B] |

### **USE GETALL COMMAND TO GATHER INFO FOR ENG:**

# /nas/sbin/navicli -h 192.168.1.200 getall >getall.txt

Server IP Address: 192.168.1.200

## **CELERRA ISSUE WITH TRESPASSED LUNS:**

Do not run server\_devconfig –create if any LUNS are trespassed on the Celerra [Camdisk and Volumes files become inconsistent when failed back to normal state]—see emc82523.

**# /nas/sbin/navicli -h 10.241.168.57 getlun -tresspass –status**

## **CONSIDERATIONS TO TAKE INTO ACCOUNT BEFORE RESTORING LUNS TO SP OWNER:**

**Note:** Typically, the WebUI>Storage>Systems screen will show a Storage Processor in, “Is Ready to Restore” status

1. Ensure Data Movers have both fibre channel paths “bound” by doing “fcp bind show”
2. Ensure that Data Movers can see down both backend paths by doing “server\_devconfig –p –s –a”
3. Compare camdisk to probe to make sure that no inconsistencies are noted
4. Click on the “Is Ready to Restore” icon in the WebUI during a time when the NASDB Backup is NOT running
5. If Luns fail to trespass back, make sure that LUNs are in the proper Storage group, then try trespassing back manually using CLI:

**# /nas/sbin/navicli -h 10.241.169.36 trespass lun 9**

## **SERVER LOG SHOWING TRESPASSED LUN:**

2007-09-04 13:22:23: STORAGE: 4: 5: volume 150 has moved from SPB to SPA

2007-09-04 13:22:23: CAM: 3: I/O Error: c16t1112 Irp 0xe5270e04 CamStatus 0x84 ScsiStatus 0x02 Sense 0x05/0x04/0x00

**Note:** The 05/04/00 Sense code indicates that Celerra is trying to access a lun owned by the other SP

## **FAILING OVER LUNS TO ALTERNATE SP:**

**# /nas/sbin/navicli -h 172.24.173.64 trespass all**

**Note:** This command is listed here for illustration purposes only—you would probably not want to risk panicking the Celerra if you choose the wrong SP. This command must be run to the SP that is up and running!

## **FAILING BACK CELERRA LUNS TO OWNER SP:**

\$nas\_storage –l [obtain Serial Number of system]

**\$nas\_storage -failback WRE00022000779**

## **FAILING BACK TO SPB AFTER REPAIRS:**

**#/nas/sbin/navicli -h 192.168.10.10 trespass mine** [IP for SPB, requesting LUNs be given back to SPB]

**Caution:** Do not use this command against all luns on an SP if the Clariion has other hosts besides the Celerra. Rather, trespass back each Celerra lun individually using the alu number found in the storagegroup –list. PowerPath hosts can allow for automatic failback of LUNs, Celerra does not. Also, power cycling an array will reset all LUNs back to their default owners.

## **FAILING BACK LUNS/RESTORING LUNS/TRESPASSING LUNS BACK TO OWNER SP:**

### **Option 1:**

**# /nas/sbin/navicli -h 10.241.169.36 trespass lun 16**

**Note:** Must run command from SP to which you are trespassing the lun to

### **Option 2:**

**# nas\_storage -failback id=1**

id = 1

serial\_number = APM00040400145

name = APM00040400145

acl = 0

**Note:** Purpose of this command is to failback all NAS Luns to their correct SP Owner. Check nas\_log.al for command start and completion, but run getlun –default –owner to verify that luns go back to their rightful Owner. In some cases, the specific lun must be trespassed back individually.

### **nas log.al**

2005-12-07 17:30:15.210 db:0:4332:S: nas\_storage -failback id=1

2005-12-07 17:30:15.382 db:0:4332:E: nas\_storage -failback id=1

### **Option 3:**

Celerra Manager> Click on Storage>Restore SP A>then click on o.k. to restore

### **Option 4:**

If LUNs will not remained trespassed back to their Owner SP, try running “fcp bind show”, as this command invokes a Test Unit Ready (TUR) message that forces “cam” layer to reset path failed bit—see AR74104 for more details 5.4.22.1 fix

### **Option 5:**

If a specific HBA path is down, issue the port reset command:

# .server\_config server\_2 -v "fcp portreset=0"

#### Option 6:

If LUNS constantly bounce back, try disabling the no\_trespass param, and then trespass LUNs back—this should disable DART from initiating LUN trespassing while trying to get things back to their proper configuration:

\$ .server\_config server\_2 -v “param clarion no\_tresspass=1”

#### Option 7:

Shutting down the Celerra, then the array, and bringing the array back up will restore all LUNS to their proper SP

#### Option 8:

If there is a fundamental binding table issue or a path issue where the HBA Chains have been diskmarked down the wrong chain, use one of the following two methods to restore LUNs to their rightful path:

a.) Failover to Standby → Clear Bind tables on faulted non-production slot → Do setup\_slot –init on faulted slot → Do devconfig –create to remark paths → Failback to original slot

b.) Temp. unmount all file systems on affected DM → Trespass luns back to correct SP → do devconfig –create to remark chains → Remount all file systems and verify

### **VERIFY CACHE SETTINGS:**

# /nas/sbin/navicli -h 172.24.11.110 [Write cache should be Enabled!]

SP B

Memory Size For The SP: 2048

### **DISABLING READ & WRITE CACHE AT ARRAY LEVEL:**

# /nas/sbin/navicli -h 172.24.11.110 setcache -wc 0 -rca 0 -rcb 0

**Note:** Write Cache could be disabled by faulted SP, faulted SPS power supply, Bad vault drive in first DAE, requires min. of (1) fully charged SPS

### **ALLOCATING 1/3RD READ CACHE & 2/3RD WRITE CACHE:**

# /nas/sbin/navicli -h 172.24.11.110 setcache -wsza 1197 -wszb 1197 -rsza 300 -rszb 300

### **ENABLING READ & WRITE CACHE AT ARRAY LEVEL:**

# /nas/sbin/navicli -h 172.24.11.110 setcache -rca 1 -rcb 1 -wc 1 [Enabling Read & Write cache]

# /nas/sbin/navicli -h 172.24.11.110 setcache -wc 1 [Enabling write cache only]

## **RE-SETTING READ & WRITE CACHE ON SP's WITH 50:50 RATIO:**

**Note:** Perform during period of relative inactivity, as these steps could impact users

### **1. DISABLE WRITE & READ CACHE:**

```
# /nas/sbin/navicli -h 192.168.1.200 setcache -wc 0 (SPA)
# /nas/sbin/navicli -h 192.168.1.201 setcache -wc 0 (SPB)
# /nas/sbin/navicli -h 192.168.1.200 setcache -rca 0 (SPA)
# /nas/sbin/navicli -h 192.168.1.201 setcache -rcb 0 (SPB)
```

### **2. ZERO OUT WRITE & READ CACHE VALUES:**

```
#/nas/sbin/navicli -h 192.168.1.200 setcache -wsza 0 (SPA)
#/nas/sbin/navicli -h 192.168.1.201 setcache -wszb 0 (SPB)
#/nas/sbin/navicli -h 192.168.1.200 setcache -rsza 0 (SPA)
#/nas/sbin/navicli -h 192.168.1.201 setcache -rszb 0 (SPB)
```

### **3. SET NEW WRITE & READ CACHE VALUES:**

```
#/nas/sbin/navicli -h 192.168.1.200 setcache -wsza 1465
#/nas/sbin/navicli -h 192.168.1.201 setcache -wszb 1465
#/nas/sbin/navicli -h 192.168.1.200 setcache -rsza 32
#/nas/sbin/navicli -h 192.168.1.201 setcache -rszb 32
```

### **4. RE-ENABLE WRITE & READ CACHE:**

```
$ /nas/sbin/navicli -h 192.168.1.200 setcache -wc 1
$ /nas/sbin/navicli -h 192.168.1.201 setcache -wc 1
$ /nas/sbin/navicli -h 192.168.1.200 setcache -rca 1
$ /nas/sbin/navicli -h 192.168.1.201 setcache -rcb 1
```

### **5. VERIFY SETTINGS:**

\$ /nas/sbin/navicli -h 192.168.1.200 getcache

|                        |         |

| SPB Write Cache State  | Enabled |
| SPA Read Cache Size =  | 1497    |
| SPB Read Cache Size =  | 1497    |
| SPA Write Cache Size = | 1497    |
| SPB Write Cache Size = | 1497    |

### **6. VERIFY THAT CACHE IS ENABLED ON EACH SP:**

```
# /nas/sbin/navicli -h 192.168.1.200 getlog |grep -i cache |tail
# /nas/sbin/navicli -h 192.168.1.201 getlog |grep -i cache |tail
```

```
03/16/2005 11:10:13 SP A      (639) System Cache Enabled [System cache is Write cache]
03/16/2005 11:09:59 SP B      (639) System Cache Enabled
07/27/2005 14:05:14 SP A      (714) Read cache enabled
07/27/2005 14:08:49 SP B      (714) Read cache enabled
```

### **SETTING CACHE ON BOTH SP's WITH ONE COMMAND:**

#/nas/sbin/navicli -h 192.168.1.200 setcache -wsza 1497 -wszb 1497 -rsza 1497 -rszb 1497

\$ /nas/sbin/navicli -h 10.0.1.200 getcache

|                          |        |
|--------------------------|--------|
| Low Watermark:           | 70     |
| High Watermark:          | 90     |
| SPA Cache pages:         | 190783 |
| SPB Cache pages:         | 190784 |
| Unassigned Cache Pages:  | 0      |
| Prct Dirty Cache Pages = | 1      |

**Note:** If dirty cache pages were to approach LWM, then Clariion performance would be impacted as it flushes to disk

## **WRITE CACHE AND EFD LUNS:**

See emc234527. CLARiiON best practice states that both Read and Write cache be disabled at the LUN level for EFD drives.

Celerra best practice is to have Read cache disabled, but Write cache enabled. This has caused confusion in the field. Also, NAS 5.6.47 code diskmarking will fail if Read cache is disabled. Therefore, in order to diskmark EFD luns, make sure that both Read & Write cache are enabled.

**Workaround:**

1) Enable Read & Write cache on the lun(s):

```
$ /nas/sbin/navicli -h 10.241.168.188 chglun -l 16 -c rw
```

2) Diskmark from CLI or Rescan the disk devices from Celerra Manager in order to bring them into the Celerra database:

```
$ server_devconfig server_2 -c -s -a [or nas_diskmark -m -a]
```

Discovering storage (may take several minutes)

server\_2 : done

3) Disable Read cache on the EFD Celerra LUN(s):

```
$ /nas/sbin/navicli -h 10.241.168.188 chglun -l 16 -c write
```

4) Verify:

```
$ /nas/sbin/navicli -h 10.241.168.188 getlun 16 -wc -rc
```

Write cache:       ENABLED

Read cache:      DISABLED

**DISABLING READ & WRITE CACHE ON A LUN:**

**# /nas/sbin/navicli -h 10.241.168.188 chglun -l 16 -c none**

**ENABLING READ & WRITE CACHE ON A LUN:**

**# /nas/sbin/navicli -h 10.241.168.188 chglun -l 16 -c rw**

**VERIFYING READ & WRITE CACHE STATUS ON A LUN:**

**# /nas/sbin/navicli -h 10.241.168.188 getlun 16 -wc -rc**

**ENABLING WRITE CACHE ONLY:**

**# /nas/sbin/navicli -h 10.241.168.188 chglun -l 16 -c write**

**# /nas/sbin/navicli -h 10.241.168.188 getlun 16 -wc -rc**

Write cache:       ENABLED

Read cache:      DISABLED

**CHECK SP LOGS:**

**#/nas/sbin/navicli -h 172.24.11.110 getlog >spalog** [Dump log for SPA & SPB to file and troubleshoot SP issues]

**VERIFYING FIBRE PATHS TO BACKEND:**

**\$server\_config server\_x -v "fcip bind show"** [Should show four paths to backend]

Persistent Binding Table

Chain 0000: WWN 5006016000600251 HBA 0 SP-a0 [SPA-0]

Chain 0016: WWN 5006016800600251 HBA 0 SP-b0 [SPB-0]

Chain 0032: WWN 5006016100600251 HBA 1 SP-a1 [SPA-1]

Chain 0048: WWN 5006016900600251 HBA 1 SP-b1 [SPB-1]

**NAVICLI COMMANDS FAIL WITH “Aborted”:**

Possible cause is that /etc/hosts file and /sbin/ifconfig are not up-to-date with external IP address]

Run uname -a and /sbin/ifconfig -a to obtain proper Hostname and External IP to add to /etc/hosts file

**SAMPLE:**

**# uname -a**

Linux cel9cs0 2.4.9-34.8.EMC #1 Thu Feb 6 16:34:45 EST 2003 i686 unknown

**#/sbin/ifconfig -a**

```
eth1 Link encap:Ethernet HWaddr 00:02:B3:B9:EB:0D
      inet addr:10.64.25.90 Bcast:10.64.25.255 Mask:255.255.254.0
          UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1
          RX packets:5387497 errors:0 dropped:0 overruns:0 frame:0
          TX packets:2173368 errors:0 dropped:0 overruns:0 carrier:117
          collisions:188 txqueuelen:100
          RX bytes:667840133 (636.9 Mb) TX bytes:404120327 (385.3 Mb)
          Interrupt:10 Base address:0x6000
```

**#cat /etc/hosts**

```
10.64.25.90 cel9cs0
```

**CELLERRA WITH CLARIION BACKENDS:**

**LUN AUTO-ASSIGN FEATURE FOR SP's:**

**AUTO-ASSIGN DEFINED:**

Auto-Assign is a Clariion function that controls the ownership of a LUN when an SP fails. With this feauture Enabled, if an SP that owns a LUN fails and the Host system tries to access the LUN via the second SP, the latter will assume ownership (via LUN trespass) until the failed SP can be replaced. After replacement, the ownership of the LUN needs to be trespassed back to the default owner. This mechanism was devised in those configurations where failover software is not employed.

Primus emc87328 states that all direct-attached Clariion storage and Fabric-attached systems should have auto-assign enabled so that unowned Luns trespass to partner SP—change from ‘DISABLED’ to ‘ENABLED’. This function works on the Backend but is monitored by DART. If the DM loses connectivity to LUNs owned by a specific SP, LUN failover occurs. Failover of LUN 50 from SPA to SPB could occur as an example. All Clariion systems attached to Celerra should implement auto-assign.

**Note:** New default behavior with NAS 5.2.16.x and 5.3.10.4 is to have Auto-Assign Enabled on all Celerra systems with Clariion backends that have conducted a full package upgrade or new install of 5.3

## **ENABLING AUTO ASSIGN ON NS600/700 DIRECT-ATTACHED SYSTEMS:**

1. Verify Current Status:

**\$ /nas/sbin/navicli -h <sp\_ip> getlun -owner -default -state -aa**

LOGICAL UNIT NUMBER 16

|                |          |
|----------------|----------|
| Current owner: | SP A     |
| Default Owner: | SP A     |
| State:         | Bound    |
| Auto-assign:   | DISABLED |

2. Enable auto-assign of Luns:

**\$ /nas/sbin/navicli -h <sp\_ip> chglun -l <lun ID> -a 1** [ALU lun number]

**Note:** Run this command to enable Auto-assign for each each LUN. Starting with NAS 5.4 and higher, the auto-assign value should be disabled on all Celerra systems connected to Clariion arrays.

## **ENABLING CLARIION TRESPASS OF LUNS FOR CLARIION BACKENDS:**

**param clariion no\_tresspass=0**

**Note:** Older NAS versions had trespass set to 1 by default to enable the Clariion LUN trespass feature for switched environments, but set to 0 by default for dedicated storage systems such as an NS600 and NS600G direct-attached [i.e., not switch-connected]. Param is implemented so that when external Host clients are trying to drive I/O down a specific path, or chain, an auto trespass would be initiated if a path was no longer available—trespassing from Chain 0 to Chain 16, as an example.

**Note 2:** NAS 5.3.10.4 & 5.2.16.x officially changes trespass default to clariion no\_tresspass=0, or disabled

**NASDB:** NAS configuration database, mostly located on /nbsnas partition /dev/nde1 on LUN 4

## **CONTROL LUN PARTITIONS:**

**/nbsnas:** Mountpoint for NBS partition on /dev/nde1, LUN 4 [Contains mountpoints for DOS & VAR partitions]

**/nas:** Mountpoint for NAS Partition on /dev/hda5 containing Celerra/IP Configuration files—many files are links to /nbsbas directory

**/nas/dos:** FAT16 DOS Partition containing DART OS using LUN 0 on BackEnd--/nas/dos is a symbolic link to /nbsnas/dos [CS0 sees as /dev/nda1]. DART loads OS and Configuration Files from this partition via Fibre connection.

**/nas/var:** LOG Partition for NAS\_DB Backups, Dumps, and Logs, using LUN 5 on BackEnd--/nas/var is a symbolic link to /dev/ndf1 [CS0 sees as /dev/ndf1]

## **USING FDISK TO VERIFY COMMUNICATION TO NBSNAS:**

**# /sbin/fdisk -l /dev/nda (/nas/dos or /nbsnas/dos)**

**# /sbin/fdisk -l /dev/nde (/nas or /nbsnas)**

**# /sbin/fdisk -l /dev/ndf (/nas/var or /nbsnas/var)**

## **VERIFYING PARTITIONS/VOLUMES:**

**# /sbin/fdisk -l**

**# cat /etc/fstab**

**# df -k        #df -h**

## **RECREATING DOS PARTITION USING install\_init -r:**

1. #umount /nas/dos

2. #fdisk -l /dev/nda [verify partition accessibility]

3. #/nas/sbin/install\_init -r

Creating the DOS Partition on /dev/nda1 with fdisk...

Building the DOS filesystem on /dev/nda1 with mkfs.msdos...

**Note:** Remount /nas/dos before running setup\_slot -r

4. #/nasmcd/sbin/setup\_slot -r 2

Initializing server in slot 2 as server\_2

5. #/nasmcd/sbin/setup\_slot -r 3

6. #sync

7. #/nasmcd/sbin/t2reset reboot -s 2 | -s 3

## **RECREATING /nas/var PARTITION:**

1. Delete old partition  
# /sbin/fdisk /dev/ndf  
p | d | 1 | p | w
2. Recreate partition  
# /sbin/fdisk /dev/ndf  
n | 1 | 1 | +1800M | w
3. Format Partition  
# /sbin/mkfs -t ext2 /dev/ndf1 1847443 (as seen in output of fdisk -l /dev/ndf)
4. Change to journal file system ext3  
# /sbin/mke2fs -j /dev/ndj1
5. Confirm and then create necessary directories and change ownership to nasadmin

## **CONTROL STATION RECOVERY (Prior to NAS 5.6):**

**Note:** Use this if Linux cannot boot

1. Insert CFS CD ROM and Floppy disk
2. Reboot CS # reboot or # reboot -n -f [Force, no sync reboot]
3. Prompt, type >**serialinstall rescue**

**Note:** Ignore failure to find Linux partition message

4. At prompt fsck root file system:

```
#fsck -f /dev/hda1 #fsck -f /dev/hda3 #mkdir /mnt/sysimage #mount /dev/hda3 /mnt/sysimage #chroot /mnt/sysimage #mount /dev/hda1 /boot  
5. If FSCK doesn't appear to fix any problems, then boot configuration file could be corrupt  
/mnt/sysimage/boot/grub.conf  
default=0  
timeout=10  
serial .unit=1 .speed=19200  
terminal .timeout=10 serial console  
title linux
```

6. Repair and reinstall GRUB boot loader  
#grub-install --recheck /dev/hda

7. #umount /boot #exit #umount /mnt/sysimage #exit

**CONTROL STATION RECOVERY:** Linux won't boot and serial console connection shows blank screen

1. Connect to serial port ttyS1 on CS and start hyperterminal session
2. Boot from CD and Floppy and at prompt type: serialinstall
3. Complete install and at boot backend LUNS should be detected and recovery script will attempt to run (does not touch NASDB)
4. If system contains non-default IP addresses for SPs (192.168.1.200), let script error out, then login as root
5. Change CS Internal Interface to be same subnet as SPs:

```
#ifconfig eth0 10.6.8.100 netmask 255.255.255.0 broadcast 10.6.8.255
```

6. Change SPB IP address back to default:

**#/nasmcd/tftpboot/bin/navicli -h 10.6.8.201 networkadmin -set address 192.168.1.201 -subnetmask 255.255.255.0 -gateway 192.168.1.100**

**Note:** Let SPB reboot and then repeat for SPA, then change CS internal interface back to default

7. Change DMs internal IPs back to defaults if needed

```
/tftpboot/bin/t2tty -c 2 "logsys add output console" "ifconfig", repeat for slot_3
```

```
/tftpboot/bin/t2tty -c 2 "ifconfig el30 protocol=IP device=fpx0 local=192.168.1.2 netmask=255.255.255.0 broadcast=192.168.1.255
```

**Note:** Repeat above for slot\_3, then turn off DART console: "logsys set output disk=root\_log\_2"

8. Run recovery script: #/etc/rc3.d/S95nas

9. If successful, verify nbs.conf and repair if necessary using following;

**#/nasmcd/sbin/setup\_slot -nbs -add 2 | 3**

10. Update /etc/hosts with backend array IP addresses:

**#/nas/sbin/setup\_clariion -init**

11. Manually add SPA and SPA aliases to /etc/hosts

```
192.168.1.200 A_APM00023400700 SPA
```

12. Reboot CS and verify

## **CS RECOVERY FOR NASDB PARTITION CORRUPTED:** /dev/nde1

**#/fsck -f /dev/nde1**

**Note:** Reboot to see if /nbsnas will mount

If NASDB cannot be repaired, conduct reinstall using #emcrpm -install, which recreates /nbsnas /nbsnas/dos /nbsnas/var /nas, then restore NASDB from backup

1. Script reinstalls all NASDB partitions from scratch-last resort only!
2. PXE boot data movers and ensure NBS devices are accessible
3. Save installed package to temp directory: #cp /var/sadm/pkg/emcnas/\*.rpm /root/tmp
4. Uninstall old package: #emcrpm -e emcnas
5. Install new package: #emcrpm -i /root/tmp/emcnas~...i385.rpm
6. Recover NASDB from backup and restore

### **RECOVERING ROOT CS PASSWORD:**

1. Boot to single user mode by entering “e” at grub boot loader screen
2. Add word ‘single’ at end of kernel /vmlinuz ro root=/dev/hda3 console=ttyS1,19200 line, then press enter, then ‘b’ to boot

**kernel /vmlinuz ro root=/dev/hda3 console=ttyS1,19200 single**

3. #vi /etc/passwd and change root:x: to root::
4. Reboot and then change password after logging in

### **FAILED NAS UPGRADE:**

**Note:** Retry upgrade.

1. Change /nas from a symbolic link to /nbsnas back to normal /nas /dev/hda5.
2. Delete nas mountpoint, mkdir nas, mount /nas
3. Rerun NAS Upgrade

### **RECOVERING FROM CORRUPTED BOOT CONFIG FILES:**

1. Verify /nas/dos/slot files, nas.exe, and boot.bat files
2. Run setup\_slot -i 2 to repair files
3. Find backup file and extract to /temp [tar -zxf bkup04.tar.gz]
4. Copy recovered files back to appropriate /nas/server directory:  
#cp -Rf server/server\_1/\* /nas/server/server\_1/
5. Run setup slot to regenerate boot.cfg file

### **REPLACING DATA MOVER:**

1. Ensure NAS Services are stopped and DM is halted
2. Cable up new data mover and manually mount /nas /nbsnas /nas/dos /nas/var
3. #export NAS\_DB=/nas
4. Run setup\_slot -i 2 on new data mover and start NAS Services

**PTY Ports:** Linux Serial ports used on Control Station—accessed by Reading & Writing files in /dev/ttx directories

/dev/ttys0—Serial modem access, back of CS

/dev/ttys1—Serial console access, front of CS

/dev/ttys4—Connects to Slot\_2, on 4-port serial cable

/dev/ttys5—Connects to Slot\_3, on 4-port serial cable

**PXE:** Pre-Execution Boot Environment allows CS to act as PXE server to which DMs boot DART from via network connection

### **SYSTEM READINESS:**

**/nasmcd/sbin/getreason -s 2**

getboxmask

### **NS INTEGRATED CALLHOMES:**

Celerra IP uses a single CallHome for both DART & Clariion hardware [Diagnose BackEnd using NaviCLI commands]

### **REBOOTING SYSTEM:**

/nasmcd/sbin/t2reset reboot -s 2

server\_cpu

/nas/tools/server\_peer\_powerctrl -reboot 2

### **CONFIGURING BACKEND:**

\$ ls -l /nasmcd/tftpboot/bin

\$/nasmcd/tftpboot/setup\_backend

agent.pm → Properties and subroutines for SP agent

common.pm → common definitions and subroutines

disk.pm → properties & routines pertaining to physical disks  
enclosure.pm → Enclosure subroutines  
enclosure.cfg → Config file used to build RAID volumes  
nas\_raid.log → nas\_raid command log file  
system.pm → properties for creating Celerra Clariion system

## **SYSTEM LOGS:**

/nas/log/sys\_log [Panics, Hardware Errors, Hardware Status]  
/nas/log/agent.log [Navisphere agent log]  
/nas/log/navimon.log [Navisphere monitor log]  
/nas/log/setup\_clariion2.log [BackEnd install log]

## **TESTING TTY SERIAL CONNECTIVITY & ISSUING DM COMMANDS: .server\_tty -t**

**Note:** Would use in the event the Ethernet network was not available

1. service nas stop
2. /nas/tools/.server\_tty -t [Test serial connectivity]
2. /nas/tools/.server\_tty -c 2 “**logsys add output console**” [allows command output to Console]
3. /nas/tools/.server\_tty -c 2 “ifconfig”
4. Disable Console Output: /nas/tools/.server\_tty -c 2 “**logsys set output disk=root\_log\_server2**”

## **EXAMPLES TTY COMMANDS:**

```
# /nas/tools/.server_peer_powerctrl -chkins 3
# /nas/tools/.server_tty -s 3
Slot-3 (ttyS5) on
# /nas/tools/.server_tty -t
ttyS4 on [DM2]
ttyS5 on [DM3]
ttyS6 off
ttyS7 off
ttyS8 off
# /nas/tools/.server_tty -c 2 "sib" [Check getreason status of DMs]
reason_code=05
```

## **USE T2TTY TO CHANGE GETREASON, CHECK IFCONFIG OR RUN CMDS—“fcp bind show”:**

1. Must set console output to console:

```
# ./t2tty -c 3 "logsys add output console"
```

logsys add output console

2. Verify SIB Status:

```
# ./t2tty -c 3 "sib"
```

reason\_code=05

3. Verifying NIC Configuration on DMs:

```
# ./t2tty -c 3 "ifconfig"
```

ifconfig

Devices:

fxp0 dmtu=1500, dmac=8:0:1b:43:58:7

cge0 dmtu=9000, dmac=8:0:1b:42:4a:86

loop dmtu=65536, dmac=0:0:0:0:0:0

Interfaces:(4)

el30 on fxp0 l=192.168.1.3 n=255.255.255.0 b=192.168.1.255 DNIF UP

    mtu=1500, dmtu=1500, vlid=0, mac=8:0:1b:43:58:7 dmac=8:0:1b:43:58:7

el31 on fxp0 l=192.168.2.3 n=255.255.255.0 b=192.168.2.255 DNIF UP

    mtu=1500, dmtu=1500, vlid=0, mac=8:0:1b:43:58:7 dmac=8:0:1b:43:58:7

cge0 on cge0 l=10.241.169.45 n=255.255.255.0 b=10.241.169.255 DNIF UP

    mtu=1500, dmtu=9000, vlid=0, mac=8:0:1b:42:4a:86 dmac=8:0:1b:42:4a:86

loop on loop l=127.0.0.1 n=255.0.0.0 b=127.255.255.255 UP

    mtu=32768, dmtu=65536, vlid=0, mac=0:0:0:0:0:0 dmac=0:0:0:0:0:0

4. Changing SIB Status:

# ./t2tty -c 3 "sib attention=4"

sib attention=4

reason\_code=04

5. Redirect Console Output to Log after completing T2TTY session:

# ./t2tty -c 3 "logsys set output disk=root\_log\_server\_3"

logsys set output disk=root\_log\_server\_3

## **CHANGING INTERNAL IP ADDRESSES TEMPORARILY FOR NAS INSTALL RECOVERY:**

1. #.server\_tty -c 2 "logsys add output console"

2. #.server\_tty -c 2 "ifconfig"

3. #.server\_tty -c 3 "logsys add output console"

4. #.server\_tty -c 3 "ifconfig"

5. #.server\_tty -c 2 "ifconfig el30 protocol=IP device=fxp0 local=192.168.1.2 netmask=255.255.255.0 broadcast=192.168.1.255"

6. #.server\_tty -c 3 "ifconfig el30 protocol=IP device=fxp0 local=192.168.1.3 netmask=255.255.255.0 broadcast=192.168.1.255"

7. Verify ping and then turn off console logging: #.server\_tty -c 2 "logsys set output disk=root\_log\_server2"

8. Run recovery install script → /etc/rc3.d/S95nas

**BACKING UP NAS DATABASE:** Stored in (2) locations

### **(1) BACKUP STORED LOCAL CS IDE DRIVE:**

/nasmcd/sbin/nasdb\_backup /nas /home/nasadmin 120702

**OTHER BACKUP STORED ON** /nas/var/backup on array LUN 5

## **VARIOUS NASDB BACKUP FILES:**

-rw-r--r-- 1 nasadmin nasadmin 5203347 Jan 7 12:06 \_nasbkup.12.tar.gz [One of (12) hourly backups maintained on CS]

-rw-r--r-- 1 nasadmin nasadmin 5759420 Jan 7 21:06 nasdb\_backup.1.tar.gz [Latest hourly backup + extra log files]

-rw-r--r-- 1 nasadmin root 5631868 Jan 4 20:16 nasdb\_backup.b.tar.gz [Backup after last CS reboot]

## **VERIFYING ARRAY STATUS:**

/nas/sbin/navicli -h spa getagent [Checks status of backend storage array—shows mapping of LUN numbers to Celerra partitions]

/nas/sbin/navicli -h spa getlun 05 -state [Verifies indicated LUN]

/nas/sbin/navicli -h spa getlun -aa -state [Status of all LUNs]

/nas/sbin/navicli -h spa getlun 05 -owner

/nas/sbin/navicli -h spa trespass lun 06 [Assign a LUN to specific]

# **./nas/sbin/navicli -h 10.241.169.35 getlun -state -owner -default** [Ownership of Luns and Bound state]

# **./nas/sbin/navicli -h 10.241.168.57 getlun -trespass** (use to verify trespassed luns)

## **RESTORING SP LUNs:**

\$./nas/sbin/navicli -h spa trespass mine

**Note:** When trespassing control LUNs back to original SPs, CS0 may reboot. Also note that for arrays that have other hosts connected to them, it is NOT recommended to run trespass mine against all luns on an SP. Rather, issue the command to each Celerra alu in order to trespass back.

## **ETHERNET BROADCOM CONTROLLER ISSUES:**

\$#.server\_config server\_2 -v "bcm cgeN stop"

\$#.server\_config server\_2 -v "bcm cgeN start"

\$#.server\_config server\_2 -v "bcm cgeN stat"

\$#.server\_config server\_2 -v "bcm fgeN stat"

## **CELERRA NBS NETWORK BLOCK STORAGE PROTOCOL:**

iSCSI technology that allows clients to access block storage devices on Servers [Control Station NBS Client connects to DM NBS Server on one of the following three partitions]

NBS Client runs on Control Station [Doesn't have an HBA to communicate with, so uses the NBS protocol to write to BackEnd db] NBS Servers run on Data Movers [/nas /nas/dos /nas/var]

\$ ps -ef |grep nd-clnt [Should find one instance of NBS running for /nas, /nas/dos, & /nas/var partitions]

root 6354 1 0 Jan15 ? 00:00:02 [nd-clnt 0 1]

root 6367 1 0 Jan15 ? 00:00:02 [nd-clnt 4 5]

root 6386 1 0 Jan15 ? 00:00:00 [nd-clnt 5 6]

\$ /sbin/fdisk -l /dev/nda = /nas/dos NBS [Verifies that partitions are accessible]

\$ /sbin/fdisk -l /dev/nde = /nas NBS

\$ /sbin/fdisk -l /dev/ndf = /nas/var NBS

### **MOUNTING NBS PARTITIONS:**

```
#mount /nas          [/nbsnas on /dev/nde1]  
#mount /nas/dos     [/dev/nda1]  
#mount /nas/var     [/dev/ndf1]
```

### **TROUBLESHOOTING NBS:**

# cat /etc/nbs.conf

```
#  
# Simple configuration file for nbs service  
#  
# Format: devIndex:NbsId:Host1,host2,...:  
0:1:server_2,server_3b,server_2b,server_3:  
4:5:server_2,server_3b,server_2b,server_3:  
5:6:server_2,server_3b,server_2b,server_3:
```

# ls /proc/driver/nd/devices

1 5 6

# ps -ef |grep nd-clnt

```
root  6975  1 0 May08 ?    00:01:10 [nd-clnt 0 1]  
root  6979  1 0 May08 ?    00:10:33 [nd-clnt 4 5]  
root  6983  1 0 May08 ?    00:00:28 [nd-clnt 5 6]
```

**Note:** Above represents normal NBS processes for /nas, /nas/dos, /nas/var partitions, as seen by Control Station

# /sbin/fdisk -l /dev/nda

Disk /dev/nda: 255 heads, 63 sectors, 1435 cylinders

Units = cylinders of 16065 \* 512 bytes

| Device    | Boot | Start | End | Blocks | Id | System |
|-----------|------|-------|-----|--------|----|--------|
| /dev/nda1 | *    | 1     | 17  | 136521 | 6  | FAT16  |

# /sbin/fdisk -l /dev/nde

Disk /dev/nde: 255 heads, 63 sectors, 261 cylinders

Units = cylinders of 16065 \* 512 bytes

| Device    | Boot | Start | End      | Blocks | Id    | System |
|-----------|------|-------|----------|--------|-------|--------|
| /dev/nde1 | 1    | 230   | 1847443+ | 83     | Linux |        |

# /sbin/fdisk -l /dev/ndf

Disk /dev/ndf: 255 heads, 63 sectors, 261 cylinders

Units = cylinders of 16065 \* 512 bytes

| Device    | Boot | Start | End      | Blocks | Id    | System |
|-----------|------|-------|----------|--------|-------|--------|
| /dev/ndf1 | 1    | 230   | 1847443+ | 83     | Linux |        |

**Note:** Above output means that CS can see each of the NBS partitions

**\$ .server\_config server\_2 -v "nbsstat"**

## **MANUALLY RESTARTING NBS SERVICES ON CS:**

**\$/usr/local/bin/nd-clnt 0 1 server\_2,server\_3** | 192.168.1.2, .3 [Starting NBS on /dev/nda for /nas/dos]

**\$/usr/local/bin/nd-clnt 4 5 server\_2,server\_3** [Starting NBS on /dev/nde for /nas]

**\$/usr/local/bin/nd-clnt 5 6 server\_2,server\_3** [Starting NBS on /dev/ndf for /nas/var]

### # /usr/local/bin/nd-cfg

Usage: nd-cfg [-a action] [-d dev\_name] [-i NbsId | -l] [-s server\_name] [ -v]

nd-cfg -i NbsId -s server\_name

nd-cfg -l -s server\_name

nd-cfg -a addServ -s server\_name -d /dev/nda

nd-cfg -a remServ -s server\_name -d /dev/nda

nd-cfg -a setRetry\_# -d /dev/nda

nd-cfg -a stop -d /dev/nda

nd-cfg -a disconnect -s server\_name -d /dev/nda

## **PROCEDURE TO CORRECT NBS SERVICES FOR A SPECIFIC DATA MOVER:**

1. Run command to add missing nbs configuration for server\_3:

**#/nasmcd/sbin/setup\_slot -nbs -add 3**

2. Check that server\_3 & server\_3b have been added to the config file:

**#cat /etc/nbs.conf**

3. Stop NAS services using the command:

**#/sbin/service nas stop**

4. Recycle NBS service using:

**#/sbin/service nbs restart**

5. Check that NBS has started correctly with the added servers:

**#/sbin/service nbs status**

**Note:** Should see output for each NBS device with the following server list:

Configured NBS devices:

254: 0 NbsId: 1

Disk\_Name: nda

Capacity: 11534272 KB

Crnt\_Server: 0X202a8c0

**Server\_List: 0X301a8c0 0X201a8c0 0X302a8c0 0X202a8c0**

num\_io: 22199 time 901410 ms num\_sect 1396388 que 0

Avg\_blk: 31 K throughput 774 K/s resp\_tm: 17 ms, ops/sec 24

254: 16 NbsId: 5

Disk\_Name: nde

Capacity: 2097088 KB

Crnt\_Server: 0X201a8c0

**Server\_List: 0X201a8c0 0X302a8c0 0X202a8c0 0X301a8c0**

num\_io: 26935 time 901400 ms num\_sect 488192 que 0

Avg\_blk: 9 K throughput 270 K/s resp\_tm: 2 ms, ops/sec 29

254: 20 NbsId: 6

Disk\_Name: ndf

Capacity: 2097088 KB

Crnt\_Server: 0X202a8c0

**Server\_List: 0X302a8c0 0X202a8c0 0X301a8c0 0X201a8c0**

num\_io: 23246 time 901400 ms num\_sect 1405496 que 0

Avg\_blk: 30 K throughput 779 K/s resp\_tm: 138 ms, ops/sec 25

6. Restart NAS services using the command:

**#/sbin/service nas start**

### **TROUBLESHOOTING IF PXEBOOT FAILS TO REGAIN ACCESS TO BACKEND:**

**Note:** Many variables can affect access to the backend devices via NBS, but the following steps should eliminate most of the issues

- a) Check Control Station's NBS configuration file (Single Blade system shown)

```
# cat /etc/nbs.conf  
#  
# Simple configuration file for nbs service  
#  
# Format: devIndex:NbsId:Host1,host2,...:  
0:1:server_2,server_2b:  
4:5:server_2,server_2b:  
5:6:server_2,server_2b:  
b) Could be that the NBS Service is not running properly on the Control Station
```

```
# ps -ef |grep nd-
```

**Note:** If services are not running, do the following

- c) First verify that the Control Station can access the backend via IP and Internal network (ping IP addresses, run /ftptboot/bin/navicli)

- d) Stop NAS Services

```
# /sbin/service nas stop →If this fails to stop any NAS Services that are running, manually kill the processes
```

- e) Restart NBS on the Control Station

```
# /sbin/service nbs restart →Restarts NBS services
```

- f) Verify that NBS processes are running correctly

```
# ps -ef |grep nd-
```

```
root 4368 1 0 11:40 ? 00:00:00 [nd-clnt 0 1]  
root 4369 1 0 11:40 ? 00:00:00 [nd-clnt 4 5]  
root 4370 1 0 11:40 ? 00:00:00 [nd-clnt 5 6]  
root 4371 1 0 11:40 ? 00:00:00 [nd-snnd 4 5]  
root 4372 1 0 11:40 ? 00:00:00 [nd-snnd 5 6]  
root 4373 1 0 11:40 ? 00:00:00 [nd-snnd 0 1]
```

- g) Restart NAS Services

```
# /sbin/service nas start
```

- h) Verify backend partitions

```
# df -h →Should see NAS partitions mounted
```

```
# /sbin/fdisk -l
```

-----abridged-----

| Device    | Boot | Start | End  | Blocks  | Id | System    |
|-----------|------|-------|------|---------|----|-----------|
| /dev/nda1 | *    | 1     | 17   | 136521  | 6  | FAT16     |
| /dev/nda3 |      | 654   | 1435 | 6281415 | 8e | Linux LVM |

### **POST NAS 5.2.7.0:**

1. Stop NAS and remount partitions
2. Start PXE services: t2pxe -s -R 2
3. PXE Boot DM's: t2tty -p 2
4. Shutdown pxe services when completed: t2pxe -e

### **RESTORING A DATA MOVER'S CONFIGURATION:**

1. #/nasmcd/sbin/setup\_slot -r 2
2. #/nasmcd/sbin/t2reset soft -s 2

### **RECREATING DOS PARTITION (/nas/nda1):**

1. #umount /nas/dos
2. #fdisk -l /dev/nda
3. #/mnt/source/EMC/nas/install\_init -r or #/nas/sbin/install\_init -r
4. #/nasmcd/sbin/setup\_slot -r 2 or #/nas/sbin/build\_config /nas/server/slot\_2 /nas/dos/slot\_2
5. #sync
6. /nasmcd/sbin/t2reset reboot -s 2

### **REINSTALLING NAS DATABASE:**

1. PXE Boot Datamovers are per above procedure
2. Ensure NBS Service and Partitions are accessible

3. Uninstall old EMCNAS Package: #emcrpm -r emcnas
4. Run Setup Script: #/mnt/source/EMC/nas/setup
5. Use nasdb\_restore to restore NASDB from /home/nasadmin or /nas/var/backup

## **USING LINUX RESCUE FOR FAILED NAS UPGRADE:**

1. Press F5 key at ‘Starting MS-DOS’ prompt
2. Type ‘rescue’ to startup mini linux root file system at c:> prompt
3. Create two mount points /mnt1 & /mnt2, and mount to /dev/sdc1 & /dev/sda1, respectively
4. Replace current vmlinuz & initrd.img with aok versions
5. Reboot CS and re-run NAS setup

**Note:** See Primus emc67387 & emc63091

## **RUNNING FSCK ON LINUX PARTITION:**

**#e2fsck -f /dev/nd1**

#reboot or #reboot -n -f [Force, no-sync reboot method]

## **RUNNING FSCK ON DOS PARTITION:**

1. Unmount Partition first: #umount /nas/dos
2. Run FSCK: #e2fsck -f /dev/nd1

## **CONTROL STATION BOOT PROCESS:**

1. Motherboard BIOS initialization
2. IDE Drive Discovery via Fibre or SCSI
3. BIOS for Adapter Card loads
4. DOS boots from IDE drive /dev/hda1
5. exec autoexec.bat & exec t2slot -f programs run
6. /nas/dos/vmlinuz [Loads LINUX kernel]
7. /nas/dos/bin/initrd.img [RAM disk img file]
8. LINUX completes load via scripts: /etc/rc.d/init.d [using /etc/inittab settings]
9. Root Volumes: /dev/hda3

## **DATAMOVER BOOT PROCESS:**

1. BIOS initializes & system boots from TLUN 00
2. DOS loads and reads autoexec.bat file, which then runs exec t2slot -f program to discover proper slot
3. NAS then loads using exec flashupg.exe -rUU
4. gload program, from boot.bat, loads both NAS and the ascii configuration file (boot.cfg) into memory [NAS overlays DOS]
5. Control is passed to DART’s init assembler routine called “sysinit”, which performs hardware setup, determines physical memory size, stack & memory initialization, interrupt descriptors, clock initialization, etc. MEMinit is called by ‘sysinit’ to initialize page allocator and marks ownership of pages used by BIOS, DART, data, symbol table, etc.
6. Main program starts the config thread, which begins parsing the ‘boot.cfg’ file to load the Data Mover configuration: →boot.cfg file loads buffers, parameters, devices, and interface settings; Volumes & UFSLOG are then replayed for all file systems; filesystems mounted & exported and Quotas started; network protocols started; nbs configured & started; nfs services started

## **MISC:**

### **SYR SYSTEMS REPORTING:**

SYR has the ability to collect monthly configuration & statistical information for EMC products. Celerra uses the log\_config command to collect information, which is called home monthly according to last digit of serial number that matches day.

**/nas/sbin/log\_config -d -c** [creates CallHome with payload info]

### **LOG CONFIG SCRIPT & SYR:**

#### **Monthly CallHomes via System Cron Job:**

```
# cat /etc/cron.d/nas_syslog grep log_config  
59 3 11 * * root /nas/sbin/log_config -d -c >/dev/null 2>&1
```

→So, in the above example, the log\_config script runs at 3:59 a.m. on the 11<sup>th</sup> Day of each Month, with the –default and –callhome switches, and a postevent at the end of the script generates an XML callhome to deliver the log\_config.gz file

#### **From /nas/sbin/log\_config Bourne Shell script:**

```
# Facility = SYR (143), event ID = 5, severity = INFO (6)  
$SDIR/postevent -c 6 -f 143 -s 6 -i 5 -n src_file_path -t 8 -v "$LOG" -n dest_extension -t 8 -v 'log_config.gz'
```

**Verify that log config was sent as a Callhome:**

```
# view /nas/opt/connectemc/logs/archive/ConnectEMC.archive
```

```
-- Time : 03-12-2008 12:38:27.
-- Filename : /opt/connectemc/poll/RSC_APM00083103123_120308_123724919.xml.
```

```
<?xml version="1.0" encoding="UTF-8"?>

## ADMINISTRATIVE TASKS:

### CELERRA ESRS (EMC Secure Remote Support) SUPPORT:

→Supported with NAS 5.4 and higher—deployed from the following zip

<http://www.cs.isus.emc.com/csweb2/esrs/celerra.ZIP>

→Customers want this feature for secure IP-based access that provides authorization, auditing, and authentication, and reduced costs

→Ideal configuration is to have a single Server running the ESRS Gateway and Policy Manager applications, with the Server installed inside the customer's network (i.e., inside the external firewalls)

→Need connectivity between all managed devices and the ESRS Gateway server, and to EMC

→Use of the ESRS product requires a SecureID, membership in the ESRS Group, and resident on an EMC network  
→EMC Support/Partners would connect to a customer's end device via a secure tunnel through the ESRS Gateway, but not actually to the Gateway itself  
→Connection permissions are Always Allowed, Never Allow, or Always Ask. Our preference is for Always Allowed, but with Always Ask, a customer can grant access for the device. Never Allow would require a permission change to allow and then grant access

→To connect to the Gateway Server requires Webex session

→ESRS connection is made to IPs provided by one of (4) different connection islands maintained around the world by EMC

→The Gateway Server initiates the remote sessions to EMC in response to events or customer-initiated actions

→EMC uses IP over TCP via an industry standard SSL VPN encrypted tunnel, using Triple DES encryption

#### **Deploying ESRS Gateway 1.01.0x with Celerra 5.3.31 or later:**

1. Need operational Gateway and Policy Manager Servers

2. FTP to Gateway Server to download GWExt utility to create the Celerra as a target device:

```
$ ftp <IP_address_Gateway>
```

```
esrsconfig
```

```
esrsconfig
```

```
>cd /utilities/GWExt/linux
```

```
>bin
```

```
>mget *
```

```
GWExt & GWExt.ini
```

```
$ chmod 755 *
```

```
$ ./GWExt
```

3. Configure and test ConnectHome

**Note:** ESRS Gateway forwards FTP or Email ConnectHome payloads to EMC

```
# /nas/sbin/nas_connecthome -modify -ftp_ipport <IP_addr:21> -ftp_folder incoming -ftp_user onalert -ftp_passwd  
EMCCONNECT -ftp_mode passive  
# /nas/sbin/nas_connecthome -modify -ftp_ipport_2 <IP_addr:21> -ftp_folder_2 incoming -ftp_user_2 onalert -ftp_passwd_2  
EMCCONNECT -ftp_mode_2 passive  
# /nas/sbin/nas_connecthome -modify -ftp_priority 1  
# /nas/sbin/nas_connecthome -modify -encryption_enabled yes  
# /nas/sbin/nas_connecthome -info  
# /nas/sbin/nas_connecthome -test -ftp_1
```

#### **USING WEBEX SUPPORT SESSION:**

1. Open Web Browser and go to <http://emcsupport2.webex.com> (or https://emcsupport.webex.com)

2. Click on My WebEx Navigator bar and Log In using NTlogon name and pass123

3. Click on Start a Support Session and record Session Number [#751953066]

4. Provide Session ID Number to customer

5. Customer enters ID number and customer info will be displayed on your screen

6. Click on Desktop tab to take control of Remote System to access Celerra via Telnet, SSH, etc.

**Other Passwords:** pass123

#### **CREATING FILTERS FOR WIRESHARK (formerly Ethereal) TRACES:**

Filter: ip.addr == 138.127.59.219 [To filter by a given IP Address]

```
ip.src == 10.1.1.32 ip.dst == 10.1.1.32
```

Filter: smb.nt\_status == 0xc0000022 [To filter by NT Status Error Message—‘STATUS\_ACCESS\_DENIED’]

**Note:** Click on ‘Filter’ → Add Expression → Drill down to “SMB” & select “NT Status” → Select ‘Relation’ of “==” and then choose the appropriate error code or plug in a known NT Error Status Code.

#### **MOUNTING ISO IMAGE WITHOUT CD-ROM ON WINDOWS OR LINUX:**

For Windows, download sw from [www.daemon-tools.cc/dtcc/portal/download.php](http://www.daemon-tools.cc/dtcc/portal/download.php) and you can mount iso images as virtual drives.

For Linux, do following: **#mount /tmp/toolsandapps5.3.15.3.iso /mnt -t iso9660 -o loop=/dev/loop0**
